The **sequence** <*number*> parameter specifies the order in which a statement appears in an IPv6 ACL and is therefore applied to a request. You can specify a value from 0 – 4294967295.

For more information on the syntax, refer to “ACL syntax” on page 1773.

Adding a comment to an IPv6 ACL entry

You can optionally add a comment to describe entries in an IPv6 ACL. The comment appears in the output of **show** commands that display ACL information.

You can add a comment by entering the **remark** command immediately preceding an ACL entry, or specify the ACL entry to which the comment applies.

For example, to enter comments for preceding an ACL entry, enter commands such as the following.

```
NetIron(config)#ipv6 access-list rtr
NetIron(config-ipv6-access-list rtr)# remark This entry permits ipv6 packets from
3002::2 to any destination
NetIron(config-ipv6-access-list rtr)# permit ipv6 host 3000::2 any
NetIron(config-ipv6-access-list rtr)# remark This entry denies udp packets from
any source to any destination
NetIron(config-ipv6-access-list rtr)# deny udp any any
NetIron(config-ipv6-access-list rtr)# remark This entry denies IPv6 packets from
any source to any destination
NetIron(config-ipv6-access-list rtr)# deny ipv6 any any
NetIron(config-ipv6-access-list rtr)# write memory
```

Syntax: [no] remark <*comment-text*>

The <*comment-text*> can be up to 256 characters in length.

To apply a comment to a specific ACL entry, specify the ACL's entry number with the **remark-entry sequence** command. Use the **show ipv6 access-list** command to list ACL entry number. Enter commands such as the following .

```
NetIron(config)# ipv6 access-list netw
NetIron(config-ipv6-access-list netw) remark-entry sequence 10 This entry permits
ipv6 packets from 3000::2 to any destination
NetIron(config-ipv6-access-list netw)# remark-entry sequence 20 This entry denies
UDP packets from any source to any destination
NetIron(config-ipv6-access-list netw)# remark-entry sequence 30 This entry denies
IPv6 packets from any source to any destination
```

Syntax: [no] remark-entry sequence <*sequence number*> <*comment-text*>

The <*sequence number*> is the line number assigned to the ACL entry. For a list of ACL entry numbers, use the **show ipv6 access-list** command.

The <*comment-text*> can be up to 256 characters in length. The comment must be entered separately from the actual ACL entry; that is, you cannot enter the ACL entry and the ACL comment with the same command.

You can use the **show running-config** or **show ipv6 access-list** commands to display IPv6 ACLs and comments.

The following shows the comment text for the ACL named "rtr" in a show running-config display.

```
NetIron# show running-config
ipv6 access-list rtr
 remark This entry permits ipv6 packets from 3002::2 to any destination
 permit ipv6 host 3000::2 any
 remark This entry denies udp packets from any source to any destination
 deny udp any any
 remark This entry denies IPv6 packets from any source to any destination
 deny ipv6 any any
```

Syntax: show running-config

The following example shows the comment text for the ACL named "rtr" in a **show ipv6 access-list** display.

```
NetIron# show ipv6 access-list rtr
ipv6 access-list rtr: 3 entries
 10: remark This entry permits ipv6 packets from 3002::2 to any destination
 10: permit ipv6 host 3000::2 any
 20: remark This entry denies udp packets from any source to any destination
 20: deny udp any any
 30: remark This entry denies IPv6 packets from any source to any destination
 30: deny ipv6 any any
```

Syntax: show ipv6 access-list [<*access-list-name*>]

For the <*access-list-name*> parameter, specify the name of an IPv6 ACL created using the **ipv6 access-list** command.

Use the **all** keyword to display all IPv6 ACLs configured on the device.

ACL CAM sharing for inbound IPv6 ACLs

ACL CAM sharing allows you to conserve CAM by sharing it between ports that are supported by the same packet processor (PPCR). If this feature is enabled globally, you can share CAM space that is allocated for inbound ACLs between instances on ports that share the same packet processor (PPCR). For example, if you have bound- inbound ACL 101 to ports 1/1 and 1/5, the ACL is stored in a single location in CAM and used by both ports. Table 10 describes which ports share PPCRs and can participate in ACL CAM sharing.

TABLE 312 Common ports per PPCR

Module type	PPCR number	Ports supported by PPCR
20 x 1G	PPCR 1	1 - 20
4 x 10G	PPCR 1	1 - 2
	PPCR 2	3 - 4
2 x 10G	PPCR 1	1 - 2

Considerations when implementing this feature

The following consideration apply when implementing this feature:

- If you enable ACL CAM sharing, ACL statistics will be generated per-PPCR instead of per-port. If you require the statistics per-port granularity for your application, you cannot use this feature.
- This feature cannot be applied to a virtual interface.

- CAM entry matching within this feature is based on the ACL group ID.

Configuring ACL CAM sharing for IPv6 ACLs

When enabled, ACL CAM sharing for IPv6 inbound ACLs is applied across all ports in a system. To apply ACL CAM sharing for IPv6 ACLs globally on a PowerConnect router, use the following command.

```
NetIron(config)# ipv6 enable-acl-cam-sharing
```

Syntax: ipv6 enable-acl-cam-sharing

Filtering and priority manipulation based on 802.1p priority

Filtering and priority manipulation based on a packet's 801.1p priority is supported in the PowerConnect devices through the following QoS options:

- **priority-force** – Assigns packets of outgoing traffic that match the ACL to a specific hardware forwarding queue, even though the incoming packet may be assigned to another queue. Specify one of the following QoS queues:
  - 0 – qosp0
  - 1 – qosp1
  - 2 – qosp2
  - 3 – qosp3
  - 4 – qosp4
  - 5 – qosp5
  - 6 – qosp6
  - 7 – qosp7

  If a packet's 802.1p value is forced to another value by its assignment to a lower value queue, it will retain that value when it is sent out through the outbound port.

  The default behavior on previous revisions of this feature was to send the packet out with the higher of two possible values: the initial 802.1p value that the packet arrived with or the new (higher) priority that the packet has been "forced" to.
- **priority-mapping** – Matches on the packet's 802.1p value. This option does not change the packet's forwarding priority through the device or mark the packet.

Example using the priority force option

In the following IPv6 ACL example, access list acl1 assigns tcp packets with the source address specified and any destination address to the internal priority 7.

```
NetIron(config)# ipv6 access-list acl1
NetIron(config-ipv6-access-list acl1)# permit tcp 4000:1::/64 any priority-force
7
```

The **priority-force** parameter specifies one of the 8 internal priorities of the PowerConnect Router. Possible values are between 0 and 7.

Example using the priority mapping option

In the following IPv6 example, access list acl2 permits udp packets with the source address specified, any destination address and the 802.1p priority 5.

```
NetIron(config)# ipv6 access-list acl2
NetIron(config-ipv6-access-list acl2)# permit udp 4000:1::/64 any
priority-mapping 5
```

The **priority-mapping** parameter specifies one of the eight possible 802.1p priority values. Possible values are between 0 and 7.

NOTE
When the priority configured for a physical port and the 802.1p priority of an arriving packet differ, the higher of the two priorities is used.

ACL accounting

Multi-Service devices monitor the number of times an ACL is used to filter incoming or outgoing traffic on an interface. The **show ipv6 access-list accounting** command displays the number of "hits" or how many times ACL filters permitted or denied packets that matched the conditions of the filters.

NOTE
ACL accounting does not tabulate nor display the number of implicit denials by an ACL.

Counters, stored in hardware, keep track of the number of times an ACL filter is used.

The counters that are displayed on the ACL accounting report are:

- **1s** – Number of hits during the last second. This counter is updated every second.
- **1m** – Number of hits during the last minute. This counter is updated every one minute.
- **5m** – Number of hits during the last five minutes. This counter is updated every five minutes.
- **ac** – Accumulated total number of hits. This counter begins when an ACL is bound to an interface and is updated every one minute. This total is updated until it is cleared.

  The accumulated total is updated every minute. For example, a minute after an ACL is bound to a port, it receives 10 hits per second and continues to receive 10 hits per second. After one minute, the accumulated total hits is 600. After 10 minutes, there will be 6000 hits.

The counters can be cleared when the device is rebooted, when an ACL is bound to or unbound from an interface, or by entering a **clear ipv6 access-list** command.

Displaying statistics for IPv6 ACL accounting

To display statistics for IPv6 accounting, enter commands such as the following.

```
NetIron (config)# show ipv6 access-list accounting brief
Collecting IPv6 ACL accounting summary for 5/1 ...  Completed successfully.
Collecting IPv6 ACL accounting summary for 5/2 ...  Completed successfully.
IPv6 ACL Accounting Summary: (ac = accumulated since accounting started)
    Int    In ACL              Total In Hit   Out ACL             Total Out Hit
    5/1   fdry115               3551122(1s)
                              135155472(1m)
                                      0(5m)
                              135155472(ac)
    5/2                                      fdry116               3551123(1s)
                                                                 135154337(1m)
                                                                         0(5m)
                                                                 135154337(ac)
```

The display shows the following information.

This field...	Displays...
The IP multicast traffic snooping state	The first line of the display indicates whether IP multicast traffic snooping is enabled or disabled. If enabled, it indicates if the feature is configured as passive or active.
Collecting ACL accounting summary for <*interface*>	Shows for which interfaces the ACL accounting information was collected and whether or not the collection was successful.
Int	The ID of the interface for which the statistics are being reported.
In ACL	The ID of the ACL used to filter the incoming traffic on the interface.
Total In Hit*	The number of hits from incoming traffic processed by all ACL entries (filters) in the ACL. A number is shown for each counter.
Out ACL	ID of the ACL used to filter the outgoing traffic on the interface.
Total Out Hit*	The number of hits from incoming traffic processed by all ACL entries (filters) in the ACL. A number is shown for each counter.
* The Total In Hit and Total Out Hit displays the total number of hits for all the ACL entries (or filters) in an ACL. For example, if an ACL has five entries and each entry processed matching conditions three times during the last minute, then the total Hits for the 1m counter is 15.	

Syntax: show ipv6 access-list accounting brief

Displaying IPv6 accounting statistics for an interface

To display statistics for an interface, enter commands such as the following.

```
NetIron (config)# show ipv6 access-list accounting eth 5/1 in
Collecting IPv6 ACL accounting for 5/1  ...  Completed successfully.
IPv6 ACL Accounting Information:
Inbound: IPv6 ACL fdry115
   10:  permit ipv6 host 4000::2 any
       Hit count: (1 sec)             3551111   (1 min)           135155472
                  (5 min)                   0   (accum)           135155472
```

The display shows the following information.

This field...	Displays...
The IP multicast traffic snooping state	The first line of the display indicates whether IP multicast traffic snooping is enabled or disabled. If enabled, it indicates if the feature is configured as passive or active.
Collecting IPv6 ACL accounting for <*interface*>	Shows the interface included in the report and whether or not the collection was successful.
Outbound or Inbound ACL ID	Shows the direction of the traffic on the interface and the ID of the ACL used.
#	Shows the priority of the ACL entry, followed by the permit or deny condition defined for that ACL entry. ACL entries are displayed in order of ascending ACL filter priorities.
Hit count	Shows the number of hits for each counter.

Syntax: show ipv6 access-list accounting ethernet [<*slot*>/<*port*> | **ve** <*ve-number*> | **pos** [<*slot*>/<*port*>] **in | out**

Use **pos** <*slot*>/<*port*> to display a report for a POS interface.

Use **ethernet** <*slot*>/<*port*> to display a report for a physical interface.

Use **ve** <*ve-number*> to display a report for the ports that are included in a virtual routing interface. For example, if ports 1/2, 1/4, and 1/6 are all members of ve 2, the report includes information for all three ports.

Use the **in** parameter to display statistics for incoming traffic; **out** for outgoing traffic.

Clearing the ACL statistics

Statistics on the ACL account report can be cleared:

- When a software reload occurs
- When the ACL is bound to or unbound from an interface
- When you enter the **clear ipv6 access-list** command, as in the following example.

```
NetIron(config)# clear ipv6 access-list all
```

Syntax: clear ipv6 access-list all | ethernet <*slot*>/<*port*> | **ve** <*ve-num*> | **pos** <*slot*>/<*port*>

Enter **all** to clear all statistics for all ACLs.

Use **pos** <*slot*>/<*port*> to clear statistics for ACLs a physical port.

Use **ethernet** <*slot*>/<*port*> to clear statistics for ACLs a physical port.

Use **ve** <*ve-number*> to clear statistics for all ACLs bound to ports that are members of a virtual routing interface.

Chapter

41

Configuring IPv6 Routes

Table displays the IPv6 Routes features supported by PowerConnect B-MLXe Series.

- Static IPv6 Route
- IPv6 Static Multicast Route

This chapter describes how to configure a static IPv6 route. A ***static IPv6 route*** is a manually configured route, which creates a path between two IPv6 devices. A static IPv6 route is similar to a static IPv4 route. Static IPv6 routes have their advantages and disadvantages; for example, a static IPv6 route does not generate updates, which reduces processing time for an IPv6 router. Conversely, if a static IPv6 route fails or if you want to change your network topology, you might need to manually reconfigure the static IPv6 route.

Configuring a static IPv6 route

You can configure a static IPv6 route to be redistributed into a routing protocol, but you cannot redistribute routes learned by a routing protocol into the static IPv6 routing table.

Before configuring a static IPv6 route, you must enable the forwarding of IPv6 traffic on the router using the **ipv6 unicast-routing** command and enable IPv6 on at least one interface by configuring an IPv6 address or explicitly enabling IPv6 on that interface. For more information on performing these configuration tasks, refer to 38, “Configuring Basic IPv6 Connectivity”.

To configure a static IPv6 route for a destination network with the prefix 8eff::0/32, a next-hop gateway with the global address 4fee:2343:0:ee44::1, and an administrative distance of 110, enter the following command.

```
NetIron(config)# ipv6 route 8eff::0/32 4fee:2343:0:ee44::1 distance 110
```

Syntax: **[no] ipv6 route** <*dest-ipv6-prefix*>/<*prefix-length*> <*next-hop-ipv6-address*> **[**<*metric*>*]* *[distance* <*number*>**]**

To configure a static IPv6 route for a destination network with the prefix 8eff::0/32 and a next-hop gateway with the link-local address fe80::1 that the router can access through Ethernet interface 3/1, enter the following command.

```
NetIron(config)# ipv6 route 8eff::0/32 ethernet 1 fe80::1
```

Syntax: **[no] ipv6 route** <*dest-ipv6-prefix*>/<*prefix-length*> **[ethernet** <*slot/port*> **| pos** <*slot/port*> **| ve** <*num*> **| null0]** <*next-hop-ipv6-address*> **[**<*metric*>**] [tag** <num>**]** **[distance** <*number*>**]**

To configure a static IPv6 route for a destination network with the prefix 8eff::0/32 and a next-hop gateway that the router can access through tunnel 1, enter the following command.

```
NetIron(config)# ipv6 route 8eff::0/32 tunnel 1
```

Syntax: **[no] ipv6 route** <*dest-ipv6-prefix*>/<*prefix-length*> <*interface*> <*port*> **[**<*metric*>**]** **[distance** <*number*>**]**

Table 313 describes the parameters associated with this command and indicates the status of each parameter.

TABLE 313 Static IPv6 route parameters

Parameter	Configuration details	Status
The IPv6 prefix and prefix length of the route's destination network.	You must specify the <*dest-ipv6-prefix*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the <*prefix-length*> parameter as a decimal value. A slash mark (/) must follow the <*ipv6-prefix*> parameter and precede the <*prefix-length*> parameter.	Mandatory for all static IPv6 routes.
The route's next-hop gateway, which can be one of the following: • The IPv6 address of a next-hop gateway. • A tunnel interface.	You can specify the next-hop gateway as one of the following types of IPv6 addresses: • A global address. • A link-local address. If you specify a global address, you do not need to specify any additional parameters for the next-hop gateway. If you specify a link-local address, you must also specify the interface through which to access the address. You can specify one of the following interfaces: • An Ethernet interface. • A tunnel interface. • A virtual interface (VE). If you specify an Ethernet interface, also specify the port number associated with the interface. If you specify a VE or tunnel interface, also specify the VE or tunnel number. You can also specify the next-hop gateway as a tunnel interface. If you specify a tunnel interface, also specify the tunnel number.	Mandatory for all static IPv6 routes.
The route's metric.	You can specify a value from 1 – 16.	Optional for all static IPv6 routes. (The default metric is 1.)
Tag <*number*>	This parameter specifies the tag value of the route.	The possible values are 0 - 4294967295. The default is 0.
The route's administrative distance.	You must specify the **distance** keyword and any numerical value.	Optional for all static IPv6 routes. (The default administrative distance is 1.)

A metric is a value that the router uses when comparing this route to other static routes in the IPv6 static route table that have the same destination. The metric applies only to routes that the router has already placed in the IPv6 static route table.

The administrative distance is a value that the router uses to compare this route with routes from other route sources that have the same destination. (The router performs this comparison before placing a route in the IPv6 route table.) This parameter does not apply to routes that are already in the IPv6 route table. In general, a low administrative distance indicates a preferred route. By default, static routes take precedence over routes learned by routing protocols. If you want a dynamic route to be chosen over a static route, you can configure the static route with a higher administrative distance than the dynamic route.

Configuring a IPv6 static multicast route

IPv6 multicast routes allow you to control the network path used by multicast traffic. Static multicast routes are especially useful when the unicast and multicast topologies of a network are different. You can avoid the need to make the topologies similar by instead configuring static multicast routes.

NOTE
This feature is not supported for DVMRP.

You can configure more than one static IPv6 multicast route. The PowerConnect by default uses the most specific route that matches a multicast source address. You can also specify route preference using the **route-preference** command as described in "Route selection precedence for multicast" on page 1170. Thus, if you want to configure a multicast static route for a specific multicast source and also configure another multicast static route for all other sources, you can configure two static routes.

To configure a IPv6 mroute for a destination network with the prefix 8eff::0/32, a next-hop gateway with the global address 4fee:2343:0:ee44::1, and an administrative distance of 110, enter the following command.

```
NetIron(config)# ipv6 mroute 8eff::0/32 4fee:2343:0:ee44::1 distance 110
```

Syntax: [no] **ipv6 mroute** <*dest-ipv6-prefix*>/<*prefix-length*> <*next-hop-ipv6-address*> <*next-hop-enable-default*> <*next-hop-recursion*> [<*metric*>] [**distance** <*number*>] [**tag**<*number*>]

Syntax: [no] **ipv6 mroute** <*ipv6-addr*> **interface ethernet** <*slot*>/<*portnum*> | **ve** <*num*> | **tunnel** <*num*> [**distance** <*num*>] [**tag**<*number*>]

The <*ipv6-addr*> command specifies the next-hop IP address.

NOTE
In IPv6 multicasting, a route is handled in terms of its source, rather than its destination.

You can use the **ethernet** <*slot*>/<*portnum*> parameter to specify a physical port or the **ve** <*num*> parameter to specify a virtual interface.

NOTE
The **ethernet** <*slot*>/<*portnum*> parameter does not apply to PIM SM.

The **next-hop-enable-default** parameter sets the default route to resolve the static route nexthop.

The **next-hop-recursion** parameter sets the static route to resolve the static route nexthop.

The **distance** <*num*> parameter sets the administrative distance for the route. When comparing multiple paths for a route, the router prefers the path with the lower administrative distance.

NOTE
Regardless of the administrative distances, the switch always prefers directly connected routes over other routes.

Configuring RIPng 42

PowerConnect B-MLXe supports the following RIPng features:

- RIPng
- RIPng Timers
- Default Route Learning and Advertising
- Redistributing Routes Into RIPng
- Controlling Distribution of Routes through RIPng
- Distribution of Routes through RIPng
- Poison Reverse Parameters

Routing Information Protocol (RIP) is an IP route exchange protocol that uses a distance vector (a number representing a distance) to measure the cost of a given route. RIP uses a hop count as its cost or metric.

IPv6 RIP, known as ***Routing Information Protocol Next Generation*** or ***RIPng***, functions similarly to IPv4 RIP version 2. RIPng supports IPv6 addresses and prefixes.

In addition, some new commands that are specific to RIPng have been implemented. This chapter describes the commands that are specific to RIPng. This section does not describe commands that apply to both IPv4 RIP and RIPng. For more information about these commands, refer to "Configuring RIP" on page 843.

RIPng maintains a ***Routing Information Database (RIB)***, which is a local route table. The local RIB contains the lowest-cost IPv6 routes learned from other RIP routers. In turn, RIPng attempts to add routes from its local RIB into the main IPv6 route table.

This chapter describes the following:

- How to configure RIPng.
- How to clear RIPng information from the RIPng route table.
- How to display RIPng information and statistics.

Configuring RIPng

To configure RIPng, you must do the following:

- Enable RIPng globally on the device and on individual router interfaces.

The following configuration tasks are optional:

- Change the default settings of RIPng timers.
- Configure how the device learns and advertises routes.
- Configure which routes are redistributed into RIPng from other sources.
- Configure how the device distributes routes through RIPng.

- Configure poison reverse parameters.

Enabling RIPng

Before configuring the device to run RIPng, you must do the following:

- Enable the forwarding of IPv6 traffic on the device using the **ipv6 unicast-routing** command.
- Enable IPv6 on each interface over which you plan to enable RIPng. You enable IPv6 on an interface by configuring an IPv6 address or explicitly enabling IPv6 on that interface.

For more information about performing these configuration tasks, refer to 38, "Configuring Basic IPv6 Connectivity".

By default, RIPng is disabled. To enable RIPng, you must enable it globally on the device and also on individual router interfaces.

NOTE
Enabling RIPng globally on the device does not enable it on individual router interfaces.

To enable RIPng globally, enter the following command.

```
NetIron(config-rip-router)#ipv6 router rip
NetIron(config-ripng-router)#
```

After you enter this command, the device enters the RIPng configuration level, where you can access several commands that allow you to configure RIPng.

Syntax: [no] ipv6 router rip

To disable RIPng globally, use the **no** form of this command.

After enabling RIPng globally, you must enable it on individual router interfaces. You can enable it on physical as well as virtual routing interfaces. For example, to enable RIPng on Ethernet interface 3/1, enter the following commands.

```
NetIron(config)# interface ethernet 3/1
NetIron(config-if-e100-3/1)# ipv6 rip enable
```

Syntax: [no] ipv6 rip enable

To disable RIPng on an individual router interface, use the **no** form of this command.

Configuring RIPng timers

Table 314 describes the RIPng timers and provides their defaults.

TABLE 314 RIPng timers

Timer	Description	Default
Update	Amount of time (in seconds) between RIPng routing updates.	30 seconds.
Timeout	Amount of time (in seconds) after which a route is considered unreachable.	180 seconds.
Hold-down	Amount of time (in seconds) during which information about other paths is ignored.	180 seconds.
Garbage-collection	Amount of time (in seconds) after which a route is removed from the routing table.	120 seconds.

You can adjust these timers for RIPng. Before doing so, keep the following caveats in mind:

- If you adjust these RIPng timers, it is strongly recommended to set the same timer values for all routerRouting Switches and access servers in the network.
- Setting the update timer to a shorter interval can cause the routerRouting Switches to spend excessive time updating the IPv6 route table.
- It is recommended to set the timeout timer value to at least three times the value of the update timer.
- It is recommended that a shorter hold-down timer interval, because a longer interval can cause delays in RIPng convergence.

The following example sets updates to be broadcast every 45 seconds. If a route is not heard from in 135 seconds, the route is declared unusable. Further information is suppressed for an additional 10 seconds. Assuming no updates, the route is flushed from the routing table 20 seconds after the end of the hold-down period.

```
NetIron(config)# ipv6 router rip
NetIron(config-ripng-router)# timers 45 135 10 20
```

Syntax: [no] timers <*update-timer*> <*timeout-timer*> <*hold-down-timer*> <*garbage-collection-timer*>

Possible values for the timers are as follows:

- **Update timer:** 3 – 65535 seconds.
- **Timeout timer:** 9 – 65535 seconds.
- **Hold-down timer:** 9 – 65535 seconds.
- **Garbage-collection timer:** 9 – 65535 seconds.

NOTE
You must enter a value for each timer, even if you want to retain the current setting of a particular timer.

To return to the default values of the RIPng timers, use the **no** form of this command.

Configuring route learning and advertising parameters

You can configure the following learning and advertising parameters:

- Learning and advertising of RIPng default routes.
- Advertising of IPv6 address summaries.
- Metric of routes learned and advertised on a router interface.

Configuring default route learning and advertising

By default, the device does not learn IPv6 default routes (::/0). You can originate default routes into RIPng, which causes individual router interfaces to include the default routes in their updates. When configuring the origination of the default routes, you can also do the following:

- Suppress all other routes from the updates.
- Include all other routes in the updates.

For example, to originate default routes in RIPng and suppress all other routes in updates sent from Ethernet interface 3/1, enter the following commands.

```
NetIron(config)# interface ethernet 3/1
NetIron(config-if-e100-3/1)# ipv6 rip default-information only
```

To originate IPv6 default routes and include all other routes in updates sent from Ethernet interface 3/1, enter the following commands.

```
NetIron(config)# interface ethernet 3/1
NetIron(config-if-e100-3/1)# ipv6 rip default-information originate
```

Syntax: [no] ipv6 rip default-information only | originate

The **only** keyword originates the default routes and suppresses all other routes from the updates.

The **originate** keyword originates the default routes and includes all other routes in the updates.

To remove the explicit default routes from RIPng and suppress advertisement of these routes, use the **no** form of this command.

Advertising IPv6 address summaries

You can configure RIPng to advertise a summary of IPv6 addresses from a router interface and to specify an IPv6 prefix that summarizes the routes.

If a route's prefix length matches the value specified in the **ipv6 rip summary-address** command, RIPng advertises the prefix specified in the **ipv6 rip summary-address** command instead of the original route.

For example, to advertise the summarized prefix 2001:469e::/36 instead of the IPv6 address 2001:469e:0:adff:8935:e838:78:e0ff with a prefix length of 64 bits from Ethernet interface 3/1, enter the following commands.

```
NetIron(config)# interface ethernet 3/1
NetIron(config-if-e100-3/1)# ipv6 address 2001:469e:0:adff:8935:e838:78:
e0ff /64
NetIron(config-if-e100-3/1)# ipv6 rip summary-address 2001:469e::/36
```

Syntax: [no] ipv6 rip summary-address <*ipv6-prefix*>/<*prefix-length*>

You must specify the <*ipv6-prefix*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

You must specify the <*prefix-length*> parameter as a decimal value. A slash mark (/) must follow the <*ipv6-prefix*> parameter and precede the <*prefix-length*> parameter.

To stop the advertising of the summarized IPv6 prefix, use the **no** form of this command.

Changing the metric of routes learned and advertised on an interface

A router interface increases the metric of an incoming RIPng route it learns by an offset (the default is one). The device then places the route in the route table. When the device sends an update, it advertises the route with the metric plus the default offset of zero in an outgoing update message.

You can change the metric offset an individual interface adds to a route learned by the interface or advertised by the interface. For example, to change the metric offset for incoming routes learned by Ethernet interface 3/1 to one and the metric offset for outgoing routes advertised by the interface to three, enter the following commands.

```
NetIron(config)# interface ethernet 3/1
NetIron(config-if-e100-3/1)# ipv6 rip metric-offset 1
NetIron(config-if-e100-3/1)# ipv6 rip metric-offset out 3
```

In this example, if Ethernet interface 3/1 learns about an incoming route, it will increase the incoming metric by two (the default offset of 1 and the additional offset of 1 as specified in this example). If Ethernet interface 3/1 advertises an outgoing route, it will increase the metric by 3 as specified in this example.

Syntax: [no] ipv6 rip metric-offset [out] <*1 – 16*>

To return the metric offset to its default value, use the **no** form of this command.

Redistributing routes into RIPng

You can configure the device to redistribute routes from the following sources into RIPng:

- IPv6 static routes.
- Directly connected IPv6 networks.
- BGP4+.
- IPv6 IS-IS.
- OSPFv3.

When you redistribute a route from BGP4+, IPv6 IS-IS, or OSPFv3 into RIPng, the device can use RIPng to advertise the route to its RIPng neighbors.

When configuring the device to redistribute routes, such as BGP4+ routes, you can optionally specify a metric for the redistributed routes. If you do not explicitly configure a metric, the default metric value of one is used.

For example, to redistribute OSPFv3 routes into RIPng, enter the following command.

```
NetIron(config)# ipv6 router rip
NetIron(config-ripng-router)# redistribute ospf
```

Syntax: [no] redistribute bgp | connected | isis | ospf | static [metric <*number*>**]**

For the metric, specify a numerical value that is consistent with RIPng.

Controlling distribution of routes through RIPng

You can create a prefix list and then apply it to RIPng routing updates that are received or sent on a router interface. Performing this task allows you to control the distribution of routes through RIPng.

For example, to permit the inclusion of routes with the prefix 2001::/16 in RIPng routing updates sent from Ethernet interface 3/1, enter the following commands.

```
NetIron(config)# ipv6 prefix-list routesfor2001 permit 2001::/16
NetIron(config)# ipv6 router rip
NetIron(config-ripng-router)# distribute-list prefix-list routesfor2001 out
ethernet 3/1
```

To deny prefix lengths greater than 64 bits in routes that have the prefix 3EE0:A99::/64 and allow all other routes received on tunnel interface 3/1, enter the following commands.

```
NetIron(config)# ipv6 prefix-list 3ee0routes deny 3ee0:a99::/64 le 128
NetIron(config)# ipv6 prefix-list 3ee0routes permit ::/0 ge 0 le 128
NetIron(config)# ipv6 router rip
NetIron(config-ripng-router)# distribute-list prefix-list 3ee0routes in
tunnel 1
```

For information about prefix lists, including the syntax of the **ipv6 prefix-list** command, refer to Chapter 39, "Configuring an IPv6 Prefix List".

Syntax: [no] distribute-list prefix-list <*name*> **in | out** <*interface*> <*port*>

The <*name*> parameter indicates the name of the prefix list generated using the **ipv6 prefix-list** command.

The **in** keyword indicates that the prefix list is applied to incoming routing updates on the specified interface.

The **out** keyword indicates that the prefix list is applied to outgoing routing updates on the specified interface.

For the <*interface*> parameter, you can specify the **ethernet**, **pos**, **loopback**, **ve**, or **tunnel** keywords. If you specify an Ethernet or POS interface, also specify the port number associated with the interface. If you specify a VE or tunnel interface, also specify the VE or tunnel number.

To remove the distribution list, use the **no** form of this command.

Configuring poison reverse parameters

By default, poison reverse is disabled on a RIPng router. If poison reverse is enabled, RIPng advertises routes it learns from a particular interface over that same interface with a metric of 16, which means that the route is unreachable.

If poison reverse is enabled on the RIPng router, it takes precedence over split horizon (if it is also enabled).

To enable poison reverse on the RIPng router, enter the following commands.

```
NetIron(config)# ipv6 router rip
NetIron(config-ripng-router)# poison-reverse
```

Syntax: [no] poison-reverse

To disable poison-reverse, use the **no** version of this command.

By default, if a RIPng interface goes down, the device does not send a triggered update for the interface's IPv6 networks.

To better handle this situation, you can configure a RIPng router to send a triggered update containing the local routes of the disabled interface with an unreachable metric of 16 to the other RIPng routers in the routing domain. You can enable the sending of a triggered update by entering the following commands.

```
NetIron(config)# ipv6 router rip
NetIron(config-ripng-router)# poison-local-routes
```

Syntax: [no] poison-local-routes

To disable the sending of a triggered update, use the **no** version of this command.

Clearing RIPng routes from IPv6 route table

To clear all RIPng routes from the RIPng route table and the IPv6 main route table and reset the routes, enter the following command at the Privileged EXEC level or any of the Config levels of the CLI.

```
NetIron# clear ipv6 rip routes
```

Syntax: clear ipv6 rip routes

Displaying RIPng information

You can display the following RIPng information:

- RIPng configuration.
- RIPng routing table.

Displaying RIPng configuration

To display RIPng configuration information, enter the following command at any CLI level.

```
NetIron# show ipv6 rip
 IPv6 rip enabled, port 521
     Administrative distance is 120
     Updates every 30 seconds, expire after 180
     Holddown lasts 180 seconds, garbage collect after 120
     Split horizon is on; poison reverse is off
     Default routes are not generated
     Periodic updates 0, trigger updates 0
     Distribute List, Inbound : Not set
     Distribute List, Outbound : Not set
     Redistribute: CONNECTED
```

Syntax: show ipv6 rip

This display shows the following information.

TABLE 315 RIPng configuration fields

This field...	Displays...
IPv6 RIP status or port	The status of RIPng on the device. Possible status is “enabled” or “disabled.” The UDP port number over which RIPng is enabled.
Administrative distance	The setting of the administrative distance for RIPng.
Updates or expiration	The settings of the RIPng update and timeout timers.
Holddown or garbage collection	The settings of the RIPng hold-down and garbage-collection timers.
Split horizon or poison reverse	The status of the RIPng split horizon and poison reverse features. Possible status is “on” or “off.”
Default routes	The status of RIPng default routes.
Periodic updates or trigger updates	The number of periodic updates and triggered updates sent by the RIPng router.

TABLE 315 RIPng configuration fields (Continued)

This field...	Displays...
Distribution lists	The inbound and outbound distribution lists applied to RIPng.
Redistribution	The types of IPv6 routes redistributed into RIPng. The types can include the following: • STATIC – IPv6 static routes are redistributed into RIPng. • CONNECTED – Directly connected IPv6 networks are redistributed into RIPng. • BGP – BGP4+ routes are redistributed into RIPng. • ISIS – IPv6 IS-IS routes are redistributed into RIPng. • OSPF – OSPFv3 routes are redistributed into RIPng.

Displaying RIPng routing table

To display the RIPng routing table, enter the following command at any CLI level.

```
NetIron# show ipv6 rip route
IPv6 RIP Routing Table - 4 entries:
 2000:4::/64, from ::, null   (0)
          CONNECTED, metric 1, tag 0, timers: none
 2002:c0a8:46a::/64, from ::, null   (1)
          CONNECTED, metric 1, tag 0, timers: none
 2999::1/128, from ::, null   (2)
          CONNECTED, metric 1, tag 0, timers: none
 5000:2::/64, from ::, null   (3)
          CONNECTED, metric 1, tag 0, timers: none
```

Syntax: show ipv6 rip route [<*ipv6-prefix*>/<*prefix-length*> | <*ipv6-address*>]

The <*ipv6-prefix*>/<*prefix-length*> parameters restrict the display to the entries for the specified IPv6 prefix. You must specify the <*ipv6-prefix*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the <*prefix-length*> parameter as a decimal value. A slash mark (/) must follow the <*ipv6-prefix*> parameter and precede the <*prefix-length*> parameter.

The <*ipv6-address*> parameter restricts the display to the entries for the specified IPv6 address. You must specify this parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

This display shows the following information.

TABLE 316 RIPng routing table fields

This field...	Displays...
RIPng Routing Table entries	The total number of entries in the RIPng routing table.
<*ipv6-prefix*>/<*prefix-length*> <*ipv6-address*>	The IPv6 prefix and prefix length. The IPv6 address.
Next-hop router	The next-hop router for this device. If :: appears, the route is originated locally.
Interface	The interface name. If “null” appears, the interface is originated locally.

TABLE 316 RIPng routing table fields

This field...	Displays...
Source of route	The source of the route information. The source can be one of the following: • RIP – routes learned by RIPng. • CONNECTED – IPv6 routes redistributed from directly connected networks. • STATIC – IPv6 static routes are redistributed into RIPng. • BGP – BGP4+ routes are redistributed into RIPng. • ISIS – IPv6 IS-IS routes are redistributed into RIPng. • OSPF – OSPFv3 routes are redistributed into RIPng.
Metric <*number*>	The cost of the route. The <*number*> parameter indicates the number of hops to the destination.
Tag <*number*>	The tag value of the route.
Timers:	Indicates if the hold-down timer or the garbage-collection timer is set.

Chapter

Configuring OSPF Version 3

43

The following OSPF Version 3 features supported by PowerConnect B-MLXe Series.

- OSPF Version 3
- Link-State Advertisement Router LSAs (Type 1)
- Link-State Advertisement Network LSAs (Type 2)
- Link-State Advertisement Interarea-prefix LSAs for ABRs (Type 3)
- Link-State Advertisement Interarea-router LSAs for ASBRs (Type 4)
- Link-State Advertisement Autonomous system external LSAs (Type 5)
- Link-State Advertisement Link LSAs (Type 8)
- Link-State Advertisement
- Intra-area prefix LSAs (Type 9)
- IPsec for OSPFv3
- New encryption code for passwords, authentication keys, and community strings
- Redistributing Routes into OSPFv3
- Filtering OSPFv3 Routes
- Default Route Origination
- Shortest Path First Timers
- Event Logging

Open Shortest Path First (OSPF) is a link-state routing protocol. OSPF uses link-state advertisements (LSAs) to update neighboring routers about its interfaces and information on those interfaces. The router floods LSAs to all neighboring routers to update them about the interfaces. Each router maintains an identical database that describes its area topology to help a router determine the shortest path between it and any neighboring router.

OSPF Version 3

IPv6 supports OSPF Version 3 (OSPFv3), which functions similarly to OSPF Version 2 (OSPFv2), the current version that IPv4 supports, except for the following enhancements:

- Support for IPv6 addresses and prefixes.
- Ability to configure several IPv6 addresses on a router interface. (OSPFv3 imports all or none of the the address prefixes configured on a router interface. You cannot select the addresses to import.)
- Ability to run one instance of OSPF Version 2 and one instance of OSPFv3 concurrently on a link.
- IPv6 link-state advertisements (LSAs).

In addition, some new commands that are specific to OSPFv3 have been implemented. This section describes the commands that are specific to OSPFv3.

NOTE
Although OSPF Version 2 and OSPF 3 function similarly to each other, Dell has implemented the user interface for each version independently of one another. Therefore, any configuration of OSPFv2 features will not affect the configuration of OSPFv3 features and vice versa.

Link-state advertisement types for OSPFv3

OSPFv3 supports the following types of LSAs:

- Router LSAs (Type 1)
- Network LSAs (Type 2)
- Interarea-prefix LSAs for ABRs (Type 3)
- Interarea-router LSAs for ASBRs (Type 4)
- Autonomous system external LSAs (Type 5)
- Link LSAs (Type 8)
- Intra-area-prefix LSAs (Type 9)

For more information about these LSAs, refer to RFC 2740.

Configuring OSPFv3

To configure OSPFv3, you must perform the following steps.

- Enable OSPFv3 globally.
- Assign OSPF areas.
- Assign router interfaces to an OSPF area.

The following configuration tasks are optional:

- Configure a virtual link between an Area Border Router (ABR) without a physical connection to a backbone area and the device in the same area with a physical connection to the backbone area.
- Change the reference bandwidth for the cost on OSPFv3 interfaces.
- Configure the redistribution of routes into OSPFv3.
- Configure default route origination.
- Modify the shortest path first (SPF) timers.
- Modify the administrative distances for OSPFv3 routes.
- Configure the OSPFv3 LSA pacing interval.
- Modify how often the device checks on the elimination of the database overflow condition.
- Modify the external link state database limit.
- Modify the default values of OSPFv3 parameters for router interfaces.
- Disable or re-enable OSPFv3 event logging.

Enabling OSPFv3

Before enabling the device to run OSPFv3, you must perform the following steps.

- Enable the forwarding of IPv6 traffic on the device using the **ipv6 unicast-routing** command.
- Enable IPv6 on each interface over which you plan to enable OSPFv3. You enable IPv6 on an interface by configuring an IPv6 address or explicitly enabling IPv6 on that interface.

For more information about performing these configuration tasks, refer to 38, "Configuring Basic IPv6 Connectivity".

By default, OSPFv3 is disabled. To enable OSPFv3 for a default Virtual Routing and Forwarding (VRF), you must enable it globally.

To enable OSPFv3 globally, enter the following command.

```
NetIron(config)# ipv6 router ospf
NetIron(config-ospf6-router)#
```

After you enter this command, the device enters the IPv6 OSPF configuration level, where you can access several commands that allow you to configure OSPFv3.

Syntax: [no] ipv6 router ospf [vrf]

To disable OSPFv3, enter the **no** form of this command. If you disable OSPFv3, the device removes all the configuration information for the disabled protocol from the running-configuration file. Moreover, when you save the configuration to the startup-config file after disabling one of these protocols, all the configuration information for the disabled protocol is removed from the startup-config file.

When you disable OSPFv3, the following warning message is displayed on the console.

```
NetIron(config-ospf6-router)# no ipv6 router ospf
ipv6 router ospf mode now disabled. All ospf config data will be lost when writing
to flash!
```

If you have disabled the protocol but have not yet saved the configuration to the startup-config file and reloaded the software, you can restore the configuration information by re-entering the command to enable the protocol (for example, **ipv6 router ospf**). If you have already saved the configuration to the startup-config file and reloaded the software, the configuration information is gone. If you are testing an OSPF configuration and are likely to disable and re-enable the protocol, you should make a backup copy of the startup-config file containing the protocol configuration information. This way, if you remove the configuration information by saving the configuration after disabling the protocol, you can restore the configuration by copying the backup copy of the startup-config file onto the flash memory.

Assigning OSPFv3 areas

After OSPFv3 is enabled, you can assign OSPFv3 areas. You can assign an IPv4 address or a number as the *area ID* for each area. The area ID is representative of all IPv6 addresses (subnets) on a router interface. Each router interface can support one area.

An area can be *normal* or a *stub*:

- Normal – OSPF routers within a normal area can send and receive external Link State Advertisements (LSAs).

- Stub – OSPF routers within a stub area cannot send or receive external LSAs. In addition, OSPF routers in a stub area must use a default route to the Area Border Router (ABR) or Autonomous System Boundary Router (ASBR) of the area to send traffic out of the area.

For example, to set up OSPFv3 areas 0.0.0.0, 200.5.0.0, 192.5.1.0, and 195.5.0.0, enter the following commands.

```
NetIron(config-ospf6-router)# area 0.0.0.0
NetIron(config-ospf6-router)# area 200.5.0.0
NetIron(config-ospf6-router)# area 192.5.1.0
NetIron(config-ospf6-router)# area 195.5.0.0
```

Syntax: [no] area <*number*> **|** <*ipv4-address*>

The <*number*> | <*ipv4-address*> parameter specifies the area number, which can be a number or in IPv4 address format. If you specify a number, the number can be from 0 through 2,147,483,647.

NOTE
You can assign only one area on a router interface.

Assigning a totally stubby area

By default, the device sends summary LSAs (type 3 LSAs) into stub areas. You can reduce the number of LSAs sent into a stub area by configuring the device to stop sending summary LSAs into the area. You can disable the summary LSAs when you are configuring the stub area or later after you have configured the area.

This feature disables origination of summary LSAs into a stub area, but the device still accepts summary LSAs from OSPF neighbors and floods them to other areas. The device can form adjacencies with other routers regardless of whether summarization is enabled or disabled for areas on each router.

When you disable the summary LSAs, the change takes effect immediately. If you apply the option to a previously configured area, the router flushes all of the summary LSAs it has generated (as an ABR) from the area.

NOTE
This feature applies only when the device is configured as an Area Border Router (ABR) for the area. To completely prevent summary LSAs from being sent to the area, disable the summary LSAs on each OSPF router that is an ABR for the area.

For example, to disable summary LSAs for stub area 40 and specify an additional metric of 99, enter the following command.

```
NetIron(config-ospf6-router)# area 40 stub 99 no-summary
```

Syntax: [no] area <*number*> **|** <*ipv4-address*> **stub** <*metric*> **[no-summary]**

The <*number*> | <*ipv4-address*> parameter specifies the area number, which can be a number or in IPv4 address format. If you specify a number, the number can be from 0 through 2,147,483,647.

The **stub** <*metric*> parameter specifies an additional cost for using a route to or from this area and can be from 1 through 16777215. There is no default. Normal areas do not use the cost parameter.

The **no-summary** parameter applies only to stub areas and disables summary LSAs from being sent into the area.

Assigning interfaces to an area

After you define OSPFv3 areas, you must assign router interfaces to the areas. All router interfaces must be assigned to one of the defined areas on an OSPF router. When an interface is assigned to an area, all corresponding subnets on that interface are automatically included in the assignment.

For example, to assign Ethernet interface 3/1 to area 192.5.0.0, enter the following commands.

```
NetIron(config)# interface Ethernet 3/1
NetIron(config-if-e100-3/1)# ipv6 ospf area 195.5.0.0
```

Syntax: [no] ipv6 ospf area <*number*> **|** <*ipv4-address*>

The <*number*> | <*ipv4-address*> parameter specifies the area number, which can be a number or in IPv4 address format. If you specify a number, the number can be from 0 through 2,147,483,647.

To remove the interface from the specified area, use the **no** form of this command.

Specifying a network type

You can specify a point-to-point or broadcast network type for any OSPF interface of the following types: POS, Ethernet, or VE interface. To specify the network type for an OSPF interface, use the following commands.

```
NetIron(config)# interface pos 3/1
NetIron(config-if-e100-3/1)# ipv6 ospf network broadcast
```

Syntax: [no] ipv6 ospf network point-to-point | broadcast

The **point-to-point** parameter specifies that the OSPF interface will support point-to-point networking. This is the default setting for POS interfaces.

The **broadcast** parameter specifies that the OSPF interface will support broadcast networking. This is the default setting for Ethernet and VE interfaces.

The **no** form of the command disables the command configuration.

Configuring virtual links

All ABRs must have either a direct or indirect link to an OSPF backbone area (0.0.0.0 or 0). If an ABR does not have a physical link to a backbone area, you can configure a virtual link from the ABR to another router within the same area that has a physical connection to the backbone area.

The path for a virtual link is through an area shared by the neighbor ABR (router with a physical backbone connection) and the ABR requiring a logical connection to the backbone.

Two parameters must be defined for all virtual links—transit area ID and neighbor router:

- The transit area ID represents the shared area of the two ABRs and serves as the connection point between the two routers. This number should match the area ID value.
- The neighbor router is the router ID (IPv4 address) of the router that is physically connected to the backbone when assigned from the router interface requiring a logical connection. The neighbor router is the router ID (IPv4 address) of the router requiring a logical connection to the backbone when assigned from the router interface with the physical connection.

NOTE
By default, the router ID is the IPv4 address configured on the lowest-numbered loopback interface. If the device does not have a loopback interface, the default router ID is the lowest-numbered IPv4 address configured on the device.

When you establish an area virtual link, you must configure it on both ends of the virtual link. For example, imagine that ABR1 in areas 1 and 2 is cut off from the backbone area (area 0). To provide backbone access to ABR1, you can add a virtual link between ABR1 and ABR2 in area 1 using area 1 as a transit area. To configure the virtual link, you define the link on the router that is at each end of the link. No configuration for the virtual link is required on the routers in the transit area.

To define the virtual link on ABR1, enter the following command on ABR1.

```
NetIron(config-ospf6-router)# area 1 virtual-link 209.157.22.1
```

To define the virtual link on ABR2, enter the following command on ABR2.

```
NetIron(config-ospf6-router)# area 1 virtual-link 10.0.0.1
```

Syntax: **area** <*number*> **|** <*ipv4-address*> **virtual-link** <*router-id*>

The <*number*>|<*ipv4-address*> parameter specifies the transit area ID, area number, which can be a number, or in IPv4 address format. If you specify a number, the number can be from 0 through 2,147,483,647.

The <*router-id*> parameter specifies the router ID of the OSPF router at the remote end of the virtual link. To display the router ID on a router, enter the **show ip** command.

Assigning a virtual link source address

When routers at both ends of a virtual link communicate with one another, the source address included in the packets must be a global IPv6 address. The Multi-Service IronWare software automatically selects a global IPv6 address for each transit area and advertises this address into the transit area of the Intra-area-prefix LSA. The automatically selected global IPv6 address for a transit area is the first global IPv6 address of any loopback interface in the transit area. If no global IPv6 address is available on a loopback interface in the area, then the first global IPv6 address of the lowest-numbered interface in the UP state (belonging to the transit area) will be assigned. If no global IPv6 address is configured on any of the OSPF interfaces in the transit area, then the virtual links in the transit area will not operate. The automatically selected IPv6 global address is updated whenever the previously selected IPv6 address of the interface changes, is removed, or if the interface goes down.

NOTE
The existing selected virtual link address will not change because the global IPv6 address is now available on a loopback interface or a lower-numbered interface in the transit area. To force the global IPv6 address for the virtual link to be the global IPv6 address of a newly configured loopback, or a lower-numbered interface in the area, you will have to either disable the existing selected interface or remove the currently selected global IPv6 address from the interface.

Modifying virtual link parameters

You can modify the following virtual link parameters:

- **Dead-interval:** The number of seconds that a neighbor router waits for a hello packet from the current router before declaring the router is down. The range is from 1 through 65535 seconds. The default is 40 seconds.
- **Hello-interval:** The length of time between the transmission of hello packets. The range is from 1 through 65535 seconds. The default is 10 seconds.
- **Retransmit-interval:** The interval between the retransmission of link state advertisements to router adjacencies for this interface. The range is from 0 through 3600 seconds. The default is 5 seconds.
- **Transmit-delay:** The period of time it takes to transmit Link State Update packets on the interface. The range is from 0 through 3600 seconds. The default is 1 second.

NOTE
The values of the **dead-interval** and **hello-interval** parameters must be the same at both ends of a virtual link. Therefore, if you modify the values of these parameters at one end of a virtual link, you must make the same modifications on the other end of the link.

The values of the other virtual link parameters do not require synchronization.

For example, to change the **dead-interval** parameter to 60 seconds on the virtual links defined on ABR1 and ABR2, enter the following command on ABR1.

```
NetIron(config-ospf6-router)# area 1 virtual-link 209.157.22.1
dead-interval 60
```

Enter the following command on ABR2.

```
NetIron(config-ospf6-router)# area 1 virtual-link 10.0.0.1 dead-interval 60
```

Syntax: **area** <*number*> **|** <*ipv4-address*> **virtual-link** <*router-id*> **[dead-interval** <*seconds*> **| hello-interval** <*seconds*> **| retransmit-interval** <*seconds*> **| transmit-delay** <*seconds*>**]**

The **area** <*number*> | <*ipv4-address*> parameter specifies the transit area ID.

The <*router-id*> parameter specifies the router ID of the OSPF router at the remote end of the virtual link. To display the router ID on a router, enter the **show ip** command.

The **dead-interval**, **hello-interval**, **retransmit-interval**, and **transmit-delay** parameters are described earlier in this section.

Changing the reference bandwidth for the cost on OSPFv3 interfaces

Each interface on which OSPFv3 is enabled has a cost associated with it. The device advertises its interfaces and their costs to OSPFv3 neighbors. For example, if an interface has an OSPF cost of 10, the device advertises the interface with a cost of 10 to other OSPF routers.

By default, OSPF cost of an interface is based on the port speed of the interface. The software uses the following formula to calculate the cost.

Cost = reference-bandwidth/interface-speed

By default, the reference bandwidth is 100 Mbps. If the resulting cost is less than 1, the software rounds the cost up to 1. The default reference bandwidth results in the following costs:

- 10 Mbps port cost = 100/10 = 10
- 100 Mbps port cost = 100/100 = 1

- 1000 Mbps port cost = 100/1000 = 0.10, which is rounded up to 1
- 155 Mbps port cost = 100/155 = 0.65, which is rounded up to 1
- 622 Mbps port cost = 100/622 = 0.16, which is rounded up to 1
- 2488 Mbps port cost = 100/2488 = 0.04, which is rounded up to 1

The interfaces that consist of more than one physical port is calculated as follows:

- LAG group – The combined bandwidth of all the ports.
- Virtual (Ethernet) interface – The combined bandwidth of all the ports in the port-based VLAN that contains the virtual interface.

You can change the default reference bandwidth from 100 Mbps to a value from 1 through 4294967 Mbps.

If a change to the reference bandwidth results in a cost change to an interface, the device sends a link-state update to update the costs of interfaces advertised by the device.

NOTE
If you specify a cost for an interface, your specified cost overrides the cost that the software calculates.

Some interface types are not affected by the reference bandwidth and always have the same cost regardless of the reference bandwidth in use:

- The cost of a loopback interface is always 1.
- The cost of a virtual link is calculated using the Shortest Path First (SPF) algorithm and is not affected by the auto-cost feature.
- The bandwidth for tunnel interfaces is 9 Kbps and is subject to the auto-cost feature.

For example, to change the reference bandwidth to 500, enter the following command.

```
NetIron(config-ospf6-router)# auto-cost reference-bandwidth 500
```

The reference bandwidth specified in this example results in the following costs:

- 10 Mbps port cost = 500/10 = 50
- 100 Mbps port cost = 500/100 = 5
- 1000 Mbps port cost = 500/1000 = 0.5, which is rounded up to 1
- 155 Mbps port cost = 500/155 = 3.23, which is rounded up to 4
- 622 Mbps port cost = 500/622 = 0.80, which is rounded up to 1
- 2488 Mbps port cost = 500/2488 = 0.20, which is rounded up to 1

The costs for 10 Mbps, 100 Mbps, and 155 Mbps ports change as a result of the changed reference bandwidth. Costs for higher-speed interfaces remain the same.

Syntax: [no] auto-cost reference-bandwidth *<number>*

The *<number>* parameter specifies the reference bandwidth in the range from 1 through 4294967. The default is 100.

To restore the reference bandwidth to its default value and thus restore the default costs of the interfaces to their default values, enter the **no** form of this command.

Redistributing routes into OSPFv3

In addition to specifying which routes are redistributed into OSPFv3, you can configure the following aspects related to route redistribution:

- Default metric.
- Metric type.
- Advertisement of an external aggregate route.

Configuring route redistribution into OSPFv3

You can configure the device to redistribute routes from the following sources into OSPFv3:

- IPv6 static routes.
- Directly connected IPv6 networks.
- BGP4+.
- IPv6 IS-IS.
- RIPng.

You can redistribute routes in the following ways:

- By route types, for example, the device redistributes all IPv6 static and RIPng routes.
- By using a route map to filter which routes to redistribute, for example, the device redistributes specified IPv6 static and RIPng routes only.

For example, to configure the redistribution of all IPv6 static, RIPng, and IPv6 IS-IS level-1 and level-2 routes, enter the following commands.

```
NetIron(config-ospf6-router)# redistribute static
NetIron(config-ospf6-router)# redistribute rip
NetIron(config-ospf6-router)# redistribute isis level-1-2
```

Syntax: [no] **redistribute bgp** | **connected** | **isis** [**level-1** | **level-1-2** | **level-2**] | **rip** | **static** [**metric** <*number*> | **metric-type** <*type*>]

The **bgp** | **connected** | **isis** | **rip** | **static** keywords specify the route source.

The **level-1** | **level-1-2** | **level-2** keywords (for IPv6 IS-IS only) allow you to specify that the device redistributes level-1 routes only, level-2 routes only, or both level-1 and level-2 routes.

The **metric** <*number*> parameter specifies the metric used for the redistributed route. If a value is not specified for this option, and the value for the **default-metric** command is set to 0, its default metric, then routes redistributed from the various routing protocols will have the metric value of the protocol from which they are redistributed. For information about the **default-metric** command, refer to "Modifying default metric for routes redistributed into OSPF Version 3" on page 1817.

The **metric-type** <*type*> parameter specifies an OSPF metric type for the redistributed route. You can specify external type 1 or external type 2. If a value is not specified for this option, the device uses the value specified by the **metric-type** command. For information about modifying the default metric type using the **metric-type** command, refer to "Modifying metric type for routes redistributed into OSPF Version 3" on page 1817.

For example, to configure a route map and use it for redistribution of routes into OSPFv3, enter commands such as the following.

```
NetIron(config)# ipv6 route 2001:1::/32 4823:eoff:343e::23
NetIron(config)# ipv6 route 2001:2::/32 4823:eoff:343e::23
NetIron(config)# ipv6 route 2001:3::/32 4823:eoff:343e::23 metric 5
NetIron(config)# route-map abc permit 1
NetIron(config-routemap abc)# match metric 5
NetIron(config-routemap abc)# set metric 8
NetIron(config-routemap abc)# ipv6 router ospf
NetIron(config-ospf6-router)# redistribute static route-map abc
```

The commands in this example configure some static IPv6 routes and a route map, and use the route map for redistributing the static IPv6 routes into OSPFv3.

The **ipv6 route** commands configure the static IPv6 routes. The route-map command begins configuration of a route map called “abc”. The number indicates the route map entry (called the “instance”) you are configuring. A route map can contain multiple entries. The software compares packets to the route map entries in ascending numerical order and stops the comparison once a match is found.

The **match** command in the route map matches on routes that have 5 for their metric value (cost). The **set** command changes the metric in routes that match the route map to 8.

The **redistribute** command configures the redistribution of static IPv6 routes into OSPFv3, and uses route map “abc“ to control the routes that are redistributed. In this example, the route map allows a static IPv6 route to be redistributed into OSPF only if the route has a metric of 5, and changes the metric to 8 before placing the route into the OSPF route redistribution table.

Syntax: [no] redistribute bgp | connected | isis | rip | static [route-map <*map-name*>**]**

The **bgp** | **connected** | **isis** | **rip** | **static** keywords specify the route source.

The **route-map** <*map-name*> parameter specifies the route map name. The following match parameters are valid for OSPFv3 redistribution:

- **match ip address** | **next-hop** <*acl-number*>
- **match metric** <*number*>
- **match tag** <*tag-value*>

The following set parameters are valid for OSPF redistribution:

- **set ip next hop** <*ipv4-address*>
- **set metric** [+ | -] <*number*> | none
- **set metric-type** type-1 | type-2
- **set tag** <*tag-value*>

NOTE
You must configure the route map before you configure a redistribution filter that uses the route map.

NOTE
When you use a route map for route redistribution, the software disregards the permit or deny action of the route map.

NOTE
For an external route that is redistributed into OSPFv3 through a route map, the metric value of the route remains the same unless the metric is set by a **set metric** command inside the route map or the **default-metric** <*num*> command. For a route redistributed without using a route map, the metric is set by the metric parameter if set or the **default-metric** <*num*> command if the metric parameter is not set.

Modifying default metric for routes redistributed into OSPF Version 3

The default metric is a global parameter that specifies the cost applied by default to routes redistributed into OSPFv3. The default value is 10.

If the **metric** parameter for the **redistribute** command is not set and the **default-metric** command is set to 10, its default value, then routes redistributed from the various routing protocols will have the metric value of the protocol from which they are redistributed. For information about the **redistribute** command, refer to "Configuring route redistribution into OSPFv3" on page 1815.

NOTE
You also can define the cost on individual interfaces. The interface cost overrides the default cost. For information about defining the cost on individual interfaces, refer to "Modifying OSPFv3 interface defaults" on page 1825 and "Changing the reference bandwidth for the cost on OSPFv3 interfaces" on page 1813.

To assign a default metric of 4 to all routes imported into OSPFv3, enter the following command.

```
NetIron(config-ospf6-router)# default-metric 4
```

Syntax: [no] default-metric <*number*>

You can specify a value from 0 – 65535. The default is 0.

To restore the default metric to the default value, use the **no** form of this command.

Modifying metric type for routes redistributed into OSPF Version 3

The device uses the **metric-type** parameter by default for all routes redistributed into OSPFv3 unless you specify a different metric type for individual routes using the **redistribute** command. (For more information about using the **redistribute** command, refer to "Redistributing routes into OSPFv3" on page 1815.)

A type 1 route specifies a small metric (two bytes), while a type 2 route specifies a big metric (three bytes). The default value is type 2.

To modify the default value of type 2 to type 1, enter the following command.

```
NetIron(config-ospf6-router)# metric-type type1
```

Syntax: [no] metric-type type1 | type2

To restore the metric type to the default value, use the **no** form of this command.

Configuring external route summarization

When the device is an OSPF Autonomous System Boundary Router (ASBR), you can configure it to advertise one external route as an aggregate for all redistributed routes that are covered by a specified IPv6 address range.

When you configure an address range, the range takes effect immediately. All the imported routes are summarized according to the configured address range. Imported routes that have already been advertised and that fall within the range are flushed out of the AS and a single route corresponding to the range is advertised.

If a route that falls within a configured address range is imported by the device, no action is taken if the device has already advertised the aggregate route; otherwise, the device advertises the aggregate route. If an imported route that falls within a configured address range is removed by the device, no action is taken if there are other imported routes that fall with in the same address range; otherwise the aggregate route is flushed.

You can configure up to 32 address ranges. The device sets the forwarding address of the aggregate route to zero and sets the tag to zero.

If you delete an address range, the advertised aggregate route is flushed and all imported routes that fall within the range are advertised individually.

If an external link state database overflow (LSDB) condition occurs, all aggregate routes are flushed out of the AS, along with other external routes. When the device exits the external LSDB overflow condition, all the imported routes are summarized according to the configured address ranges.

NOTE
If you use redistribution filters in addition to address ranges, the device applies the redistribution filters to routes first, then applies them to the address ranges.

NOTE
If you disable redistribution, all the aggregate routes are flushed, along with other imported routes.

NOTE
This option affects only imported, type 5 external routes. A single type 5 LSA is generated and flooded throughout the AS for multiple external routes.

To configure the summary address 2201::/24 for routes redistributed into OSPFv3, enter the following command.

```
NetIron(config-ospf6-router)# summary-address 2201::/24
```

In this example, the summary prefix 2201::/24 includes addresses 2201::/1 through 2201::/24. Only the address FEC0::/24 is advertised in an external link-state advertisement.

Syntax: **summary-address** <*ipv6-prefix*>/<*prefix-length*>

You must specify the <*ipv6-prefix*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

You must specify the <*prefix-length*> parameter as a decimal value. A slash mark (/) must follow the <*ipv6-prefix*> parameter and precede the <*prefix-length*> parameter.

Filtering OSPFv3 routes

You can filter the routes to be placed in the OSPFv3 route table by configuring distribution lists. OSPFv3 distribution lists can be applied globally or to an interface.

The functionality of OSPFv3 distribution lists is similar to that of OSPFv2 distribution lists. However, unlike OSPFv2 distribution lists, which filter routes based on criteria specified in an Access Control List (ACL), OSPFv3 distribution lists can filter routes using information specified in an IPv6 prefix list or a route map.

Configuration examples

The following sections show examples of filtering OSPFv3 routes using prefix lists globally and for a specific interface, as well as filtering OSPFv3 routes using a route map.

You can configure the device to use all three types of filtering. When you do this, filtering using route maps has higher priority over filtering using global prefix lists. Filtering using prefix lists for a specific interface has lower priority than the other two filtering methods.

The example in this section assume the following routes are in the OSPFv3 route table.

```
NetIron# show ipv6 ospf route

  Current Route count: 5
    Intra: 3 Inter: 0 External: 2 (Type1 0/Type2 2)
    Equal-cost multi-path: 0
    Destination                  Options   Area            Cost Type2 Cost
    Next Hop Router              Outgoing Interface
*IA 3001::/64                    --------- 0.0.0.1           0 0
    ::                           ve 10
*E2 3010::/64                    --------- 0.0.0.0          10 0
    fe80::2e0:52ff:fe00:10       ve 10
*IA 3015::/64                    V6E---R-- 0.0.0.0          11 0
    fe80::2e0:52ff:fe00:10       ve 10
*IA 3020::/64                    --------- 0.0.0.0          10 0
    ::                           ve 11
*E2 6001:5000::/64               --------- 0.0.0.0          10 0
    fe80::2e0:52ff:fe00:10       ve 10
```

Configuring an OSPFv3 distribution list using an IPv6 prefix list as input

The following example illustrates how to use an IPv6 prefix list is used to filter OSPFv3 routes.

To specify an IPv6 prefix list called filterOspfRoutes that denies route 3010::/64, enter the following commands.

```
NetIron(config)# ipv6 prefix-list filterOspfRoutes seq 5 deny 3010::/64
NetIron(config)# ipv6 prefix-list filterOspfRoutes seq 7 permit ::/0 ge 1 le 128
```

Syntax: **ipv6 prefix-list** <*name*> [**seq** <*seq-value*>] [**description** <*string*>] **deny | permit** <*ipv6-addr*>/<*mask-bits*> [**ge** <*ge-value*>] [**le** <*le-value*>]

To configure a distribution list that applies the filterOspfRoutes prefix list globally.

```
NetIron(config)# ipv6 router ospf
NetIron(config-ospf6-router)# distribute-list prefix-list filterOspfRoutes in
```

Syntax: [no] **distribute-list prefix-list** <*name*> **in** [**< ethernet** <*slot/port*> **| pos** <*slot/port*> **| ve** <*num*> **| loopback** <*num*> **]**

After this distribution list is configured, route 3010::/64 would be omitted from the OSPFv3 route table.

```
NetIron# show ipv6 ospf route

  Current Route count: 4
    Intra: 3 Inter: 0 External: 1 (Type1 0/Type2 1)
    Equal-cost multi-path: 0
    Destination                    Options   Area             Cost Type2 Cost
    Next Hop Router                Outgoing Interface
*IA 3001::/64                      --------- 0.0.0.1             0 0
    ::                             ve 10
*IA 3015::/64                      V6E---R-- 0.0.0.0            11 0
    fe80::2e0:52ff:fe00:10         ve 10
*IA 3020::/64                      --------- 0.0.0.0            10 0
    ::                             ve 11
*E2 6001:5000::/64                 --------- 0.0.0.0            10 0
    fe80::2e0:52ff:fe00:10         ve 10
```

The following commands specify an IPv6 prefix list called filterOspfRoutesVe that denies route 3015::/64.

```
NetIron(config)# ipv6 prefix-list filterOspfRoutesVe seq 5 deny 3015::/64
NetIron(config)# ipv6 prefix-list filterOspfRoutesVe seq 10 permit ::/0 ge 1 le
128
```

The following commands configure a distribution list that applies the filterOspfRoutesVe prefix list to routes pointing to virtual interface 10.

```
NetIron(config)# ipv6 router ospf
NetIron(config-ospf6-router)# distribute-list prefix-list filterOspfRoutes in ve
10
```

After this distribution list is configured, route 3015::/64, pointing to virtual interface 10, would be omitted from the OSPFv3 route table.

```
NetIron# show ipv6 ospf route

  Current Route count: 4
    Intra: 3 Inter: 0 External: 1 (Type1 0/Type2 1)
    Equal-cost multi-path: 0
    Destination                    Options   Area             Cost Type2 Cost
    Next Hop Router                Outgoing Interface
*IA 3001::/64                      --------- 0.0.0.1             0 0
    ::                             ve 10
*E2 3010::/64                      --------- 0.0.0.0            10 0
    fe80::2e0:52ff:fe00:10         ve 10
*IA 3020::/64                      --------- 0.0.0.0            10 0
    ::                             ve 11
*E2 6001:5000::/64                 --------- 0.0.0.0            10 0
    fe80::2e0:52ff:fe00:10         ve 10
```

Configuring an OSPFv3 distribution list using a route map as input

The following commands configure a route map that matches internal routes.

```
NetIron(config)# route-map allowInternalRoutes permit 10
NetIron(config-routemap allowInternalRoutes)# match route-type internal
```

Refer to 22, “Policy-Based Routing” for information on configuring route maps.

The following commands configure a distribution list that applies the allowInternalRoutes route map globally to OSPFv3 routes.

```
NetIron(config)# ipv6 router ospf
NetIron(config-ospf6-router)# distribute-list route-map allowinternalroutes in
```

Syntax: [no] distribute-list route-map <*name*> **in**

After this distribution list is configured, the internal routes would be included, and the external routes would be omitted from the OSPFv3 route table.

```
NetIron# show ipv6 ospf route

  Current Route count: 3
    Intra: 3 Inter: 0 External: 0 (Type1 0/Type2 0)
    Equal-cost multi-path: 0
    Destination                    Options   Area             Cost Type2 Cost
    Next Hop Router                Outgoing Interface
*IA 3001::/64                      --------- 0.0.0.1            0 0
    ::                             ve 10
*IA 3015::/64                      V6E---R-- 0.0.0.0           11 0
    fe80::2e0:52ff:fe00:10         ve 10
*IA 3020::/64                      --------- 0.0.0.0           10 0
    ::                             ve 11
```

Configuring default route origination

When the device is an OSPF Autonomous System Boundary Router (ASBR), you can configure it to automatically generate a default external route into an OSPFv3 routing domain. This feature is called “default route origination” or “default information origination.”

By default, the device does not advertise the default route into the OSPFv3 domain. If you want the device to advertise the OSPF default route, you must explicitly enable default route origination.

When you enable OSPF default route origination, the device advertises a type 5 default route that is flooded throughout the AS (except stub areas).

The device advertises the default route into OSPF even if OSPF route redistribution is not enabled, and even if the default route is learned through an IBGP neighbor.

NOTE
The device does not advertise the OSPF default route, regardless of other configuration parameters, unless you explicitly enable default route origination.

If default route origination is enabled and you disable it, the default route originated by the device is flushed. Default routes generated by other OSPF routers are not affected. If you re-enable the feature, the feature takes effect immediately and thus does not require you to reload the software.

For example, to create and advertise a default route with a metric of 2 and as a type 1 external route, enter the following command.

```
NetIron(config-ospf6-router)# default-information-originate always metric 2
metric-type type1
```

Syntax: [no] default-information-originate [always] [metric <*value*>**] [metric-type** <*type*>**]**

The **always** keyword originates a default route regardless of whether the device has learned a default route. This option is disabled by default.

The **metric** <*value*> parameter specifies a metric for the default route. If this option is not used, the value of the **default-metric** command is used for the route. For information about this command, refer to “Modifying default metric for routes redistributed into OSPF Version 3” on page 1817.

The **metric-type** <*type*> parameter specifies the external link type associated with the default route advertised into the OSPF routing domain. The <*type*> can be one of the following:

- 1 – Type 1 external route
- 2 – Type 2 external route

If you do not use this option, the default redistribution metric type is used for the route type.

NOTE
If you specify a metric and metric type, the values are used even if you do not use the always option.

To disable default route origination, enter the **no** form of the command.

Modifying Shortest Path First timers

The device uses the following timers when calculating the shortest path for OSPFv3 routes:

- **SPF delay** – When the device receives a topology change, the software waits before it starts a Shortest Path First (SPF) calculation. By default, the software waits 5 seconds. You can configure the SPF delay to a value from 0 – 65535 seconds. If you set the SPF delay to 0 seconds, the software immediately begins the SPF calculation after receiving a topology change.
- **SPF hold time** – The device waits a specific amount of time between consecutive SPF calculations. By default, it waits 10 seconds. You can configure the SPF hold time to a value from 0 – 65535 seconds. If you set the SPF hold time to 0 seconds, the software does not wait between consecutive SPF calculations.

You can set the SPF delay and hold time to lower values to cause the device to change to alternate paths more quickly if a route fails. Note that lower values for these parameters require more CPU processing time.

You can change one or both of the timers.

NOTE
If you want to change only one of the timers, for example, the SPF delay timer, you must specify the new value for this timer as well as the current value of the SPF hold timer, which you want to retain. The device does not accept only one timer value.

NOTE
If you configure SPF timers between 0-100, they will default to 0 and be displayed incorrectly in the running configuration.

To change the SPF delay to 10 seconds and the SPF hold to 20 seconds, enter the following command.

```
NetIron(config-ospf6-router)# timers spf 10 20
```

Syntax: timers spf <*delay*> <*hold-time*>

For the <*delay*> and <*hold-time*> parameters, specify a value from 0 – 65535 seconds.

To set the timers back to their default values, enter the **no** version of this command.

Modifying administrative distance

The device can learn about networks from various protocols, including BGP4+, IPv6 IS-IS, RIPng, and OSPFv3. Consequently, the routes to a network may differ depending on the protocol from which the routes were learned. By default, the administrative distance for OSPFv3 routes is 110.

The device selects one route over another based on the source of the route information. To do so, the device can use the administrative distances assigned to the sources. You can influence the device's decision by changing the default administrative distance for OSPFv3 routes.

Configuring administrative distance based on route type

You can configure a unique administrative distance for each type of OSPFv3 route. For example, you can use this feature to influence the device to prefer a static route over an OSPF inter-area route and to prefer OSPF intra-area routes to static routes.

The distance you specify influences the choice of routes when the device has multiple routes to the same network from different protocols. The device prefers the route with the lower administrative distance.

You can specify unique default administrative distances for the following OSPFv3 route types:

- Intra-area routes
- Inter-area routes
- External routes

The default for all of these OSPFv3 route types is 110.

NOTE
This feature does not influence the choice of routes within OSPFv3. For example, an OSPF intra-area route is always preferred over an OSPF inter-area route, even if the intra-area route's distance is greater than the inter-area route's distance.

For example, to change the default administrative distances for intra-area routes to 80, inter-area routes to 90, and external routes to 100, enter the following commands.

```
NetIron(config-ospf6-router)# distance intra-area 80
NetIron(config-ospf6-router)# distance inter-area 90
NetIron(config-ospf6-router)# distance external 100
```

Syntax: distance external | inter-area | intra-area *<distance>*

The external | inter-area | intra-area keywords specify the route type for which you are changing the default administrative distance.

The *<distance>* parameter specifies the new distance for the specified route type. You can specify a value from
1 – 255.

To reset the administrative distance of a route type to its system default, enter the no form of this command.

Configuring the OSPFv3 LSA pacing interval

The device paces OSPFv3 LSA refreshes by delaying the refreshes for a specified time interval instead of performing a refresh each time an individual LSA's refresh timer expires. The accumulated LSAs constitute a group, which the device refreshes and sends out together in one or more packets.

The pacing interval, which is the interval at which the device refreshes an accumulated group of LSAs, is configurable to a range from 10 – 1800 seconds (30 minutes). The default is 240 seconds (four minutes). Thus, every four minutes, the device refreshes the group of accumulated LSAs and sends the group together in the same packets.

The pacing interval is inversely proportional to the number of LSAs the device is refreshing and aging. For example, if you have approximately 10,000 LSAs, decreasing the pacing interval enhances performance. If you have a very small database (40 – 100 LSAs), increasing the pacing interval to 10 – 20 minutes might enhance performance only slightly.

To change the OSPFv3 LSA pacing interval to two minutes (120 seconds), enter the following command.

```
NetIron(config)# ipv6 router ospf
NetIron(config-ospf6-router)# timers lsa-group-pacing 120
```

Syntax: [no] timers lsa-group-pacing <*seconds*>

The <*seconds*> parameter specifies the number of seconds and can be from 10 – 1800 (30 minutes). The default is 240 seconds (four minutes).

To restore the pacing interval to its default value, use the **no** form of the command.

Modifying exit overflow interval

If a database overflow condition occurs on the device, the device eliminates the condition by removing entries that originated on the device. The exit overflow interval allows you to set how often a device checks to see if the overflow condition has been eliminated. The default value is 0. If the configured value of the database overflow interval is 0, then the device never leaves the database overflow condition.

For example, to modify the exit overflow interval to 60 seconds, enter the following command.

```
NetIron(config-ospf6-router)# database-overflow-interval 60
```

Syntax: database-overflow-interval <*seconds*>

The <*seconds*> parameter can be a value from 0 – 86400 seconds (24 hours).

To reset the exit overflow interval to its system default, enter the **no** form of this command.

Modifying external link state database limit

By default, the link state database can hold a maximum of 2000 entries for external (type 5) LSAs. You can change the maximum number of entries from 500 – 8000. After changing this limit, make sure to save the running-config file and reload the software. The change does not take effect until you reload or reboot the software.

For example, to change the maximum number entries from the default of 2000 to 3000, enter the following command.

```
NetIron(config-ospf6-router)# external-lsdb-limit 3000
```

Syntax: **external-lsdb-limit** <*entries*>

The <*entries*> parameter can be a numerical value from 500 – 8000 seconds.

To reset the maximum number of entries to its system default, enter the **no** form of this command.

Modifying OSPFv3 interface defaults

OSPFv3 has interface parameters that you can configure. For simplicity, each of these parameters has a default value. No change to these default values is required except as needed for specific network configurations.

You can modify the default values for the following OSPF interface parameters:

- **Cost:** Indicates the overhead required to send a packet across an interface. You can modify the cost to differentiate between 100 Mbps and 1000 Mbps (1 Gbps) links. The command syntax is **ipv6 ospf cost** <*number*>. The default cost is calculated by dividing 100 million by the bandwidth. For 10 Mbps links, the cost is 10. The cost for both 100 Mbps and 1000 Mbps links is 1, because the speed of 1000 Mbps was not in use at the time the OSPF cost formula was devised.
- **Dead-interval:** Indicates the number of seconds that a neighbor router waits for a hello packet from the current router before declaring the router down. The command syntax is **ipv6 ospf dead-interval** <*seconds*>. The value can be from 1 – 2147483647 seconds. The default is 40 seconds.
- **Hello-interval:** Represents the length of time between the transmission of hello packets. The command syntax is **ipv6 ospf hello-interval** <*seconds*>. The value can be from 1 – 65535 seconds. The default is 10 seconds.
- **Instance:** Indicates the number of OSPFv3 instances running on an interface. The command syntax is **ipv6 ospf instance** <*number*>. The value can be from 0 – 255. The default is 1.
- **MTU-ignore:** Allows you to disable a check that verifies the same MTU is used on an interface shared by neighbors. The command syntax is **ipv6 ospf mtu-ignore**. By default, the mismatch detection is enabled.
- **Network:** Allows you to configure the OSPF network type. The command syntax is **ipv6 ospf network** [**point-to-multipoint**]. The default setting of the parameter depends on the network type.
- **Passive:** When you configure an OSPF interface to be passive, that interface does not send or receive OSPF route updates. This option affects all IPv6 subnets configured on the interface. The command syntax is **ipv6 ospf passive**. By default, all OSPF interfaces are active and thus can send and receive OSPF route information. Since a passive interface does not send or receive route information, the interface is in effect a stub network.
- **Priority:** Allows you to modify the priority of an OSPF router. The priority is used when selecting the designated router (DR) and backup designated routers (BDRs). The command syntax is **ipv6 ospf priority** <*number*>. The value can be from 0 – 255. The default is 1. If you set the priority to 0, the router does not participate in DR and BDR election.
- **Retransmit-interval:** The time between retransmissions of LSAs to adjacent routers for an interface. The command syntax is **ipv6 ospf retransmit-interval** <*seconds*>. The value can be from 0 – 3600 seconds. The default is 5 seconds.

- **Transmit-delay:** The time it takes to transmit Link State Update packets on this interface. The command syntax is **ipv6 ospf transmit-delay** <*seconds*>. The range is 0 – 3600 seconds. The default is 1 second.

Disabling or reenabling event logging

OSPFv3 supports the generation of SNMP traps together with the logging of OSPFv3 events. The log-status change parameter controls the generation of all OSPFv3 logs and OSPFv3 SNMP traps. You can disable or re-enable the generation of SNMP traps and the logging of events related to OSPFv3, such as neighbor state changes and database overflow conditions. By default, the device logs these events and generates the SNMP traps.

To disable the logging of events and the generation of the SNMP traps, enter the following command.

```
NetIron(config-ospf6-router)# no log-status-change
```

Syntax: [no] log-status-change

To re-enable the logging of events, enter the following command.

```
NetIron(config-ospf6-router)# log-status-change
```

IPsec for OSPFv3

This section describes the current implementation of Internet Protocol Security (IPsec) for securing OSPFv3 traffic. For background information and configuration steps, refer to "Configuring IPsec for OSPFv3" on page 1827.

IPsec is available for OSPFv3 traffic only and only for packets that are "for-us." A for-us packet is addressed to one of the IPv6 addresses on the router or to an IPv6 multicast address. Packets that are just forwarded by the line card do not receive IPsec scrutiny.

In the current release, Dell supports the following components of IPsec for IPv6-addressed packets:

- Authentication through Encapsulating Security Payload (ESP) in transport mode
- HMAC-SHA1-96 as the authentication algorithm
- Manual configuration of keys
- Configurable rollover timer

IPsec can be enabled on the following logical entities:

- Interface
- Area
- Virtual link

With respect to traffic classes, this implementation of IPSec uses a single security association (SA) between the source and destination to support all traffic classes and so does not differentiate between the different classes of traffic that the DSCP bits define.

Instructions for configuring IPsec on these entities appear in "Configuring IPsec for OSPFv3" on page 1827.

IPsec on a virtual link is a global configuration. Interface and area IPsec configurations are more granular.

Among the entities that can have IPsec protection, the interfaces and areas can overlap. The interface IPsec configuration takes precedence over the area IPsec configuration when an area and an interface within that area use IPsec. Therefore, if you configure IPsec for an interface and an area configuration also exists that includes this interface, the interface's IPsec configuration is used by that interface. However, if you disable IPsec on an interface, IPsec is disabled on the interface even if the interface has its own, specific authentication. Refer to "Disabling IPsec on an interface" on page 1832.

For IPsec, the system generates two types of databases. The *security association database* (SAD) contains a security association for each interface or one global database for a virtual link. Even if IPsec is configured for an area, each interface that uses the area's IPsec still has its own security association in the SAD. Each SA in the SAD is a generated entry that is based on your specifications of an authentication protocol (ESP in the current release), destination address, and a security policy index (SPI). The SPI number is user-specified according to the network plan. Consideration for the SPI values to specify must apply to the whole network.

The system-generated security policy databases (SPDs) contain the security policies against which the system checks the for-us packets. For each for-us packet that has an ESP header, the applicable security policy in the security policy database (SPD) is checked to see if this packet complies with the policy. The IPsec task drops the non-compliant packets. Compliant packets continue on to the OSPFv3 task.

Configuring IPsec for OSPFv3

This section describes how to configure IPsec for an interface, area, and virtual link. It also describes how to change the key rollover timer if necessary and how to disable IPsec on a particular interface for special purposes.

By default, OSPFv3 IPSec authentication is disabled. The following IPsec parameters are configurable:

- ESP security protocol
- Authentication
- HMAC-SHA1-96 authentication algorithm
- Security parameter index (SPI)
- A 40-character key using hexadecimal characters
- An option for not encrypting the keyword when it appears in **show** command output
- Key rollover timer

NOTE
In the current release, certain keyword parameters must be entered even though only one keyword choice is possible for that parameter. For example, the only authentication algorithm in the current release is HMAC-SHA1-96, but you must nevertheless enter the keyword for this algorithm. Also, ESP currently is the only authentication protocol, but you must still enter the **esp** keyword. This section describes all keywords.

General considerations

The IPsec component generates security associations and security policies based on certain user-specified parameters. The parameters are described with the syntax of each command in this section and also pointed out in the section with the **show** command examples, "IPsec examples" on page 1855. User-specified parameters and their relation to system-generated values are as follows:

- **Security association:** based on your entries for *security policy index* (SPI), *destination address*, and *security protocol* (currently ESP), the system creates a security association for each interface or virtual link.
- **Security policy database:** based on your entries for SPI, *source address*, *destination addresses*, and *security protocol*, the system creates a security policy database for each interface or virtual link.
- You can configure the same SPI and key on multiple interfaces and areas, but they still have unique IPsec configurations because the SA and policies are added to each separate security policy database (SPD) that is associated with a particular interface. If you configure an SA with the same SPI in multiple places, the rest of the parameters associated with the SA—such as key, crypto algorithm, and security protocol, and so on—must match. If the system detects a mismatch, it displays an error message.
- IPSec authentication for OSPFv3 requires the use of multiple SPDs, one for each interface. A virtual link has a separate, global SPD. The authentication configuration on a virtual link must be different from the authentication configuration for an area or interface, as required by RFC4552. The interface number is used to generate a non-zero security policy database identifier (SPDID), but for the global SPD for a virtual link, the system-generated SPDID is always zero. As a hypothetical example, the SPD for interface eth 1/1 might have the system-generated SPDID of 1, and so on.
- If you change an existing key, you must also specify a different SPI value. For example, in an interface context where you intend to change a key, you must type a different SPI value—which occurs before the key parameter on the command line—before you type the new key. The example in "Configuring IPsec for OSPFv3"illustrates this requirement.
- The old key is active for twice the current configured key-rollover-interval for the inbound direction. In the outbound direction, the old key remains active for a duration equal to the key-rollover-interval. If the key-rollover-interval is set to 0, the new key immediately takes effect for both directions. For a description of the key-rollover-interval, refer to the "Changing the key rollover timer" on page 1832section.

Interface and area IPsec considerations

This section describes the precedence of interface and area IPsec configurations.

If you configure an interface IPsec by using the **ipv6 ospf authentication** command in the context of a specific interface, that interface's IPsec configuration overrides the area configuration of IPsec.

If you configure IPsec for an area, all interfaces that utilize the area-wide IPsec (where interface-specific IPsec is not configured) nevertheles receive an SPD entry (and SPDID number) that is unique for the interface.

The area-wide SPI that you specify is a constant for all interfaces in the area that use the area IPsec, but the use of different interfaces results in an SPDID and an SA that are unique to each interface. (Recall from "IPsec for OSPFv3" on page 1826 that the security policy database depends partly on the source IP address, so a unique SPD for each interface results.)

Considerations for IPsec on virtual links

The IPsec configuration for a virtual link is global, so only one security association database and one security policy database exist for virtual links if you choose to configure IPsec for virtual links.

The virtual link IPsec SAs and policies are added to all interfaces of the transit area for the outbound direction. For the inbound direction, IPsec SAs and policies for virtual links are added to the global database.

NOTE
The security association (SA), security protocol index (SPI), security protocol database (SPD), and key have mutual dependencies, as the subsections that follow describe.

Specifying the key rollover timer

Configuration changes for authentication takes effect in a controlled manner through the key rollover procedure as specified in RFC 4552, Section 10.1. The key rollover timer controls the timing of the configuration changeover. The key rollover timer can be configured in the IPv6 router OSPF context, as the following example illustrates.

```
NetIron(config-ospf6-router)#key-rollover-interval 200
```

Syntax: **key-rollover-interval** <*time*>

The range for the key-rollover-interval is 0 – 14400 seconds. The default is 300 seconds.

Configuring IPsec on a interface

For IPsec to work, the IPsec configuration must be the same on all the routers to which an interface connects.

For multicast, IPsec does not need or use a specific destination address—the destination address is “do not care,” and this status is reflected by the lone pair of colons (::) for destination address in the **show** command output.

To configure IPsec on an interface, proceed as in the following example.

NOTE
The IPsec configuration for an interface applies to the inbound and outbound directions. Also, the same authentication parameters must be used by all routers on the network to which the interface is connected, as described in section 7 of RFC 4552.

```
NetIron(config-if-e10000-1/2)#ipv6 ospf auth ipsec spi 429496795 esp sha1
abcdef12345678900987654321fedcba12345678
```

Syntax: **[no] ipv6 ospf authentication ipsec spi** <*spinum*> **esp sha1 [no-encrypt]** <*key*>

The **no** form of this command deletes IPsec from the interface.

The **ipv6** command is available in the configuration interface context for a specific interface.

The **ospf** keyword identifies OSPFv3 as the protocol to receive IPsec security.

The **authentication** keyword enables authentication.

The **ipsec** keyword specifies IPsec as the authentication protocol.

The **spi** keyword and the <*spinum*> variable specify the security parameter that points to the security association. The near-end and far-end values for spinum must be the same. The range for <*spinum*> is decimal 256 – 4294967295.

The mandatory **esp** keyword specifies ESP (rather than authentication header) as the protocol to provide packet-level security. In the current release, this parameter can be **esp** only.

The **sha1** keyword specifies the HMAC-SHA1-96 authentication algorithm. This mandatory parameter can be only the **sha1** keyword in the current release.

Including the optional **no-encrypt** keyword means that when you display the IPsec configuration, the key is displayed in its unencrypted form and also saved as unencrypted.

The <*key*> variable must be 40 hexadecimal characters. To change an existing key, you must also specify a different SPI value. You cannot just change the key without also specifying a different SPI, too. For example, in an interface context where you intend to change a key, you must type a different SPI value—which occurs before the key parameter on the command line—before you type the new key. The example in "Configuring IPsec for OSPFv3"illustrates this requirement.

If **no-encrypt** is not entered, then the key will be encrypted. This is the default. The system adds the following in the configuration to indicate that the key is encrypted:

- encryptb64 = the key string uses proprietary base64 crytographic 2-way algorithm

This example results in the configuration shown in the screen output that follows. Note that because the optional **no-encrypt** keyword was omitted, the display of the key has the encrypted form by default.

```
interface ethernet 1/2
 enable
 ip address 40.3.3.1/8
 ipv6 address 40:3:3::1/64
 ipv6 ospf area 1
 ipv6 ospf authentication ipsec spi 429496795 esp sha1 encryptb64
$ITJkQG5HWnw4M09tWVd
```

Configuring IPsec for an area

This application of the **area** command (for IPsec) applies to all of the interfaces that belong to an area unless an interface has its own IPsec configuration. (As described in "Disabling IPsec on an interface" on page 1832, the interface IPsec can be operationally disabled if necessary.) To configure IPsec for an area in the IPv6 router OSPF context, proceed as in the following example.

```
NetIron(config-ospf6-router)#area 2 auth ipsec spi 400 esp sha1
abcef12345678901234fedcba098765432109876
```

Syntax: **area** <*area-id*> **authentication ipsec spi** <*spinum*> **esp sha1 [no-encrypt]** <*key*>

The **no** form of this command deletes IPsec from the area.

The **area** command and the <*area-id*> variable specify the area for this IPsec configuration. The <*area-id*> can be an integer in the range 0 – 2,147,483,647 or have the format of an IP address.

The **authentication** keyword specifies that the function to specify for the area is packet authentication.

The **ipsec** keyword specifies that IPsec is the protocol that authenticates the packets.

The **spi** keyword and the <*spinum*> variable specify the index that points to the security association. The near-end and far-end values for spinum must be the same. The range for <*spinum*> is decimal 256 – 4294967295.

The mandatory **esp** keyword specifies ESP (rather than authentication header) as the protocol to provide packet-level security. In the current release, this parameter can be **esp** only.

The **sha1** keyword specifies the HMAC-SHA1-96 authentication algorithm. This mandatory parameter can be only the **sha1** keyword in the current release.

Including the optional **no-encrypt** keyword means that the 40-character key is not encrypted upon either its entry or its display. The key must be 40 hexadecimal characters.

If **no-encrypt** is not entered, then the key will be encrypted. This is the default. The system adds the following in the configuration to indicate that the key is encrypted:

- encryptb64 = the key string uses proprietary base64 crytographic 2-way algorithm

The configuration in the preceding example results in the configuration for area 2 that is illustrated in the following.

```
ipv6 router ospf
 area 0
 area 1
 area 2
 area 2 auth ipsec spi 400 esp sha1 abcef12345678901234fedcba098765432109876
```

Configuring IPsec for a virtual link

IPsec on a virtual link has a global configuration.

To configure IPsec on a virtual link, enter the IPv6 router OSPF context of the CLI and proceed as the following example illustrates. (Note the **no-encrypt** option in this example.)

```
NetIron(config-ospf6-router)#area 1 vir 2.2.2.2 auth ipsec spi 360 esp sha1
no-encrypt 1234567890098765432112345678990987654321
```

Syntax: [no] **area** <*area-id*> **virtual** <*nbrid*> **authentication ipsec spi** <*spinum*> **esp sha1** [**no-encrypt**] <*key*>

The **no** form of this command deletes IPsec from the virtual link.

The **area** command and the <*area-id*> variable specify the area is to be configured. The <*area-id*> can be an integer in the range 0 – 2,147,483,647 or have the format of an IP address.

The **virtual** keyword indicates that this configuration applies to the virtual link identified by the subsequent variable <*nbrid*>. The variable <*nbrid*> is in dotted decimal notation of an IP address.

The **authentication** keyword specifies that the function to specify for the area is packet authentication.

The **ipsec** keyword specifies that IPsec is the protocol that authenticates the packets.

The **spi** keyword and the <*spinum*> variable specify the index that points to the security association. The near-end and far-end values for spinum must be the same. The range for <*spinum*> is decimal 256 – 4294967295.

The mandatory **esp** keyword specifies ESP (rather than authentication header) as the protocol to provide packet-level security. In the current release, this parameter can be **esp** only.

The **sha1** keyword specifies the HMAC-SHA1-96 authentication algorithm. This mandatory parameter can be only the **sha1** keyword in the current release.

Including the optional **no-encrypt** keyword means that the 40-character key is not encrypted in **show** command displays. If **no-encrypt** is not entered, then the key will be encrypted. This is the default. The system adds the following in the configuration to indicate that the key is encrypted:

- encryptb64 = the key string uses proprietary base64 crytographic 2-way algorithm

This example results in the following configuration.

```
area 1 virtual-link 2.2.2.2
area 1 virtual-link 2.2.2.2 authentication ipsec spi 360 esp sha1 no-encrypt 12
3456789009876543211234567890987654321
```

Disabling IPsec on an interface

For the purpose of troubleshooting, you can operationally disable IPsec on an interface by using the **ipv6 ospf authentication ipsec disable** command in the CLI context of a specific interface. This command disables IPsec on the interface whether its IPsec configuration is the area's IPsec configuration or is specific to that interface. The output of the **show ipv6 ospf interface command** shows the current setting for the disable command.

To disable IPsec on an interface, go to the CLI context of the interface and proceed as in the following example.

```
NetIron(config-if-e10000-1/2)#ipv6 ospf auth ipsec disable
```

Syntax: [no] ipv6 ospf authentication ipsec disable

The **no** form of this command restores the area and interface-specific IPsec operation.

Changing the key rollover timer

Configuration changes for authentication takes effect in a controlled manner through the key rollover procedure as specified in RFC 4552, Section 10.1. The key rollover timer controls the timing of the configuration changeover. The key rollover timer can be configured in the IPv6 router OSPF context, as the following example illustrates.

```
NetIron(config-ospf6-router)#key-rollover-interval 200
```

Syntax: key-rollover-interval <*time*>

The range for the key-rollover-interval is 0 – 14400 seconds. The default is 300 seconds.

Clearing IPsec statistics

This section describes the **clear ipsec statistics** command for clearing statistics related to IPsec. The command resets to 0 the counters (which you can view as a part of IPSecurity Packet Statistics). The counters hold IPsec packet statistics and IPsec error statistics. The following example illustrates the **show ipsec statistics** output.

```
NetIron#show ipsec statistics
                    IPSecurity Statistics
secEspCurrentInboundSAs 1          ipsecEspTotalInboundSAs:  2
secEspCurrentOutboundSA 1          ipsecEspTotalOutboundSAs: 2
                  IPSecurity Packet Statistics
secEspTotalInPkts:      20         ipsecEspTotalInPktsDrop:  0
secEspTotalOutPkts:     84
                  IPSecurity Error Statistics
secAuthenticationErrors 0
secReplayErrors:        0          ipsecPolicyErrors:        13
secOtherReceiveErrors:  0          ipsecSendErrors:          0
secUnknownSpiErrors:    0
```

To clear the statistics, enter the **clear ipsec statistics** command as in the following example.

```
NetIron#clear ipsec statistics
```

Syntax: clear ipsec statistics

This command takes no parameters.

Displaying OSPFv3 information

You can display the information for the following OSPFv3 parameters:

- Areas
- Link state databases
- Interfaces
- Memory usage
- Neighbors
- Redistributed routes
- Routes
- SPF
- Virtual links
- Virtual neighbors
- IPsec

General OSPF configuration information

To indicate whether the router is operating as ASBR or not, enter the following command at any CLI level.

```
NetIron#show ipv6 ospf
OSPFv3 Process number 0 with Router ID 0x01010101(1.1.1.1)
Running 0 days 0 hours 1 minutes 53 seconds
Number of AS scoped LSAs is 3
Sum of AS scoped LSAs Checksum is fabdd4de
External LSA Limit is 250000
Database Overflow Interval is 10
Database Overflow State is NOT OVERFLOWED
Route calculation executed 0 times
Pending outgoing LSA count 0
Authentication key rollover interval 30 seconds
```

```
Number of areas in this router is 4
Router is operating as ABR
Router is operating as ASBR, Redistribute: CONNECTED
High Priority Message Queue Full count: 0
BFD is disabled
```

The output of the **show ipv6 ospf** command will indicate if the router is operating as ASBR. If the router is not operating as ASBR, then there will be no information about redistribution in the output.

Displaying OSPFv3 area information

To display global OSPFv3 area information for the device, enter the following command at any CLI level.

```
NetIron# show ipv6 ospf area
Area 0:
  Interface attached to this area: loopback 2 ethe 3/2 tunnel 2
  Number of Area scoped LSAs is 6
  Statistics of Area 0:
    SPF algorithm executed 16 times
    SPF last updated: 335256 sec ago
    Current SPF node count: 3
      Router: 2 Network: 1
      Maximum of Hop count to nodes: 2
...
```

Syntax: show ipv6 ospf area [<*area-id*>]

You can specify the <*area-id*> parameter in the following formats:

- As an IPv4 address, for example, 192.168.1.1.
- As a numerical value from 0 – 2,147,483,647.

The <*area-id*> parameter restricts the display to the specified OSPF area.

This display shows the following information.

TABLE 317 OSPFv3 area information fields

This field...	Displays...
Area	The area number.
Interface attached to this area	The router interfaces attached to the area.
Number of Area scoped LSAs is *N*	Number of LSAs (*N*) with a scope of the specified area.
SPF algorithm executed is *N*	The number of times (*N*) the OSPF Shortest Path First (SPF) algorithm is executed within the area.
SPF last updated	The interval in seconds that the SPF algorithm was last executed within the area.
Current SPF node count	The current number of SPF nodes in the area.
Router	Number of router LSAs in the area.
Network	Number of network LSAs in the area.
Indx	The row number of the entry in the router's OSPF area table.
Statistics of Area	The number of the area whose statistics are displayed.
Maximum hop count to nodes.	The maximum number of hop counts to an SPF node within the area.

Displaying OSPFv3 database information

You can display a summary of the device's link state database or detailed information about a specified LSA type.

To display a summary of a device's link state database, enter the following command at any CLI level.

```
NetIron# show ipv6 ospf database
LSA Key - Rtr:Router Net:Network Inap:InterPrefix Inar:InterRouter
          Extn:ASExternal Grp:GroupMembership Typ7:Type7 Link:Link
          Iap:IntraPrefix
Area ID         Type LSID       Adv Rtr         Seq(Hex) Age  Cksum Len
1               Link 1          2.2.2.2         80000002 998  d1b7  56
1               Link 1          1.1.1.1         80000002 996  dbb2  56

```

Syntax: **show ipv6 ospf database [advrtr** <*ipv4-address*> **| as-external[advrtr** <*ipv4-address*> **| link-id** <*number*> **] | extensive | inter-prefix [advrtr** <*ipv4-address*> **| link-id** <*number*> **] | inter-router[advrtr** <*ipv4-address*> **| link-id** <*number*> **] | intra-prefix [advrtr** <*ipv4-address*> **| link-id** <*number*> **] | link [advrtr** <*ipv4-address*> **| link-id** <*number*> **] | link-id** <*number*> **| network [advrtr** <*ipv4-address*> **| link-id** <*number*> **] | router [advrtr** <*ipv4-address*> **| link-id** <*number*> **]]**

The **advrtr** <*ipv4-address*> parameter displays detailed information about the LSAs for a specified advertising router only.

The **as-external** keyword displays detailed information about the AS externals LSAs only.

The **extensive** keyword displays detailed information about all LSAs in the database.

The **inter-prefix** keyword displays detailed information about the inter-area prefix LSAs only.

The **inter-router** keyword displays detailed information about the inter-area router LSAs only.

The **intra-prefix** keyword displays detailed information about the intra-area prefix LSAs only.

The **link** keyword displays detailed information about the link LSAs only.

The **link-id** <*number*> parameter displays detailed information about the specified link LSAs only.

The **network** <*number*> displays detailed information about the network LSAs only.

The **router** <*number*> displays detailed information about the router LSAs only.

The **scope** <*area-id*> parameter displays detailed information about the LSAs for a specified area, AS, or link.

This display shows the following information.

TABLE 318 OSPFv3 database summary fields

This field...	Displays...
Area ID	The OSPF area in which the device resides.
Type	Type of LSA. LSA types can be the following: • Rtr – Router LSAs (Type 1). • Net – Network LSAs (Type 2). • Inap – Inter-area prefix LSAs for ABRs (Type 3). • Inar – Inter-area router LSAs for ASBRs (Type 4). • Extn – AS external LSAs (Type 5). • Link – Link LSAs (Type 8). • Iap – Intra-area prefix LSAs (Type 9).
LS ID	The ID of LSA in Decimal.
Adv Rtr	The device that advertised the route.
Seq(Hex)	The sequence number of the LSA. The OSPF neighbor that sent the LSA stamps it with a sequence number to enable the device and other OSPF routers to determine which LSA for a given route is the most recent.
Age	The age of the LSA, in seconds.
Chksum	A checksum for the LSA packet. The checksum is based on all the fields in the packet except the age field. The device uses the checksum to verify that the packet is not corrupted.
Len	The length, in bytes, of the LSA.

For example, to display detailed information about all LSAs in the database, enter the following command at any CLI level.

```
NetIron# show ipv6 ospf database extensive
Area ID         Type LS ID    Adv Rtr         Seq(Hex) Age  Cksum  Len

NOTE

Portions of this display are truncated for brevity. The purpose of this display is to show all possible fields that might display rather than to show complete output.

The fields that display depend upon the LSA type as shown in the following.

TABLE 319 OSPFv3 detailed database information fields

This field...	Displays...
Router LSA (Type 1) (Rtr) Fields	
Capability Bits	A bit that indicates the capability of the device. The bit can be set to one of the following: B – The device is an area border router. E – The device is an AS boundary router. V – The device is a virtual link endpoint. W – The device is a wildcard multicast receiver.
Options	A 24-bit field that enables IPv6 OSPF routers to support the optional capabilities. When set, the following bits indicate the following: V6 – The device should be included in IPv6 routing calculations. E – The device floods AS-external-LSAs as described in RFC 2740. MC – The device forwards multicast packets as described in RFC 1586. N – The device handles type 7 LSAs as described in RFC 1584. R – The originator is an active router. DC –The device handles demand circuits.
Type	The type of interface. Possible types can be the following: Point-to-point – A point-to-point connection to another router. Transit – A connection to a transit network. Virtual link – A connection to a virtual link.
Metric	The cost of using this router interface for outbound traffic.
Interface ID	The ID assigned to the router interface.
Neighbor Interface ID	The interface ID that the neighboring router has been advertising in hello packets sent on the attached link.
Neighbor Router ID	The router ID (IPv4 address) of the neighboring router that advertised the route. (By default, the router ID is the IPv4 address configured on the lowest numbered loopback interface. If the device does not have a loopback interface, the default router ID is the lowest numbered IPv4 address configured on the device.)

TABLE 319 OSPFv3 detailed database information fields (Continued)

This field...	Displays...
Network LSA (Type 2) (Net) Fields	
Options	A 24-bit field that enables IPv6 OSPF routers to support the optional capabilities. When set, the following bits indicate the following: V6 – The device should be included in IPv6 routing calculations. E – The device floods AS-external-LSAs as described in RFC 2740. MC – The device forwards multicast packets as described in RFC 1586. N – The device handles type 7 LSAs as described in RFC 1584. R – The originator is an active router. DC –The device handles demand circuits.
Attached Router	The address of the neighboring router that advertised the route.
Inter-Area Prefix LSA (Type 3) (Inap) Fields	
Metric	The cost of the route.
Prefix Options	An 8-bit field describing various capabilities associated with the prefix.
Prefix	The IPv6 prefix included in the LSA.
Inter-Area Router LSA (Type 4) (Inar) Fields	
Options	A 24-bit field that enables IPv6 OSPF routers to support the optional capabilities. When set, the following bits indicate the following: V6 – The device should be included in IPv6 routing calculations. E – The device floods AS-external-LSAs as described in RFC 2740. MC – The device forwards multicast packets as described in RFC 1586. N – The device handles type 7 LSAs as described in RFC 1584. R – The originator is an active router. DC –The device handles demand circuits.
Metric	The cost of the route.
Destination Router ID	The ID of the router described in the LSA.
AS External LSA (Type 5) (Extn) Fields	
Bits	The bit can be set to one of the following: • E – If bit E is set, a Type 2 external metric. If bit E is zero, a Type 1 external metric. • F – A forwarding address is included in the LSA. • T – An external route tag is included in the LSA.
Metric	The cost of this route, which depends on bit E.
Prefix Options	An 8-bit field describing various capabilities associated with the prefix.
Referenced LS Type	If non-zero, an LSA with this LS type is associated with the LSA.
Prefix	The IPv6 prefix included in the LSA.
Link LSA (Type 8) (Link) Fields	
Router Priority	The router priority of the interface attaching the originating router to the link.
Options	The set of options bits that the router would like set in the network LSA that will be originated for the link.
Link Local Address	The originating router's link-local interface address on the link.
Number of Prefix	The number of IPv6 address prefixes contained in the LSA.

TABLE 319 OSPFv3 detailed database information fields (Continued)

This field...	Displays...
Prefix Options	An 8-bit field of capabilities that serve as input to various routing calculations: • NU – The prefix is excluded from IPv6 unicast calculations. • LA – The prefix is an IPv6 interface address of the advertising router. • MC – The prefix is included in IPv6 multicast routing calculations. • P – NSSA area prefixes are readvertised at the NSSA area border.
Prefix	The IPv6 prefix included in the LSA.
Intra-Area Prefix LSAs (Type 9) (Iap) Fields	
Number of Prefix	The number of prefixes included in the LSA.
Referenced LS Type, Referenced LS ID	Identifies the router-LSA or network-LSA with which the IPv6 address prefixes are associated.
Referenced Advertising Router	The address of the neighboring router that advertised the route.
Prefix Options	An 8-bit field describing various capabilities associated with the prefix.
Metric	The cost of using the advertised prefix.
Prefix	The IPv6 prefix included in the LSA.
Number of Prefix	The number of prefixes included in the LSA.

Displaying IPv6 interface information

You can use the following command to display a summary of IPv6 Interface information.

```
NetIron#show ipv6 interface
    Routing Protocols : R - RIP  O - OSPF I - ISIS
    Interface  Status/Protocol  Routing  IPv6 Address
    eth 1/7      up/up          I         fe80::20c:dbff:fef4:7106
                                          bb::21/64
                                          2001::2/64
    pos 4/2    down/down        I         4001::15/64
    loopback 1 up/up                      fe80::20c:dbff:fef4:7100
                                          4004::1/128
```

Syntax: show ipv6 interface [ethernet *<port>* **| pos** *<port>* **| loopback** *<number>* **| tunnel** *<number>* **| ve** *<number>* **]**

The **ethernet | pos | loopback | tunnel | ve** parameter specifies the interface for which to display information. If you specify an Ethernet interface, also specify the port number associated with the interface. If you specify a loopback, tunnel, or VE interface, also specify the number associated with the interface.

This display shows the following information.

TABLE 320 Summary of IPv6 interface information

This field...	Displays...
Interface	The interface type, and the port number or number of the interface.
Status or Protocol	The status of the link and the protocol. Possible status include the following: • Up. • Down.

TABLE 320 Summary of IPv6 interface information (Continued)

This field...	Displays...
Routing	The routing protocol enabled on the interface. Possible values include: • R – RIP • O – OSPF • I – ISIS
IPv6 Address	The link local IPv6 address and any other IPv6 addresses configured for the interface.

Displaying IPv6 OSPFv3 interface information

IPv6 Interface information can be displayed in either a brief or full mode. The following sections describe the command to display these modes and the resulting output:

- Displaying IPv6 OSPFv3 Interface Information in Brief Mode
- Displaying IPv6 OSPFv3 Interface Information in Full Mode

Displaying IPv6 OSPFv3 interface information in brief mode

You can use the following command to display a summary of IPv6 Interface information.

```
NetIron# show ipv6 ospf interface brief
Interface  Area           Status  Type Cost  State     Nbrs (F/C)
eth 1/1    0              up      BCST 1     DROther   1/1
loopback 1 0              up      BCST 1     Loopback  0/0
```

Syntax: show ipv6 ospf interface brief

This display shows the following information.

TABLE 321 Summary of OSPFv3 interface brief information

This field...	Displays...
Interface	The interface type, and the port number or number of the interface.
Area	The OSPF area configured on the interface.
Status	The status of the link and the protocol. Possible status include the following: • Up. • Down.
Type	The type of OSPFv3 circuit running on the interface. Possible types include the following: • BCST- Broadcast interface type • P2P- Point-to-point interface type • UNK- The interface type is not known at this time
Cost	The overhead required to send a packet across an interface.

TABLE 321 Summary of OSPFv3 interface brief information (Continued)

This field...	Displays...
State	The state of the interface. Possible states include the following: • DR – The interface is functioning as the Designated Router for OSPFv3. • BDR – The interface is functioning as the Backup Designated Router for OSPFv3. • Loopback – The interface is functioning as a loopback interface. • P2P – The interface is functioning as a point-to-point interface. • Passive – The interface is up but it does not take part in forming an adjacency. • Waiting – The interface is trying to determine the identity of the BDR for the network. • None – The interface does not take part in the OSPF interface state machine. • Down – The interface is unusable. No protocol traffic can be sent or received on such a interface. • DR other – The interface is a broadcast or NBMA network on which another router is selected to be the DR.
Nbrs (F/C)	The number of adjacent neighbor routers. The number to the left of the "/" are the neighbor routers that are fully adjacent and the number to the right represents all adjacent neighbor routers.

Displaying IPv6 OSPFv3 interface information in full mode

You can display detailed information about all OSPFv3 interfaces by using the **show ipv6 ospf interface** command, as the following truncated example illustrates.

```
NetIron#show ipv6 ospf interface
eth 1/3 is down, type BROADCAST
   Interface is disabled
eth 1/8 is up, type BROADCAST
  IPv6 Address:
      2100:18:18:18:18::1/64

  ....................................
```

You can display detailed OSPFv3 information about a specific interface using the following command at any level of the CLI.

Syntax: show ipv6 ospf interface [ethernet <*slot/port*> **| pos** <*slot/port*> **| loopback** <*number*> **| tunnel** <*number*> **| ve** <*number*> **]**

This display shows the following information.

TABLE 322 Detailed OSPFv3 interface information

This field...	Displays...
Interface status	The status of the interface (POS or Ethernet). Possible status includes the following: • Up. • Down.
Type	The type of OSPFv3 circuit running on the interface. Possible types include the following: • BROADCAST • POINT TO POINT UNKNOWN • POINT TO POINT
IPv6 Address	The IPv6 address(es) assigned to the interface.
Instance ID	An identifier for an instance of OSPFv3.
Router ID	The IPv4 address of the device. By default, the router ID is the IPv4 address configured on the lowest numbered loopback interface. If the device does not have a loopback interface, the default router ID is the lowest numbered IPv4 address configured on the device.
Area ID	The IPv4 address or numerical value of the area in which the interface belongs.
Cost	The overhead required to send a packet through the interface.
State	The state of the interface. Possible states include the following: • DR – The interface is functioning as the Designated Router for OSPFv3. • BDR – The interface is functioning as the Backup Designated Router for OSPFv3. • Loopback – The interface is functioning as a loopback interface. • P2P – The interface is functioning as a point-to-point interface. • Passive – The interface is up but it does not take part in forming an adjacency. • Waiting – The interface is trying to determine the identity of the BDR for the network. • None – The interface does not take part in the OSPF interface state machine. • Down – The interface is unusable. No protocol traffic can be sent or received on such a interface. • DR other – The interface is a broadcast or NBMA network on which another router is selected to be the DR.
Transmit delay	The amount of time, in seconds, it takes to transmit Link State Updates packets on the interface.
Priority	The priority used when selecting the DR and the BDR. If the priority is 0, the interface does not participate in the DR and BDR election.
Timer intervals	The interval, in seconds, of the hello-interval, dead-interval, and retransmit-interval timers.
DR	The router ID (IPv4 address) of the DR.

TABLE 322 Detailed OSPFv3 interface information (Continued)

This field...	Displays...
BDR	The router ID (IPv4 address) of the BDR.
Number of I/F scoped LSAs	The number of interface LSAs scoped for a specified area, AS, or link.
DR Election	The number of times the DR election occurred.
Delayed LSA Ack	The number of the times the interface sent a delayed LSA acknowledgement.
Neighbor Count	The number of neighbors to which the interface is connected.
Adjacent Neighbor Count	The number of neighbors with which the interface has formed an active adjacency.
Neighbor	The router ID (IPv4 address) of the neighbor. This field also identifies the neighbor as a DR or BDR, if appropriate.
Interface statistics	The following statistics are provided for the interface: • Unknown – The number of Unknown packets transmitted and received by the interface. Also, the total number of bytes associated with transmitted and received Unknown packets. • Hello – The number of Hello packets transmitted and received by the interface. Also, the total number of bytes associated with transmitted and received Hello packets. • DbDesc – The number of Database Description packets transmitted and received by the interface. Also, the total number of bytes associated with transmitted and received Database Description packets. • LSReq – The number of link-state requests transmitted and received by the interface. Also, the total number of bytes associated with transmitted and received link-state requests. • LSUpdate – The number of link-state updates transmitted and received by the interface. Also, the total number of bytes associated with transmitted and received link-state requests. • LSAck – The number of link-state acknowledgements transmitted and received by the interface. Also, the total number of bytes associated with transmitted and received link-state acknowledgements.

Displaying OSPFv3 memory usage

To display information about OSPFv3 memory usage, enter the following command at any level of the CLI.

```
NetIron# show ipv6 ospf memory
Total Static Memory Allocated : 5829 bytes
Total Dynamic Memory Allocated : 0 bytes
Memory Type               Size       Allocated  Max-alloc  Alloc-Fails
MTYPE_OSPF6_TOP           0          0          0          0
MTYPE_OSPF6_LSA_HDR       0          0          0          0
MTYPE_OSPF6_RMAP_COMPILED 0          0          0          0
MTYPE_OSPF6_OTHER         0          0          0          0
MTYPE_THREAD_MASTER       0          0          0          0

MTYPE_THREAD              0          0          0          0
```

Syntax: show ipv6 ospf memory

This display shows the following information.

TABLE 323 OSPFv3 memory usage information

This field...	Displays...
Total Static Memory Allocated	A summary of the amount of static memory allocated, in bytes, to OSPFv3.
Total Dynamic Memory Allocated	A summary of the amount of dynamic memory allocated, in bytes, to OSPFv3.
Memory Type	The type of memory used by OSPFv3. (This information is for use by Dell technical support in case of a problem.)
Size	The size of a memory type.
Allocated	The amount of memory currently allocated to a memory type.
Max-alloc	The maximum amount of memory that was allocated to a memory type.
Alloc-Fails	The number of times an attempt to allocate memory to a memory type failed.

Displaying OSPFv3 neighbor information

You can display a summary of OSPFv3 neighbor information for the device or detailed information about a specified neighbor.

To display a summary of OSPFv3 neighbor information for the device, enter the following command at any CLI level.

```
NetIron# show ipv6 ospf neighbor
RouterID        Pri State    DR              BDR             Interface[State]
1.1.1.1           1 Full     223.223.223.223 1.1.1.1         ethe 3/2   [DR]
```

Syntax: show ipv6 ospf neighbor [router-id <*ipv4-address*>**]**

The **router-id** <*ipv4-address*> parameter displays only the neighbor entries for the specified router.

This display shows the following information.

TABLE 324 Summary of OSPFv3 neighbor information

Field	Description
Router ID	The IPv4 address of the neighbor. By default, the router ID is the IPv4 address configured on the lowest numbered loopback interface. If the device does not have a loopback interface, the default router ID is the lowest numbered IPv4 address configured on the device.
Pri	The OSPFv3 priority of the neighbor. The priority is used during election of the DR and BDR.
State	The state between the device and the neighbor. The state can be one of the following: • Down • Attempt • Init • 2-Way • ExStart • Exchange • Loading • Full
DR	The router ID (IPv4 address) of the DR.
BDR	The router ID (IPv4 address) of the BDR.
Interface [State]	The interface through which the router is connected to the neighbor. The state of the interface can be one of the following: • DR – The interface is functioning as the Designated Router for OSPFv3. • BDR – The interface is functioning as the Backup Designated Router for OSPFv3. • Loopback – The interface is functioning as a loopback interface. • P2P – The interface is functioning as a point-to-point interface. • Passive – The interface is up but it does not take part in forming an adjacency. • Waiting – The interface is trying to determine the identity of the BDR for the network. • None – The interface does not take part in the OSPF interface state machine. • Down – The interface is unusable. No protocol traffic can be sent or received on such a interface. • DR other – The interface is a broadcast or NBMA network on which another router is selected to be the DR.

For example, to display detailed information about a neighbor with the router ID of 1.1.1.1, enter the following command at any CLI level.

```
NetIron# show ipv6 ospf neighbor router-id 3.3.3.3
RouterID        Pri State    DR              BDR             Interface[State]
3.3.3.3           1 Full     3.3.3.3         1.1.1.1         ve 10    [BDR]
DbDesc bit for this neighbor: --s
Nbr Ifindex of this router: 1
Nbr DRDecision: DR 3.3.3.3, BDR 1.1.1.1
Last received DbDesc: opt:xxx ifmtu:0 bit:--s seqnum:0
Number of LSAs in DbDesc retransmitting: 0
Number of LSAs in SummaryList: 0
Number of LSAs in RequestList: 0
Number of LSAs in RetransList: 0
SeqnumMismatch 0 times, BadLSReq 0 times
OnewayReceived 0 times, InactivityTimer 0 times
DbDescRetrans 0 times, LSReqRetrans 0 times
LSUpdateRetrans 1 times
LSAReceived 12 times, LSUpdateReceived 6 times
```

This display shows the following information.

TABLE 325 Detailed OSPFv3 neighbor information

Field	Description
Router ID	For information about this field, refer to Table 324 on page 1847.
Pri	For information about this field, refer to Table 324 on page 1847.
State	For information about this field, refer to Table 324 on page 1847.
DR	For information about this field, refer to Table 324 on page 1847.
BDR	For information about this field, refer to Table 324 on page 1847.
Interface [State]	For information about this field, refer to Table 324 on page 1847.
DbDesc bit...	The Database Description packet, which includes 3 bits of information: • The first bit can be “i” or “-”. “i” indicates the inet bit is set. “-” indicates the inet bit is not set. • The second bit can be “m” or “-”. “m” indicates the more bit is set. “-” indicates the more bit is not set. • The third bit can be “m” or “s”. An “m” indicates the master. An “s” indicates standby.
Index	The ID of the LSA from which the neighbor learned of the router.
DR Decision	The router ID (IPv4 address) of the neighbor’s elected DR and BDR.
Last Received Db Desc	The content of the last database description received from the specified neighbor.
Number of LSAs in Db Desc retransmitting	The number of LSAs that need to be retransmitted to the specified neighbor.
Number of LSAs in Summary List	The number of LSAs in the neighbor’s summary list.
Number of LSAs in Request List	The number of LSAs in the neighbor’s request list.
Number of LSAs in Retransmit List	The number of LSAs in the neighbor’s retransmit list.
Seqnum Mismatch	The number of times sequence number mismatches occurred.

TABLE 325 Detailed OSPFv3 neighbor information (Continued)

Field	Description
BadLSReq	The number of times the neighbor received a bad link-state request from the device.
One way received	The number of times a hello packet, which does not mention the router, is received from the neighbor. This omission in the hello packet indicates that the communication with the neighbor is not bidirectional.
Inactivity Timer	The number of times that the neighbor's inactivity timer expired.
Db Desc Retransmission	The number of times sequence number mismatches occurred.
LSReqRetrans	The number of times the neighbor retransmitted link-state requests to the device.
LSUpdateRetrans	The number of times the neighbor retransmitted link-state updates to the device.
LSA Received	The number of times the neighbor received LSAs from the device.
LS Update Received	The number of times the neighbor received link-state updates from the device.

Displaying routes redistributed into OSPFv3

You can display all IPv6 routes or a specified IPv6 route that the device has redistributed into OSPFv3.

To display all IPv6 routes that the device has redistributed into OSPFv3, enter the following command at any level of the CLI.

```
NetIron# show ipv6 ospf redistribute route
Id     Prefix                                    Protocol  Metric Type  Metric
 snIpAsPathAccessListStringRegExpression
1      2002::/16                                 Static    Type-2       1
2      2002:1234::/32                            Static    Type-2       1
```

Syntax: show ipv6 ospf redistribute route [<*ipv6-prefix*>]

The <*ipv6-prefix*> parameter specifies an IPv6 network prefix. (You do not need to specify the length of the prefix.)

For example, to display redistribution information for the prefix 2002::, enter the following command at any level of the CLI.

```
NetIron# show ipv6 ospf redistribute route 2002::
Id     Prefix                                    Protocol  Metric Type  Metric
1      2002::/16                                 Static    Type-2       1
```

These displays show the following information.

TABLE 326 OSPFv3 redistribution information

This field...	Displays...
ID	An ID for the redistributed route.
Prefix	The IPv6 routes redistributed into OSPFv3.

TABLE 326 OSPFv3 redistribution information (Continued)

This field...	Displays...
Protocol	The protocol from which the route is redistributed into OSPFv3. Redistributed protocols can be the following: • BGP – BGP4+. • RIP – RIPng. • ISIS – IPv6 IS-IS. • Static – IPv6 static route table. • Connected – A directly connected network.
Metric Type	The metric type used for routes redistributed into OSPFv3. The metric type can be the following: • Type-1 – Specifies a small metric (2 bytes). • Type-2 – Specifies a big metric (3 bytes).
Metric	The value of the default redistribution metric, which is the OSPF cost of redistributing the route into OSPFv3.

Displaying OSPFv3 route information

You can display the entire OSPFv3 route table for the device or only the route entries for a specified destination.

To display the entire OSPFv3 route table for the device, enter the following command at any level of the CLI.

```
NetIron#sh ipv6 ospf route
  Current Route count: 4
    Intra: 4 Inter: 0 External: 0 (Type1 0/Type2 0)
    Equal-cost multi-path: 0
    OSPF Type: IA- Intra, OA - Inter, E1 - External Type1, E2 - External Type2
   Destination                    Cost       E2Cost     Tag        Flags    Dis
IA 3000:200:1::1/128              0          0          0          00000003 110
   Next_Hop_Router                Outgoing_Interface Adv_Router
   ::                             loopback 1         10.1.2.1
   Destination                    Cost       E2Cost     Tag        Flags    Dis
IA 4000:200:1::1/128              0          0          0          00000003 110
   Next_Hop_Router                Outgoing_Interface Adv_Router
   ::                             loopback 2         10.1.2.1
   Destination                    Cost       E2Cost     Tag        Flags    Dis
IA 3000:300:1::1/128              0          0          0          00000003 110
   Next_Hop_Router                Outgoing_Interface Adv_Router
   ::                             loopback 1         10.1.2.1
   Destination                    Cost       E2Cost     Tag        Flags    Dis
IA 4000:300:1::1/128              0          0          0          00000003 110
   Next_Hop_Router                Outgoing_Interface Adv_Router
   ::                             loopback 2         10.1.2.1
```

Syntax: show ipv6 ospf routes [<*ipv6-prefix*>]

The <*ipv6-prefix*> parameter specifies a destination IPv6 prefix. (You do not need to specify the length of the prefix.) If you use this parameter, only the route entries for this destination are shown.

For example, to display route information for the destination prefix 2000:4::, enter the following command at any level of the CLI.

```
 NetIron# show ipv6 ospf route 2000::
Destination                 Cost       E2Cost     Tag        Flags      Dis
IA 2000::/64                   1          0         0         00000003   110
   Next_Hop_Router              Outgoing_Interface Adv_Router
   ::                              eth 1/1             10.1.1.1
```

These displays show the following information.

TABLE 327 OSPFv3 route information

This field...	Displays...
Current Route Count (Displays with the entire OSPFv3 route table only)	The number of route entries currently in the OSPFv3 route table.
Intra/Inter/External (Type1/Type2) (Displays with the entire OSPFv3 route table only)	The breakdown of the current route entries into the following route types: • Inter – The number of routes that pass into another area. • Intra – The number of routes that are within the local area. • External1 – The number of type 1 external routes. • External2 – The number of type 2 external routes.
Equal-cost multi-path (Displays with the entire OSPFv3 route table only)	The number of equal-cost routes to the same destination in the OSPFv3 route table. If load sharing is enabled, the router equally distributes traffic among the routes.
Destination	The IPv6 prefixes of destination networks to which the device can forward IPv6 packets. "*IA" indicates the next router is an intra-area router.
Cost	The type 1 cost of this route.
E2 Cost	The type 2 cost of this route.
Tag	The route tag for this route.
Flags	Flags associated with this route.
Dis	Administrative Distance for this route.
Next-Hop Router	The IPv6 address of the next router a packet must traverse to reach a destination.
Outgoing Interface	The router interface through which a packet must traverse to reach the next-hop router.
Adv_Router	The IP address of the advertising router.

Displaying OSPFv3 SPF information

You can display the following OSPFv3 SPF information:

- SPF node information for a specified area.
- SPF table for a specified area.
- SPF tree for a specified area.

For example, to display information about SPF nodes in area 0, enter the following command at any level of the CLI.

```
NetIron# show ipv6 ospf spf node area 0
SPF node for Area 0
SPF node 223.223.223.223,  cost: 0,  hops: 0
 nexthops to node:
 parent nodes:
 child nodes: 223.223.223.223:88

SPF node 223.223.223.223:88,  cost: 1,  hops: 1
 nexthops to node:    :: ethe 3/2
 parent nodes: 223.223.223.223
 child nodes: 1.1.1.1:0

SPF node 1.1.1.1:0,  cost: 1,  hops: 2
 nexthops to node:    fe80::2e0:52ff:fe91:bb37 ethe 3/2
 parent nodes: 223.223.223.223:88
 child nodes:
```

Syntax: show ipv6 ospf spf node area [<*area-id*>]

The **node** keyword displays SPF node information.

The **area** <*area-id*> parameter specifies a particular area. You can specify the <*area-id*> in the following formats:

- As an IPv4 address; for example, 192.168.1.1.
- As a numerical value from 0 – 2,147,483,647.

This display shows the following information.

TABLE 328 OSPFv3 SPF node information

This field...	Displays...
SPF node	Each SPF node is identified by its router ID (IPv4 address). If the node is a child node, it is additionally identified by an interface on which the node can be reached appended to the router ID in the format <*router-id*>:<*interface-id*>.
Cost	The cost of traversing the SPF node to reach the destination.
Hops	The number of hops needed to reach the parent SPF node.
Next Hops to Node	The IPv6 address of the next hop-router or the router interface through which to access the next-hop router.
Parent Nodes	The SPF node's parent nodes. A ***parent node*** is an SPF node at the highest level of the SPF tree, which is identified by its router ID.
Child Nodes	The SPF node's child nodes. A ***child node*** is an SPF node at a lower level of the SPF tree, which is identified by its router ID and interface on which the node can be reached.

For example, to display the SPF table for area 0, enter the following command at any level of the CLI.

```
NetIron# show ipv6 ospf spf table area 0
  SPF table for Area 0
  Destination         Bits Options  Cost  Nexthop                   Interface
R 1.1.1.1             ---- V6E---R-    1  fe80::2e0:52ff:fe91:bb37  ethe 3/2
N 223.223.223.223[88] ---- V6E---R-    1  ::                        ethe 3/2
```

Syntax: show ipv6 ospf spf table area <*area-id*>

The **table** parameter displays the SPF table.

The **area** <*area-id*> parameter specifies a particular area. You can specify the <*area-id*> in the following formats:

- As an IPv4 address, for example, 192.168.1.1.
- As a numerical value from 0 – 2,147,483,647.

This display shows the following information.

TABLE 329 OSPFv3 SPF table

This field...	Displays...
Destination	The destination of a route, which is identified by the following: • "R", which indicates the destination is a router. "N", which indicates the destination is a network. • An SPF node's router ID (IPv4 address). If the node is a child node, it is additionally identified by an interface on which the node can be reached appended to the router ID in the format <*router-id*>:<*interface-id*>.
Bits	A bit that indicates the capability of the device. The bit can be set to one of the following: • B – The device is an area border router. • E – The device is an AS boundary router. • V – The device is a virtual link endpoint. • W – The device is a wildcard multicast receiver.
Options	A 24-bit field that enables IPv6 OSPF routers to support the optional capabilities. When set, the following bits indicate the following: V6 – The router should be included in IPv6 routing calculations. E – The router floods AS-external-LSAs as described in RFC 2740. MC – The router forwards multicast packets as described in RFC 1586. N – The router handles type 7 LSAs as described in RFC 1584. R – The originator is an active router. DC –The router handles demand circuits.
Cost	The cost of traversing the SPF node to reach the destination.
Next hop	The IPv6 address of the next hop-router.
Interface	The router interface through which to access the next-hop router.

For example, to display the SPF tree for area 0, enter the following command at any level of the CLI.

```
NetIron# show ipv6 ospf spf tree area 0
   SPF tree for Area 0
 +- 223.223.223.223 cost 0
     +- 223.223.223.223:88 cost 1
         +- 1.1.1.1:0 cost 1
```

Syntax: show ipv6 ospf spf tree area <*area-id*>

The **tree** keyword displays the SPF table.

The **area** <*area-id*> parameter specifies a particular area. You can specify the <*area-id*> in the following formats:

- As an IPv4 address; for example, 192.168.1.1.
- As a numerical value from 0 – 2,147,483,647.

In this sample output, consider the SPF node with the router ID 223.223.223.223 to be the top (root) of the tree and the local router. Consider all other layers of the tree (223.223.223.223:88 and 1.1.1.1:0) to be destinations in the network. Therefore, traffic destined from router 223.223.223.223 to router 1.1.1.1:0 must first traverse router 223.223.223.223:88.

Displaying IPv6 OSPF virtual link information

To display OSPFv3 virtual link information on a device, enter the following command.

```
NetIron# show ipv6 ospf virtual-link
Index Transit Area ID  Router ID        Interface Address             State
1     1                1.1.1.1          3003::2                       P2P
```

Syntax: show ipv6 ospf virtual-link

This display shows the following information.

TABLE 330 OSPFv3 virtual link information

This field...	Displays...
Index	An index number associated with the virtual link.
Transit Area ID	The ID of the shared area of two ABRs that serves as a connection point between the two routers.
Router ID	Router ID of the router at the other end of the virtual link (virtual neighbor).
Interface Address	The local address used to communicate with the virtual neighbor.
State	The state of the virtual link. Possible states include the following: • P2P – The link is functioning as a point-to-point interface. • DOWN – The link is down.

Displaying OSPFv3 virtual neighbor information

To display OSPFv3 virtual neighbor information for the device, enter the following command at the enabled level of the CLI.

```
NetIron#show ipv6 ospf virtual-neighbor
Index Router ID        Address                       State     Interface
1     14.14.14.14      2004:44:44:44::4              Full      eth 1/8
                Option: 00-00-00    QCount: 0    Timer: 408
2     14.14.14.14      2004:44:44:44::4              Full      tunnel 256
                Option: 00-00-00    QCount: 0    Timer: 43
```

Syntax: show ipv6 ospf virtual-neighbor [brief]

The [brief] option results in an output that omits the Option, QCount, and Timer fields. The command output shows the following information.

TABLE 331 OSPFv3 virtual neighbor information

This field...	Displays...
Index	An index number associated with the virtual neighbor.
Router ID	IPv4 address of the virtual neighbor.
Address	The IPv6 address to be used for communication with the virtual neighbor.

TABLE 331 OSPFv3 virtual neighbor information (Continued)

This field...	Displays...
State	The state between the device and the virtual neighbor. The state can be one of the following: • Down • Attempt • Init • 2-Way • ExStart • Exchange • Loading • Full
Interface	The IPv6 address of the virtual neighbor.
Option	The bits set in the virtual-link hello or database descriptors.
QCount	The number of packets that are in the queue and ready for transmission. If the system is stable, this number should always be 0.
Timer	A timer that counts down until a hello packet should arrive. If "timers" elapses and a hello packet has not arrived, the VL neighbor is declared to be down.

IPsec examples

This section contains examples of IPsec configuration and the output from the IPsec-specific **show** commands. In addition, IPsec-related information appears in general **show** command output for interfaces and areas.

The **show** commands that are specific to IPsec are:

- **show ipsec sa**
- **show ipsec policy**
- **show ipsec statistics**

The other **show** commands with IPsec-related information are:

- **show ipv6 ospf area**
- **show ipv6 ospf interface**
- **show ipv6 ospf vrf**

Showing IPsec security association information

The **show ipsec sa** command displays the IPSec security association databases, as follows.

```
NetIron#show ipsec sa
IPSEC Security Association Database(Entries:8)
SPDID(vrf:if) Dir Encap SPI        Destination          AuthAlg  EncryptAlg

```

Syntax: show ipsec sa

Showing IPsec policy

The **show ipsec policy** command displays the database for the IPSec security policies. The fields for this **show** command output appear in the screen output example that follows. However, you should understand the layout and column headings for the display before trying to interpret the information in the example screen.

Each policy entry consists of two categories of information:

- The policy information
- The SA used by the policy

The policy information line in the screen begins with the heading Ptype and also has the headings Dir, Proto, Source (Prefix:TCP.UDP Port), and Destination (Prefix:TCP/UDPPort). The SA line contains the SPDID, direction, encapsulation (always ESP in the current release), the user-specified SPI, For readability, the policy information is described in Table 332, and SA-specific information is in Table 333.

```
NetIron#show ipsec policy
            IPSEC Security Policy Database(Entries:8)
PType  Dir Proto Source(Prefix:TCP/UDP Port)    Destination(Prefix:TCP/UDPPort)
SA: SPDID(vrf:if) Dir Encap SPI       Destination
use    in  OSPF  FE80::/10:any                  ::/0:any
SA: 2:e1/2        in  ESP   302        FE80::
use    out OSPF  FE80::/10:any                  ::/0:any
SA: 2:e1/2        out ESP   302        ::
use    in  OSPF  FE80::/10:any                  ::/0:any
SA: 1:e1/1        in  ESP   302        FE80::
use    out OSPF  FE80::/10:any                  ::/0:any
SA: 1:e1/1        out ESP   302        ::
use    in  OSPF  35:1:1::1/128:any              10:1:1::2/128:any
SA: 1:ALL         in  ESP   512        10:1:1::2
use    out OSPF  10:1:1::2/128:any              35:1:1::1/128:any
SA: 1:e1/1        out ESP   512        35:1:1::1
use    in  OSPF  35:1:1::1/128:any              10:1:1::2/128:any
SA: 2:ALL         in  ESP   512        10:1:1::2
use    out OSPF  10:1:1::2/128:any              35:1:1::1/128:any
```

Syntax: show ipsec policy

This command takes no parameters.

TABLE 332 IPsec policy information

This field...	Displays...
PType	This field contains the policy type. Of the existing policy types, only the “use” policy type is supported, so each entry can have only “use.”
Dir	The direction of traffic flow to which the IPsec policy is applied. Each direction has its own entry.
Proto	The only possible routing protocol for the security policy in the current release is OSPFv3.

TABLE 332 IPsec policy information (Continued)

This field...	Displays...
Source	The source address consists of the IPv6 prefix and the TCP or UDP port identifier.
Destination	The destination address consists of the IPv6 prefix. Certain logical elements have a bearing on the meaning of the destination address and its format, as follows: For IPsec on an interface or area, the destination address is shown as a prefix of 0xFE80 (link local). The solitary "::" (no prefix) indicates a "do not-care" situation because the connection is multicast. In this case, the security policy is enforced without regard for the destination address. For a virtual link (SPDID = 0), the address is required.

TABLE 333 SA used by the policy

This field...	Displays...
SA	This heading points at the SA-related headings for information used by the security policy. Thereafter, on each line of this part of the IPsec entry (which alternates with lines of policy information Table 332), "SA:" points at the fields under those SA-related headings. The remainder of this table describes each of the SA-related items.
SPDID	The security policy database identifier (SPDID) consists of two parts; the first part is an VRF id and the second part is an interface ID. The SPDID 0/ALL is a global database for the default VRF that applies to all interfaces.
Dir	The Dir field is either 'in" for inbound or "out" for outbound.
Encap	The type of encapsulation in the current release is ESP.
SPI	Security parameter index.
Destination	The IPv6 address of the destination endpoint. From the standpoint of the near interface and the area, the destination is not relevant and therefore appears as ::/0:any. For a virtual link, both the inbound and outbound destination addresses are relevant.

Showing IPsec statistics

The **show ipsec statistics** command displays the error and other counters for IPSec, as this example shows.

```
NetIron#show ipsec statistics
                        IPSecurity Statistics
secEspCurrentInboundSAs 1          ipsecEspTotalInboundSAs:  2
secEspCurrentOutboundSA 1          ipsecEspTotalOutboundSAs: 2
                    IPSecurity Packet Statistics
secEspTotalInPkts:      19         ipsecEspTotalInPktsDrop:  0
secEspTotalOutPkts:     83
                    IPSecurity Error Statistics
secAuthenticationErrors 0
secReplayErrors:        0          ipsecPolicyErrors:        13
secOtherReceiveErrors:  0          ipsecSendErrors:          0
secAuthenticationErrors 0
secReplayErrors:        0          ipsecPolicyErrors:        13
secOtherReceiveErrors:  0          ipsecSendErrors:          0
secUnknownSpiErrors:    0
```

Syntax: show ipsec statistics

This command takes no parameters.

Displaying IPsec configuration for an area

The **show ipv6 ospf area** [<*area-id*>] command includes information about IPsec for one area or all areas. In the example that follows, the IPsec information is in bold. IPsec is enabled in the first area (area 0) in this example but not in area 3. Note that in area 3, the IPsec key was specified as not encrypted.

```
NetIron(config-ospf6-router)#show ipv6 ospf area
  Authentication: Configured
   KeyRolloverTime(sec): Configured: 25 Current: 20
   KeyRolloverState: Active,Phase1
   Current: None
   New: SPI:400, ESP, SHA1
      Key:$Z|83OmYW{QZ|83OmYW{QZ|83OmYW{QZ|83OmYW{Q
  Interface attached to this area: eth 1/1
  Number of Area scoped LSAs is 6
  Sum of Area LSAs Checksum is 0004f7de
  Statistics of Area 0:
    SPF algorithm executed 6 times
    SPF last updated: 482 sec ago
    Current SPF node count: 1
      Router: 1 Network: 0
      Maximum of Hop count to nodes: 0
Area 3:
  Authentication: Not Configured
  Interface attached to this area:
  Number of Area scoped LSAs is 3
```

Syntax: show ipv6 ospf area [<*area-id*>]

The <*area-id*> parameter restricts the display to the specified OSPF area. You can specify the <*area-id*> parameter in the following formats:

- An IPv4 address, for example, 192.168.1.1
- A numerical value in the range 0 – 2,147,483,647

TABLE 334 Area configuration of IPsec

This field...	Displays...
Authentication	This field shows whether or not authentication is configured. If this field says "Not Configured," the IPsec-related fields (bold in example screen output) are not displayed at all.
KeyRolloverTime	The number of seconds between each initiation of a key rollover. This field shows the configured and current times.
KeyRolloverState	Can be: Not active: key rollover is not active> Active phase 1: rollover is in its first interval. Active phase 2: rollover is in its second interval.
Current	Shows current SPI, authentication algorithm (currently ESP only), encryption algorithm (currently SHA1 only), and the current key.
New	Shows new SPI (if changed), authentication algorithm (currently ESP only), encryption algorithm (currently SHA1 only), and the new key.
Old	Shows old SPI (if changed), authentication algorithm (currently ESP only), encryption algorithm (currently SHA1 only), and the old key.

Displaying IPsec for an interface

To see IPsec configuration for a particular interface or all interfaces, use the **show ipv6 ospf interface** command as in the following example (IPsec information in bold).

```
NetIron#show ipv6 ospf interface
eth 1/3 is down, type BROADCAST
   Interface is disabled

eth 1/8 is up, type BROADCAST
  IPv6 Address:
      2100:18:18:18:18::1/64
      2100:18:18:18::/64
  Instance ID 255, Router ID 1.1.1.1
  Area ID 1, Cost 1
  State BDR, Transmit Delay 1 sec, Priority 1
  Timer intervals :
    Hello 10, Hello Jitter 10  Dead 40, Retransmit 5
  Authentication: Enabled
   KeyRolloverTime(sec): Configured: 30 Current: 0
   KeyRolloverState: NotActive
   Outbound: SPI:121212, ESP, SHA1
      Key:12345678901234567890123456789012345678901234567890
   Inbound: SPI:121212, ESP, SHA1
      Key:12345678901234567890123456789012345678901234567890
  DR:2.2.2.2 BDR:1.1.1.1  Number of I/F scoped LSAs is 2
  DRElection:     1 times, DelayedLSAck:    83 times
  Neighbor Count = 1,   Adjacent Neighbor Count= 1
     Neighbor:
      2.2.2.2 (DR)
    Statistics of interface eth 1/8:
      Type     tx         rx         tx-byte    rx-byte
      Unknown  0          0          0          0
      Hello    1415       1408       56592      56320
      DbDesc   3          3          804        804
      LSReq    1          1          28         28
      LSUpdate 193        121        15616      9720
      LSAck    85         109        4840       4924
      OSPF messages dropped,no authentication: 0
```

Syntax: show ipv6 ospf interface [ethernet <*slot/port*> | pos <*slot/port*> | loopback <*number*> | tunnel <*number*> | ve <*number*>]

TABLE 335 Area configuration of IPsec

This field...	Displays...
Authentication	This field shows whether or not authentication is configured. If this field says "Not Configured," the IPsec-related fields (bold in example screen output) are not displayed at all.
KeyRolloverTime	The number of seconds between each initiation of a key rollover. This field shows the configured and current times.
KeyRolloverState	Can be: Not active: key rollover is not active> Active phase 1: rollover is in its first interval. Active phase 2: rollover is in its second interval.
Current	Shows current SPI, authentication algorithm (currently ESP only), encryption algorithm (currently SHA1 only), and the current key.
New (Inbound or Outbound)	Shows new SPI (if changed), authentication algorithm (currently ESP only), encryption algorithm (currently SHA1 only), and the new key.

TABLE 335 Area configuration of IPsec (Continued)

This field...	Displays...
Old (Inbound or Outbound)	Shows old SPI (if changed), authentication algorithm (currently ESP only), encryption algorithm (currently SHA1 only), and the old key.
OSPF messages dropped	Shows the number of packets dropped because the packets failed authentication (for any reason).

Displaying IPsec for a virtual link

To display IPsec for a virtual link, run the **show ipv6 ospf virtual-link brief** or **show ipv6 ospf virtual-link** command, as the following examples illustrate.

```
NetIron#show ipv6 ospf virtual-link brief
Index Transit Area ID  Router ID        Interface Address             State
1     1                14.14.14.14      3000:1:1:1::1                 P2P

NetIron#show ipv6 ospf virtual-link
Transit Area ID  Router ID        Interface Address             State
1                14.14.14.14      3000:1:1:1::1                 P2P
  Timer intervals(sec) :
    Hello 10, Hello Jitter 10,  Dead 40, Retransmit 5, TransmitDelay 1
  DelayedLSAck:     5 times
  Authentication: Configured
   KeyRolloverTime(sec): Configured: 10 Current: 0
   KeyRolloverState: NotActive
   Outbound: SPI:100004, ESP, SHA1
      Key:12345678901234567890123456789012345678901234567890
   Inbound: SPI:100004, ESP, SHA1
      Key:12345678901234567890123456789012345678901234567890
  Statistics:
      Type     tx         rx         tx-byte    rx-byte
      Unknown  0          0          0          0
      Hello    65         65         2600       2596
      DbDesc   4          4          2752       2992
      LSReq    1          1          232        64
      LSUpdate 11         5          1040       1112
      LSAck    5          8          560        448
      OSPF messages dropped,no authentication: 0
Neighbor: State: Full Address: 2004:44:44:44::4 Interface: eth 2/2
```

Syntax: show ipv6 ospf virtual-link [brief]

The optional [brief] keyword limits the display to the Transit, Area ID, Router ID, Interface Address, and State fields for each link.

Changing a key

In this example, the key is changed as illustrated in the two command lines that follow. Note that the SPI value is changed from 300 to 310 to comply with the requirement that you change the SPI when you change the key.

Initial configuration command.

```
NetIron(config-if-e10000-1/3)#ipv6 ospf auth ipsec spi 300 esp sha1
no-encrypt 1234567890098765543123456789 0aabbccddef
```

Command line for changing the key.

```
NetIron(config-if-e10000-1/3)#ipv6 ospf auth ipsec spi 310 esp sha1
no-encrypt 9898989890098765543212345678 90aabbccddef
```

Displaying IPv6 OSPF information for a VRF

To display IPv6 OSPF information for a VRF or all VRF interfaces, use the **show ipv6 ospf vrf** command as in the following example.

```
PowerConnect#show ipv6 ospf vrf red
OSPFv3 Process number 0 with Router ID 0x02020202(2.2.2.2)
Running 0 days 0 hours 5 minutes 49 seconds
Number of AS scoped LSAs is 0
Sum of AS scoped LSAs Checksum is 00000000
External LSA Limit is 250000
Database Overflow Interval is 10
Database Overflow State is NOT OVERFLOWED
Route calculation executed 0 times
Pending outgoing LSA count 0
Authentication key rollover interval 30 seconds
Number of areas in this router is 4
Router is operating as ABR
Router is operating as ASBR, Redistribute: CONNECTED
High Priority Message Queue Full count: 0
BFD is disabled
```

Syntax: show ipv6 ospf vrf <vrf-name> **area** [<area-id>] | [<virtual-links>]

The <vrf-name> parameter specifies the VRF that you want the OSPF area information for.

The <area-id> parameter shows information for the specified area.

The <virtual-link> parameter displays the entry that corresponds to the IP address you enter.

Use the **show ipv6 ospf vrf** command to display the currently selected IPv6 global address for use by the Virtual Links in each transit area.

```
PowerConnect#show ipv6 ospf vrf red area
Area 3:
        Authentication: Not Configured
        Interface attached to this area:
        Number of Area scoped LSAs is 3
        Sum of Area LSAs Checksum is 0001a6c4
        Statistics of Area 3:
                SPF algorithm executed 3 times
                SPF last updated: 302 sec ago
                Current SPF node count: 1
                Router: 1 Network: 0
                Maximum of Hop count to nodes: 0
Area 2:
        Authentication: Not Configured
        Interface attached to this area:
        Number of Area scoped LSAs is 3
        Sum of Area LSAs Checksum is 000192d6
        Statistics of Area 2:
                SPF algorithm executed 3 times
                SPF last updated: 302 sec ago
                Current SPF node count: 1
                Router: 1 Network: 0
                Maximum of Hop count to nodes: 0
Area 1:
        Authentication: Not Configured
        Interface attached to this area: eth 1/1
        Number of Area scoped LSAs is 6
        Sum of Area LSAs Checksum is 00046630
        Statistics of Area 1:
                SPF algorithm executed 3 times
                SPF last updated: 302 sec ago
                Current SPF node count: 3
                Router: 2 Network: 1
                Maximum of Hop count to nodes: 2
                Global IPv6 Address used by Virtual Links in this area:10:1:1::2
Area 0.0.0.0 :
        Authentication: Not Configured
        Interface attached to this area: VLink 1
        Number of Area scoped LSAs is 6
        Sum of Area LSAs Checksum is 0002cc53
        Statistics of Area 0.0.0.0:
                SPF algorithm executed 3 times
                SPF last updated: 302 sec ago
                Current SPF node count: 2
```

Syntax: show ipv6 ospf vrf <vrf-name> **area** [<area-id>] | [<virtual-links>]

Use the **show ipv6 ospf vrf** neighbor command to display the currently selected neighbor for use by the Virtual Links in each transit area.

```
NetIron#sh ipv6 ospf vrf red neighbor
Total number of neighbors in all states: 1
Number of neighbors in state Full      : 1

Type     tx         rx         tx-byte    rx-byte
      Unknown  0          0          0          0
      Hello    32         32         1276       1280
      DbDesc   2          2          116        116
      LSReq    1          1          52         52
      LSUpdate 2          2          184        200
      LSAck    2          2          112        112
      OSPF messages dropped,no authentication: 0
  Neighbor: State: Full Address: 35:1:1::1 Interface: eth 1/1
```

OSPFv3 clear commands

The following OSPFv3 clear commands are supported.

Clearing all OSPFv3 data

You can use the **ospf all** command to clear all OSPF data by disabling and enabling the OSPFv3 processes as shown in the following.

```
NetIron# clear ipv6 ospf all
```

Syntax: clear ipv6 ospf all

Clearing all OSPFv3 packet counters

You can use the **ospf traffic** command to clear all OSPFv3 packet counters as shown in the following.

```
NetIron# clear ipv6 ospf traffic
```

Syntax: clear ipv6 ospf traffic

Scheduling Shortest Path First (SPF) calculation

You can use the **ospf force-spf** command to perform the SPF calculation without clearing the OSPF database, as shown in the following.

```
NetIron# clear ipv6 ospf force-spf
```

Syntax: clear ipv6 ospf force-spf

Clearing all redistributed routes from OSPF

You can use the **ospf redistribution** command to clear all redistributed routes from OSPF, as shown in the following.

```
NetIron# clear ipv6 ospf redistribution
```

Syntax: clear ipv6 ospf redistribution

Clearing OSPF neighbors

You can use the **ospf neighbor** command to delete and relearn OSPF neighbors, as shown in the following:

- Clearing all OSPF Neighbors
- Clearing OSPF Neighbors Attached to a Specified Interface

Clearing all OSPF neighbors

You can use the **ospf neighbor all** command to delete and relearn all OSPF neighbors, as shown in the following.

```
NetIron# clear ipv6 ospf neighbor all
```

Syntax: clear isv6 ospf neighbor all

Clearing OSPF neighbors attached to a specified interface

You can use the **ospf neighbor interface** command to delete and relearn the OSPF neighbors attached to a specified interface, as shown in the following.

```
NetIron# clear ipv6 ospf neighbor interface ethernet 1/1
```

Syntax: clear isv6 ospf neighbor interface ethernet <*slot/port*> **| pos** <*slot/port*> **| ve** <*port-no*> **| tunnel** <*tunnel-port*> [<*nbrid*>]

Specify the interface options as shown in the following options.

ethernet <*slot/port*> – clears OSPF neighbors on the specified Ethernet interface.

pos <*slot/port*> – clears OSPF neighbors on the specified POS interface.

ve <*port-no*> – clears OSPF neighbors on the specified virtual interface.

tunnel <*tunnel-port*> – clears OSPF neighbors on the specified tunnel interface.

Specifying the <*nbrid*> variable limits the **clear ipv6 ospf neighbor** command to an individual OSPF neighbor attached to the interface.

Clearing OSPF counters

You can use the **ospf counts** command to clear OSPF neighbor's counters as described in the following:

- Clearing all OSPF Counters
- Clearing the OSPF Counters for a Specified Neighbor
- Clearing the OSPF Counters for a Specified Interface

Clearing all OSPF counters

You can clear all OSPF counters using the **clear ipv6 counts** command, as shown in the following.

```
NetIron# clear ipv6 ospf counts
```

Syntax: clear ipv6 ospf counts

Clearing OSPF counters for a specified neighbor

You can clear all OSPF counters for a specified neighbor using the **clear ipv6 counts neighbor** command, as shown in the following.

```
NetIron# clear ipv6 ospf counts neighbor 136.10.10.1
```

Syntax: clear ipv6 ospf counts neighbor <*nbrid*>

The <*nbrid*> variable specifies the neighbor ID of the OSPF neighbor whose counters you want to clear.

Clearing OSPF counters for a specified interface

You can clear all OSPF counters for a specified interface using the **clear ipv6 counts neighbor interface** command, as shown in the following.

```
NetIron# clear ipv6 ospf counts interface ethernet 3/1
```

Syntax: clear ipv6 ospf counts neighbor interface ethernet <*slot/port*> **| pos** <*slot/port*> **| ve** <*port-no*> **| tunnel** <*tunnel-port*> [<*nbrid*>]

Specify the interface options as shown in the following options.

ethernet <*slot/port*> – clears OSPF counters for OSPF neighbors on the specified Ethernet interface.

pos <*slot/port*> – clears OSPF counters for OSPF neighbors on the specified POS interface.

ve <*port-no*> – clears OSPF counters for OSPF neighbors on the specified virtual interface.

tunnel <*tunnel-port*> – clears OSPF counters for OSPF neighbors on the specified tunnel interface.

Using an <*nbrid*> value limits the displayed output to an individual OSPF neighbor attached to the interface.

Configuring IPv6 IS-IS

PowerConnect B-MLXe supports the following IPv6 IS-IS features:

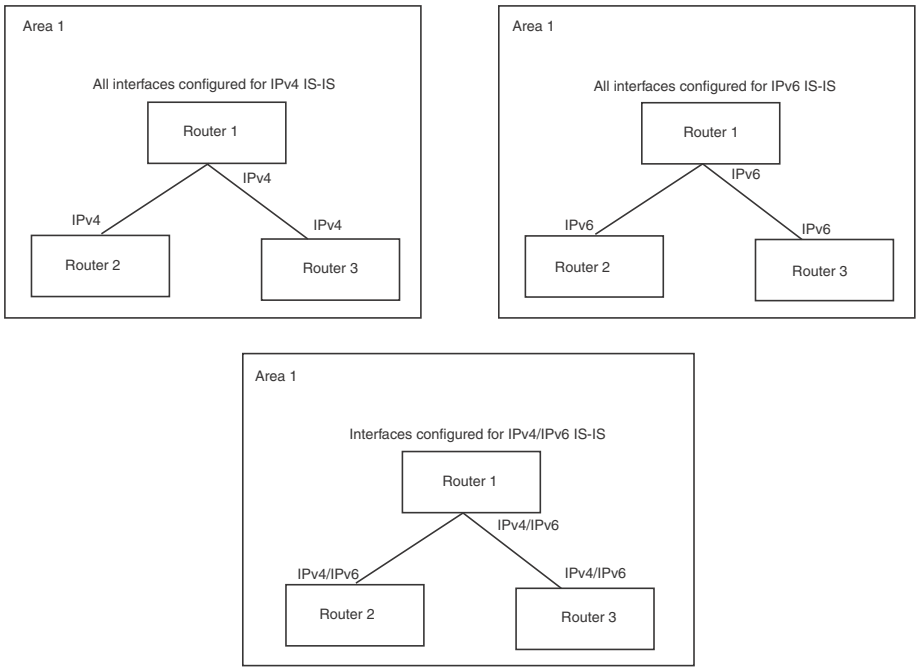
- IPv6 IS-IS
- Redistributing BGP4+ Routes into IPv6 IS-IS
- Redistributing RIPng Routes into IPv6 IS-IS
- Redistributing OSPFv3. Routes into IPv6 IS-IS
- Redistributing Static IPv6 Routes into IPv6 IS-IS
- Redistributing IPv6 routes learned from directly connected networks
- IPv6 Protocol-Support Consistency Checks

A description of the IS-IS protocol is provided in 25, “Configuring IS-IS (IPv4)”. This chapter describes the specific requirements for configuring a PowerConnect router for IPv6 IS-IS.

IPv6 IS-IS single-topology mode

IPv6 IS-IS supports single-topology mode, which means that you can run IPv6 IS-IS concurrently with other network protocols such as IPv4 IS-IS throughout a topology. However, when implementing a single topology, all routers in an area (Level 1 routing) or domain (Level 2 routing) must be configured with the same set of network protocols on all its interfaces, even on loopback interfaces. You can configure IPv4 IS-IS only, IPv6 IS-IS only, or both IPv4 IS-IS and IPv6 IS-IS ((Figure). For example, to successfully implement both IPv4 and IPv6 IS-IS in an area, you must configure both IPv4 and IPv6 IS-IS on all router interfaces in the area.

FIGURE 218



A single shortest path first (SPF) per level computes the IPv4 and IPv6 routes. The use of a single SPF indicates that both IPv4 and IPv6 IS-IS routing protocols must share a common network topology

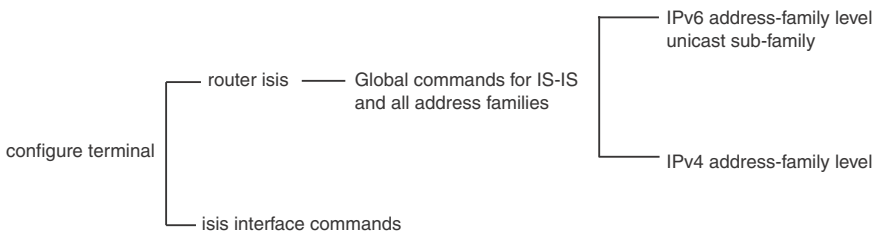
The implementation of IPv4 IS-IS supports type, length, and value (TLV) parameters to advertise reachability to IPv4 networks. The TLVs specify the types of data, the maximum length of the data, and the valid values for the data. IPv6 IS-IS advertises its information using new TLV parameters. The new TLV parameters for IPv6 support an extended default metric value.

In a single topology, if both IPv4 and IPv6 are configured on an interface, metric-style must be set to wide in both address families. Narrow is the default for IPv4. Wide is the default for IPv6.

IS-IS CLI levels

The CLI includes various levels of commands for IS-IS. Figure 219 diagrams these levels that includes the levels used for IPv6 IS-IS.

FIGURE 219 IPv6 IS-IS CLI levels



The IPv6 IS-IS CLI levels are as follows:

- A global level for the configuration of the IS-IS protocol. At this level, all IS-IS configurations at this level apply to IPv4 and IPv6. You enter this layer using the **router isis** command.
  - Under the global level, you specify an address family. Address families separate the IS-IS configuration IPv6 and IPv4. You enter configurations that are for a specific You enter this level by entering the **address-family** command at the router isis level.
  - Under the address family level, you select a sub-address family, which is the type of routes for the configuration. For IS-IS, you specify **unicast**.
- An interface level

Global configuration level

You enter the global configuration level of ISIS by entering the following command:

```
NetIron(config)#router isis
NetIron(config-isis-router)#
```

Syntax: router isis

The `(config-isis-router)#` prompt indicates that you are at the global level for IS-IS. Configurations you enter at this level apply to both IS-IS IPv4 and IS-IS IPv6.

Address family configuration level

The implementation of IPv6 IS-IS includes a new configuration level: address family. You enter IS-IS definitions for IPv6 IS-IS under this level. Address-family allows you to create configurations for IPv6 IS-IS unicast routes that are separate and distinct from configurations for IPv4 IS-IS unicast routes.

Under the address family level, Dell currently supports the unicast address family configuration level only. The device enters the IPv6 IS-IS unicast address family configuration level when you enter the following command while at the global IS-IS configuration level:

```
NetIron(config-isis-router)# address-family ipv6 unicast
NetIron(config-isis-router-ipv6u)#
```

Syntax: address-family ipv6 unicast

The `(config-isis-router-ipv6u)#` prompt indicates that you are at the IPv6 IS-IS unicast address family configuration level. While at this level, you can access several commands that allow you to configure IPv6 IS-IS unicast routes.

NOTE
Each address family configuration level allows you to access commands that apply to that particular address family only. To enable a feature in a particular address family, you must specify any associated commands for that feature in that particular address family. You cannot expect the feature, which you may have configured in the IPv4 IS-IS unicast address family, to work in the IPv6 IS-IS unicast address family unless it is explicitly configured in the IPv6 IS-IS unicast address family.

To exit from the IPv6 IS-IS unicast address family configuration level, enter the following command:

```
NetIron(config-isis-router-ipv6u)# exit-address-family
NetIron(config-isis-router)#
```

Entering this command returns you to the global IS-IS configuration level.

Interface level

Some IS-IS definitions are entered at the interface level. To change to the interface level for IS-IS configuration, enter the following command.

```
NetIron(config)# interface ethernet 2/3
NetIron(config-if-e1000-2/3)#ipv6 router isis
```

Syntax: ipv6 router isis

Configuring IPv6 IS-IS

Enabling IPv6 IS-IS globally

Follow the steps listed below to configure IPv6 IS-IS globally.

1. You must enable the forwarding of IPv6 traffic on the device using the **ipv6 unicast-routing** command. Enter a command such as the following:

   ```
   NetIron#configure terminal
   NetIron(config)# ipv6 unicast-routing
   ```

   Syntax: [no] ipv6 unicast-routing

2. Globally enable IS-IS by entering the following command:

   ```
   NetIron(config)# router isis
   ISIS: Please configure NET!
   ```

   Once you enter **router isis**, the device enters the IS-IS router configuration level.

   Syntax: [no] router isis

   To disable IS-IS, use the **no** form of this command.

3. If you have not already configured a NET for IS-IS, enter commands such as the following:

   ```
   NetIron(config-isis-router)# net 49.2211.aaaa.bbbb.cccc.00
   NetIron(config-isis-router)#
   ```

   The commands in the example above configure a NET that has the area ID 49.2211, the system ID aaaa.bbbb.cccc (the device's base MAC address), and SEL value 00.

   Syntax: [no] net <*area-id*>.<*system-id*>.<*sel*>

   The <*area-id*> parameter specifies the area and has the format xx or xx.xxxx. For example, 49 and 49.2211 are valid area IDs.

   The <*system-id*> parameter specifies the router's unique IS-IS router ID and has the format xxxx.xxxx.xxxx. You can specify any value for the system ID. A common practice is to use the device's base MAC address as the system ID. The base MAC address is also the MAC address of port 1. To determine the base MAC address, enter the following command at any level of the CLI: **show interfaces brief**. The base MAC address is listed in the first row of information, in the MAC column.

   You must use the same system ID in all the NETs on the device.

NOTE
The parameter descriptions above are the recommended values for the NET. However, the CLI accepts any value that fits within the following lengths and formats:

xx.xxxx.xxxx.xxxx.00 – minimum length of NET

xx.xxxx.xxxx.xxxx.xxxx.xxxx.xxxx.xxxx.xxxx.xxxx.00 – maximum length of NET

The <*sel*> parameter specifies the NSAP Selector (SEL). This value must always be 00 (two zeros). The value 00 indicates that this address is an NET.

To delete a NET, use the **no** form of this command.

4. Configure an IPv6 IS-IS single topology. Refer to "Configuring IPv6 IS-IS single topology" on page 1872.
5. Configure ISIS parameters. Refer to the sections "Globally configuring IS-IS on a device" on page 1872, "Configuring IPv6 specific address family route parameters" on page 1872, and "Configuring ISIS properties on an interface" on page 1879.

Enabling IS-IS and assigning an IPv6 address to an interface

To configure IPv6 IS-IS on the desired router interfaces, enter commands such as the following:

```
NetIron(config)# interface ethernet 3/1
NetIron(config-if-e100-3/1)# ipv6 address 2001:200:12D:1300::/64 eui-64
NetIron(config-if-e100-3/1)# ipv6 router isis
```

The commands in this example assign the global IPv6 prefix 2001:200:12d:1300::/64 to Ethernet interface 3/1 and enable IPv6 IS-IS on the interface.

Syntax: ipv6 address <*ipv6-prefix*>/<*prefix-length*> **[eui-64]**

You must specify the <*ipv6-prefix*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

You must specify the <*prefix-length*> parameter as a decimal value. A slash mark (/) must follow the <*ipv6-prefix*> parameter and precede the <*prefix-length*> parameter.

The **eui-64** keyword configures the global or site-local address with an EUI-64 interface ID in the low-order 64 bits. The interface ID is automatically constructed in IEEE EUI-64 format using the interface's MAC address.

Syntax: [no] ipv6 router isis

To disable IPv6 IS-IS on an interface, use the **no** form of this command.

The following configuration tasks are optional:

- Configure IPv6 route parameters.
- Redistribute routes from other route sources into IPv6 IS-IS.
- Perform IPv6 IS-IS adjacency checks.
- Disable partial SPF calculations

Configuring IPv6 IS-IS single topology

If your IS-IS single topology will support both IPv6 and IPv4, you can configure both IPv6 and IPv4 on an IS-IS interface for Level 1, Level 2, or both Level 1 and Level 2. However, if you configure both IPv6 and IPv4 on an IS-IS interface, they must be configured to run on the same level. For example, you can configure IPv6 to run on Level 1 on an interface and IPv4 to also run on Level 1 on the same interface. However, you cannot configure IPv6 to run on Level 1 on an interface and IPv4 to run to Level 2 on the same interface.

To configure an IPv6 IS-IS single topology, you must perform the tasks listed below.

1. Globally enable IS-IS and configure at least one Network Entity Title (NET). The NET is the device's network interface with IS-IS. You can configure up to three NETs on a device.
2. Configure the desired router interfaces with an IPv6 address and enable IPv6 IS-IS on the router interfaces.
3. Configure ISIS parameters. Refer to the sections "Globally configuring IS-IS on a device" on page 1872, "Configuring IPv6 specific address family route parameters" on page 1872, and "Configuring ISIS properties on an interface" on page 1879.

Globally configuring IS-IS on a device

The following configuration tasks described in 25, "Configuring IS-IS (IPv4)", apply to IS-IS IPv6 configuration:

- Setting the Overload Bit
- Configuring Authentication
- Changing the IS-IS Level Globally
- Disabling or Re-enabling Display of Hostname
- Changing the Sequence Numbers PDU Interval
- Changing the Maximum LSP Lifetime
- Changing the LSP Refresh Interval
- Changing the LSP Generation Interval
- Changing the LSP Interval and Retransmit
- Changing the SPF Timer
- Globally Disabling or Re-Enabling Hello Padding
- Logging Adjacency Changes
- Disabling Partial SPF Calculations.

Configuring IPv6 specific address family route parameters

This section describes how to modify the IS-IS the parameters for the IS-IS IPv6 address family.

Changing the maximum number of load sharing paths

By default, IPv6 IS-IS can calculate and install four equal-cost paths into the IPv6 forwarding table. You can change the number of paths IPv6 IS-IS can calculate and install in the IPv6 forwarding table to an amount from
1 – 8. If you change the number of paths to one, the device does not load share route paths learned from IPv6 IS-IS.

For example, to change the number of paths IPv6 IS-IS can calculate and install in the IPv6 forwarding table to three, enter the following command at the IPv6 IS-IS unicast address family configuration level:

```
NetIron(config-isis-router-ipv6u)# maximum-paths 8
```

Syntax: [no] maximum-paths <*number*>

The <*number*> parameter specifies the number of paths IPv6 IS-IS can calculate and install in the IPv6 forwarding table.

To return to the default number of maximum paths, enter the **no** form of this command.

Enabling advertisement of a default route

By default, the device does not generate or advertise a default route to its neighboring ISs. A default route is not advertised even if the device's IPv6 route table contains a default route. You can enable the device to advertise a default route to all neighboring ISs using one of the following methods. By default, the feature originates the default route at Level 2 only. However, you can apply a route map to originate the default route to Level 1 only or at both Level 1 and Level 2.

NOTE
This feature requires the presence of a default route in the IPv6 route table.

To enable the device to advertise a default route that is originated a Level 2, enter the following command at the IPv6 IS-IS unicast address family configuration level:

```
NetIron(config-isis-router-ipv6u)# default-information-originate
```

This command enables the device to advertise a default route into the IPv6 IS-IS area to which the device is attached.

Syntax: [no] default-information-originate [route-map <*name*>**]**

The **route-map** <*name*> parameter allows you to specify the level on which to advertise the default route. You can specify one of the following:

- Advertise to Level-1 ISs only.
- Advertise to Level-2 ISs only.
- Advertise to Level-1 and Level-2 ISs.

NOTE
The route map must be configured before you can use the route map as a parameter with the **default-information-originate** command.

To use a route map to specify the router to advertise a default route to Level 1, enter commands such as the following at the Global CONFIG level:

```
NetIron(config)# route-map default_level1 permit 1
NetIron(config-routemap default_level1)# set level level-1
NetIron(config-routemap default_level1)# router isis
NetIron(config-isis-router)# address-family ipv6 unicast
NetIron(config-isis-router-ipv6u)# default-information-originate route-map
default_level1
```

These commands configure a route map to set the default advertisement level to Level 1 only.

Syntax: [no] route-map <*map-name*> **permit | deny** <*sequence-number*>

Syntax: [no] set level level-1 | level-1-2 | level-2

For this use of a route map, use the **permit** option and do not specify a **match** statement. Specify a **set** statement to set the level to one of the following:

- **level-1** – Level 1 only.
- **level-1-2** – Level 1 and Level 2.
- **level-2** – Level 2 only (default).

Changing the administrative distance for IPv6 IS-IS

When the device has paths from multiple routing protocols to the same destination, it compares the administrative distances of the paths and selects the path with the lowest administrative distance to place in the IPv6 route table.

For example, if the router has a path from RIPng, from OSPFv3, and IPv6 IS-IS to the same destination, and all the paths are using their protocols' default administrative distances, the router selects the OSPFv3 path, because that path has a lower administrative distance than the RIPng and IPv6 IS-IS paths.

Here are the default IPv6 administrative distances on the device:

- Directly connected – 0 (this value is not configurable)
- Static – 1 (applies to all static routes, including default routes)
- EBGP – 20
- OSPFv3 – 110
- IPv6 IS-IS – 115
- RIPng – 120
- IBGP – 200
- Local BGP – 200
- Unknown – 255 (the device will not use this route)

Lower administrative distances are preferred over higher distances. For example, if the device receives routes for the same network from IPv6 IS-IS and from RIPng, it will prefer the IPv6 IS-IS route by default.

To change the administrative distance for IPv6 IS-IS routes, enter the following command at the IPv6 IS-IS unicast address family configuration level:

```
NetIron(config-isis-router-ipv6u)# distance 100
```

Syntax: [no] distance <*number*>

This command changes the administrative distance for all IPv6 IS-IS routes to 100.

The <*number*> parameter specifies the administrative distance. You can specify a value from 1 – 255. (Routes with a distance value of 255 are not installed in the routing table.) The default for IPv6 IS-IS is 115.

Configuring summary prefixes

You can configure summary prefixes to aggregate IPv6 IS-IS route information. Summary prefixes can enhance performance by reducing the size of the Link State database, reducing the amount of data a router needs to send to its neighbors, and reducing the CPU cycles used for IPv6 IS-IS.

When you configure a summary prefix, the prefix applies only to Level-2 routes by default. You can specify Level-1 only, Level-2 only, or Level-1 and Level-2 when you configure the prefix.

For example, to configure a summary prefix of 2001:e0ff::/32 to be advertised to Level-1 routes only, enter the following command at the IPv6 IS-IS unicast address family configuration level:

```
NetIron(config-isis-router-ipv6u)# summary-prefix 2001:e0ff::/32 level-1
```

Syntax: [no] summary-prefix <*ipv6-prefix*>**/**<*prefix-length*> **[level-1 | level-1-2 | level-2-only]**

The <*ipv6-prefix*>/<*prefix-length*> parameter specifies the aggregate address. You must specify the <*ipv6-prefix*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the <*prefix-length*> parameter as a decimal value. A slash mark (/) must follow the <*ipv6-prefix*> parameter and precede the <*prefix-length*> parameter.

The **level-1** | **level-1-2** | **level-2-only** parameter specifies the route types to which the aggregate route applies. The default is **level-2-only**.

Redistributing routes into IPv6 IS-IS

To redistribute routes into IPv6 IS-IS, you can perform the following configuration tasks:

- Change the default redistribution metric (optional).
- Configure the redistribution of a particular route type into IPv6 IS-IS (mandatory).

The device can redistribute routes from the following route sources into IPv6 IS-IS:

- BGP4+.
- RIPng.
- OSPFv3.
- Static IPv6 routes.
- IPv6 routes learned from directly connected networks.

The device can also can redistribute Level-1 IPv6 IS-IS routes into Level-2 IPv6 IS-IS routes, and Level-2 IPv6 IS-IS routes into Level-1 IPv6 IS-IS routes.

Route redistribution from other sources into IPv6 IS-IS is disabled by default. When you enable redistribution, the device redistributes routes only into Level 2 by default. You can specify Level 1 only, Level 2 only, or Level 1 and Level 2 when you enable redistribution.

The device automatically redistributes Level-1 routes into Level-2 routes. Thus, you do not need to enable this type of redistribution. You also can enable redistribution of Level-2 routes into Level-1 routes.

The device attempts to use the redistributed route's metric as the route's IPv6 IS-IS metric. For example, if an OSPFv3 route has an OSPF cost of 20, the router uses 20 as the route's IPv6 IS-IS metric. The device uses the redistributed route's metric as the IPv6 IS-IS metric unless the route does not a have a valid metric. In this case, the device assigns the default metric value to the route. For information about the default metric, refer to the "Changing the Default Redistribution Metric" section, which follows this section.

Changing the default redistribution metric

When IPv6 IS-IS redistributes a route from another route source (such as OSPFv3, BGP4+, or a static IPv6 route) into IPv6 IS-IS, it uses the route's metric value as its metric when the metric is not modified by a route map or metric parameter and the default redistribution metric is set to its default value of 0. You can change the default metric to a value from 0 – 65535.

NOTE
The implementation of IS-IS does not support the optional metric types Delay, Expense, or Error.

For example, to change the default metric to 20, enter the following command at the IPv6 IS-IS unicast address family configuration level.

```
NetIron(config-isis-router-ipv6u)# default-metric 20
```

Syntax: [no] **default-metric** <*number*>

The <*number*> parameter specifies the default metric. You can specify a value from 0 – 65535. The default is 0.

The restore the default value for the default metric, enter the **no** form of this command.

Redistributing static IPv6 routes into IPv6 IS-IS

To redistribute static IPv6 routes from the IPv6 static route table into IPv6 IS-IS routes, enter the following command at the IPv6 IS-IS unicast address family configuration level.

```
NetIron(config-isis-router-ipv6u)# redistribute static
```

This command configures the device to redistribute all static IPv6 routes into Level-2 IS-IS routes.

Syntax: [no] **redistribute static [level-1 | level-1-2 | level-2 | metric** <*number*> **| metric-type external | internal | route-map** <*name*>**]**

The **level-1**, **level-1-2**, and **level-2** keywords restrict redistribution to the specified IPv6 IS-IS level.

The **metric** <*num*> parameter changes the metric. You can specify a value from 0 - 4294967295.

The **metric-type external** | **internal** parameter restricts redistribution to one of the following:

- **external** – The metric value is not comparable to an IPv6 IS-IS internal metric and is always higher than the IPv6 IS-IS internal metric.
- **internal** – The metric value is comparable to metric values used by IPv6 IS-IS. This is the default.

The **route-map** <*name*> parameter restricts redistribution to those routes that match the specified route map. The route map must already be configured before you use the route map name with the **redistribute** command. For example, to configure a route map that redistributes only the static IPv6 routes to the destination networks 2001:100::/32, enter commands such as the following.

```
NetIron(config)# ipv6 access-list static permit any 2001:100::/32
NetIron(config)# route-map static permit 1
NetIron(config-routemap static)# match ip address static
NetIron(config-routemap static)# router isis
NetIron(config-isis-router)# address-family ipv6 unicast
NetIron(config-isis-router-ipv6u)# redistribute static route-map static
```

For information about the IPv6 ACL and route map syntax, refer to the following:

- Chapter 40, “Configuring an IPv6 Access Control List”.

Redistributing directly connected routes into IPv6 IS-IS

To redistribute directly connected IPv6 routes into IPv6 IS-IS routes, enter the following command at the IPv6 IS-IS unicast address family configuration level.

```
NetIron(config-isis-router-ipv6u)# redistribute connected
```

This command configures the device to redistribute all directly connected routes in the IPv6 route table into Level-2 IPv6 IS-IS.

Syntax: [no] **redistribute connected [level-1 | level-1-2 | level-2 | metric** <*number*> **| metric-type external | internal | route-map** <*name*>]

The parameters are the same as the parameters for the **redistribute static** command.

Redistributing RIPng routes into IPv6 IS-IS

To redistribute RIPng routes into IPv6 IS-IS, enter the following command at the IPv6 IS-IS unicast address family configuration level.

```
NetIron(config-isis-router-ipv6u)# redistribute rip
```

This command configures the device to redistribute all RIPng routes into Level-2 IS-IS.

Syntax: [no] **redistribute rip [level-1 | level-1-2 | level-2 | metric** <*number*> **| metric-type external | internal | route-map** <*name*>]

The parameters are the same as the parameters for the **redistribute static** command.

Redistributing OSPF version 3 routes into IPv6 IS-IS

To redistribute OSPFv3 routes into IPv6 IS-IS, enter the following command at the IPv6 IS-IS unicast address family configuration level.

```
NetIron(config-isis-router-ipv6u)# redistribute ospf
```

This command configures the device to redistribute all OSPFv3 routes into Level-2 IPv6 IS-IS.

Syntax: [no] **redistribute ospf [level-1 | level-1-2 | level-2 | match external1 | external2 | internal | metric** <*number*> **| metric-type external | internal | route-map** <*name*>]

Most of the parameters are the same as the parameters for the **redistribute static** command. However, the **redistribute ospf** command also has the **match external1** | **external2** | **internal** parameter. This parameter specifies the OSPF route type you want to redistribute into IPv6 IS-IS. By default, the **redistribute ospf** command redistributes only internal routes:

- **external1** – An OSPF type 1 external route.

- **external2** – An OSPF type 2 external route.
- **internal** – An internal route calculated by OSPF.

Redistributing BGP4+ routes into IPv6 IS-IS

To redistribute BGP4+ routes into IPv6 IS-IS, enter the following command at the IPv6 IS-IS unicast address family configuration level.

```
NetIron(config-isis-router-ipv6u)# redistribute bgp
```

This command configures the router to redistribute all its BGP4 routes into Level-2 IPv6 IS-IS.

Syntax: **[no] redistribute bgp [level-1 | level-1-2 | level-2 | metric** <*number*> **| metric-type external | internal | route-map** <*name*>**]**

The parameters are the same as the parameters for the **redistribute static** command.

Redistributing IPv6 IS-IS routes within IPv6 IS-IS

In addition to redistributing routes from other route sources into IPv6 IS-IS, the device can redistribute Level 1 IPv6 IS-IS routes into Level 2 IPv6 IS-IS routes, and Level 2 IPv6 IS-IS routes into Level 1 IPv6 IS-IS routes. By default, the device redistributes routes from Level 1 into Level 2.

NOTE
The device automatically redistributes Level 1 routes into Level 2 routes, even if you do not enable redistribution.

For example, to redistribute all IPv6 IS-IS routes from Level 2 into Level 1, enter the following command at the IPv6 IS-IS unicast address family configuration level.

```
NetIron(config-isis-router-ipv6u)# redistribute isis level-2 into level-1
```

The router automatically redistributes Level-1 routes into Level 2.

Syntax: **[no] redistribute isis level-1 into level-2 | level-2 into level-1 [prefix-list** <*name*>**]**

The **level-1 into level-2** | **level-2 into level-1** parameter specifies the direction of the redistribution:

- **level-1 into level-2** – Redistributes Level 1 routes into Level 2. This is the default.
- **level-2 into level-1** – Redistributes Level 2 routes into Level 1.

The optional **prefix-list** <*name*> parameter allows you to specify the IPv6 prefixes that you want redistributed from Level 1 into Level 2 and from Level 2 into Level 1. Specify the name of the IPv6 prefix list that contains the desired prefixes. (For information about prefix lists, including the syntax of the **ipv6 prefix-list** command, refer to Chapter 39, “Configuring an IPv6 Prefix List”.)

For example, to redistribute the IPv6 prefix 2001::/16 from Level 2 into Level 1, enter commands such as the following.

```
NetIron(config)# ipv6 prefix-list routesfor2001 permit 2001::/16
NetIron(config)# router isis
NetIron(config-isis-router)# address-family ipv6 unicast
NetIron(config-isis-router-ipv6u)# redistribute isis level-2 into level-1
prefix-list routesfor2001
```

Disabling and re-enabling IPv6 protocol-support consistency checks

As discussed in "IPv6 IS-IS single-topology mode" on page 1867, an IS-IS single topology must be configured to run the same set of network protocols (IPv4 IS-IS only, IPv6 IS-IS only, or both IPv4 IS-IS and IPv6 IS-IS).

By default, IS-IS performs consistency checks on hello packets. If a hello packet does not have the same configured network protocols, IS-IS rejects the packet. For example, a hello packet from a router running IPv4 and IPv6 IS-IS will be rejected by a router running either IPv4 IS-IS only or IPv6 IS-IS only, and the two routers will not become adjacent.

To allow two routers running different sets of network protocols to form an adjacency, enter the following command at the IPv6 IS-IS unicast address family configuration level.

```
NetIron(config-isis-router-ipv6u)# no adjacency-check
```

This command disables the IPv6 IS-IS consistency check.

Syntax: [no] adjacency-check

To re-enable the consistency check, enter the following command at the IPv6 IS-IS unicast address family configuration level.

```
NetIron(config-isis-router-ipv6u)# adjacency-check
```

Configuring ISIS properties on an interface

The parameter settings for configuring IS-IS properties on a device apply to both IS-IS IPv4 and IS-IS IPv6 except for "Changing the metric added to advertised routes" as described below. For details on how to perform all other IS-IS properties on an Interface, refer to 25, "Configuring IS-IS (IPv4)"

Changing the metric added to advertised routes

When the PowerConnect originates an IS-IS route or calculates a route, the PowerConnect adds a metric (cost) to the route. Each IS-IS interface has a separate metric value. The default is 10.

The PowerConnect applies the interface-level metric to routes originated on the interface and also when calculating routes. The PowerConnect does not apply the metric to link-state information that the PowerConnect receives from one IS and floods to other ISs.

The default interface metric is 10. You can change the metric on an individual interface to a value in one of the following ranges:

- 1 – 63 for the narrow metric style (the default metric style)
- 1 – 16777215 for the wide metric style

NOTE
If the metric value you want to use is higher than 63 but you have not changed the metric style to wide, change the metric style first, then set the metric. The IS-IS neighbors that will receive the advertisements also must be enabled to receive wide metrics.

To change the IS-IS metric on an interface, use the following CLI method.

```
NetIron(config-isis-router)# interface ethernet 2/8
NetIron(config-if-e1000-2/8)# isis metric 44
```

Syntax: [no] isis metric <*num*>

The <*num*> parameter specifies the metric. The range of values you can specify depends on the metric style. You can specify 1 – 63 for the narrow metric style or 1 – 16777215 for the wide metric style. The default in either case is 10.

When IPv6 IS-IS is enabled in a single topology, you must set the metric-style to be wide if you want to use an interface metric greater than 63.

Displaying IPv6 IS-IS information

You can display the following information about IPv6 IS-IS:

- General IPv6 IS-IS information.
- IPv6 IS-IS configuration information.
- IPv6 IS-IS error statistics.
- LSP database entries.
- IS-IS system ID to hostname mappings.
- IPv6 IS-IS interface information.
- IPv6 IS-IS memory usage information.
- IPv6 IS-IS neighbor information.
- IPv6 IS-IS path information.
- IPv6 IS-IS redistribution information.
- IPv6 IS-IS route information.
- IPv6 IS-IS traffic statistics.

Displaying IPv6 IS-IS information

To display general IPv6 IS-IS information, enter the following command at any CLI level.

```
NetIron# show ipv6 isis
 IS-IS  Routing Protocol Operation State: Enabled
 IS-Type: Level-1-2
 System ID: 8888.5555.0008
 Manual area address(es):
   49.8585
 Interfaces with Integrated IS-IS for IPv6 configured:
    Interface 4/1    Interface 4/2    Interface 4/11    Interface 4/12
    Interface 4/13   Interface 4/14   Interface 4/15    Interface 4/16
    Interface 4/17   Interface 4/35   Interface 4/36    Interface 4/37
    Interface 4/38   Interface v43    Interface v44     Interface lb1
 Following Routes are Redistributed into IS-IS for IPv6:
   CONNECTED
 Number of Routes redistributed into IS-IS: 1
 Domain password: None
 Area password: None
 IS-IS for IPV6 Route Administrative Distance: 115
 Hold Time Between Two SPF Calculations: 5
 Global Hello Padding: Enabled
```

Syntax: show ipv6 isis

This display shows the following information.

TABLE 336 IPv6 IS-IS information fields

This field...	Displays...
IS-IS Routing Protocol Operation State	The operating state of IPv6 IS-IS. Possible states include the following: • Enabled – IPv6 IS-IS is enabled. • Disabled – IPv6 IS-IS is disabled.
IS Type	The intermediate system type. Possible types include the following: • Level 1 only – The device routes traffic only within the area in which it resides. • Level 2 only – The device routes traffic between areas of a routing domain. • Level 1-2 – The device routes traffic within the area in which it resides and between areas of a routing domain.
System ID	The unique IS-IS router ID. Typically, the device's base MAC address is used as the system ID.
Manual area address(es)	Area address(es) of the device.
Interfaces with Integrated IS-IS for IPv6 configured	Interfaces on which IPv6 IS-IS is configured.
Following Routes are Redistributed into IS-IS for IPv6	Routes that are redistributed into IPv6 IS-IS. Possible routes include the following: • BGP – BGP4+ routes are redistributed into IPv6 IS-IS. • RIP – RIPng routes are redistributed into IPv6 IS-IS. • OSPF – OSPFv3 routes are redistributed into IPv6 IS-IS. • STATIC – Static IPv6 routes are redistributed into IPv6 IS-IS. • CONNECTED – IPv6 routes learned from directly connected networks are redistributed into IPv6 IS-IS.

TABLE 336 IPv6 IS-IS information fields (Continued)

This field...	Displays...
Number of Routes redistributed into IS-IS	The number of routes distributed into IS-IS
Domain password	The domain password, if one is configured.
Area password	The domain password, if one is configured.
IS-IS IPv6 Route Administrative Distance	The current setting of the IPv6 IS-IS administrative distance.
Hold Time Between Two SPF Calculations	The setting of the SPF timer, which causes the router to recalculate the SPF tree of its IPv6 IS-IS links following a change in topology or the link state database.
Global Hello Padding	The setting of the global hello padding feature, which can be one of the following: • Disabled – Global padding for hello packets is disabled. • Enabled – Global padding for hello packets is enabled.

Displaying the IPv6 IS-IS configuration in the running configuration

You can display the IPv6 IS-IS commands that are in effect on the device.

NOTE
The running configuration does not list the default values. Only commands that change a setting or add configuration information are displayed.

To display the IPv6 IS-IS configuration, enter the following command at any CLI level.

```
NetIron# show ipv6 isis config
Current ISIS configuration:
router isis
 net  49.6561.2222.2222.2222.00

 address-family ipv4 unicast
 distance  135
 redistribute static
 exit-address-family

 address-family ipv6 unicast
 redistribute static
 exit-address-family

end
```

Syntax: show ipv6 isis config

The running configuration shown in this example contains the following commands:

- Global IPv6 IS-IS commands that enable IS-IS.
- Address family commands that configure IPv4 IS-IS unicast routes.
- Address family commands that configure IPv6 IS-IS unicast routes.

Displaying IPv6 IS-IS error statistics

To display IPv6 IS-IS error statistics, enter the following command at any level of the CLI.

```
NetIron# show ipv6 isis counts
Area Mismatch: 0
Max Area Mismatch: 0
System ID Length Mismatch: 0
Authentication Fail: 0
Corrupted LSP: 0
LSP Sequence Number Skipped: 0
LSP Max Sequence Number Exceeded: 0
Level-1 Database Overload: 0
Level-2 Database Overload: 0
Our LSP Purged: 0
```

Syntax: show ipv6 isis counts

This display shows the following information.

TABLE 337 IPv6 IS-IS error statistics

This field...	Displays...
Area Mismatch	The number of times the router interface was unable to create a Level-1 adjacency with a neighbor because the router interface and the neighbor did not have any areas in common.
Max Area Mismatch	The number of times the device received a PDU with a value for maximum number of area addresses that did not match the device's value for maximum number of area addresses.
System ID Length Mismatch	The number of times the device received a PDU with an ID field that was a different length than the ID field length configured on the router.
Authentication Fail	The number of times authentication failed because the device was configured to authenticate IPv6 IS-IS packets in the packet's domain or area, but the packet did not contain the correct password.
Corrupted LSP	The number of times the device detected a corrupted LSP in the device's memory.
LSP Sequence Number Skipped	The number of times the device received an LSP with a sequence number that was more than 1 higher than the sequence number of the previous LSP received from the same neighbor.
LSP Max Sequence Number Exceeded	The number of times the device attempted to set an LSP sequence number to a value higher than the highest number in the CSNP sent by the Designated IS.
Level-1 Database Overload	The number of times the Level-1 state on the router changed from Waiting to On or from On to Waiting: • Waiting to On – This change can occur when the device recovers from a previous Level-1 LSP database overload and is again ready to receive new LSPs. • On to Waiting – This change can occur when the device's Level-1 LSP database is full and the device receives an additional LSP, for which there is no room.

TABLE 337 IPv6 IS-IS error statistics (Continued)

This field...	Displays...
Level-2 Database Overload	The number of times the Level-2 state on the device changed from Waiting to On or from On to Waiting: • The change from Waiting to On can occur when the device recovers from a previous Level-2 LSP database overload and is again ready to receive new LSPs. • The change from On to Waiting can occur when the device's Level-2 LSP database is full and the device receives an additional LSP, for which there is no room.
Our LSP Purged	The number of times the device received an LSP that was originated by the device itself and had age zero (aged out).

Displaying LSP database entries

You can display summary or detailed information about the entries in the LSP database.

NOTE
The router maintains separate LSP databases for Level 1 LSPs and Level 2 LSPs.

To display summary information about the entries in the LSP database, enter the following command at any level of the CLI.

```
NetIron# show ipv6 isis database
IS-IS Level-1 Link State Database
LSPID                 LSP Seq Num  LSP Checksum  LSP Holdtime      ATT/P/OL
Router1.00-00         0x00000003   0x9a6b        574               0/0/0
Router2.00-00*        0x00000002   0x609d        540               0/0/0
Router2.01-00*        0x00000001   0x0fcf        539               0/0/0

IS-IS Level-2 Link State Database
LSPID                 LSP Seq Num  LSP Checksum  LSP Holdtime      ATT/P/OL
Router1.00-00         0x00000003   0xe2da        574               0/0/0
Router2.00-00*        0x00000002   0x0585        540               0/0/0
Router2.01-00*        0x00000001   0x0fcf        539               0/0/0
```

The command in this example displays information for the LSPS in the router's Level-1 and Level-2 LSP databases. Notice that the display groups the Level-1 and Level-2 LSPs separately.

Syntax: show ipv6 isis database [<HHHH.HHHH.HHHH.HH-HH> | detail | l1 | l2 | level1 | level2]

The <HHHH.HHHH.HHHH.HH-HH> parameter restricts the display to the entry for the specified LSPID. (The LSPID consists of the source ID (HHHH.HHHH.HHHH), the pseudonode (HH-), and LSPID (-HH). To determine the router's source ID, use the **show ipv6 isis** command. For more information, refer to "Displaying IPv6 IS-IS information" on page 1881. To determine the pseudonode and LSPID, use the **show ipv6 isis database** command.

NOTE
Name mapping is enabled by default. When name mapping is enabled, the output of the **show ipv6 isis database** command uses the hostname instead of the system ID. To disable mapping so that these displays use the system ID instead, enter the **no hostname** command at the IS-IS router configuration level.

The **detail** parameter displays detailed information about the LSPs. The detailed information display is discussed later in this section.

The **l1** and **level1** parameters restrict the display to the Level-1 LSP entries. You can use these parameters interchangeably.

The **l2** and **level2** parameters restrict the display to the Level-2 LSP entries. You can use these parameters interchangeably.

This display shows the following information.

TABLE 338 IPv6 IS-IS summary LSP database information

This field...	Displays...
LSPID	The LSP ID, which consists of the source ID (HHHH.HHHH.HHHH), the pseudonode (HH-), and LSPID (-HH). **Note**: If the address has an asterisk (*) at the end, this indicates that the LSP is locally originated.
LSP Seq Num	The sequence number of the LSP.
LSP Checksum	The checksum calculated by the device that sent the LSP and used by the device to verify that the LSP was not corrupted during transmission over the network.
LSP Holdtime	The maximum number of seconds during which the LSP will remain valid. **Note**: The IS that originates the LSP starts the timer for the LSP. As a result, LSPs do not all have the same amount of time remaining when they enter the device's LSP database.
ATT	A 4-bit value extracted from bits 4 – 7 in the Attach field of the LSP.
P	The value in the Partition option field of the LSP. The field can have one of the following values: • 0 – The IS that sent the LSP does not support partition repair. • 1 – The IS that sent the LSP supports partition repair.
OL	The value in the LSP database overload field of the LSP. The field can have one of the following values: • 0 – The overload bit is off. • 1 – The overload bit is on, indicating that the IS that sent the LSP is overloaded and should not be used as a Level-2 router.

To display detailed information for all the LSPs in the device's LSP databases, enter the following command at any level of the CLI.

```
NetIron# show ipv6 isis database detail
IS-IS Level-1 Link State Database
LSPID                 LSP Seq Num  LSP Checksum  LSP Holdtime      ATT/P/OL
Router1.00-00         0x00000003   0x9a6b        566               0/0/0
   Area Address:  49.6561
   Metric:  10    IS Router2.01
   Metric:  12    IS Router1.02
   Metric:  10    IS Router1.03
   NLPID:  8e  cc
   IP address:  10.0.0.1
   Metric:  10    IP-Internal 110.10.0.0       255.255.0.0
   Metric:  10    IP-Internal 110.20.0.0       255.255.0.0
   Metric:  10    IP-Internal 110.30.0.0       255.255.0.0
    ...
     Hostname:  Router1
   IPv6 address:  3001::1
   Metric:  10    IPv6 Reachability 1111:5000::/32  UP bit: 0
   Metric:  10    IPv6 Reachability 1111:4000::/32  UP bit: 0
   Metric:  10    IPv6 Reachability 1111:3000::/32  UP bit: 0
...
```

NOTE
Portions of this display are truncated for brevity. The purpose of this display is to show all possible fields that might display rather than to show complete output.

Syntax: show ipv6 isis database detail [l1 | l2 | level1 | level2]

The **l1** and **level1** parameters restrict the display to the Level-1 LSP entries. You can use these parameters interchangeably.

The **l2** and **level2** parameters restrict the display to the Level-2 LSP entries. You can use these parameters interchangeably.

For example, to display details about Level-1 LSPs only, enter a command such as the following at any CLI level.

```
NetIron# show ipv6 isis database detail l1
```

This display shows the following information.

TABLE 339 IPv6 IS-IS detailed LSP database information

This field...	Displays...
LSPID	Refer to the description in Table 338 on page 1885.
LSP Seq Num	Refer to the description in Table 338 on page 1885.
LSP Checksum	Refer to the description in Table 338 on page 1885.
LSP Holdtime	Refer to the description in Table 338 on page 1885.
ATT/P/OL	Refer to the description in Table 338 on page 1885.
Area Address	The address of the area.

TABLE 339 IPv6 IS-IS detailed LSP database information (Continued)

This field...	Displays...
TLVs	The remaining output displays the type, length, and value (TLV) parameters included in the LSPs. These parameters advertise reachability to IPv6 devices or networks. For example: • A router identified as an IS and its hostname (Router2.01) can be reached using the default metric of 10. • An end system within the current area identified as an IP-Internal and with the IP address of 110.10.0.0 and sub-net mask of 255.255.0.0 can be reached using the default metric of 10. • An IPv6 prefix of 1111:5000::/32 is up and can be reached using the default metric of 10.
NLPID	The Network Layer Protocol Identifier (NLPID), which specifies the protocol the IS that sent the LSP is using. Usually, this value is “cc” but can also be “iso”.
IP address	The IP address of the interface that sent the LSP. The device can use this address as the next hop in routes to the addresses listed in the rows below.
Hostname	The hostname of the router that contains the LSP database that is displayed.
IPv6 address	The IPv6 address of the interface that sent the LSP. The device can use this address as the next hop in routes to the addresses listed in the rows below.

Displaying the system ID to name mappings

IS-IS maps the IS-IS system IDs to the hostnames of the devices with those IS. To display these mappings, enter the following command at any level of the CLI.

```
NetIron# show ipv6 isis hostname
Total number of entries in IS-IS Hostname Table: 2
   System ID       Hostname            * = local IS
 * 2222.2222.2222  Router2
   1111.1111.1111  Router1
```

Syntax: show ipv6 isis hostname

This example contains two mappings for this device. The device’s IS-IS system ID is “2222.2222.2222“and its hostname is “Router2”. The display contains an entry for another router. The display contains one entry for each IS that supports name mapping.

NOTE
Name mapping is enabled by default. When name mapping is enabled, the output of the **show ipv6 isis database** and **show ipv6 isis neighbor** commands uses the hostname instead of the system ID. To disable mapping so that these displays use the system ID instead, enter the **no hostname** command at the IS-IS router configuration level.

Displaying IPv6 IS-IS interface information

To display information about the interfaces on which IPv6 IS-IS is enabled, enter the following command at any level of the CLI.

```
NetIron# show ipv6 isis interface
Total number of IS-IS Interfaces: 4

Interface : 2/1     Local Circuit Number: 00000001
   Circuit Type : BCAST Circuit Mode : LEVEL-1-2
   Circuit State: UP Passive State: FALSE
   MTU : 1497
   Level-1 Metric: 10, Level-1 Priority: 64
   Level-1 Hello Interval: 10 Level-1 Hello Multiplier: 3
   Level-1 Designated IS: Router2.01-22         Level-1 DIS Changes: 8
   Level-2 Metric: 10, Priority: 64
   Level-2 Hello Interval: 10 Level-2 Hello Multiplier: 3
   Level-2 Designated IS: Router2.01-00 Level-2 DIS Changes: 8
   Next IS-IS LAN Level-1 Hello in 1 seconds
   Next IS-IS LAN Level-2 Hello in 1 seconds
   Number of active Level-1 adjacencies: 1
   Number of active Level-2 adjacencies: 1
  Circuit State Changes: 0 Circuit Adjacencies State Changes: 2
   Rejected Adjacencies: 0
   Circuit Authentication Fails: 0 Bad LSP 0
   Control Messages Sent: 1696 Control Messages Received: 159
   IP Enabled: TRUE
   IP Address and Subnet Mask:
      10.0.0.2           255.0.0.0
     192.147.201.150     255.255.255.0
  IPv6 Enabled: TRUE
   IPv6 Address :
     3001::2
. . .
```

NOTE
The latter part of this display is truncated for brevity. The purpose of this display is to show all possible fields that might display rather than to show complete output.

Syntax: show ipv6 isis interface

This display shows the following information.

TABLE 340 IPv6 IS-IS interface information

This field...	Displays...
Total number of IS-IS interfaces	The number of interfaces on which IPv6 IS-IS is enabled.
Interface	The port or virtual interface number to which the information listed below applies.
Local Circuit Number	The ID that the instance of IPv6 IS-IS running on the interface applied to the circuit between this interface and the interface at the other end of the link.
Circuit Type	The type of IS-IS circuit running on the interface. The circuit type can be one of the following: • BCAST– broadcast • PTP – point-to-point

TABLE 340 IPv6 IS-IS interface information (Continued)

This field...	Displays...
Circuit Mode	The IS-IS type in use on the circuit. The mode can be one of the following: • LEVEL-1 • LEVEL-2 • LEVEL-1-2
Circuit State	The state of the circuit, which can be one of the following: • DOWN • UP
Passive State	The state of the passive option, which determines whether the interface is allowed to form an IS-IS adjacency with the IS at the other end of the circuit. The state can be one of the following: • FALSE – The passive option is disabled. The interface can form an adjacency with the IS at the other end of the link. • TRUE – The passive option is enabled. The interface cannot form an adjacency, but can still advertise itself into the area.
MTU	The maximum length supported for IS-IS PDUs sent on this interface.
Level-1 Metric	The default-metric value that the device inserts in IS-IS Level-1 PDUs originated on this interface.
Level-1 Priority	The priority of this IS to be elected as the Designated IS for Level-1 in this broadcast network.
Level-1 Hello Interval	The number of seconds the software waits between sending Level-1 hello PDUs to the IS at the other end of the circuit.
Level-1 Hello Multiplier	The number by which the software multiplies the hello interval to calculate the hold time for Level-1 Hello messages received on the circuit.
Level-1 Designated IS	The NET of the Level-1 Designated IS.
Level-1 DIS Changes	The number of times the NET of the Level-1 Designated IS has changed.
Level-2 Metric	The default-metric value that the router inserts in IS-IS Level-2 PDUs originated on this interface.
Level-2 Priority	The priority of this IS to be elected as the Designated IS for Level-2 in this broadcast network.
Level-2 Hello Interval	The number of seconds the software waits between sending Level-2 Hello messages to the IS at the other end of the circuit.
Level-2 Hello Multiplier	The number by which the software multiplies the hello interval to calculate the hold time for Level-2 LSPs received on the circuit.
Level-2 Designated IS	The NET of the Level-2 Designated IS.
Level-2 DIS Changes	The number of times the NET of the Level-2 Designated IS has changed.
Next IS-IS LAN Level-1 Hello	Number of seconds before next Level-1 Hello message will be transmitted by the device.
Next IS-IS LAN Level-2 Hello	Number of seconds before next Level-2 Hello message will be transmitted by the device.
Number of active Level-1 adjacencies	The number of ISs with which this interface has an active Level-1 adjacency.
Number of active Level-2 adjacencies	The number of ISs with which this interface has an active Level-2 adjacency.
Circuit State Changes	The number of times the state of the circuit has changed.

TABLE 340 IPv6 IS-IS interface information (Continued)

This field...	Displays...
Circuit State Adjacencies Changes	The number of times an adjacency has started or ended on this circuit.
Rejected Adjacencies	The number of adjacency attempts by other ISs rejected by the router.
Circuit Authentication Fails	The number of times the device rejected a circuit because the authentication did not match the authentication configured on the device.
Bad LSP	The number of times the interface received a bad LSP from an IS at the other end of the circuit. The following conditions can cause an LSP to be bad: • Invalid checksum • Invalid length • Invalid lifetime value
Control Messages Sent	The number of IS-IS control PDUs sent on this interface.
Control Messages Received	The number of IS-IS control PDUs received on this interface.
IP Enabled	The state of IP on the interface, which can be one of the following: • TRUE – IP is enabled. • FALSE – IP is disabled.
IP Address and Subnet Mask	The IP address(es) and sub-net masks configured on this interface.
IPv6 Enabled	The state of IPv6 on the interface, which can be one of the following: • TRUE – IPv6 is enabled. • FALSE – IPv6 is disabled.
IPv6 Address	The IPv6 address(es) configured on this interface.

Displaying IPv6 IS-IS memory usage

To display information about IPv6 IS-IS memory usage, enter the following command at any level of the CLI.

```
NetIron# show ipv6 isis memory
Total Static Memory Allocated : 1333 bytes
Total Dynamic Memory Allocated : 157952 bytes
Memory Type               Size       Allocated  Max-alloc  Alloc-Fails
MTYPE_ISIS_IP6_SUMMARY_PR 0          0          0          0
MTYPE_ISIS_OTHER          20         0          1          0
MTYPE_ISIS_IP6_ROUTE_NODE 21         22         1024       0
MTYPE_ISIS_IP6_ROUTE_INFO 12         17         1024       0
MTYPE_ISIS_IP6_NEXTHOP    24         2          256        0
MTYPE_ISIS_IP6_REDIS_ROUT 12         5          256        0
```

Syntax: show ipv6 isis memory

This display shows the following information.

TABLE 341 IPv6 IS-IS memory usage information

This field...	Displays...
Total Static Memory Allocated	A summary of the amount of static memory allocated, in bytes, to IPv6 IS-IS.
Total Dynamic Memory Allocated	A summary of the amount of dynamic memory allocated, in bytes, to IPv6 IS-IS.

TABLE 341 IPv6 IS-IS memory usage information (Continued)

This field...	Displays...
Memory Type	The type of memory used by IPv6 IS-IS. (This information is for use by Dell technical support in case of a problem.)
Size	The size of a memory type.
Allocated	The amount of memory currently allocated to a memory type.
Max-alloc	The maximum amount of memory that was allocated to a memory type.
Alloc-Fails	The number of times an attempt to allocate memory to a memory type failed.

Displaying IPv6 IS-IS neighbor information

You can display a summary or detailed information for all neighbors with which the device has formed an IS-IS adjacency.

To display a summary of all IPv6 IS-IS neighbors of a router, enter the following command at any level of the CLI.

```
NetIron# show ipv6 isis neighbor
Total number of IS-IS Neighbors: 2
System Id      Interface   SNPA           State Holdtime Type Pri StateChgeTime
Router1        Ether 3/2   00e0.5200.0020 UP    30       ISL2 64  0  :0 :14:1
Router1        Ether 3/2   00e0.5200.0020 UP    30       ISL1 64  0  :0 :14:1
```

Syntax: show ipv6 isis neighbor [detail]

This display shows the following information.

TABLE 342 Summary of IPv6 IS-IS neighbor information

This field...	Displays...
Total number of IS-IS Neighbors	The number of ISs with which the device has formed an IS-IS adjacency.
System ID	The system ID of the neighbor. **Note:** Name mapping is enabled by default. When name mapping is enabled, the output of the **show ipv6 isis neighbor** command uses the hostname instead of the system ID. To disable mapping so that these displays use the system ID instead, enter the **no hostname** command at the IS-IS router configuration level. For more information about performing this task, refer to the " 25, "Configuring IS-IS (IPv4)"" .
Interface	The router port or virtual interface attached to the neighbor.
SNPA	The Subnetwork Point of Attachment (SNPA), which is the MAC address of the device physical or virtual interface attached to the neighbor.
State	The state of the adjacency with the neighbor. The state can be one of the following: • DOWN – The adjacency is down. • INIT – The adjacency is being established and is not up yet. • UP – The adjacency is up.
Holdtime	The time between transmissions of IS-IS hello messages.

TABLE 342 Summary of IPv6 IS-IS neighbor information (Continued)

This field...	Displays...
Type	The IS-IS type of the adjacency. The type can be one of the following: • ISL1 – Level-1 IS • ISL2 – Level-2 IS • PTP – Point-to-Point IS • ES – ES **Note**: The device forms a separate adjacency for each IS-IS type. Thus, if the router has both types of IS-IS adjacencies with the neighbor, the display contains a separate row of information for each adjacency.
Pri	The priority of this IS to be elected as the Designated IS in this broadcast network.
StateChgeTime	The amount of time that has passed since the adjacency last changed state.

To display detailed information about all IPv6 IS-IS neighbors of a router, enter the following command at any level of the CLI.

```
NetIron# show ipv6 isis neighbor detail
Total number of IS-IS Neighbors: 2
System ID      Interface   SNPA           State Holdtime Type Pri StateChgeTime

This field...	Displays...
IPv6 Address	The IPv6 address(es) assigned to the neighbor interface.
Circuit ID	The ID of the IS-IS circuit running on the neighbor interface.

Displaying IPv6 IS-IS redistribution information

To display information about the IPv6 routes redistributed into IPv6 IS-IS, enter the following command at any level of the CLI.

```
NetIron# show ipv6 isis redistributed-routes
Prefix                                    Protocol  Level        Metric
5555:1002::/32                            Static    Level-2       1
5555:2002::/32                            Static    Level-2       1
5555:3002::/32                            Static    Level-2       1
5555:4002::/32                            Static    Level-2       1
5555:5002::/32                            Static    Level-2       1
```

Syntax: show ipv6 isis redistributed-routes

This display shows the following information.

TABLE 344 IPv6 IS-IS redistribution information

This field...	Displays...
Prefix	The IPv6 routes redistributed into IPv6 IS-IS.
Protocol	The protocol from which the route is redistributed into IPv6 IS-IS. Possible protocols include the following: • BGP – BGP4+. • RIP – RIPng. • OSPF – OSPFv3. • Static – IPv6 static route table. • Connected – A directly connected network.
Level	The IS-IS level into which a route is redistributed. Possible levels include the following: • Level-1 • Level-2 • Level-1-2
Metric	The value of the default redistribution metric, which is the IS-IS cost of redistributing the route into IPv6 IS-IS.

Displaying the IPv6 IS-IS route information

To display the routes in the router's IPv6 IS-IS route table, enter the following command at any level of the CLI.

```
NetIron# show ipv6 isis routes
ISIS IPv6 Routing Table
Total Routes: 17  Level1: 17 Level2: 0 Equal-cost multi-path: 0
Type IPv6 Prefix                Next Hop Router           Interface  Cost
L1   1111:1000::/32             fe80::2e0:52ff:fe00:20    ethe 3/2   20
L1   1111:2000::/32             fe80::2e0:52ff:fe00:20    ethe 3/2   20
L1   1111:3000::/32             fe80::2e0:52ff:fe00:20    ethe 3/2   20
L1   1111:4000::/32             fe80::2e0:52ff:fe00:20    ethe 3/2   20
L1   1111:5000::/32             fe80::2e0:52ff:fe00:20    ethe 3/2   20
L1   2222:1000::/32             fe80::2e0:52ff:fe00:20    ethe 3/2   30
L1   2222:2000::/32             fe80::2e0:52ff:fe00:20    ethe 3/2   30
L1   2222:3000::/32             fe80::2e0:52ff:fe00:20    ethe 3/2   30
L1   2222:4000::/32             fe80::2e0:52ff:fe00:20    ethe 3/2   30
```

Syntax: show ipv6 isis routes

This display shows the following information.

TABLE 345 IPv6 IS-IS route information

This field...	Displays...
Total Routes	The total number of routes in the router's IPv6 IS-IS route table. The total includes Level-1 and Level-2 routes.
Level1	The total number of Level-1 routes in the IPv6 IS-IS route table.
Level2	The total number of Level-1 routes in the IPv6 IS-IS route table.
Equal-cost multi-path	The total number of equal-cost routes to the same destination in the IPv6 IS-IS route table. If load sharing is enabled, the router equally distributes traffic among the routes.
Type	The route type, which can be one of the following: • L1 – Level-1 route • L2 – Level-2 route
IPv6 Prefix	The IPv6 prefix of the route.
Next Hop Router	The IPv6 address of the next-hop interface to the destination.
Interface	The router interface (physical or virtual interface) attached to the next hop.
Cost	The IPv6 IS-IS default metric for the route, which is the cost of using this route to reach the next-hop router to this destination.

Displaying IPv6 IS-IS traffic statistics

The router maintains statistics for common IS-IS PDU types. To display the IPv6 traffic statistics, enter the following command at any level of the CLI.

```
NetIron# show ipv6 isis traffic
                        Message Received     Message Sent
Level-1 Hellos            98                   1171
Level-2 Hellos            96                   1170
PTP Hellos                0                    0
Level-1 LSP               3                    6
Level-2 LSP               3                    6
Level-1 CSNP              1                    110
Level-2 CSNP              1                    110
Level-1 PSNP              0                    0
Level-2 PSNP              0                    0
```

Syntax: show ipv6 isis traffic

This display shows the following information.

TABLE 346 IPv6 IS-IS traffic statistics

This field...	Displays...
Level-1 Hellos	The number of Level-1 hello PDUs sent and received by the router.
Level-2 Hellos	The number of Level-2 hello PDUs sent and received by the router.
PTP Hellos	The number of point-to-point hello PDUs sent and received by the router.
Level-1 LSP	The number of Level-1 link-state PDUs sent and received by the router.
Level-2 LSP	The number of Level-2 link-state PDUs sent and received by the router.
Level-1 CSNP	The number of Level-1 Complete Sequence Number PDUs (CSNPs) sent and received by the router.
Level-2 CSNP	The number of Level-2 CSNPs sent and received by the router.
Level-1 PSNP	The number of Level-1 Partial Sequence Number PDUs (PSNPs) sent and received by the router.
Level-2 PSNP	The number of Level-2 PSNPs sent and received by the router.

Chapter

Configuring BGP4+ 45

PowerConnect B-MLXe supports the folllowing BGP+ features:

- BGP+
- Configuring BGP4+ Neighbors Using Global or Site-Local IPv6 Addresses
- Importing Routes into BGP4+
- Advertising the Default BGP4+ Route
- Clearing BGP4+ Information
- Displaying BGP4+ Information

The implementation of IPv6 supports multi protocol BGP (MBGP) extensions, which allow IPv6 BGP (known as ***BGP4+***) to distribute routing information for protocols such as IPv4 BGP. The supported protocols are identified by address families. (For information about address families, refer to "Address family configuration level" on page 1897 and Appendix B, "Global and Address Family Configuration Levels".) The extensions allow a set of BGP4+ peers to exchange routing information for multiple address families and sub-address families.

IPv6 MBGP functions similarly to IPv4 MBGP except for the following enhancements:

- An IPv6 unicast address family and network layer reachability information (NLRI).
- Next hop attributes that use IPv6 addresses.

NOTE
The implementation of BGP4+ supports the advertising of routes among different address families. However, it supports BGP4+ unicast routes only; it does not currently support BGP4+ multicast routes.

Address family configuration level

The implementation of BGP4+ includes a new configuration level: address family. For IPv6, the PowerConnect devices currently supports the BGP4+ unicast address family configuration level only. (For IPv4, the PowerConnect devices supports the BGP4 unicast and BGP4 multicast address family configuration levels.) The enters the BGP4+ unicast address family configuration level when you enter the following command while at the global BGP configuration level:

```
NetIron(config-bgp)# address-family ipv6 unicast
NetIron(config-bgp-ipv6u)#
```

The `(config-bgp-ipv6u)#` prompt indicates that you are at the BGP4+ unicast address family configuration level.

While at the BGP4+ unicast address family configuration level, you can access several commands that allow you to configure BGP4+ unicast routes. The commands that you enter at this level apply only to IPv6 unicast address family only. You can generate a configuration for BGP4+ unicast routes that is separate and distinct from configurations for IPv4 unicast routes and IPv4 BGP multicast routes.

NOTE
The commands that you can access while at the IPv6 unicast address family configuration level are also available at the IPv4 unicast and multicast address family configuration levels. Where relevant, this section discusses and provides IPv6-unicast-specific examples. You must first configure IPv6 unicast-routing in order for any IPv6 routing protocol to be active.

NOTE
Each address family configuration level allows you to access commands that apply to that particular address family only. To enable a feature in a particular address family, you must specify any associated commands for that feature in that particular address family. You cannot expect the feature, which you may have configured in the BGP4 unicast address family, to work in the BGP4+ unicast address family unless it is explicitly configured in the BGP4+ unicast address family.

To exit from the IPv6 unicast address family configuration level, enter the following command:

```
NetIron(config-bgp-ipv6u)# exit-address-family
NetIron(config-bgp)#
```

Entering this command returns you to the global BGP configuration level.

For complete information about the new CLI levels, refer to Appendix B, "Global and Address Family Configuration Levels".

Configuring BGP4+

Before enabling BGP4+ on a , you must enable the forwarding of IPv6 traffic on the using the **ipv6 unicast-routing** command and enable IPv6 on at least one interface by configuring an IPv6 address or explicitly enabling IPv6 on that interface. For more information on performing these configuration tasks, refer to 38, "Configuring Basic IPv6 Connectivity".

To configure BGP4+, you must do the following:

- Enable BGP4+.
- Configure BGP4+ neighbors using one of the following methods:
  - Add one neighbor at a time (neighbor uses global or site-local IPv6 address).
  - Add one neighbor at a time (neighbor uses a link-local IPv6 address).
  - Create a peer group and add neighbors individually.

The following configuration tasks are optional:

- Advertise the default route.
- Import specified routes into BGP4+.
- Redistribute prefixes into BGP4+.
- Aggregate routes advertised to BGP4 neighbors.
- Use route maps.

Enabling BGP4+

To enable BGP4+, enter commands such as the following:

```
NetIron(config)# router bgp
BGP: Please configure 'local-as' parameter in order to run BGP4.
NetIron(config-bgp)# local-as 1000
```

These commands enables the BGP4+ router and configure the autonomous system (1000) in which your resides.

Syntax: [no] router bgp

To disable BGP, enter the **no** form of this command.

Syntax: local-as <*number*>

Specify the AS number in which the you are configuring resides.

After enabling BGP4+, you can add neighbors to a BGP4+ router by entering a commands such as the following:

```
NetIron(config-bgp)# address-family ipv6 unicast
NetIron(config-bgp-ipv6u)# neighbor 2001:4383:e0ff:783a::4 remote-as 1001
NetIron(config-bgp-ipv6u)# neighbor 2001:4383:e0ff:783a::5 remote-as 1001
```

These commands add two neighbors with global IPv6 addresses 2001:4383:e0ff:783a::4 and 2001:4383:e0ff:783a::5 in AS 1001.

NOTE
The example above adds IPv6 neighbors at the BGP4+ unicast address family configuration level. These neighbors, by default, are enabled to exchange BGP4+ unicast prefixes. However, if you add IPv6 neighbors while at the global BGP configuration or IPv4 BGP unicast address family configuration level, the neighbors will not exchange BGP4+ unicast prefixes until you explicitly enable them to do so by entering the **neighbor** <*ipv6-address*> | <*peer-group-name*> **activate** command at the BGP4+ unicast address family configuration level.

This section provides minimal information about adding BGP4+ neighbors, because its focus is to provide information about configuring BGP4+.

Configuring BGP4+ neighbors using global or site-local IPv6 addresses

To configure BGP4+ neighbors using global or site-local IPv6 addresses, you must add the IPv6 address of a neighbor in a remote AS to the BGP4+ neighbor table of the local . You must repeat this procedure for each neighbor that you want to add to a local .

For example, to add the IPv6 address 2011:f3e9:93e8:cc00::1 of a neighbor in remote AS 4500 to the BGP4+ neighbor table of a , enter the following commands:

```
NetIron(config-bgp)# address-family ipv6 unicast
NetIron(config-bgp-ipv6u)# neighbor 2011:f3e9:93e8:cc00::1 remote-as 4500
```

Syntax: neighbor <*ipv6-address*> **remote-as** <*as-number*>

NOTE
The example above adds an IPv6 neighbor at the BGP4+ unicast address family configuration level. This neighbor, by default, is enabled to exchange BGP4+ unicast prefixes. However, if you add an IPv6 neighbor while at the global BGP configuration or IPv4 BGP unicast address family configuration level, the neighbor will not exchange BGP4+ unicast prefixes until you explicitly enable it to do so by entering the **neighbor** <*ipv6-address*> | <*peer-group-name*> activate command at the BGP4+ unicast address family configuration level.

The **ipv6-address** parameter specifies the IPv6 address of the neighbor. You must specify the **ipv6-address** parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The **as-number** parameter indicates the number of the AS in which the neighbor resides.

To delete the neighbor from the BGP4+ neighbor table, enter the **no** form of this command.

Adding BGP4+ neighbors using link-local addresses

To configure BGP4+ neighbors that use link-local addresses, you must do the following:

- Add the IPv6 address of a neighbor in a remote AS to the BGP4+ neighbor table of the local .
- Identify the neighbor interface over which the neighbor and local will exchange prefixes.
- Configure a route map to set up a global next hop for packets destined for the neighbor.

Adding BGP4+ neighbor

To add the IPv6 link-local address fe80:4398:ab30:45de::1 of a neighbor in remote AS 1000 to the BGP4+ neighbor table of a , enter the following commands:

```
NetIron(config-bgp)# address-family ipv6 unicast
NetIron(config-bgp-ipv6u)# neighbor fe80:4398:ab30:45de::1 remote-as 1000
```

Syntax: neighbor <*ipv6-address*> **remote-as** <*as-number*>

NOTE
The example above adds an IPv6 neighbor at the BGP4+ unicast address family configuration level. This neighbor, by default, is enabled to exchange BGP4+ unicast prefixes. However, if you add an IPv6 neighbor while at the global BGP configuration or IPv4 BGP unicast address family configuration level, the neighbor will not exchange BGP4+ unicast prefixes until you explicitly enable it to do so by entering the **neighbor** <*ipv6-address*> | <*peer-group-name*> **activate** command at the BGP4+ unicast address family configuration level.

The <*ipv6-address*> parameter specifies the IPv6 link-local address of the neighbor. A link-local address has a fixed prefix of FE80::/10. You must specify the <*ipv6-address*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The <*as-number*> parameter indicates the number of the AS in which the neighbor resides.

To delete the neighbor from the BGP4+ neighbor table, enter the **no** form of this command.

Identifying a neighbor interface

To specify Ethernet interface 3/1 as the neighbor interface over which the neighbor and local will exchange prefixes, enter the following command:

```
NetIron(config-bgp)# neighbor fe80:4398:ab30:45de::1 update-source ethernet 3/1
```

Syntax: neighbor <*ipv6-address*> **update-source** <*ipv4-address*> **| ethernet** <*port*> **| loopback** <*number*> **| ve** <*number*>

The <*ipv6-address*> parameter specifies the IPv6 link-local address of the neighbor. A link-local address has a fixed prefix of FE80::/10. You must specify the <*ipv6-address*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The <*ipv4-address*> parameter specifies the IPv4 address of the update source.

The **ethernet | loopback | ve** parameter specifies the neighbor interface over which the neighbor and local will exchange prefixes. If you specify an Ethernet interface, also specify the port number associated with the interface. If you specify a loopback or VE interface, also specify the loopback or VE number.

Configuring a route map

To configure a route map that filters routes advertised to a neighbor or sets up a global next hop for packets destined for the neighbor with the IPv6 link-local address fe80:4393:ab30:45de::1, enter commands such as the following (start at the BGP4+ unicast address family configuration level):

```
NetIron(config-bgp-ipv6u)# neighbor fe80:4398:ab30:45de::1 route-map out next-hop
NetIron(config-bgp-ipv6u)# exit
NetIron(config)# route-map next-hop permit 10
NetIron(config-route-map)# match ipv6 address prefix-list next-hop-ipv6
NetIron(config-route-map)# set ipv6 next-hop 2011:e0ff:3764::34
```

This route map applies to the BGP4+ unicast address family under which the **neighbor route-map** command is entered. This route map applies to the outgoing routes on the neighbor with the IPv6 link-local address fe80:4393:ab30:45de::1. If an outgoing route on the neighbor matches the route map, the route is distributed through the next hop router with the global IPv6 address 2011:e0ff:3764::34.

Syntax: neighbor <*ipv6-address*> **route-map [in | out]** <*name*>

The <*ipv6-address*> parameter specifies the IPv6 link-local address of the neighbor. A link-local address has a fixed prefix of FE80::/10. You must specify the <*ipv6-address*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The **in** keyword applies the route map to incoming routes. The **out** keyword applies the route map to outgoing routes.

The <*name*> parameter specifies a route map name.

Syntax: route-map <*name*> **deny | permit** <*sequence-number*>

The **name** parameter specifies a route map name.

The **deny** keyword denies the distribution of routes that match the route map. The **permit** keyword permits the distribution of routes that match the route map.

The <*sequence-number*> parameter specifies a sequence number for the route map statement.

Syntax: match ipv6 address prefix-list <*name*>

The **match ipv6 address prefix-list** command distributes any routes that have a destination IPv6 address permitted by a prefix list.

The <*name*> parameter specifies an IPv6 prefix list name.

Syntax: set ipv6 next-hop <*ipv6-address*>

The <*ipv6-address*> parameter specifies the IPv6 global address of the next-hop router. You must specify the <*ipv6-address*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

Configuring a BGP4+ peer group

If a has multiple neighbors with similar attributes, you can configure a peer group, then add neighbors to the group instead of configuring neighbors individually for all parameters as described in "Configuring BGP4+ neighbors using global or site-local IPv6 addresses" on page 1899 and "Adding BGP4+ neighbors using link-local addresses" on page 1900.

NOTE
You can add IPv6 neighbors only to an IPv6 peer group. You cannot add an IPv4 neighbor to an IPv6 peer group and vice versa. IPv6 and IPv6 peer groups must remain separate.

To configure a BGP4+ peer group, you must perform the tasks listed below.

1. Create a peer group.
2. Add a neighbor to the local .
3. Assign the IPv6 neighbor to the peer group.

Creating a BGP4+ peer group

To create a peer group named "peer_group1," enter the following commands:

```
NetIron(config-bgp)# address-family ipv6 unicast
NetIron(config-bgp-ipv6u)# neighbor peer_group1 peer-group
```

Syntax: neighbor <*peer-group-name*> **peer-group**

Specify a name for the peer group.

To delete the peer group, enter the **no** form of this command.

Adding a neighbor to a local

To add the IPv6 address 2001:efff:89::23 of a neighbor in remote AS 1001 to the BGP4+ neighbor table of a , enter the following command:

```
NetIron(config-bgp-ipv6u)# neighbor 2001:efff:89::23 remote-as 1001
```

NOTE
The example above adds an IPv6 neighbor at the BGP4+ unicast address family configuration level. This neighbor, by default, is enabled to exchange BGP4+ unicast prefixes. However, if you add an IPv6 neighbor while at the global BGP configuration or IPv4 BGP unicast address family configuration level, the neighbor will not exchange BGP4+ unicast prefixes until you explicitly enable it to do so by entering the **neighbor** <*ipv6-address*> | <*peer-group-name*> **activate** command at the BGP4+ unicast address family configuration level.

Syntax: neighbor <*ipv6-address*> **remote-as** <*as-number*>

The **ipv6-address** parameter specifies the IPv6 address of the neighbor. You must specify the <*ipv6-address*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The <*as-number*> parameter indicates the number of the AS in which the neighbor resides.

To delete the neighbor from the BGP4+ neighbor table, enter the **no** form of this command.

Assigning IPv6 neighbor to peer group

To assign an already configured neighbor (2001:efff:89::23) to the peer group peer_group1, enter the following command at the BGP4+ unicast address family configuration level:

```
NetIron(config-bgp-ipv6u)# neighbor 2001:efff:89::23 peer-group peer_group1
```

Syntax: **neighbor** <*ipv6-address*> **peer-group** <*peer-group-name*>

The <*ipv6-address*> parameter specifies the IPv6 address of the neighbor. You must specify the <*ipv6-address*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The **peer-group** <*peer-group-name*> parameter indicates the name of the already created peer group.

To delete the mapping of the neighbor IPv6 address to the peer group, enter the **no** form of this command.

Advertising the default BGP4+ route

By default, the BGP4+ router does not originate and advertise a default BGP4+ route. A default route is the IPv6 address :: and the route prefix 0; that is, ::/0.

You can enable the BGP4+ router to advertise the default BGP4+ route by specifying the **default-information-originate** command at the BGP4+ unicast address family configuration level. Before entering this command, the default route ::/0 must be present in the IPv6 route table.

To enable the BGP4+ router to advertise the default route, enter the following command:

```
NetIron(config-bgp-ipv6u)# default-information-originate
```

Syntax: **[no] default-information-originate**

You can also enable the BGP4+ router to send the default route to a particular neighbor by specifying the **neighbor** <*ipv6-address*> **default-originate** command at the BGP4+ unicast address family configuration level. This command does not require the presence of the default route ::/0 in the IPv6 route table.

For example, to enable the BGP4+ router to send the default route to a neighbor with the IPv6 address of 2001:efff:89::23, enter a command such as the following:

```
NetIron(config-bgp-ipv6u)# neighbor 2001:efff:89::23 default-originate
```

Syntax: **[no] neighbor** <*ipv6-address*> **default-originate [route-map** <*name*>**]**

The <*ipv6-address*> parameter specifies a neighbor by its IPv6 address. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

Specifying the optional **route-map** <*name*> parameter injects the default route conditionally, based on the match conditions in the route map.

Importing routes into BGP4+

By default, the does not import routes into BGP4+. This section explains how to use the **network** command to enable the importing of specified routes into BGP4+.

NOTE
The routes imported into BGP4+ must first exist in the IPv6 unicast route table.

For example, to import the IPv6 prefix 3ff0:ec21::/32 into the BGP4+ database, enter the following command at the BGP4+ unicast address family configuration level:

```
NetIron(config-bgp-ipv6u)# network 3ff0:ec21::/32
```

Syntax: **network** <*ipv6-prefix*>/<*prefix-length*> [**route-map** <*name*>]

You must specify the <*ipv6-prefix*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

You must specify the <*prefix-length*> parameter as a decimal value. A slash mark (/) must follow the <*ipv6-prefix*> parameter and precede the <*prefix-length*> parameter.

You can specify the optional **route-map** <*name*> parameter if you want to change attributes of a route when importing it into BGP4+.

To disable the importing of a specified route, enter the **no** form of this command without the route-map parameter.

Redistributing prefixes into BGP4+

You can configure the to redistribute routes from the following sources into BGP4+:

- Static IPv6 routes.
- Directly connected IPv6 networks.
- OSPFv3.
- RIPng.

You can redistribute routes in the following ways:

- By route types, for example, the redistributes all IPv6 static and RIPng routes.
- By using a route map to filter which routes to redistribute, for example, the redistributes specified IPv6 static and RIPng routes only.

For example, to configure the redistribution of all RIPng routes into the BGP4+ unicast database, enter the following commands at the BGP4+ address family configuration level:

```
NetIron(config-bgp-ipv6u)# redistribute rip
```

Syntax: **redistribute** <*protocol*> [**level-1 | level-1-2 | level-2**] [**match external1 | external2 | internal**] [**metric** <*metric-value*>] [**route-map** <*name*>]

The <*protocol*> parameter can be **connected**, **ospf**, **rip**, or **static**.

If you specify **ospf** as the protocol, you can optionally specify the redistribution of external 1, external 2, or internal routes. (The default is internal.)

The **metric** <*metric-value*> parameter specifies the metric used for the redistributed route. If a value is not specified for this option, and no value is specified using the **default-metric** command at the BGP4+ unicast address family configuration level, the metric value for the IPv6 static, RIPng, or IPv6 OSPF route is used. Use a value consistent with the destination protocol.

The <*name*> parameter specifies a route map name.

Aggregating routes advertised to BGP4 neighbors

By default, a advertises individual BGP4+ routes for all the networks. The aggregation feature allows you to configure a to aggregate routes in a range of networks into a single IPv6 prefix. For example, without aggregation, a will individually advertise routes for networks ff00:f000:0001:0000::/64, ff00:f000:0002:0000::/64,ff00:f000:0003:0000::/64, and so on. You can configure the to instead send a single, aggregate route for the networks. The aggregate route would be advertised as ff00:f000::/24 to BGP4 neighbors.

To aggregate BGP4+ routes for ff00:f000:0001:0000::/64, ff00:f000:0002:0000::/64,ff00:f000:0003:0000::/64, enter the following command.

```
NetIron(config-bgp)# aggregate-address ff00:f000::/24 summary-only
```

Syntax: **aggregate-address** <*ipv6-prefix*>/<*prefix-length*> **[as-set] [summary-only] [suppress-map** <*map-name*>**] [advertise-map** <*map-name*>**] [attribute-map** <*map-name*>**]**

The <*ipv6-prefix*>/<*prefix-length*> parameter specifies the aggregate value for the networks. You must specify the <*ipv6-prefix*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the <*prefix-length*> parameter as a decimal value. A slash mark (/) must follow the <*ipv6-prefix*> parameter and precede the <*prefix-length*> parameter.

The **as-set** keyword causes the device to aggregate AS-path information for all the routes in the aggregate address into a single AS-path.

The **summary-only** keyword prevents the device from advertising more specific routes contained within the aggregate route.

The **suppress-map** <*map-name*> parameter prevents the more specific routes contained in the specified route map from being advertised.

The **advertise-map** <*map-name*> parameter configures the device to advertise the more specific routes in the specified route map.

The **attribute-map** <*map-name*> parameter configures the device to set attributes for the aggregate routes based on the specified route map.

NOTE
For the **suppress-map**, **advertise-map**, and **attribute-map** parameters, the route map must already be defined.

To remove an aggregate route from a BGP4 neighbor advertisement, use the **no** form of this command without any parameters.

Using route maps

You can use a route map to filter and change values in BGP4+ routes. Currently, you can apply a route map to IPv6 unicast routes that are independent of IPv4 routes.

To configure a route map to match on IPv6 unicast routes, enter commands such as the following.

```
NetIron(config)# router bgp
NetIron(config-bgp)# address-family ipv6 unicast
NetIron(config-bgp-ipv6u)# neighbor 2001:eff3:df78::67 remote-as 1001
NetIron(config-bgp-ipv6u)# neighbor 2001:eff3:df78::67 route-map in map1
```

```
NetIron(config-bgp-ipv6u)# exit
NetIron(config)# ipv6 prefix-list ipv6_uni seq 10 permit 2001:eff3::/32
NetIron(config)# route-map map1 permit 10
NetIron(config-routemap-map1)# match ipv6 address prefix-list ipv6_uni
```

This example configures a route map named “map1” that permits incoming IPv6 unicast routes that match the prefix list named “ipv6_uni” (2001:eff3::/32). Note that you apply the route map while at the BGP4+ unicast address family configuration level.

Clearing BGP4+ information

This section contains information about clearing the following for BGP4+:

- Route flap dampening.
- Route flap dampening statistics.
- Neighbor information.
- BGP4+ routes in the IPv6 route table.
- Neighbor traffic counters.

NOTE
The **clear** commands implemented for BGP4+ correspond to the **clear** commands implemented for IPv4 BGP. For example, you can specify the **clear ipv6 bgp flap-statistics** command for IPv6 and the **clear ip bgp flap-statistics** for IPv4.

Removing route flap dampening

You can un-suppress routes by removing route flap dampening from the routes. The allows you to un-suppress all routes at once or un-suppress individual routes.

To un-suppress all the suppressed routes, enter the following command at the Privileged EXEC level or any of the Config levels of the CLI.

```
NetIron# clear ipv6 bgp dampening
```

Syntax: clear ipv6 bgp dampening [<*ipv6-prefix*>/<*prefix-length*>]

You must specify the <*ipv6-prefix*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

You must specify the <*prefix-length*> parameter as a decimal value. A slash mark (/) must follow the <*ipv6-prefix*> parameter and precede the <*prefix-length*> parameter.

To un-suppress a specific route, enter a command such as the following.

```
NetIron# clear ipv6 bgp dampening 2001:e0ff::/32
```

This command un-suppresses only the routes for network 2001:e0ff::/32.

Clearing route flap dampening statistics

The allows you to clear all route flap dampening statistics or statistics for a specified IPv6 prefix or a regular expression.

NOTE
Clearing the dampening statistics for a route does not change the dampening status of the route.

To clear all the route dampening statistics, enter the following command at the Privileged EXEC level or any of the Config levels of the CLI.

```
NetIron# clear ipv6 bgp flap-statistics
```

Syntax: **clear ipv6 bgp flap-statistics** [<*ipv6-prefix*>/<*prefix-length*> | **neighbor** <*ipv6-address*> | **regular-expression** <*regular-expression*>]

The <*ipv6-prefix*>/<*prefix-length*> parameter clears route flap dampening statistics for a specified IPv6 prefix. You must specify the <*ipv6-prefix*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the <*prefix-length*> parameter as a decimal value. A slash mark (/) must follow the <*ipv6-prefix*> parameter and precede the <*prefix-length*> parameter.

The **neighbor** <*ipv6-address*> parameter clears route flap dampening statistics only for routes learned from the neighbor with the specified IPv6 address.

The **regular-expression** <*regular-expression*> parameter is a regular expression.

Clearing BGP4+ local route information

You can clear locally imported or routes redistributed into BGP4+.

To clear all local route information, enter the following command at the Privileged EXEC level or any of the Config levels of the CLI.

```
NetIron# clear ipv6 bgp local routes
```

Syntax: **clear ipv6 bgp local routes**

Clearing BGP4+ neighbor information

You can perform the following tasks related to BGP4+ neighbor information:

- Clear diagnostic buffers.
- Reset a session to send and receive Outbound Route Filters (ORFs).
- Close a session, or reset a session and resend or receive an update.
- Clear traffic counters.
- Clear route flap dampening statistics.

Clearing BGP4+ neighbor diagnostic buffers

You can clear the following BGP4+ neighbor diagnostic information in buffers:

- The first 400 bytes of the last packet that contained an error.
- The last NOTIFICATION message either sent or received by the neighbor.

To display these buffers, use the **last-packet-with-error** keyword with the **show ipv6 bgp neighbors** command. For more information about this command, refer to "Displaying last error packet from a BGP4+ neighbor" on page 1937.

You can clear the buffers for all neighbors, for an individual neighbor, or for all the neighbors within a specific peer group or AS.

To clear these buffers for neighbor 2000:e0ff:37::1, enter the following commands at the Privileged EXEC level or any of the Config levels of the CLI.

```
NetIron# clear ipv6 bgp neighbor 2000:e0ff:37::1 last-packet-with-error
NetIron# clear ipv6 bgp neighbor 2000:e0ff:37::1 notification-errors
```

Syntax: clear ipv6 bgp neighbor all | <*ipv6-address*> | <*peer-group-name*> | <*as-number*> last-packet-with-error | notification-errors

The **all** | <*ipv6-address*> | <*peer-group-name*> | <*as-num*> specifies the neighbor. The <*ipv6-address*> parameter specifies a neighbor by its IPv6 address. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373. The <*peer-group-name*> specifies all neighbors in a specific peer group. The <*as-num*> parameter specifies all neighbors within the specified AS. The **all** keyword specifies all neighbors.

The **last-packet-with-error** keyword clears the buffer containing the first 400 bytes of the last packet that contained errors.

The **notification-errors** keyword clears the notification error code for the last NOTIFICATION message sent or received.

Resetting a BGP4+ neighbor session to send and receive ORFs

You can perform a hard or soft reset of a BGP4+ neighbor session to send or receive ORFs.

To perform a hard reset of a neighbor session and send ORFs to the neighbor, enter a command such as the following.

```
NetIron# clear ipv6 bgp neighbor 2000:e0ff:38::1
```

This command resets the BGP4+ session with neighbor 2000:e0ff:38::1 and sends the ORFs to the neighbor when the neighbor comes up again. If the neighbor sends ORFs to the , the accepts them if the send capability is enabled.

To perform a soft reset of a neighbor session and send ORFs to the neighbor, enter a command such as the following.

```
NetIron(config)# clear ipv6 bgp neighbor peer_group1 soft in prefix-list
```

Syntax: clear ipv6 bgp neighbor <*ipv6-address*> **|** <*peer-group-name*> **[soft in prefix-filter]**

The <*ipv6-address*> parameter specifies a neighbor by its IPv6 address. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The <*peer-group-name*> specifies all neighbors in a specific peer group.

If you use the **soft in prefix-filter** keyword, the sends an updated IPv6 prefix list to the neighbor as part of its route refresh message to the neighbor.

Closing or resetting a BGP4+ neighbor session

You can close a neighbor session or resend route updates to a neighbor. You can specify all neighbors, a single neighbor, or all neighbors within a specific peer group or AS.

If you close a neighbor session, the and the neighbor clear all the routes they learned from each other. When the and neighbor establish a new BGP4+ session, they exchange route tables again. Use this method if you want the to relearn routes from the neighbor and resend its own route table to the neighbor.

If you use the **soft-outbound** keyword, the compiles a list of all the routes it would normally send to the neighbor at the beginning of a session. However, before sending the updates, the also applies the filters and route maps you have configured to the list of routes. If the filters or route maps result in changes to the list of routes, the sends updates to advertise, change, or even withdraw routes on the neighbor as needed. This ensures that the neighbor receives only the routes you want it to contain. Even if the neighbor already contains a route learned from the that you later decided to filter out, using the soft-outbound option removes that route from the neighbor. If no change is detected from the previously sent routes, an update is not sent.

For example, to close all neighbor sessions and thus flush all the routes exchanged by the and all neighbors, enter the following command at the Privileged EXEC level or any of the Config levels of the CLI.

```
NetIron# clear ipv6 bgp neighbor all
```

Syntax: clear ipv6 bgp neighbor all | <*ipv6-address*> **|** <*peer-group-name*> **|** <*as-number*> **[soft-outbound | soft [in | out]]**

The **all** | <*ipv6-address*> | <*peer-group-name*> | <*as-number*> specifies the neighbor. The <*ipv6-address*> parameter specifies a neighbor by its IPv6 address. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373. The <*peer-group-name*> specifies all neighbors in a specific peer group. The <*as-number*> parameter specifies all neighbors within the specified AS. The **all** keyword specifies all neighbors.

Use the **soft-outbound** keyword to perform a soft reset of a neighbor session and resend only route update changes to a neighbor.

Use the **soft in** parameter to perform a soft reset of a neighbor session and requests a route update from a neighbor.

Use the **soft out** parameter to perform a soft reset of a neighbor session and resend all routes to a neighbor.

Clearing BGP4+ neighbor traffic counters

You can clear the BGP4+ message counter (reset them to 0) for all neighbors, a single neighbor, or all neighbors within a specific peer group or AS.

For example, to clear the BGP4+ message counter for all neighbors within an AS 1001, enter a command such as the following at the Privileged EXEC level or any of the Config levels of the CLI.

```
NetIron# clear ipv6 bgp neighbor 1001 traffic
```

Syntax: clear ipv6 bgp neighbor all | <*ipv6-address*> **|** <*peer-group-name*> **|** <*as-number*> **traffic**

The **all** | <*ipv6-address*> | <*peer-group-name*> | <*as-number*> specifies the neighbor. The <*ipv6-address*> parameter specifies a neighbor by its IPv6 address. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373. The <*peer-group-name*> specifies all neighbors in a specific peer group. The <*as-number*> parameter specifies all neighbors within the specified AS. The **all** keyword specifies all neighbors.

Specify the **traffic** keyword to clear the BGP4+ message counter.

Clearing BGP4+ neighbor route flap dampening statistics

The allows you to clear all route flap dampening statistics for a specified BGP4+ neighbor.

NOTE
Clearing the dampening statistics for a neighbor does not change the dampening status of a route.

To clear all of the route flap dampening statistics for a neighbor, enter a command such as the following at the Privileged EXEC level or any of the Config levels of the CLI.

```
NetIron# clear ipv6 bgp neighbor 2000:e0ff:47::1 flap-statistics
```

Syntax: clear ipv6 bgp neighbor <*ipv6-address*> **flap-statistics**

The <*ipv6-address*> parameter specifies a neighbor by its IPv6 address. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

Specify the **flap-statistics** keyword to clear route flap dampening statistics for the specified neighbor.

Clearing and resetting BGP4+ routes in the IPv6 route table

You can clear all BGP4+ routes or only those routes associated with a particular IPv6 prefix from the IPv6 route table and reset the routes. When cleared, the BGP4+ routes are removed from the IPv6 main route table and then restored again.

For example, to clear all BGP4+ routes and reset them, enter the following command at the Privileged EXEC level or any of the Config levels of the CLI.

```
NetIron# clear ipv6 bgp routes
```

Syntax: clear ip bgp routes [<*ipv6-prefix*>/<*prefix-length*>]

The <*ipv6-prefix*>/<*prefix-length*> parameter clears routes associated with a particular IPv6 prefix. You must specify the <*ipv6-prefix*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the <*prefix-length*> parameter as a decimal value. A slash mark (/) must follow the <*ipv6-prefix*> parameter and precede the <*prefix-length*> parameter.

Clearing traffic counters for all BGP4+ neighbors

To clear the message counters (reset them to 0) for all BGP4+ neighbors, enter the following command.

```
NetIron(config)# clear ipv6 bgp traffic
```

Syntax: clear ipv6 bgp traffic

Displaying BGP4+ information

You can display the following BGP4+ information:

- BGP4+ route table.
- BGP4+ route information.
- BGP4+ route-attribute entries.

- BGP4+ configuration information.
- Dampened BGP4+ paths.
- Filtered-out BGP4+ routes.
- BGP4+ route flap dampening statistics.
- BGP4+ neighbor information.
- BGP4+ peer group configuration information.
- BGP4+ summary information.

NOTE
The **show** commands implemented for BGP4+ correspond to the **show** commands implemented for IPv4 BGP. For example, you can specify the **show ipv6 bgp** command for IPv6 and the **show ip bgp** command for IPv4. Also, the displays for the IPv4 and IPv6 versions of the **show** commands are similar except where relevant, IPv6 neighbor addresses replace IPv4 neighbor addresses, IPv6 prefixes replace IPv4 prefixes, and IPv6 next-hop addresses replace IPv4 next-hop addresses.

Displaying the BGP4+ route table

BGP4+ uses filters you define, as well as an algorithm to determine the preferred route to a destination. (For information about the algorithm, see .) BGP4+ sends only the preferred route to the 's IPv6 table. However, if you want to view all the routes BGP4+ knows about, you can display the BGP4+ table.

To display the BGP4+ route table, enter the following command at any level of the CLI.

```
NetIron# show ipv6 bgp routes
Total number of BGP Routes: 2
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED
       Prefix              Next Hop        Metric     LocPrf     Weight Status
1      2002::/16           ::              1          100        32768  BL
         AS_PATH:
2      2002:1234::/32      ::              1          100        32768  BL
         AS_PATH:
```

This display shows the following information.

TABLE 347 Summary of BGP4+ routes

This field...	Displays...
Number of BGP4+ Routes	The number of routes displayed by the command.
Status codes	A list of the characters the display uses to indicate the route's status. The status code appears in the Status column of the display. The status codes are described in the command's output.
Prefix	The route's prefix.
Next Hop	The next-hop router for reaching the route from the .
Metric	The value of the route's MED attribute. If the route does not have a metric, this field is blank.
LocPrf	The degree of preference for the advertised route relative to other routes in the local AS. When the BGP4+ algorithm compares routes on the basis of local preferences, the route with the higher local preference is chosen. The preference can have a value from 0 – 4294967295.

TABLE 347 Summary of BGP4+ routes (Continued)

This field...	Displays...
Weight	The value that this associates with routes from a specific neighbor. For example, if the receives routes to the same destination from two BGP4+ neighbors, the prefers the route from the neighbor with the larger weight.
Status	The route's status, which can be one or more of the following: • A – AGGREGATE. The route is an aggregate route for multiple networks. • B – BEST. BGP4+ has determined that this is the optimal route to the destination. • b – NOT-INSTALLED-BEST – BGP4+ has determined that this is the optimal route to the destination but did not install it in the IPv6 route table because the received better routes from other sources (such as OSPFv3, RIPng, or static IPv6 routes). • C – CONFED_EBGP. The route was learned from a neighbor in the same confederation and AS, but in a different sub-AS within the confederation. • D – DAMPED. This route has been dampened (by the route dampening feature), and is currently unusable. • E – EBGP. The route was learned through a in another AS. • H – HISTORY. Route dampening is configured for this route, and the route has a history of flapping and is unreachable now. • I – IBGP. The route was learned through a in the same AS. • L – LOCAL. The route originated on this . • M – MULTIPATH. BGP4+ load sharing is enabled and this route was selected as one of the best ones to the destination. The best route among the multiple paths also is marked with "B". **NOTE:** If the "m" is shown in lowercase, the software was not able to install the route in the IPv6 route table. • S – SUPPRESSED. This route was suppressed during aggregation and thus is not advertised to neighbors.
AS-PATH	The AS-path information for the route.

Syntax: **show ipv6 bgp routes** [<*ipv6-prefix*>/<*prefix-length*> | <*table-entry-number*> | **age** <*seconds*> | **as-path-access-list** <*name*> | **as-path-filter** <*number*> | **best** | **cidr-only** | [**community** <*number*> | **no-export** | **no-advertise** | **internet** | **local-as**] | **community-access-list** <*name*> | **community-filter** <*number*> | **detail** [<*option*>] | **local** | **neighbor** <*ipv6-address*> | **nexthop** <*ipv6-address*> | **no-best** | **prefix-list** <*name*> | **regular-expression** <*regular-expression*> | **route-map** <*name*> | **summary** | **unreachable**]

You can use the following options with the **show ipv6 bgp routes** command to determine the content of the display:

The <*ipv6-prefix*>/<*prefix-length*> parameter displays routes for a specific network. You must specify the <*ipv6-prefix*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the <*prefix-length*> parameter as a decimal value. A slash mark (/) must follow the <*ipv6-prefix*> parameter and precede the <*prefix-length*> parameter.

The <*table-entry-number*> parameter specifies the table entry with which you want the display to start. For example, if you specify 100, the display shows entry 100 and all entries subsequent to entry 100.

The **age** <*seconds*> parameter displays only the routes that have been received or updated more recently than the number of seconds you specify.

The **as-path-access-list** <*name*> parameter filters the display using the specified AS-path ACL.

The **as-path-filter** <*number*> parameter filters the display using the specified AS-path filter.

The **best** keyword displays the routes received from neighbors that the selected as the best routes to their destinations.

The **cidr-only** keyword lists only the routes whose network masks do not match their class network length.

The **community** <*number*> parameter lets you display routes for a specific community. You can specify **local-as**, **no-export**, **no-advertise**, **internet**, or a private community number. You can specify the community number as either two five-digit integer values of up to 1– 65535, separated by a colon (for example, 12345:6789) or a single long integer value.

The **community-access-list** <*name*> parameter filters the display using the specified community ACL.

The **community-filter** <*number*> parameter lets you display routes that match a specific community filter.

The **detail** <*option*> parameter lets you display more details about the routes. You can refine your request by also specifying one of the other parameters after the **detail** keyword.

The **local** keyword displays routes that are local to the .

The **neighbor** <*ipv6-address*> parameter displays routes learned from a specified BGP4+ neighbor.

The **nexthop** <*ipv6-address*> parameter displays the routes for a specified next-hop IPv6 address. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The **no-best** keyword displays the routes for which none of the routes to a given prefix were selected as the best route. The IPv6 route table does not contain a BGP4+ route for any of the routes listed using this option.

The **prefix-list** <*name*> parameter filters the display using the specified IPv6 prefix list.

The **regular-expression** <*regular-expression*> parameter filters the display based on a regular expression.

The **route-map** <*name*> parameter filters the display using the specified route map. The software displays only the routes that match the match statements in the route map. The software disregards the route map's set statements.

The **summary** keyword displays summary information for the routes.

The **unreachable** keyword displays the routes that are unreachable because the does not have a valid RIPng, OSPFv3, or static IPv6 route to the next hop.

To display details about BGP4+ routes, enter the following command at any level of the CLI.

```
NetIron# show ipv6 bgp routes detail
Total number of BGP Routes: 2
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED
1       Prefix: 2002::/16,  Status: BL,  Age: 2d17h10m42s
         NEXT_HOP: ::,  Learned from Peer: Local Router
          LOCAL_PREF: 100,  MED: 1,  ORIGIN: incomplete,  Weight: 32768
           AS_PATH:
            Adj_RIB_out count: 1,  Admin distance 190
2       Prefix: 2002:1234::/32,  Status: BL,  Age: 2d17h10m42s
         NEXT_HOP: ::,  Learned from Peer: Local Router
          LOCAL_PREF: 100,  MED: 1,  ORIGIN: incomplete,  Weight: 32768
           AS_PATH:
            Adj_RIB_out count: 1,  Admin distance 190
```

This display shows the following information.

TABLE 348 Detailed BGP4+ route information

This field...	Displays...
Number of BGP4+ Routes advertised to specified neighbor (appears only in display for all routes)	For information about this field, refer to Table 347 on page 1911.
Status codes	For information about this field, refer to Table 347 on page 1911.
Prefix	For information about this field, refer to Table 347 on page 1911.
Status	For information about this field, refer to Table 347 on page 1911.
Age	The age of the advertised route, in seconds.
Next Hop	For information about this field, refer to Table 347 on page 1911.
Learned from Peer	The IPv6 address of the neighbor from which this route is learned. “Local Router” indicates that the itself learned the route.
LOCAL_PREF	For information about this field, refer to Table 347 on page 1911.
MED	The value of the advertised route’s MED attribute. If the route does not have a metric, this field is blank.

TABLE 348 Detailed BGP4+ route information (Continued)

This field...	Displays...
Origin	The source of the route information. The origin can be one of the following: • A – AGGREGATE. The route is an aggregate route for multiple networks. • B – BEST. BGP4+ has determined that this is the optimal route to the destination. • b – NOT-INSTALLED-BEST – BGP4+ has determined that this is the optimal route to the destination but did not install it in the IPv6 route table because the received better routes from other sources (such as OSPFv3, RIPng, or static IPv6 routes). • C – CONFED_EBGP. The route was learned from a neighbor in the same confederation and AS, but in a different sub-AS within the confederation. • D – DAMPED. This route has been dampened (by the route dampening feature), and is currently unusable. • EGP – The routes with this set of attributes came to BGP4+ through EGP. • H – HISTORY. Route dampening is configured for this route, and the route has a history of flapping and is unreachable now. • IGP – The routes with this set of attributes came to BGP4+ through IGP. • L – LOCAL. The route originated on this . • M – MULTIPATH. BGP4+ load sharing is enabled and this route was selected as one of the best ones to the destination. The best route among the multiple paths also is marked with "B". **NOTE:** If the "m" is shown in lowercase, the software was not able to install the route in the IPv6 route table. • S – SUPPRESSED. This route was suppressed during aggregation and thus is not advertised to neighbors.
Weight	For information about this field, refer to Table 347 on page 1911.
AS-PATH	For information about this field, refer to Table 347 on page 1911.
Adj_RIB_out count	The number of neighbors to which the route has been or will be advertised. This is the number of times the route has been selected as the best route and placed in the Adj-RIB-Out (outbound queue) for a BGP4+ neighbor.
Admin Distance	The administrative distance of the route.

Syntax: **show ipv6 bgp routes detail** [<*ipv6-prefix*>/<*prefix-length*> | <*table-entry-number*> | **age** <*seconds*> | **as-path-access-list** <*name*> | **as-path-filter** <*number*> | **best** | **cidr-only** | [**community** <*number*> | **no-export** | **no-advertise** | **internet** | **local-as**] | **community-access-list** <*name*> | **community-filter** <*number*> | **local** | **neighbor** <*ipv6-address*> | **nexthop** <*ipv6-address*> | **no-best** | **prefix-list** <*name*> | **regular-expression** <*regular-expression*> | **route-map** <*name*> | **summary** | **unreachable**]

You can use the following options with the **show ipv6 bgp routes detail** command to determine the content of the display.

The <*ipv6-prefix*>/<*prefix-length*> option displays details about routes for a specific network. You must specify the <*ipv6-prefix*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the <*prefix-length*> parameter as a decimal value. A slash mark (/) must follow the <*ipv6-prefix*> parameter and precede the <*prefix-length*> parameter.

The <*table-entry-number*> parameter specifies the table entry with which you want the display to start. For example, if you specify 100, the display shows entry 100 and all entries subsequent to entry 100.

The **age** <*seconds*> parameter displays only the routes that have been received or updated more recently than the number of seconds you specify.

The **as-path-access-list** <*name*> parameter filters the display using the specified AS-path ACL.

The **as-path-filter** <*number*> parameter filters the display using the specified AS-path filter.

The **best** keyword displays the routes received from neighbors that the selected as the best routes to their destinations.

The **cidr-only** keyword lists only the routes whose network masks do not match their class network length.

The **community** <*number*> parameter lets you display routes for a specific community. You can specify **local-as**, **no-export**, **no-advertise**, **internet**, or a private community number. You can specify the community number as either two five-digit integer values of up to 1– 65535, separated by a colon (for example, 12345:6789) or a single long integer value.

The **community-access-list** <*name*> parameter filters the display using the specified community ACL.

The **community-filter** <*number*> parameter lets you display routes that match a specific community filter.

The **detail** keyword lets you display more details about the routes. You can refine your request by also specifying one of the other parameters after the **detail** keyword.

The **local** keyword displays routes that are local to the .

The **neighbor** <*ipv6-address*> parameter displays routes learned from a specified BGP4+ neighbor.

The **nexthop** <*ipv6-address*> option displays the routes for a specified next-hop IPv6 address. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The **no-best** keyword displays the routes for which none of the routes to a given prefix were selected as the best route. The IPv6 route table does not contain a BGP4+ route for any of the routes listed using this option.

The **prefix-list** <*name*> parameter filters the display using the specified IPv6 prefix list.

The **regular-expression** <*regular-expression*> parameter filters the display based on a regular expression.

The **route-map** <*name*> parameter filters the display using the specified route map. The software displays only the routes that match the match statements in the route map. The software disregards the route map's set statements.

The **summary** keyword displays summary information for the routes.

The **unreachable** keyword displays the routes that are unreachable because the does not have a valid RIPng, OSPFv3 or static IPv6 route to the next hop.

Displaying BGP4+ route information

You can display all BGP4+ routes known by a , only those routes that match a specified prefix, or routes that match a specified or longer prefix.

To display all BGP4+ routes known by the , enter the following command at any level of the CLI.

```
NetIron# show ipv6 bgp
Total number of BGP Routes: 2
Status codes: s suppressed, d damped, h history, * valid, > best, i internal
Origin codes: i - IGP, e - EGP, ? - incomplete
    Network            Next Hop        Metric LocPrf Weight Path
*>  2002::/16          ::              1      100    32768  ?
*>  2002:1234::/32     ::              1      100    32768  ?
```

Syntax: show ipv6 bgp <*ipv6-prefix*>/<*prefix-length*> **[longer-prefixes]**

The <*ipv6-prefix*>/<*prefix-length*> parameter allows you to display routes that match a specified BGP prefix only. You must specify the <*ipv6-prefix*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the <*prefix-length*> parameter as a decimal value. A slash mark (/) must follow the <*ipv6-prefix*> parameter and precede the <*prefix-length*> parameter.

The **longer-prefixes** keyword allows you to display routes that match a specified or longer BGP prefix. For example, if you specify **2002::/16 longer-prefixes**, then all routes with the prefix 2002::/16 or that have a longer prefix (such as 2002:e016::/32) are displayed.

To display only those routes that match prefix 2002::/16, enter the following command at any level of the CLI.

```
NetIron# show ipv6 bgp 2002::/16
Number of BGP Routes matching display condition : 1
Status codes: s suppressed, d damped, h history, * valid, > best, i internal
Origin codes: i - IGP, e - EGP, ? - incomplete
    Network            Next Hop        Metric LocPrf Weight Path
*>  2002::/16          ::              1      100    32768  ?
       Route is advertised to 1 peers:
        2000:4::110(65002)
```

For example, to display routes that match prefix 2002::/16 or longer, enter the following command at any level of the CLI.

```
NetIron# show ipv6 bgp 2002::/16 longer-prefixes
Number of BGP Routes matching display condition : 3
Status codes: s suppressed, d damped, h history, * valid, > best, i internal
Origin codes: i - IGP, e - EGP, ? - incomplete
    Network            Next Hop        Metric LocPrf Weight Path
*>  2002::/16          ::              1      100    32768  ?
*>  2002:1234::/32     ::              1      100    32768  ?
*>  2002:e0ff::/32     ::              1      100    32768  ?
       Route is advertised to 1 peers:
        2000:4::110(65002)
```

These displays show the following information.

TABLE 349 BGP4+ route information

This field...	Displays...
Total number of BGP Routes (appears in display of all BGP routes only)	The number of routes known by the .
Number of BGP Routes matching display condition (appears in display that matches specified and longer prefixes)	The number of routes that matched the display parameters you entered. This is the number of routes displayed by the command.
Status codes	A list of the characters the display uses to indicate the route's status. The status code appears in the left column of the display, to the left of each route. The status codes are described in the command's output.
Origin codes	A character the display uses to indicate the route's origin. The origin code appears to the right of the AS path (Path field). The origin codes are described in the command's output.
Network	The network prefix and prefix length.
Next Hop	The next-hop router for reaching the network from the .
Metric	The value of the route's MED attribute. If the route does not have a metric, this field is blank.
LocPrf	The degree of preference for this route relative to other routes in the local AS. When the BGP4+ algorithm compares routes on the basis of local preferences, the route with the higher local preference is chosen. The preference can have a value from 0 – 4294967295.
Weight	The value that this associates with routes from a specific neighbor. For example, if the receives routes to the same destination from two BGP4+ neighbors, the prefers the route from the neighbor with the larger weight.
Path	The route's AS path.

Displaying BGP4+ route-attribute entries

The route-attribute entries table lists sets of BGP4+ attributes stored in the 's memory. Each set of attributes is unique and can be associated with one or more routes. In fact, the typically has fewer route attribute entries than routes.

To display the IPv6 route-attribute entries table, enter the following command.

```
NetIron# show ipv6 bgp attribute-entries
        Total number of BGP Attribute Entries: 378
1       Next Hop  :::                 Metric   :1              Origin:INCOMP
        Originator:0.0.0.0            Cluster List:None
        Aggregator:AS Number :0      Router-ID:0.0.0.0         Atomic:None
        Local Pref:100               Communities:Internet
        AS Path   :(65002) 65001 4355 2548 3561 5400 6669 5548
        Address: 0x27a4cdb0  Hash:877 (0x03000000) Reference Counts: 2:0:2
...
```

NOTE
Portions of this display are truncated for brevity. The purpose of this display is to show all possible fields that might display rather than to show complete output.

Syntax: show ipv6 bgp attribute-entries

For information about display displaying route-attribute entries for a specified BGP4+ neighbor, refer to "Displaying BGP4+ neighbor route-attribute entries" on page 1935.

This display shows the following information.

TABLE 350 BGP4+ route-attribute entries information

This field...	Displays...
Total number of BGP Attribute Entries	The number of entries contained in the 's BGP4+ route-attribute entries table.
Next Hop	The IPv6 address of the next hop router for routes that have this set of attributes.
Metric	The cost of the routes that have this set of attributes.
Origin	The source of the route information. The origin can be one of the following: • EGP – The routes with this set of attributes came to BGP4+ through EGP. • IGP – The routes with this set of attributes came to BGP4+ through IGP. • INCOMPLETE – The routes came from an origin other than one of the above. For example, they may have been redistributed from OSPFv3 or RIPng. When BGP4+ compares multiple routes to a destination to select the best route, IGP is preferred over EGP, and both are preferred over INCOMPLETE.
Originator	The originator of the route in a route-reflector environment.
Cluster List	The route-reflector clusters through which this set of attributes has passed.
Aggregator	Aggregator information: • AS Number shows the AS in which the network information in the attribute set was aggregated. This value applies only to aggregated routes and is otherwise 0. • Router-ID shows the router that originated this aggregator.
Atomic	Whether the network information in this set of attributes has been aggregated and this aggregation has resulted in information loss: • TRUE – Indicates information loss has occurred • FALSE – Indicates no information loss has occurred • None – Indicates this attribute is not present. **NOTE:** Information loss under these circumstances is a normal part of BGP4+ and does not indicate an error.
Local Pref	The degree of preference for routes that use this set of attributes relative to other routes in the local AS.
Communities	The communities that routes with this set of attributes are in.
AS Path	The ASs through which routes with this set of attributes have passed. The local AS is shown in parentheses.
Address	For debugging purposes only.
Hash	For debugging purposes only.
Reference Counts	For debugging purposes only.

Displaying the BGP4+ running configuration

To view the active BGP4+ configuration information contained in the running configuration without displaying the entire running configuration, enter the following command at any level of the CLI.

```
NetIron# show ipv6 bgp config
Current BGP configuration:
router bgp
 local-as 1000
 neighbor peer_group1 peer-group
 neighbor 2001:4383:e0ff:783a::3 remote-as 1001
 neighbor 2001:4484:edd3:8389::1 remote-as 1002
 neighbor 2001:efff:80::23 peer-group peer_group1
 neighbor 2001:efff:80::23 remote-as 1003
 address-family ipv4 unicast
 no neighbor 2001:4383:e0ff:783a::3 activate
 no neighbor 2001:4484:edd3:8389::1 activate
 no neighbor 2001:efff:80::23 activate
 exit-address-family

 address-family ipv4 multicast
 exit-address-family

 address-family ipv6 unicast
 network 3ff0:ec21::/32
 neighbor peer_group1 activate
 neighbor 2001:4484:edd3:8389::1 activate
 exit-address-family

end
```

Syntax: show ipv6 bgp config

Displaying dampened BGP4+ paths

To display BGP4+ paths that have been dampened (suppressed) by route flap dampening, enter the following command at any level of the CLI.

```
NetIron# show ipv6 bgp dampened-paths
Status Code >:best d:damped h:history *:valid
    Network From Flaps Since Reuse Path
*d  8::/13 2000:1:1::1 1 0 :1 :14 0 :2 :20 100 1002 1000
*d  1::/16 2000:1:1::1 1 0 :1 :14 0 :2 :20 100 1002 1000
*d  4::/14 2000:1:1::1 1 0 :1 :14 0 :2 :20 100 1002 1000
*d  2::/15 2000:1:1::1 1 0 :1 :14 0 :2 :20 100 1002 1000
*d  0:8000::/17 2000:1:1::1 1 0 :1 :14 0 :2 :20 100 1002 1000
*d  2000:1:17::/642000:1:1::1 1 0 :1 :18 0 :2 :20 100
```

Syntax: show ipv6 bgp dampened-paths

This display shows the following information.

TABLE 351 Dampened BGP4+ path information

This field...	Displays...
Status codes	A list of the characters the display uses to indicate the path's status. The status code appears in the left column of the display, to the left of each route. The status codes are described in the command's output. The status column displays a "d" for each dampened route.
Network	The destination network of the route.
From	The IPv6 address of the advertising peer.
Flaps	The number of times the path has flapped.
Since	The amount of time (in hh:mm:ss) since the first flap of this route.
Reuse	The amount of time (in hh:mm:ss) after which the path is available again.
Path	The AS path of the route.

Displaying filtered-out BGP4+ routes

When you enable the soft reconfiguration feature, the saves all updates received from the specified neighbor or peer group. The saved updates include those that contain routes that are filtered out by the BGP4+ route policies in effect on the .

You can display a summary or more detailed information about routes that have been filtered out by BGP4+ route policies.

To display a summary of the routes that have been filtered out by BGP4+ route policies, enter the following command at any level of the CLI.

```
NetIron# show ipv6 bgp filtered-routes
Searching for matching routes, use ^C to quit...
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED F:FILTERED
       Prefix              Next Hop        Metric     LocPrf     Weight Status
1      3000::/16           2000:4::110                 100        0        EF
         AS_PATH: 65001 4355 701 80
2      4000::/16           2000:4::110                 100        0        EF
         AS_PATH: 65001 4355 1
3      5000::/16           2000:4::110                 100        0        EF
         AS_PATH: 65001 4355 701 1 189
```

The routes displayed by the command are the routes that the 's BGP policies filtered out. The did not place the routes in the BGP4+ route table, but did keep the updates. If a policy change causes these routes to be permitted, the does not need to request the route information from the neighbor, but instead uses the information in the updates.

Syntax: show ipv6 bgp filtered-routes [<*ipv6-prefix*>/<*prefix-length*> **[longer-prefixes] | [as-path-access-list** <*name*>**] | [prefix-list** <*name*>**]**

The <*ipv6-prefix*>/<*prefix-length*> parameter displays the specified IPv6 prefix of the destination network only. You must specify the <*ipv6-prefix*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the <*prefix-length*> parameter as a decimal value. A slash mark (/) must follow the <*ipv6-prefix*> parameter and precede the <*prefix-length*> parameter.

The **longer-prefixes** keyword allows you to display routes that match a specified or longer IPv6 prefix. For example, if you specify **2002::/16 longer-prefixes**, then all routes with the prefix 2002::/16 or that have a longer prefix (such as 2002:e016::/32) are displayed.

The **as-path-access-list** <*name*> parameter specifies an AS-path ACL. Specify an ACL name. Only the routes permitted by the AS-path ACL are displayed.

The **prefix-list** <*name*> parameter specifies an IPv6 prefix list. Only the routes permitted by the prefix list are displayed.

This display shows the following information.

TABLE 352 Summary of filtered-out BGP4+ route information

This field...	Displays...
Number of BGP4+ Routes matching display condition	The number of routes that matched the display parameters you entered. This is the number of routes displayed by the command.
Status codes	A list of the characters the display uses to indicate the route's status. The status code appears in the left column of the display, to the left of each route. The status codes are described in the command's output. The status column displays an "F" for each filtered route.
Prefix	The network address and prefix.
Next Hop	The next-hop router for reaching the network from the .
Metric	The value of the route's MED attribute. If the route does not have a metric, this field is blank.
LocPrf	The degree of preference for this route relative to other routes in the local AS. When the BGP4+ algorithm compares routes on the basis of local preferences, the route with the higher local preference is chosen. The preference can have a value from 0 – 4294967295.

TABLE 352 Summary of filtered-out BGP4+ route information (Continued)

This field...	Displays...
Weight	The value that this associates with routes from a specific neighbor. For example, if the receives routes to the same destination from two BGP4+ neighbors, the prefers the route from the neighbor with the larger weight.
Status	The route's status, which can be one or more of the following: • A – AGGREGATE – The route is an aggregate route for multiple networks. • B – BEST – BGP4+ has determined that this is the optimal route to the destination. • b – NOT-INSTALLED-BEST – BGP4+ has determined that this is the optimal route to the destination but did not install it in the IPv6 route table because the received better routes from other sources (such as OSPFv3, RIPng, or static IPv6 routes). • C – CONFED_EBGP – The route was learned from a neighbor in the same confederation and AS, but in a different sub-AS within the confederation. • D – DAMPED – This route has been dampened (by the route dampening feature), and is currently unusable. • E – EBGP – The route was learned through a in another AS. • H – HISTORY – Route dampening is configured for this route, and the route has a history of flapping and is unreachable now. • I – IBGP – The route was learned through a in the same AS. • L – LOCAL – The route originated on this . • M – MULTIPATH – BGP4+ load sharing is enabled and this route was selected as one of the best ones to the destination. The best route among the multiple paths also is marked with "B". **NOTE:** If the "m" is shown in lowercase, the software was not able to install the route in the IPv6 route table. • S – SUPPRESSED – This route was suppressed during aggregation and thus is not advertised to neighbors. • F – FILTERED – This route was filtered out by BGP4+ route policies on the , but the saved updates containing the filtered routes.

To display detailed information about the routes that have been filtered out by BGP4+ route policies, enter the following command at any level of the CLI.

```
NetIron# show ipv6 bgp filtered-routes detail
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED F:FILTERED
1   Prefix: 800:2:1::/64, Status: EF, Age: 0h0m10s

    AS_PATH: 100
6   Prefix: 2000:1:17::/64, Status: EF, Age: 0h0m10s
    NEXT_HOP: 2000:1:1::1, Learned from Peer: 2000:1:1::1 (100)
    LOCAL_PREF: 100, MED: 0, ORIGIN: incomplete, Weight: 0
    AS_PATH: 100
```

Syntax: show ipv6 bgp filtered-routes detail [<*ipv6-prefix*>/<*prefix-length*> **[longer-prefixes] | [as-path-access-list** <*name*>] **| [prefix-list** <*name*>]

The <*ipv6-prefix*>/<*prefix-length*> parameter displays the specified IPv6 prefix of the destination network only. You must specify the <*ipv6-prefix*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the <*prefix-length*> parameter as a decimal value. A slash mark (/) must follow the <*ipv6-prefix*> parameter and precede the <*prefix-length*> parameter.

The **longer-prefixes** keyword allows you to display routes that match a specified or longer IPv6 prefix. For example, if you specify **2002::/16 longer-prefixes**, then all routes with the prefix 2002::/16 or that have a longer prefix (such as 2002:e016::/32) are displayed.

The **as-path-access-list** <*name*> parameter specifies an AS-path ACL. Only the routes permitted by the AS-path ACL are displayed.

The **prefix-list** <*name*> parameter specifies an IPv6 prefix list. Only the routes permitted by the prefix list are displayed.

This display shows the following information.

TABLE 353 Detailed filtered-out BGP4+ route information

This field...	Displays...
Status codes	A list of the characters the display uses to indicate the route's status. The Status field display an "F" for each filtered route.
Prefix	For information about this field, refer to Table 352 on page 1922.

TABLE 353 Detailed filtered-out BGP4+ route information (Continued)

This field...	Displays...
Status	For information about this field, refer to Table 352 on page 1922.
Age	The age of the route, in seconds.
Next hop	For information about this field, refer to Table 352 on page 1922.
Learned from peer	The IPv6 address of the neighbor from which this route is learned. "Local Router" indicates that the itself learned the route.
Local pref	For information about this field, refer to Table 352 on page 1922.
MED	The value of the advertised route's MED attribute. If the route does not have a metric, this field is blank.
Origin	The source of the route information. The origin can be one of the following: • A – AGGREGATE – The route is an aggregate route for multiple networks. • B – BEST – BGP4+ has determined that this is the optimal route to the destination. • b – NOT-INSTALLED-BEST – BGP4+ has determined that this is the optimal route to the destination but did not install it in the IPv6 route table because the received better routes from other sources (such as OSPFv3, RIPng, or static IPv6 routes). • C – CONFED_EBGP – The route was learned from a neighbor in the same confederation and AS, but in a different sub-AS within the confederation. • D – DAMPED – This route has been dampened (by the route dampening feature), and is currently unusable. • E – EBGP – The route was learned through a in another AS. • H – HISTORY – Route dampening is configured for this route, and the route has a history of flapping and is unreachable now. • I – IBGP – The route was learned through a in the same AS. • L – LOCAL – The route originated on this . • M – MULTIPATH – BGP4+ load sharing is enabled and this route was selected as one of the best ones to the destination. The best route among the multiple paths also is marked with "B". **NOTE:** If the "m" is shown in lowercase, the software was not able to install the route in the IPv6 route table. • S – SUPPRESSED – This route was suppressed during aggregation and thus is not advertised to neighbors. • F – FILTERED – This route was filtered out by BGP4+ route policies on the , but the saved updates containing the filtered routes.
Weight	For information about this field, refer to Table 352 on page 1922.
AS path	The ASs through which routes with this set of attributes have passed. The local AS is shown in parentheses.

Displaying route flap dampening statistics

To display route dampening statistics for all dampened routes, enter the following command at any level of the CLI.

```
NetIron# show ipv6 bgp flap-statistics
Total number of flapping routes: 14
    Status Code  >:best d:damped h:history *:valid
    Network            From            Flaps Since    Reuse    Path
h>  2001:2::/32        3001:23::47      1    0 :0 :13 0 :0 :0  65001 4355 1 701
*>  3892:34::/32       3001:23::47      1    0 :1 :4  0 :0 :0  65001 4355 701 62
```

Syntax: **show ipv6 bgp flap-statistics** [*<ipv6-prefix>*/*<prefix-length>* **[longer-prefixes] | as-path-filter** *<number>* **| neighbor** *<ipv6-address>* **| regular-expression** *<regular-expression>*]

The *<ipv6-prefix>*/*<prefix-length>* parameter displays statistics for the specified IPv6 prefix only. You must specify the *<ipv6-prefix>* parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the *<prefix-length>* parameter as a decimal value. A slash mark (/) must follow the *<ipv6-prefix>* parameter and precede the *<prefix-length>* parameter.

The **longer-prefixes** keyword allows you to display statistics for routes that match a specified or longer IPv6 prefix. For example, if you specify **2000::/16 longer-prefixes**, then all routes with the prefix 2002:: or that have a longer prefix (such as 2002:e016::/32) are displayed.

The **as-path-filter** *<number>* parameter specifies an AS path filter to display. Specify a filter number.

The **neighbor** *<ipv6-address>* parameter displays statistics for routes learned from the specified neighbor only. You also can display route flap statistics for routes learned from a neighbor by entering the following command: **show ipv6 bgp neighbor** *<ipv6-address>* **flap-statistics**.

The **regular-expression** *<regular-expression>* parameter is a regular expression. The regular expressions are the same ones supported for BGP4 AS-path filters.

You can also display route flap dampening statistics for a specified IPv6 neighbor. For more information, refer to "Displaying route flap dampening statistics for a BGP4+ neighbor" on page 1936.

This display shows the following information.

TABLE 354 Route flap dampening statistics

This field...	Displays...
Total number of flapping routes	The total number of routes in the 's BGP4+ route table that have changed state and thus have been marked as flapping routes.
Status code	Indicates the dampening status of the route, which can be one of the following: • > – This is the best route among those in the BGP4+ route table to the route's destination. • d – This route is currently dampened, and thus unusable. • h – The route has a history of flapping and is unreachable now. • * – The route has a history of flapping but is currently usable.
Network	The destination network of the route.
From	The IPv6 address of the advertising peer.
Flaps	The number of flaps (state changes) the route has experienced.

TABLE 354 Route flap dampening statistics

This field...	Displays...
Since	The amount of time (in hh:mm:ss) since the first flap of this route.
Reuse	The amount of time (in hh:mm:ss) after which the path is again available.
Path	The AS path of the route.

You also can display all the dampened routes by using the **show ipv6 bgp dampened-paths** command. For more information, refer to "Displaying dampened BGP4+ paths" on page 1920.

Displaying BGP4+ neighbor information

You can display the following information about a 's BGP4+ neighbors:

Configuration information and statistics:

- Router advertisements.
- Route-attribute entries.
- Route flap dampening statistics.
- The last packet containing an error.
- Received Outbound Route Filters (ORFs).
- Routes received from a neighbor.
- BGP4+ Routing Information Base (RIB).
- Received best, not installed best, and unreachable routes.
- Route summary.

Displaying IPv6 neighbor configuration information and statistics

To display BGP4+ neighbor configuration information and statistics, enter the following command at any level of the CLI.

```
NetIron# show ipv6 bgp neighbor 2000:4::110
1   IP Address: 2000:4::110, AS: 65002 (EBGP), RouterID: 1.1.1.1
    State: ESTABLISHED, Time: 5d20h38m54s, KeepAliveTime: 60, HoldTime: 180
       RefreshCapability: Received
    Messages:    Open    Update  KeepAlive Notification Refresh-Req

...
```

NOTE
Portions of this display are truncated for brevity. The purpose of this display is to show all possible fields that might display rather than to show complete output.

The display shows all the configured parameters for the neighbor. Only the parameters that have values different from their defaults are shown.

In this example, the number in the far left column indicates the neighbor for which information is displayed. When you list information for multiple neighbors, this number makes the display easier to read.

The TCP statistics at the end of the display show status for the TCP session with the neighbor. Most of the fields show information stored in the 's Transmission Control Block (TCB) for the TCP session between the and its neighbor. These fields are described in detail in section 3.2 of RFC 793, "Transmission Control Protocol Functional Specification".

Syntax: show ipv6 bgp neighbor [<*ipv6-address*>]

The <*ipv6-address*> parameter allows you to display information for a specified neighbor only. You must specify the <*ipv6-address*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

This display shows the following information.

TABLE 355 BGP4+ neighbor configuration information and statistics

This field...	Displays...
IP Address	The IPv6 address of the neighbor.
AS	The AS in which the neighbor resides.
EBGP or IBGP	Whether the neighbor session is an IBGP session, an EBGP session, or a confederation EBGP session: • EBGP – The neighbor is in another AS. • EBGP_Confed – The neighbor is a member of another sub-AS in the same confederation. • IBGP – The neighbor is in the same AS.
RouterID	The neighbor's router ID.

State	The state of the 's session with the neighbor. The states are from the 's perspective of the session, not the neighbor's perspective. The state values can be one of the following:
	• IDLE – The BGP4+ process is waiting to be started. Usually, enabling BGP4 or establishing a neighbor session starts the BGP4+ process.
	  • A minus sign (-) indicates that the session has gone down and the software is clearing or removing routes.
	• ADMND – The neighbor has been administratively shut down.
	  • A minus sign (-) indicates that the session has gone down and the software is clearing or removing routes.
	• CONNECT – BGP4+ is waiting for the connection process for the TCP neighbor session to be completed.
	• ACTIVE – BGP4+ is waiting for a TCP connection from the neighbor.
	NOTE: If the state frequently changes between CONNECT and ACTIVE, there may be a problem with the TCP connection.
	• OPEN SENT – BGP4+ is waiting for an Open message from the neighbor.
	• OPEN CONFIRM – BGP4+4 has received an OPEN message from the neighbor and is now waiting for either a KEEPALIVE or NOTIFICATION message. If the receives a KEEPALIVE message from the neighbor, the state changes to Established. If the message is a NOTIFICATION, the state changes to Idle.
	• ESTABLISHED – BGP4+ is ready to exchange UPDATE messages with the neighbor.
	  • If there is more BGP data in the TCP receiver queue, a plus sign (+) is also displayed.
	NOTE: If you display information for the neighbor using the **show ipv6 bgp neighbor** <*ipv6-address*> command, the TCP receiver queue value will be greater than 0.

Time	The amount of time this session has been in its current state.
KeepAliveTime	The keep alive time, which specifies how often this sends keep alive messages to the neighbor.
HoldTime	The hold time, which specifies how many seconds the will wait for a KEEPALIVE or UPDATE message from a BGP4+ neighbor before deciding that the neighbor is dead.
RefreshCapability	Whether the has received confirmation from the neighbor that the neighbor supports the dynamic refresh capability.
Messages Sent and Received	The number of messages this has sent to and received from the neighbor. The display shows statistics for the following message types: • Open • Update • KeepAlive • Notification • Refresh-Req

TABLE 355 BGP4+ neighbor configuration information and statistics (Continued)

This field...	Displays...
Last Update Time	Lists the last time updates were sent and received for the following: • NLRIs • Withdraws

Last Connection Reset Reason	The reason the previous session with this neighbor ended. The reason can be one of the following:
	• No abnormal error has occurred.
	• Reasons described in the BGP specifications:
	  • Message Header Error
	  • Connection Not Synchronized
	  • Bad Message Length
	  • Bad Message Type
	  • OPEN Message Error
	  • Unsupported Version Number
	  • Bad Peer AS Number
	  • Bad BGP Identifier
	  • Unsupported Optional Parameter
	  • Authentication Failure
	  • Unacceptable Hold Time
	  • Unsupported Capability
	  • UPDATE Message Error
	  • Malformed Attribute List
	  • Unrecognized Well-known Attribute
	  • Missing Well-known Attribute
	  • Attribute Flags Error
	  • Attribute Length Error
	  • Invalid ORIGIN Attribute
	  • Invalid NEXT_HOP Attribute
	  • Optional Attribute Error
	  • Invalid Network Field
	  • Malformed AS_PATH
	  • Hold Timer Expired
	  • Finite State Machine Error
	  • Rcv Notification

Last Connection Reset Reason (cont.)	• Reasons specific to the implementation:
	  • Reset All Peer Sessions
	  • User Reset Peer Session
	  • Port State Down
	  • Peer Removed
	  • Peer Shutdown
	  • Peer AS Number Change
	  • Peer AS Confederation Change
	  • TCP Connection KeepAlive Timeout
	  • TCP Connection Closed by Remote
	  • TCP Data Stream Error Detected

TABLE 355 BGP4+ neighbor configuration information and statistics (Continued)

This field...	Displays...

Notification Sent	If the receives a NOTIFICATION message from the neighbor, the message contains an error code corresponding to one of the following errors. Some errors have subcodes that clarify the reason for the error. Where applicable, the subcode messages are listed underneath the error code messages.
	• Message Header Error
	  • Connection Not Synchronized
	  • Bad Message Length
	  • Bad Message Type
	  • Unspecified
	• Open Message Error
	  • Unsupported Version
	  • Bad Peer As
	  • Bad BGP Identifier
	  • Unsupported Optional Parameter
	  • Authentication Failure
	  • Unacceptable Hold Time
	  • Unspecified
	• Update Message Error
	  • Malformed Attribute List
	  • Unrecognized Attribute
	  • Missing Attribute
	  • Attribute Flag Error
	  • Attribute Length Error
	  • Invalid Origin Attribute
	  • Invalid NextHop Attribute
	  • Optional Attribute Error
	  • Invalid Network Field
	  • Malformed AS Path
	  • Unspecified
	• Hold Timer Expired
	• Finite State Machine Error
	• Cease
	• Unspecified

Notification Received	See above.
Neighbor NLRI Negotiation	The state of the 's NLRI negotiation with the neighbor. The states can include the following: • Peer negotiated IPv6 unicast capability. • Peer configured for IPv6 unicast routes. • Peer negotiated IPv4 unicast capability. • Peer negotiated IPv4 multicast capability.

TABLE 355 BGP4+ neighbor configuration information and statistics (Continued)

This field...	Displays...
TCP Connection state	The state of the connection with the neighbor. The connection can have one of the following states: • LISTEN – Waiting for a connection request. • SYN-SENT – Waiting for a matching connection request after having sent a connection request. • SYN-RECEIVED – Waiting for a confirming connection request acknowledgment after having both received and sent a connection request. • ESTABLISHED – Data can be sent and received over the connection. This is the normal operational state of the connection. • FIN-WAIT-1 – Waiting for a connection termination request from the remote TCP, or an acknowledgment of the connection termination request previously sent. • FIN-WAIT-2 – Waiting for a connection termination request from the remote TCP. • CLOSE-WAIT – Waiting for a connection termination request from the local user. • CLOSING – Waiting for a connection termination request acknowledgment from the remote TCP. • LAST-ACK – Waiting for an acknowledgment of the connection termination request previously sent to the remote TCP (which includes an acknowledgment of its connection termination request). • TIME-WAIT – Waiting for enough time to pass to be sure the remote TCP received the acknowledgment of its connection termination request. • CLOSED – There is no connection state.
Byte Sent	The number of bytes sent.
Byte Received	The number of bytes received.
Local host	The IPv6 address of the .
Local port	The TCP port the is using for the BGP4+ TCP session with the neighbor.
Remote host	The IPv6 address of the neighbor.
Remote port	The TCP port the neighbor is using for the BGP4+ TCP session with the .
ISentSeq	The initial send sequence number for the session.
SendNext	The next sequence number to be sent.
TotUnAck	The number of sequence numbers sent by the that have not been acknowledged by the neighbor.
TotSent	The number of sequence numbers sent to the neighbor.
ReTrans	The number of sequence numbers that the retransmitted because they were not acknowledged.
UnAckSeq	The current acknowledged sequence number.
IRcvSeq	The initial receive sequence number for the session.
RcvNext	The next sequence number expected from the neighbor.
SendWnd	The size of the send window.
TotalRcv	The number of sequence numbers received from the neighbor.
DupliRcv	The number of duplicate sequence numbers received from the neighbor.
RcvWnd	The size of the receive window.
SendQue	The number of sequence numbers in the send queue.

TABLE 355 BGP4+ neighbor configuration information and statistics (Continued)

This field...	Displays...
RcvQue	The number of sequence numbers in the receive queue.
CngstWnd	The number of times the window has changed.

Displaying routes advertised to a BGP4+ neighbor

You can display a summary or detailed information about the following:

- All routes a has advertised to a neighbor.
- A specified route a has advertised to a neighbor.

For example, to display a summary of all routes a has advertised to neighbor 2000:4::110, enter the following command at any level of the CLI.

```
NetIron# show ipv6 bgp neighbor 2000:4::110 advertised-routes
       There are 2 routes advertised to neighbor 2000:4::110
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST E:EBGP I:IBGP L:LOCAL
       Prefix              Next Hop        Metric     LocPrf     Weight Status
1      2002:1234::/32      ::              1                     32768  BL
         AS_PATH:
2      2002::/16           ::              1                     32768  BL
         AS_PATH:
```

Syntax: **show ipv6 bgp neighbor** <*ipv6-address*> **advertised-routes [detail]** <*ipv6-prefix*>/<*prefix-length*>

The <*ipv6-address*> parameter displays routes advertised to a specified neighbor. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The **detail** keyword displays detailed information about the advertised routes. If you do not specify this keyword, a summary of the advertised routes displays.

The <*ipv6-prefix*>/<*prefix-length*> parameter displays the specified route advertised to the neighbor only. You must specify the <*ipv6-prefix*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the <*prefix-length*> parameter as a decimal value. A slash mark (/) must follow the <*ipv6-prefix*> parameter and precede the <*prefix-length*> parameter.

This display shows the following information.

TABLE 356 Summary of route information advertised to a BGP4+ neighbor

This field...	Displays...
Number of BGP4+ Routes advertised to specified neighbor (appears only in display for all routes)	The number of routes displayed by the command.
Status codes	A list of the characters the display uses to indicate the route's status. The status code appears in the Status column of the display. The status codes are described in the command's output.
Prefix	The advertised route's prefix.
Next Hop	The next-hop for reaching the advertised route from the .
Metric	The value of the advertised route's MED attribute. If the route does not have a metric, this field is blank.

TABLE 356 Summary of route information advertised to a BGP4+ neighbor (Continued)

This field...	Displays...
LocPrf	The degree of preference for the advertised route relative to other routes in the local AS. When the BGP4+ algorithm compares routes on the basis of local preferences, the route with the higher local preference is chosen. The preference range is 0 – 4294967295.
Weight	The value that this associates with routes from a specific neighbor. For example, if the receives routes to the same destination from two BGP4+ neighbors, the prefers the route from the neighbor with the larger weight.
Status	The advertised route's status, which can be one or more of the following: • A – AGGREGATE. The route is an aggregate route for multiple networks. • B – BEST. BGP4+ has determined that this is the optimal route to the destination. • b – NOT-INSTALLED-BEST – BGP4+ has determined that this is the optimal route to the destination but did not install it in the IPv6 route table because the received better routes from other sources (such as OSPFv3, RIPng, or static IPv6 routes). • E – EBGP. The route was learned through a in another AS. • I – IBGP. The route was learned through a in the same AS. • L – LOCAL. The route originated on this .
AS-PATH	The AS-path information for the route.

For example, to display details about all routes a has advertised to neighbor 2000:4::110, enter the following command at any level of the CLI.

```
NetIron# show ipv6 bgp neighbor 2000:4::110 advertised-routes detail
There are 2 routes advertised to neighbor 2000:4::110
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST E:EBGP I:IBGP L:LOCAL
1       Prefix: 2002:1234::/32,  Status: BL,  Age: 6d13h28m7s
         NEXT_HOP: 2000:4::106,  Learned from Peer: Local Router
          LOCAL_PREF: none,  MED: 1,  ORIGIN: incomplete,  Weight: 32768
           AS_PATH:
            Adj_RIB_out count: 1,  Admin distance 190
2       Prefix: 2002::/16,  Status: BL,  Age: 6d13h31m22s
         NEXT_HOP: 2000:4::106,  Learned from Peer: Local Router
          LOCAL_PREF: none,  MED: 1,  ORIGIN: incomplete,  Weight: 32768
           AS_PATH:

            Adj_RIB_out count: 1,  Admin distance 190
```

This display shows the following information.

TABLE 357 Detailed route information advertised to a BGP4+ neighbor

This field...	Displays...
Number of BGP4+ Routes advertised to specified neighbor (appears only in display for all routes)	For information about this field, refer to Table 356 on page 1933.
Status codes	For information about this field, refer to Table 356 on page 1933.
Prefix	For information about this field, refer to Table 356 on page 1933.

TABLE 357 Detailed route information advertised to a BGP4+ neighbor (Continued)

This field...	Displays...
Status	For information about this field, refer to Table 356 on page 1933.
Age	The age of the advertised route, in seconds.
Next Hop	For information about this field, refer to Table 356 on page 1933.
Learned from Peer	The IPv6 address of the neighbor from which this route is learned. "Local Router" indicates that the itself learned the route.
LOCAL_PREF	For information about this field, refer to Table 356 on page 1933.
MED	The value of the advertised route's MED attribute. If the route does not have a metric, this field is blank.
Origin	The source of the route information. The origin can be one of the following: • EGP – The routes with this set of attributes came to BGP4+ through EGP. • IGP – The routes with this set of attributes came to BGP4+ through IGP. • INCOMPLETE – The routes came from an origin other than one of the above. For example, they may have been redistributed from OSPFv3 or RIPng. When BGP4+ compares multiple routes to a destination to select the best route, IGP is preferred over EGP and both are preferred over INCOMPLETE.
Weight	For information about this field, refer to Table 356 on page 1933.
AS-PATH	The AS-path information for the route.
Adj RIB out count	The number of routes in the 's current BGP4+ Routing Information Base (Adj-RIB-Out) for a specified neighbor.
Admin distance	The administrative distance of the route.

Displaying BGP4+ neighbor route-attribute entries

The route-attribute entries table lists sets of BGP4+ attributes stored in the 's memory. Each set of attributes is unique and can be associated with one or more routes. In fact, the typically has fewer route attribute entries than routes.

For example, to display the route-attribute entries table for a BGP4+ neighbor 2000:4::110, enter the following command.

```
NetIron# show ipv6 bgp neighbor 2000:4::110 attribute-entries
               Total number of BGP Attribute Entries: 1
1       Next Hop  :2000:4::106        Metric   :1              Origin:INCOMP
        Originator:0.0.0.0            Cluster List:None
        Aggregator:AS Number :0      Router-ID:0.0.0.0         Atomic:None
        Local Pref:100               Communities:Internet
        AS Path   :65001
        Address: 0x26579354  Hash:332 (0x0301fcd4) Reference Counts: 2:0:0
```

Syntax: show ipv6 bgp neighbor <*ipv6-address*> **attribute-entries**

The <*ipv6-address*> parameter displays the route attribute entries for a specified neighbor. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

This display shows the following information.

TABLE 358 BGP4+ neighbor route-attribute entries information

This field...	Displays...
Total number of BGP Attribute Entries	The number of route attribute entries for the specified neighbor.
Next Hop	The IPv6 address of the next hop router for routes that have this set of attributes.
Metric	The cost of the routes that have this set of attributes.
Origin	The source of the route information. The origin can be one of the following: • EGP – The routes with this set of attributes came to BGP4+ through EGP. • IGP – The routes with this set of attributes came to BGP4+ through IGP. • INCOMPLETE – The routes came from an origin other than one of the above. For example, they may have been redistributed from OSPFv3 or RIPng. When BGP4+ compares multiple routes to a destination to select the best route, IGP is preferred over EGP and both are preferred over INCOMPLETE.
Originator	The originator of the route in a route reflector environment.
Cluster List	The route-reflector clusters through which this set of attributes has passed.
Aggregator	Aggregator information: • `AS Number` shows the AS in which the network information in the attribute set was aggregated. This value applies only to aggregated routes and is otherwise 0. • `Router-ID` shows the that originated this aggregator.
Atomic	Whether the network information in this set of attributes has been aggregated *and* this aggregation has resulted in information loss: • TRUE – Indicates information loss has occurred • FALSE – Indicates no information loss has occurred • None – Indicates the attribute is not present. Note: Information loss under these circumstances is a normal part of BGP4+ and does not indicate an error.
Local Pref	The degree of preference for routes that use this set of attributes relative to other routes in the local AS.
Communities	The communities that routes with this set of attributes are in.
AS Path	The ASs through which routes with this set of attributes have passed. The local AS is shown in parentheses.
Address	For debugging purposes only.
Hash	For debugging purposes only.
Reference Counts	For debugging purposes only.

Displaying route flap dampening statistics for a BGP4+ neighbor

To display route flap dampening statistics for a specified BGP4+ neighbor, enter the following command at any level of the CLI.

```
NetIron# show ipv6 bgp neighbor 2000:4::110 flap-statistics
Total number of flapping routes: 14
    Status Code  >:best d:damped h:history *:valid
    Network            From            Flaps Since    Reuse    Path
h>  2001:2::/32        166.90.213.77   1     0 :0 :13 0 :0 :0  65001 4355 1 701
*>  3892:34::/32       166.90.213.77   1     0 :1 :4  0 :0 :0  65001 4355 701 62
```

Syntax: show ipv6 bgp neighbor <*ipv6-address*> **flap-statistics**

The <*ipv6-address*> parameter displays the route flap dampening statistics for a specified neighbor. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

This display shows the following information.

TABLE 359 Route flap dampening statistics for a BGP4+ neighbor

This field...	Displays...
Total number of flapping routes	The total number of routes in the neighbor's BGP4+ route table that have changed state and thus have been marked as flapping routes.
Status code	Indicates the status of the route, which can be one of the following: • > – This is the best route among those in the neighbor's BGP4+ route table to the route's destination. • d – This route is currently dampened, and thus unusable. • h – The route has a history of flapping and is unreachable now. • * – The route has a history of flapping but is currently usable.
Network	The destination network of the route.
From	The IPv6 address of the advertising peer.
Flaps	The number of flaps (state changes) the route has experienced.
Since	The amount of time (in hh:mm:ss) since the first flap of this route.
Reuse	The amount of time (in hh:mm:ss) after which the path is again available.
Path	The AS path of the route.

You also can display all the dampened routes by using the **show ipv6 bgp dampened-paths** command. For more information, refer to "Displaying dampened BGP4+ paths" on page 1920.

Displaying last error packet from a BGP4+ neighbor

You can display information about the last packet that contained an error from any of a 's neighbors. The displayed information includes the error packet's contents decoded in a human-readable format.

For example, to display information about the last error packet from any of a 's neighbors, enter the following command.

```
NetIron# show ipv6 bgp neighbor last-packet-with-error
    Total number of BGP Neighbors: 266
No received packet with error logged for any neighbor
```

Syntax: show ipv6 bgp neighbor last-packet-with-error

This display shows the following information.

TABLE 360 Last error packet information for BGP4+ neighbors

This field...	Displays...
Total number of BGP Neighbors	The total number of configured neighbors for a .
Last error	The error packet's contents decoded in a human-readable format or notification that no packets with an error were received.

Displaying Outbound Route Filters received from a BGP4+ neighbor

You can display the Outbound Route Filters (ORFs) received from a BGP4+ neighbor. This option applies to cooperative route filtering feature.

For example, to display the ORFs received from neighbor 2000:2::110, enter the following command.

```
NetIron# show ipv6 bgp neighbor 2000:2::110 received prefix-filter
ip prefix-list 2000:2::110: 4 entries
     seq 5 permit 3000:3::45/16 ge 18 le 28
     seq 10 permit 4000:4::88/24
     seq 15 permit 5000:5::37/8 le 32
     seq 20 permit 6000:6::83/16 ge 18
```

Syntax: show ipv6 bgp neighbor <*ipv6-address*> **received prefix-filter**

The <*ipv6-address*> parameter displays the prefix filter learned from a specified neighbor. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

Displaying routes received from a BGP4+ neighbor

You can display a summary or detailed route information received in route updates from a specified BGP4+ neighbor since you enabled the soft reconfiguration feature.

For example, to display a summary of the route information received in route updates from neighbor 2000:4::10, enter the following command at any level of the CLI.

```
NetIron# show ipv6 bgp neighbor 2:2:2:2:: received-routes
There are 4 received routes from neighbor 2:2:2:2::
Searching for matching routes, use ^C to quit...
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED F:FILTERED
    PrefixNext HopMetricLocPrfWeightStatus
1   2002::/642:2:2:2:: 01000BE
AS_PATH: 400
2   2003::/642:2:2:2:: 11000BE
AS_PATH: 400
3   2004::/642:2:2:2:: 11000BE
AS_PATH: 400
4   2005::/642:2:2:2:: 11000BE
AS_PATH: 400
```

Syntax: show ipv6 bgp neighbor <*ipv6-address*> **received-routes [detail]**

The <*ipv6-address*> parameter displays route information received from a specified neighbor. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The **detail** keyword displays detailed route information. If you do not specify this parameter, a summary of route information displays.

This display shows the following information.

TABLE 361 Summary of route information received from a BGP4+ neighbor

This field...	Displays...
Number of BGP4+ Routes received from a neighbor	The number of routes displayed by the command.
Status codes	A list of the characters the display uses to indicate the route's status. The status code appears in the Status column of the display. The status codes are described in the command's output.
Prefix	The received route's prefix.
Next Hop	The IPv6 address of the next that is used when forwarding a packet to the received route.
Metric	The value of the route's MED attribute. If the route does not have a metric, this field is blank.
LocPrf	The degree of preference for the advertised route relative to other routes in the local AS. When the BGP4+ algorithm compares routes on the basis of local preferences, the route with the higher local preference is chosen. The preference can have a value from 0 – 4294967295.
Weight	The value that this associates with routes from a specific neighbor. For example, if the receives routes to the same destination from two BGP4+ neighbors, the prefers the route from the neighbor with the larger weight.
Status	The advertised route's status, which can be one or more of the following: A – AGGREGATE. The route is an aggregate route for multiple networks. B – BEST. BGP4+ has determined that this is the optimal route to the destination. b – NOT-INSTALLED-BEST – BGP4+ has determined that this is the optimal route to the destination but did not install it in the IPv6 route table because the received better routes from other sources (such as OSPFv3, RIPng, or static IPv6 routes). D – DAMPED. This route has been dampened (by the route dampening feature), and is currently unusable. E – EBGP. The route was learned through a in another AS. H – HISTORY. Route dampening is configured for this route, and the route has a history of flapping and is unreachable now. I – IBGP. The route was learned through a in the same AS. L – LOCAL. The route originated on this . M – MULTIPATH. BGP4+ load sharing is enabled and this route was selected as one of the best ones to the destination. The best route among the multiple paths also is marked with "B". **NOTE:** If the "m" is shown in lowercase, the software was not able to install the route in the IPv6 route table. S – SUPPRESSED. This route was suppressed during aggregation and thus is not advertised to neighbors. F – FILTERED. This route was filtered out by BGP4+ route policies on the , but the saved updates containing the filtered routes.

For example, to display details about routes received from neighbor 2000:1:1::1, enter the following command at any level of the CLI.

```
NetIron# show ipv6 bgp neighbor 2000:1:1::1 received-routes detail
There are 4 received routes from neighbor 2000:1:1::1
Searching for matching routes, use ^C to quit...

This display shows the following information.

TABLE 362 Detailed route information received from a BGP4+ neighbor

This field...	Displays...
Number of BGP4+ routes received from a neighbor	For information about this field, refer to Table 361 on page 1939.
Status codes	For information about this field, refer to Table 361 on page 1939.
Prefix	For information about this field, refer to Table 361 on page 1939.
Status	For information about this field, refer to Table 361 on page 1939.
Age	The age of the route, in seconds.
Next hop	The next-hop router for reaching the route from the .
Learned from peer	The IPv6 address of the neighbor from which this route is learned. “Local Router” indicates that the itself learned the route.
Local pref	For information about this field, refer to Table 361 on page 1939.
MED	The value of the route’s MED attribute. If the route does not have a metric, this field is blank.
Origin	The source of the route information. The origin can be one of the following: • EGP – The routes with this set of attributes came to BGP4+ through EGP. • IGP – The routes with this set of attributes came to BGP4+ through IGP. • INCOMPLETE – The routes came from an origin other than one of the above. For example, they may have been redistributed from OSPFv3 or RIPng. When BGP4+ compares multiple routes to a destination to select the best route, IGP is preferred over EGP and both are preferred over INCOMPLETE.
Weight	For information about this field, refer to Table 361 on page 1939.
AS Path	For information about this field, refer to Table 361 on page 1939.

TABLE 362 Detailed route information received from a BGP4+ neighbor (Continued)

This field...	Displays...
Adj RIB out count	The number of routes in the 's current BGP4+ Routing Information Base (Adj-RIB-Out) for a specified neighbor.
Admin distance	The administrative distance of the route.

Displaying the Adj-RIB-Out for a BGP4+ neighbor

You can display a summary or detailed information about the following:

- All routes in a 's current BGP4+ Routing Information Base (Adj-RIB-Out) for a specified neighbor.
- A specified route in a 's current BGP4+ RIB for a specified neighbor.

The RIB contains the routes that the either has most recently sent to the neighbor or is about to send to the neighbor.

For example, to display a summary of all routes in a 's RIB for neighbor 2000:4::110, enter the following command at any level of the CLI.

```
NetIron# show ipv6 bgp neighbor 2000:4::110 rib-out-routes
       There are 2 RIB_out routes for neighbor 2000:4::110
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST E:EBGP I:IBGP L:LOCAL
       Prefix             Next Hop        Metric     LocPrf     Weight Status
1      2002:1234::/32     ::              1          100        32768  BL
         AS_PATH:
2      2002::/16          ::              1          100        32768  BL
         AS_PATH:
```

Syntax: **show ipv6 bgp neighbor** <*ipv6-address*> **rib-out-routes** [<*ipv6-prefix*>/<*prefix-length*> | **detail** [<*ipv6-prefix*>/<*prefix-length*> <*network-mask*>]]

The <*ipv6-address*> parameter displays the RIB routes for a specified neighbor. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The <*ipv6-prefix*>/<*prefix-length*> parameter displays the specified RIB route for the neighbor. You must specify the <*ipv6-prefix*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the <*prefix-length*> parameter as a decimal value. A slash mark (/) must follow the <*ipv6-prefix*> parameter and precede the <*prefix-length*> parameter.

The **detail** <*ipv6-prefix*>/<*prefix-length*> <*network-mask*> parameter displays detailed information about the specified RIB routes. If you do not specify this parameter, a summary of the RIB routes displays. You must specify the <*ipv6-prefix*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the <*prefix-length*> parameter as a decimal value. A slash mark (/) must follow the <*ipv6-prefix*> parameter and precede the <*prefix-length*> parameter. You must specify the <*network-mask*> parameter using 8-bit values in dotted decimal notation.

This display shows the following information.

TABLE 363 Summary of RIB route information for a BGP4+ neighbor

This field...	Displays...
Number of RIB_out routes for a specified neighbor (appears only in display for all RIB routes)	The number of RIB routes displayed by the command.
Status codes	A list of the characters the display uses to indicate the route's status. The status code appears in the Status column of the display. The status codes are described in the command's output.
Prefix	The RIB route's prefix.
Next Hop	The next-hop router for reaching the route from the .
Metric	The value of the advertised route's MED attribute. If the route does not have a metric, this field is blank.
LocPrf	The degree of preference for the route relative to other routes in the local AS. When the BGP4+ algorithm compares routes on the basis of local preferences, the route with the higher local preference is chosen. The preference can have a value from 0 – 4294967295.
Weight	The value that this associates with routes from a specific neighbor. For example, if the receives routes to the same destination from two BGP4+ neighbors, the prefers the route from the neighbor with the larger weight.
Status	The RIB route's status, which can be one or more of the following: • A – AGGREGATE. The route is an aggregate route for multiple networks. • B – BEST. BGP4+ has determined that this is the optimal route to the destination. E – EBGP. The route was learned through a in another AS. • I – IBGP. The route was learned through a in the same AS. • L – LOCAL. The route originated on this .
AS-PATH	The AS-path information for the route.

For example, to display details about all RIB routes for neighbor 2000:4::110, enter the following command at any level of the CLI.

```
NetIron# show ipv6 bgp neighbor 2000:4::110 rib-out-routes detail
                    There are 2 RIB_out routes for neighbor 2000:4::110
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST E:EBGP I:IBGP L:LOCAL
1       Prefix: 2002:1234::/32,  Status: BL,  Age: 6d18h17m53s

            Adj_RIB_out count: 1,  Admin distance 190
```

This display shows the following information.

TABLE 364 Detailed RIB route information for a BGP4+ neighbor

This field...	Displays...
Number of RIB_out routes for a specified neighbor (appears only in display for all routes)	For information about this field, refer to Table 363 on page 1942.
Status codes	For information about this field, refer to Table 363 on page 1942.
Prefix	For information about this field, refer to Table 363 on page 1942.
Status	For information about this field, refer to Table 363 on page 1942.
Age	The age of the RIB route, in seconds.
Next Hop	For information about this field, refer to Table 363 on page 1942.
Learned from Peer	The IPv6 address of the neighbor from which this route is learned. “Local Router” indicates that the itself learned the route.
LOCAL_PREF	For information about this field, refer to Table 363 on page 1942.
MED	The value of the RIB route’s MED attribute. If the route does not have a metric, this field is blank.
Origin	The source of the route information. The origin can be one of the following: • EGP – The routes with this set of attributes came to BGP4+ through EGP. • IGP – The routes with this set of attributes came to BGP4+ through IGP. • INCOMPLETE – The routes came from an origin other than one of the above. For example, they may have been redistributed from OSPFv3 or RIPng. When BGP4+ compares multiple routes to a destination to select the best route, IGP is preferred over EGP and both are preferred over INCOMPLETE.
Weight	For information about this field, refer to Table 363 on page 1942.
AS-PATH	For information about this field, refer to Table 363 on page 1942.

Displaying the best and unreachable routes received from a BGP4+ neighbor

You can display a summary or detailed information about the following types of BGP4+ routes received from a specified neighbor:

- **Best routes** – The “best” routes to their destinations, which are installed in the ’s IPv6 route table.
- **Unreachable** – The routes whose destinations are unreachable using any of the BGP4+ paths in the IPv6 route table.

For example, to display a summary of the best routes to a destination received from neighbor 2000:4::106, enter the following command.

```
NetIron# show ipv6 bgp neighbor 2000:4::106 routes best
       There are 2 accepted routes from neighbor 2000:4::106
Searching for matching routes, use ^C to quit...
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED F:FILTERED
       Prefix             Next Hop        Metric     LocPrf     Weight Status
1      2002::/16          2000:4::106     1          100        0      BE
         AS_PATH: 65001
2      2002:1234::/32     2000:4::106     1          100        0      BE
         AS_PATH: 65001
```

Syntax: show ipv6 bgp neighbor <*ipv6-address*> **routes best | detail [best | unreachable] | unreachable**

The <*ipv6-address*> parameter displays the routes for a specified neighbor. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The **best** keyword displays the "best" routes, which are installed in the IPv6 route table.

The **unreachable** keyword displays the routes whose destinations are unreachable using any of the BGP4+ paths in the IPv6 route table.

The **detail** keyword displays detailed information about the routes. If you do not specify this parameter, a summary of the routes displays.

This display shows the following information.

TABLE 365 Summary of best and unreachable routes from a BGP4+ neighbor

This field...	Displays...
Number of accepted routes from a specified neighbor	The number of routes displayed by the command.
Status codes	A list of the characters the display uses to indicate the route's status. The status code appears in the Status column of the display. The status codes are described in the command's output.
Prefix	The route's prefix.
Next Hop	The next-hop router for reaching the route from the .
Metric	The value of the route's MED attribute. If the route does not have a metric, this field is blank.
LocPrf	The degree of preference for the route relative to other routes in the local AS. When the BGP4+ algorithm compares routes on the basis of local preferences, the route with the higher local preference is chosen. The preference can have a value from 0 – 4294967295.
Weight	The value that this associates with routes from a specific neighbor. For example, if the receives routes to the same destination from two BGP4+ neighbors, the prefers the route from the neighbor with the larger weight.

TABLE 365 Summary of best and unreachable routes from a BGP4+ neighbor (Continued)

This field...	Displays...
Status	The route's status, which can be one or more of the following: • A – AGGREGATE. The route is an aggregate route for multiple networks. • B – BEST. BGP4+ has determined that this is the optimal route to the destination. • C – CONFED_EBGP. The route was learned from a neighbor in the same confederation and AS, but in a different sub-AS within the confederation. • D – DAMPED. This route has been dampened (by the route dampening feature), and is currently unusable. • E – EBGP. The route was learned through a in another AS. • H – HISTORY. Route dampening is configured for this route, and the route has a history of flapping and is unreachable now. • I – IBGP. The route was learned through a in the same AS. • L – LOCAL. The route originated on this . • M – MULTIPATH. BGP4+ load sharing is enabled and this route was selected as one of the best ones to the destination. The best route among the multiple paths also is marked with "B". **NOTE:** If the "m" is shown in lowercase, the software was not able to install the route in the IPv6 route table. • S – SUPPRESSED. This route was suppressed during aggregation and thus is not advertised to neighbors. • F – FILTERED. This route was filtered out by BGP4+ route policies on the , but the saved updates containing the filtered routes.
AS-PATH	The AS-path information for the route.

For example, to display detailed information about the best routes to a destination received from neighbor 2000:4::106, enter the following command.

```
NetIron# show ipv6 bgp neighbor 2000:4::106 routes detail best
       There are 2 accepted routes from neighbor 2000:4::106
Searching for matching routes, use ^C to quit...

          LOCAL_PREF: 100,  MED: 1,  ORIGIN: incomplete,  Weight: 0
           AS_PATH: 65001
```

This display shows the following information.

TABLE 366 Detailed best and unreachable routes from a BGP4+ neighbor

This field...	Displays...
Number of accepted routes from a specified neighbor (appears only in display for all routes)	For information about this field, refer to Table 365 on page 1944.
Status codes	For information about this field, refer to Table 365 on page 1944.
Prefix	For information about this field, refer to Table 365 on page 1944.
Status	For information about this field, refer to Table 365 on page 1944.

TABLE 366 Detailed best and unreachable routes from a BGP4+ neighbor (Continued)

This field...	Displays...
Age	The age of the route, in seconds.
Next Hop	For information about this field, refer to Table 365 on page 1944.
Learned from Peer	The IPv6 address of the neighbor from which this route is learned. "Local Router" indicates that the itself learned the route.
LOCAL_PREF	For information about this field, refer to Table 365 on page 1944.
MED	The value of the RIB route's MED attribute. If the route does not have a metric, this field is blank.
Origin	The source of the route information. The origin can be one of the following: • EGP – The routes with this set of attributes came to BGP4+ through EGP. • IGP – The routes with this set of attributes came to BGP4+ through IGP. • INCOMPLETE – The routes came from an origin other than one of the above. For example, they may have been redistributed from OSPFv3 or RIPng. When BGP4+ compares multiple routes to a destination to select the best route, IGP is preferred over EGP and both are preferred over INCOMPLETE.
Weight	For information about this field, refer to Table 365 on page 1944.
AS-PATH	For information about this field, refer to Table 365 on page 1944.

Displaying IPv6 neighbor route summary information

You can display route summary information for all neighbors or a specified neighbor only.

For example, to display summary information for neighbor 2000:4::110, enter the following command at any level of the CLI.

```
NetIron# show ipv6 bgp neighbor 2000:4::110 routes-summary
1   IP Address: 2000:4::110
Routes Accepted/Installed:0,  Filtered/Kept:0,  Filtered:0
   Routes Selected as BEST Routes:0
      BEST Routes not Installed in IP Forwarding Table:0
   Unreachable Routes (no IGP Route for NEXTHOP):0
   History Routes:0

NLRIs Received in Update Message:0,  Withdraws:0 (0),  Replacements:0
   NLRIs Discarded due to
      Maximum Prefix Limit:0, AS Loop:0

Syntax: show ipv6 bgp neighbor [<*ipv6-address*>] **routes-summary**

This display shows the following information.

TABLE 367 BGP4+ neighbor route summary information

This field...	Displays...
IP Address	The IPv6 address of the neighbor
Routes Received	How many routes the has received from the neighbor during the current BGP4+ session: • Accepted or Installed – Indicates how many of the received routes the accepted and installed in the BGP4+ route table. • Filtered or Kept – Indicates how many routes were filtered out, but were nonetheless retained in memory for use by the soft reconfiguration feature. • Filtered – Indicates how many of the received routes were filtered out.
Routes Selected as BEST Routes	The number of routes that the selected as the best routes to their destinations.
BEST Routes not Installed in IPv6 Forwarding Table	The number of routes received from the neighbor that are the best BGP4+ routes to their destinations, but were nonetheless not installed in the IPv6 route table because the received better routes from other sources (such as OSPFv3, RIPng, or static IPv6 routes).
Unreachable Routes	The number of routes received from the neighbor that are unreachable because the does not have a valid RIPng, OSPFv3, or static IPv6 route to the next hop.
History Routes	The number of routes that are down but are being retained for route flap dampening purposes.
NLRIs Received in Update Message	The number of routes received in Network Layer Reachability (NLRI) format in UPDATE messages: • Withdraws – The number of withdrawn routes the has received. • Replacements – The number of replacement routes the has received.
NLRIs Discarded due to	Indicates the number of times the discarded an NLRI for the neighbor due to the following reasons: • Maximum Prefix Limit – The 's configured maximum prefix amount had been reached. • AS Loop – An AS loop occurred. An AS loop occurs when the BGP4+ AS-path attribute contains the local AS number. • Invalid Nexthop Address – The next hop value was not acceptable. • Duplicated Originator_ID – The originator ID was the same as the local router ID. • Cluster_ID – The cluster list contained the local cluster ID, or contained the local router ID (see above) if the cluster ID is not configured.
Routes Advertised	The number of routes the has advertised to this neighbor: • To be Sent – The number of routes the has queued to send to this neighbor. • To be Withdrawn – The number of NLRIs for withdrawing routes the has queued up to send to this neighbor in UPDATE messages.

TABLE 367 BGP4+ neighbor route summary information (Continued)

This field...	Displays...
NLRIs Sent in Update Message	The number of NLRIs for new routes the has sent to this neighbor in UPDATE messages: • Withdraws – The number of routes the has sent to the neighbor to withdraw. • Replacements – The number of routes the has sent to the neighbor to replace routes the neighbor already has.
Peer Out of Memory Count for	Statistics for the times the has run out of BGP4+ memory for the neighbor during the current BGP4+ session: • Receiving Update Messages – The number of times UPDATE messages were discarded because there was no memory for attribute entries. • Accepting Routes(NLRI) – The number of NLRIs discarded because there was no memory for NLRI entries. This count is not included in the Receiving Update Messages count. • Attributes – The number of times there was no memory for BGP4+ attribute entries. • Outbound Routes (RIB-out) – The number of times there was no memory to place a “best” route into the neighbor's route information base (Adj-RIB-Out) for routes to be advertised. • Outbound Routes Holder – For debugging purposes only.

Displaying BGP4+ peer group configuration information

You can display configuration information for all peer groups or a specified peer group configured on a .

For example, to display configuration information for a peer group named peer1, enter the following command at any level of the CLI.

```
NetIron# show ipv6 bgp peer-group peer1
1   BGP peer-group is pg1, Remote AS: 65002
    Description: device group 1
       NextHopSelf: yes
      Address family : IPV4 Unicast
      Address family : IPV4 Multicast
      Address family : IPV6 Unicast
    Members:
       IP Address: 192.169.102.2
       IP Address: 192.169.100.2
       IP Address: 192.169.101.2
       IP Address: 192.169.103.2
       IP Address: 192.169.104.2
       IP Address: 192.169.105.2
       IP Address: 192.169.106.2
       IP Address: 192.169.107.2
       IP Address: 192.169.108.2
       IP Address: 192.169.109.2
       IP Address: 192.169.110.2
       IP Address: 192.169.111.2
       IP Address: 192.169.112.2
```

Syntax: show ipv6 bgp peer-group [<*peer-group-name*>]

The display shows only parameters that have values different from their default settings.

Displaying BGP4+ summary

To view summary BGP4+ information for the , enter the following command at any level of the CLI.

```
NetIron# show ipv6 bgp summary
BGP4 Summary
Router ID: 223.223.223.223   Local AS Number : 65001
Confederation Identifier : not configured
Confederation Peers:
Maximum Number of Paths Supported for Load Sharing : 1
Number of Neighbors Configured : 1
Number of Routes Installed : 2
Number of Routes Advertising to All Neighbors : 2
Number of Attribute Entries Installed : 1
Neighbor Address  AS#   State   Time     Rt:Accepted Filtered Sent   ToSend
2000:4::110       65002 ESTAB  21h32m32s    0        0        2      0
```

Syntax: show ipv6 bgp summary

This display shows the following information.

TABLE 368 BGP4+ summary information

This field...	Displays...
Router ID	The 's router ID.
Local AS Number	The BGP4+ AS number in which the resides.
Confederation Identifier	The AS number of the confederation in which the resides.
Confederation Peers	The numbers of the local ASs contained in the confederation. This list matches the confederation peer list you configure on the .
Maximum Number of Paths Supported for Load Sharing	The maximum number of route paths across which the can balance traffic to the same destination. The feature is enabled by default but the default number of paths is 1. You can increase the number from 2 – 8 paths.
Number of Neighbors Configured	The number of BGP4+ neighbors configured on this .
Number of Routes Installed	The number of BGP4+ routes in the 's BGP4+ route table. To display the BGP4+ route table, refer to "Displaying the BGP4+ route table" on page 1911.
Number of Routes Advertising to All Neighbors	The total of the RtSent and RtToSend columns for all neighbors.
Number of Attribute Entries Installed	The number of BGP4+ route-attribute entries in the 's route-attributes table. To display the route-attribute table, refer to "Displaying BGP4+ route-attribute entries" on page 1918.
Neighbor Address	The IPv6 addresses of this 's BGP4+ neighbors.
AS#	The AS number.

TABLE 368 BGP4+ summary information (Continued)

This field...	Displays...

State	The state of this 's neighbor session with each neighbor. The states are from this 's perspective of the session, not the neighbor's perspective. The state values can be one of the following for each :
	• IDLE – The BGP4+ process is waiting to be started. Usually, enabling BGP4+ or establishing a neighbor session starts the BGP4+ process.
	  • A minus sign (-) indicates that the session has gone down and the software is clearing or removing routes.
	• ADMND – The neighbor has been administratively shut down.
	  • A minus sign (-) indicates that the session has gone down and the software is clearing or removing routes.
	• CONNECT – BGP4+ is waiting for the connection process for the TCP neighbor session to be completed.
	• ACTIVE – BGP4+ is waiting for a TCP connection from the neighbor.
	NOTE: If the state frequently changes between CONNECT and ACTIVE, there may be a problem with the TCP connection.
	• OPEN SENT – BGP4+ is waiting for an Open message from the neighbor.
	• OPEN CONFIRM – BGP4+ has received an OPEN message from the neighbor and is now waiting for either a KEEPALIVE or NOTIFICATION message. If the receives a KEEPALIVE message from the neighbor, the state changes to Established. If the message is a NOTIFICATION, the state changes to Idle.
	• ESTABLISHED – BGP4+ is ready to exchange UPDATE packets with the neighbor.
	  • If there is more BGP data in the TCP receiver queue, a plus sign (+) is also displayed.
	NOTE: If you display information for the neighbor using the **show ipv6 bgp neighbor** <*ipv6-address*> command, the TCP receiver queue value will be greater than 0.

Time	The time that has passed since the state last changed.
Accepted	The number of routes received from the neighbor that this installed in the BGP4+ route table. Usually, this number is lower than the RoutesRcvd number. The difference indicates that this filtered out some of the routes received in the UPDATE messages.
Filtered	The routes or prefixes that have been filtered out. • If soft reconfiguration is enabled, this field shows how many routes were filtered out (not placed in the BGP4+ route table) but retained in memory. • If soft reconfiguration is not enabled, this field shows the number of BGP4+ routes that have been filtered out.
Sent	The number of BGP4+ routes that the has sent to the neighbor.
ToSend	The number of routes the has queued to send to this neighbor.

Chapter

Configuring IPv6 Multicast Features

46

PowerConnect B-MLXe supports the IPv6 Multicast features:

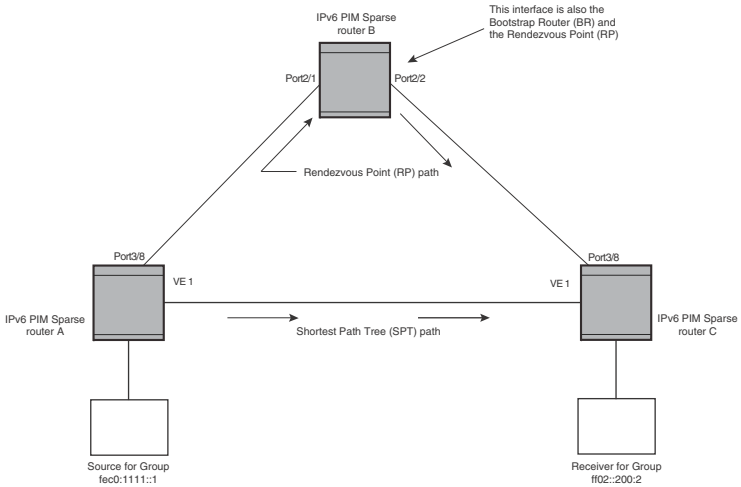
- IPv6 PMRI
- IPv6 PIM-SSM
- IPv6 PIM Sparse
- IPv6 PIM Anycast RP
- Multicast Listener Discovery (MLD)
- PIM and MLD Snooping for IPv6
- VRF Support for IPv6 Multicast

IPv6 PIM Sparse

IPv6 Protocol Independent Multicast (PIM) Sparse is supported. IPv6 PIM Sparse provides multicasting that is especially suitable for widely distributed multicast environments.

In an IPv6 PIM Sparse network, an IPv6 PIM Sparse router that is connected to a host that wants to receive information for a multicast group must explicitly send a join request on behalf of the receiver (host).

FIGURE 220 Example IPv6 PIM Sparse domain



PIM Sparse router types

Routers that are configured with PIM Sparse interfaces also can be configured to fill one or more of the following roles:

- BSR – The Bootstrap Router (BSR) distributes RP information to the other PIM Sparse routers within the domain. Each PIM Sparse domain has one active BSR. For redundancy, you can configure ports on multiple routers as candidate BSRs. The PIM Sparse protocol uses an election process to select one of the candidate BSRs as the BSR for the domain. The BSR with the highest BSR priority (a user-configurable parameter) is elected. If the priorities result in a tie, then the candidate BSR interface with the highest IP address is elected. In the example in Figure 220, PIM Sparse router B is the BSR. Port 2/2 is configured as a candidate BSR.
- RP – The Rendezvous Points (RP) is the meeting point for PIM Sparse sources and receivers. A PIM Sparse domain can have multiple RPs, but each PIM Sparse multicast group address can have only one active RP. PIM Sparse routers learn the addresses of RPs and the groups for which they are responsible from messages that the BSR sends to each of the PIM Sparse routers. In the example in Figure 220, PIM Sparse router B is the RP. Port 2/2 is configured as a candidate Rendezvous Point (RP).

  To enhance overall network performance, the device uses the RP to forward only the first packet from a group source to the group receivers. After the first packet, the device calculates the shortest path between the receiver and the source (the Shortest Path Tree, or SPT) and uses the SPT for subsequent packets from the source to the receiver. The device calculates a separate SPT for each source-receiver pair.

NOTE
It is recommended that you configure the same ports as candidate BSRs and RPs.

RP paths and SPT paths

Figure 220 shows two paths for packets from the source for group fec0:1111::1 and a receiver for the group. The source is attached to PIM Sparse router A and the recipient is attached to PIM Sparse router C. PIM Sparse router B is the RP for this multicast group. As a result, the default path for packets from the source to the receiver is through the RP. However, the path through the RP sometimes is not the shortest path. In this case, the shortest path between the source and the receiver is over the direct link between router A and router C, which bypasses the RP (router B).

To optimize PIM traffic, the protocol contains a mechanism for calculating the Shortest Path Tree (SPT) between a given source and a receiver. PIM Sparse routers can use the SPT as an alternative to using the RP for forwarding traffic from a source to a receiver. By default, the device forwards the first packet it receives from a given source to a given receiver using the RP path, but subsequent packets from that source to that receiver through the SPT. In Figure 220, router A forwards the first packet from group fec0:1111::1 source to the destination by sending the packet to router B, which is the RP. Router B then sends the packet to router C. For the second and all future packets that router A receives from the source for the receiver, router A forwards them directly to router C using the SPT path.

RFC 3513 and RFC 4007 compliance for IPv6 multicast scope-based forwarding

The IPv6 multicast implementation recognizes scopes and conforms to the scope definitions in RFC 3513. Per RFC 3513, scopes 0 and 3 are reserved and packets are not forwarded with an IPv6 destination multicast address of scopes 0 and 3. Additionally, scopes 1 and 2 are defined as Node-Local and Link-Local and are not forwarded. Thus, the implementation forwards only those packets with an IPv6 multicast destination address with scope 4 or higher.

RFC 4007 defines ‘scope zones’ and requires that the forwarding of packets received on any interface of a particular scope zone be restricted to that scope zone. Currently, the device supports one zone for each scope, and the default zone for scope 4 and higher consists of all interfaces in the system. Thus, the default zones for scope 4 and higher are the same size.

Configuring PIM Sparse

To configure the device for IPv6 PIM Sparse, perform the following tasks:

- Enable the IPv6 PIM Sparse of multicast routing.
- Configure an IPv6 address on the interface.
- Enable IPv6 PIM Sparse.
- Identify the interface as an IPv6 PIM Sparse border, if applicable.
- Enable IPv6 Protocol Independent Multicast Sparse mode (PIM-SM) for a specified VRF, if applicable.
- Identify the device as a candidate PIM Sparse Bootstrap Router (BSR), if applicable.
- Identify the device as a candidate PIM Sparse Rendezvous Point (RP), if applicable.
- Specify the IP address of the RP (if you want to statically select the RP).

NOTE
It is recommended that you configure the same device as both the BSR and the RP.

IPv6 PIM-Sparse mode

To configure a device for IPv6 PIM Sparse, perform the following tasks:

- Identify the Layer 3 switch as a candidate sparse Rendezvous Point (RP), if applicable.
- Specify the IPv6 address of the RP (to configure statically).

The following example enables IPv6 PIM-SM routing. Enter the following command at the configuration level to enable IPv6 PIM-SM globally.

```
NetIron(config)# ipv6 router pim
NetIron(config-ipv6-pim-router)#
```

To enable IPv6 PIM Sparse mode on an interface, enter commands such as the following.

```
NetIron(config)# interface ethernet 2/2
NetIron(config-if-e10000-2/2)# ipv6 address a000:1111::1/64
NetIron(config-if-e10000-2/2)# ipv6 pim-sparse
```

Syntax: [no] ipv6 pim-sparse

Use the **no** option to remove IPv6 PIM sparse configuration from the interface.

The commands in this example add an IPv6 interface to port 2/2, then enable IPv6 PIM Sparse on the interface.

Configuring IPv6 PIM-SM on a virtual routing interface

You can enable IPv6 PIM-SM on a virtual routing interface by entering commands such as the following.

```
NetIron(config)# interface ve 15
NetIron(config-vif-15)# ipv6 address a000:1111::1/64
NetIron(config-vif-15)# ipv6 pim-sparse
```

Enabling IPv6 PIM-SM for a specified VRF

To enable IPv6 PIM-SM for the VRF named “blue”, create the VRF named “blue”, enable it for IPv6 routing, and then enable IPv6 PIM-SM for the VRF, as shown in the following example.

```
NetIron(config)# vrf blue
NetIron(config-vrf-blue)# rd 11:1
NetIron(config-vrf-blue)# address-family ipv6
NetIron(config-vrf-blue-ipv6)# router pim
NetIron(config-pim-router)# ipv6 router pim vrf blue
NetIron(config-ipv6-pim-router-vrf-blue)
```

Syntax: [**no**] **ipv6 router pim** [**vrf** <*vrf-name*>]

The **vrf** parameter allows you to configure IPv6 PIM-SM on the virtual routing instance (VRF) specified by the <*vrf-name*> variable. All PIM parameters available for the default router instance are configurable for a VRF-based PIM instance.

Use the **no** option to remove all configuration for PIM multicast on the specified VRF.

Configuring BSRs

In addition to the global and interface parameters configured in the prior sections, you must identify an interface on at least one device as a candidate PIM Sparse Bootstrap Router (BSR) and a candidate PIM Sparse Rendezvous Point (RP).

NOTE
It is possible to configure the device as only a candidate BSR or an RP, but it is recommended that you configure the same interface on the same device as both a BSR and an RP.

To configure the device as a candidate BSR, enter commands such as the following.

```
NetIron(config)# ipv6 router pim
NetIron(config-ip6-pim-router)# bsr-candidate ethernet 1/3 32 64
BSR address: 31::207, hash mask length: 32, priority: 64
```

This command configures Ethernet interface 1/3 as the BSR candidate with a mask length of 32 and a priority of 64.

To configure the device as a candidate BSR for a specified VRF, enter the commands as shown in the following example.

```
NetIron(config)# ipv6 router pim vrf blue
NetIron(config-ipv6-pim-router-vrf-blue)# bsr-candidate ethernet 1/3 32 64
BSR address: 31::207, hash mask length: 32, priority: 64
```

Syntax: [**no**] **bsr-candidate ethernet** <*slot*>/<*portnum*> | **loopback** <*num*> | **ve** <*num*> <*hash-mask-length*> [<*priority*>]

Use the **no** option to remove the candidate BSR configuration for a specified VRF.

The **ethernet** <*slot*>/<*portnum*> | **loopback** <*num*> | **ve** <*num*> parameter specifies the interface. The device will advertise the specified interface's IP address as a candidate BSR:

- Enter **ethernet** <*slot*>/<*portnum*> for a physical interface (port).
- Enter **loopback** <*num*> for a loopback interface.
- Enter **ve** <*num*> for a virtual interface.

The <*hash-mask-length*> variable specifies the number of bits in a group address that are significant when calculating the group-to-RP mapping. You can specify a value from 1 through 32.

The <*priority*> variable specifies the BSR priority. You can specify a value from 0 through 255. When the election process for BSR takes place, the candidate BSR with the highest priority becomes the BSR. The default is 0.

Setting the BSR message interval

The BSR message interval timer defines the interval at which the BSR sends RP candidate data to all IPv6-enabled routers within the IPv6 PIM Sparse domain. The default is 60 seconds.

To set the IPv6 PIM BSR message interval timer to 16 seconds, enter commands such as the following.

```
NetIron(config)# ipv6 router pim
NetIron(config-ipv6-pim-router)# bsr-msg-interval 16
Changed BSR message interval to 16 seconds.
```

To set the IPv6 PIM BSR message interval timer to 16 seconds for a specified VRF, enter the commands as shown in the following example.

```
NetIron(config)# ipv6 router pim vrf blue
NetIron(config-ipv6-pim-router-vrf-blue)# bsr-msg-interval 16
Changed BSR message interval to 16 seconds.
```

Syntax: [**no**] **bsr-msg-interval** <*num*>

The <*num*> parameter specifies the number of seconds and can be from 10 – 65535. The default is 60.

Use the **no** option to disable a timer that has been configured.

Configuring candidate RP

Enter a command such as the following to configure the device as a candidate RP.

```
NetIron(config)# ipv6 router pim
NetIron(config-ipv6-pim-router)# rp-candidate ethernet 2/2
```

To configure the device as a candidate RP for a specified VRF, enter the commands as shown in the following example.

```
NetIron(config)# ipv6 router pim vrf blue
NetIron(config-ipv6-pim-router-vrf-blue)# rp-candidate ethernet 2/2
```

Syntax: [**no**] **rp-candidate ethernet** <*slot*>/<*portnum*> | **loopback** <*num*> | **ve** <*num*> | **pos** <*slot*>/<*portnum*>

The **ethernet** <*slot*>/<*portnum*> | **loopback** <*num*> | **ve** <*num*> l **pos** <*slot*>/<*portnum*> parameter specifies the interface. The device will advertise the specified interface IP address as a candidate RP:

- Enter **ethernet** <*slot*>/<*portnum*> for a physical interface (port).
- Enter **loopback** <*num*> for a loopback interface.
- Enter **ve** <*num*> for a virtual interface.
- Enter **pos** <*slot/portnum*> specifies the individual POS interface described by the <slot/port> variable.

To add address ranges for which the device is a candidate RP, enter commands such as the following.

```
NetIron(config)# ipv6 router pim
NetIron(config-ipv6-pim-router)# rp-candidate add ff02::200:2 64
```

To add address ranges for a specified VRF for which the device is a candidate RP, enter commands such as the following.

```
NetIron(config)# ipv6 router pim vrf blue
NetIron(config-ipv6-pim-router-vrf-blue)# rp-candidate add ff02::200:2 64
```

Syntax: [**no**] **rp-candidate add** <*group-ipv6 address*> <*mask-bits*>

You can delete the configured RP candidate group ranges by entering commands such as the following.

```
NetIron(config)# ipv6 router pim
NetIron(config-ipv6-pim-router)# rp-candidate delete ff02::200:1 128
```

You can delete the configured RP candidate group ranges for a specified VRF by entering commands such as the following:

```
NetIron(config)# ipv6 router pim
NetIron(config-ipv6-pim-router-vrf-blue)# rp-candidate delete ff02::200:1 128
```

Syntax: [**no**] **rp-candidate delete** <*group-ipv6 address*> <*mask-bits*>

The usage for the <*group-ipv6 address*> <*mask-bits*> parameter is the same as for the **rp-candidate add** command.

Statically specifying the RP

It is recommended that you use the IPv6 PIM Sparse mode RP election process so that a backup RP can automatically take over if the active RP router becomes unavailable. However, if you do not want the RP to be selected by the RP election process but instead you want to explicitly identify the RP by its IPv6 address, use the **rp-address** command.

If you explicitly specify the RP, the device uses the specified RP for all group-to-RP mappings and overrides the set of candidate RPs supplied by the BSR.

NOTE
Specify the same IP address as the RP on all IPv6 PIM Sparse routers within the IPv6 PIM Sparse domain. Make sure the device is on the backbone or is otherwise well-connected to the rest of the network.

To specify the IPv6 address of the RP, enter commands such as the following.

```
NetIron(config)# ipv6 router pim
NetIron(config-ipv6-pim-router)# rp-address 31::207
```

The command in the previous example identifies the router interface at IPv6 address 31:207 as the RP for the IPv6 PIM Sparse domain. The device will use the specified RP and ignore group-to-RP mappings received from the BSR.

To specify the IPv6 address of the RP for a specified VRF, enter commands such as the following.

```
NetIron(config)# ipv6 router pim vrf blue
NetIron(config-ipv6-pim-router-vrf-blue)# rp-address 31::207
```

Syntax: [**no**] **rp-address** <*ipv6-addr*>

The <*ipv6-addr*> parameter specifies the IPv6 address of the RP.

Updating IPv6 PIM Sparse forwarding entries with a new RP configuration

If you make changes to your static RP configuration, the entries in the IPv6 PIM Sparse multicast forwarding table continue to use the old RP configuration until they are aged out.

The **clear IPv6 pim rp-map** command allows you to update the entries in the static multicast forwarding table immediately after making RP configuration changes. This command is meant to be used with the **rp-address** command.

To update the entries in an IPv6 PIM Sparse static multicast forwarding table with a new RP configuration, enter the following command at the privileged EXEC level of the CLI.

```
NetIron(config)# clear ipv6 pim rp-map
```

Syntax: clear ipv6 pim rp-map

Embedded Rendezvous Point

Global deployment of IPv4 multicast relies on Multicast Source Discovery Protocol (MSDP) to convey information about the active sources. Because IPv6 provides more address space, the RP address can be included in the multicast group address.

NOTE
The IPv6 group address must be part of the FF70:/12 prefix.

Embedded RP support is enabled by default. You can disable it using the following commands.

```
NetIron(config)# ipv6 router pim
NetIron(config-ipv6-pim-router)# no rp-embedded
```

To disable embedded RP support for a specified VRF, enter the following commands.

```
NetIron(config)# ipv6 router pim vrf blue
NetIron(config-ipv6-pim-router-vrf-blue)# no rp-embedded
```

Syntax: [**no**] **rp-embedded**

Changing the Shortest Path Tree threshold

In a typical IPv6 PIM Sparse domain, there may be two or more paths from a designated router (DR) for a multicast source to an IPv6 PIM group receiver:

- **Path through the RP** – This is the path the device uses the first time it receives traffic for an IPv6 PIM group. However, the path through the RP may not be the shortest path from the device to the receiver.

- **Shortest Path** – Each IPv6 PIM Sparse router that is a DR for an IPv6 receiver calculates a short path tree (SPT) towards the source of the IPv6 multicast traffic. The first time the device configured as an IPv6 PIM router receives a packet for an IPv6 group, it sends the packet to the RP for that group, which in turn will forward it to all the intended DRs that have registered with the RP. The first time the device is a recipient, it receives a packet for an IPv6 group and evaluates the shortest path to the source and initiates a switchover to the SPT. Once the device starts receiving data on the SPT, the device proceeds to prune itself from the **RPT**.

By default, the device switches from the RP to the SPT after receiving the first packet for a given IPv6 PIM Sparse group. The device maintains a separate counter for each IPv6 PIM Sparse source-group pair.

You can change the number of packets the device receives using the RP before switching to using the SPT.

To change the number of packets the device receives using the RP before switching to the SPT, enter commands such as the following.

```
NetIron(config)# ipv6 router pim
NetIron(config-ipv6-pim-router)# spt-threshold 1000
```

To change the number of packets the device receives using the RP before switching to the SPT for a specified VRF, enter commands such as the following.

```
NetIron(config)# ipv6 router pim vrf blue
NetIron(config-ipv6-pim-router-vrf-blue)# spt-threshold 1000
```

Syntax: [**no**] **spt-threshold infinity** | <*num*>

The **infinity** | <*num*> parameter specifies the number of packets. If you specify **infinity**, the device sends packets using the RP indefinitely and does not switch over to the SPT. If you enter a specific number of packets, the device does not switch over to using the SPT until it has sent the number of packets you specify using the RP.

Setting the RP advertisement interval

To specify how frequently the candidate RP configured on the device sends candidate RP advertisement messages to the BSR, enter commands such as the following.

```
NetIron(config)# ipv6 router pim
NetIron(config-ipv6-pim-router)# rp-adv-interval 180
Changed RP ADV interval to 180 seconds.
```

To specify how frequently the candidate RP configured on the device sends candidate RP advertisement messages to the BSR for a specified VRF, enter commands such as the following.

```
NetIron(config)# ipv6 router pim vrf blue
NetIron(config-ipv6-pim-router-vrf-blue)# rp-adv-interval 180
Changed RP ADV interval to 180 seconds.
```

Syntax: **rp-adv-interval** <*seconds*>

The <*seconds* > parameter specifies the number of seconds. The default is 60 seconds.

Route selection precedence for multicast

The **route-precedence** command allows the user to specify a precedence table that dictates how routes are selected for multicast.

NOTE
PIM must be enabled at the global level.

Configuring the route precedence by specifying the route types

The **route-precedence** {mc-non-default mc-default uc-non-default uc-default none} command allows you to control the selection of routes based on the route types. There are four different types of routes:

- Non-default route from the mRTM
- Default route from the mRTM
- Non-default route from the uRTM
- Default route from the uRTM

Using the **route-precedence** command, you may specify an option for all of the precedence levels.

To specify a non-default route from the mRTM, then a non-default route from the uRTM, then a default route from the mRTM, and then a default route from the uRTM, enter commands such as the following.

```
NetIron(config)# ipv6 router pim
NetIron(config-ipv6-pim-router)# route-precedence mc-non-default uc-non-default
mc-default uc-default
```

The **none** option can be used to fill up the precedence table in order to ignore certain types of routes. To use the unicast default route for multicast, enter commands such as the following.

```
NetIron(config)# ipv6 router pim
NetIron(config-ipv6-pim-router)# route-precedence mc-non-default mc-default
uc-non-default none
```

To specify a non-default route from the mRTM, then a non-default route from the uRTM, then a default route from the mRTM, and then a default route from the uRTM for a specified VRF, enter commands such as the following.

```
NetIron(config)# ipv6 router pim vrf blue
NetIron(config-ipv6-pim-router-vrf-blue)# route-precedence mc-non-default
uc-non-default mc-default uc-default
```

The **none** option can be used to fill up the precedence table in order to ignore certain types of routes. To use the unicast default route for multicast for a specified VRF, enter commands such as the following.

```
NetIron(config)# ipv6 router pim vrf blue
NetIron(config-ipv6-pim-router-vrf-blue)# route-precedence mc-non-default
mc-default uc-non-default none
```

Syntax: [**no**] **route-precedence** {**mc-non-default** | **mc-default** | **uc-non-default** | **uc-default** | **none**}

The default value is the **route-precedence mc-non-default mc-default uc-non-default uc-default** command.

Use the **mc-non-default** parameter to specify a multicast non-default route.

Use the **mc-default** parameter to specify a multicast default route.

Use the **uc-non-default p**arameter to specify a unicast non-default route.

Use the **uc-default** parameter to specify a unicast default route.

Use the **none** parameter to ignore certain types of routes.

The **no** form of this command removes the configuration.

Changing the PIM Join and Prune message interval

By default, the device sends PIM Sparse Join or Prune messages every 60 seconds. These messages inform other PIM Sparse routers about clients who want to become receivers (Join) or stop being receivers (Prune) for PIM Sparse groups.

NOTE
Use the same Join or Prune message interval on all the PIM Sparse routers in the PIM Sparse domain. If the routers do not all use the same timer interval, the performance of PIM Sparse can be adversely affected.

To change the Join or Prune interval, enter commands such as the following.

```
NetIron(config)# ipv6 router pim
NetIron(config-ipv6-pim-router)# message-interval 30
```

To change the Join or Prune interval for a specified VRF, enter the commands as shown in the following example.

```
NetIron(config)# ipv6 router pim vrf blue
NetIron(config-ipv6-pim-router-vrf-blue)# message-interval 30
```

Syntax: [**no**] **message-interval** <*seconds*>

The <*seconds*> parameter specifies the number of seconds and can be from 1 through 65535 seconds. The default is 60 seconds.

Modifying neighbor timeout

Neighbor timeout is the interval after which a PIM router will consider a neighbor to be absent. If the timer expires before receiving a new hello message, the PIM router will time out the neighbor.

To apply an IPv6 PIM neighbor timeout value of 33 seconds to all ports on the router operating with PIM, enter the commands such as the following.

```
NetIron(config)# ipv6 router pim
NetIron(config-ipv6-pim-router)# nbr-timeout 33
```

To apply an IPv6 PIM neighbor timeout value of 33 seconds for a specified VRF operating with PIM, enter the commands such as the following.

```
NetIron(config)# ipv6 router pim vrf blue
NetIron(config-ipv6-pim-router-vrf-blue)# nbr-timeout 33
```

Syntax: [**no**] **nbr-timeout** <*seconds*>

The <*seconds*> parameter specifies the number of seconds. The valid range is from 35 through 65535 seconds.

Setting the prune wait interval

The **prune-wait** command allows you to set the amount of time the PIM router should wait for a join override before pruning an Outgoing Interface List Optimization (OIF) from the entry.

To change the default join override time to 2 seconds, enter commands such as the following.

```
NetIron(config)# ipv6 router pim
NetIron(config-ipv6-pim-router)# prune-wait 2
```

To change the default join override time to 2 seconds for a specified VRF, enter commands such as the following.

```
NetIron(config)# ipv6 router pim vrf blue
NetIron(config-ipv6-pim-router-vrf-blue)# prune-wait 2
```

Syntax: [**no**] **prune-wait** <*seconds*>

The <*seconds*> parameter specifies the number of seconds. The valid range is from 0 through 30 seconds. The default is 3 seconds.

Setting the register suppress interval

The **register-suppress-time** command allows you to set the amount of time the PIM router uses to periodically trigger the NULL register message.

NOTE
The register suppress time configuration applies only to the first hop PIM router.

To change the default register suppress time to 90 seconds, enter commands such as the following:

```
NetIron(config)# ipv6 router pim
NetIron(config-ipv6-pim-router)# register-suppress-time 90
```

To change the default register suppress time to 90 seconds for a specified VRF, enter commands such as the following:

```
NetIron(config)# ipv6 router pim vrf blue
NetIron(config-ipv6-pim-router-vrf-blue)# register-suppress-time 90
```

Syntax: [**no**] **register-suppress-time** <*seconds*>

The <*seconds*> parameter specifies the number of seconds. The valid range is from 60 through 120 seconds. The default is 60 seconds.

Setting the register probe time

The **register-probe-time** command allows you to set the amount of time the PIM router waits for a register-stop from an RP before it generates another NULL register to the PIM RP. The register probe time configuration applies only to the first hop PIM router.

NOTE
Once a PIM first hop router successfully registers with a PIM RP, the PIM first hop router will not default back to the data registration. All subsequent registers will be in the form of the NULL registration.

To change the default register probe time to 20 seconds, enter commands such as following.

```
NetIron(config)# ipv6 router pim
NetIron(config-ipv6-pim-router)# register-probe-time 20
```

To change the default register probe time to 20 seconds for a specified VRF, enter commands such as the following.

```
NetIron(config)# ipv6 router pim vrf blue
NetIron(config-ipv6-pim-router-vrf-blue)# register-probe-time 20
```

Syntax: [**no**] **register-probe-time** <*seconds*>

The <*seconds*> parameter specifies the number of seconds. The valid range is from 10 through 50 seconds. The default is 10 seconds.

Setting the inactivity timer

The router deletes a forwarding entry if the entry is not used to send multicast packets. The IPv6 PIM inactivity timer defines how long a forwarding entry can remain unused before the router deletes it.

To apply an IPv6 PIM inactivity timer of 160 seconds to all IPv6 PIM interfaces, enter the following.

```
NetIron(config)# ipv6 router pim
NetIron(config-ipv6-pim-router)# inactivity-timer 160
```

To apply an IPv6 PIM inactivity timer of 160 seconds for a specified VRF, enter the commands as shown in the following example.

```
NetIron(config)# ipv6 router pim vrf blue
NetIron(config-ipv6-pim-router-vrf-blue)# inactivity-timer 160
```

Syntax: [**no**] **inactivity-timer** <*seconds*>

The <*seconds*> parameter specifies the number of seconds. The valid range is 60 through 3600 seconds. The default is 180 seconds.

Changing the hello timer

The hello timer defines the interval at which periodic hellos are sent out to PIM interfaces. Routers use hello messages to inform neighboring routers of their presence. To change the hello timer, enter a command such as the following.

```
NetIron(config)# ipv6 router pim
NetIron(config-ipv6-pim-router)# hello-timer 62
```

To change the hello timer for a specified VRF, enter the commands as shown in the following example.

```
NetIron(config)# ipv6 router pim vrf blue
NetIron(config-ipv6-pim-router-vrf-blue)# hello-timer 62
```

Syntax: [**no**] **hello-timer** <*seconds*>

The <*seconds*> parameter specifies the number of seconds. The valid range is 10 through 3600 seconds. The default is 60 seconds.

Enabling Source-specific Multicast

Using the Any-Source Multicast (ASM) service model, sources and receivers register with a multicast address. The protocol uses regular messages to maintain a correctly configured broadcast network where all sources can send data to all receivers and all receivers get broadcasts from all sources.

With Source-specific Multicast (SSM), the “channel” concept is introduced where a “channel” consists of a single source and multiple receivers that specifically register to get broadcasts from that source. Consequently, receivers are not burdened with receiving data they have no interest in, and network bandwidth requirements are reduced because the broadcast need only go to a subset of users. The address range ff30:/12 has been assigned by the Internet Assigned Numbers Authority (IANA) for use with SSM.

SSM simplifies IPv6 PIM-SM by eliminating the RP and all protocols related to the RP.

Configuring Source-specific Multicast

IPv6 PIM-SM must be enabled on any ports on which you want SSM to operate. Enter the **ssm-enable** command under the IPv6 router PIM level to globally enable SSM filtering.

```
NetIron(config)# ipv6 router pim
NetIron(config-ipv6-pim-router)# ssm-enable ff02::200:2
```

To enable SSM for a specified VRF, enter the commands as shown in the following.

```
NetIron(config)# ipv6 router pim vrf blue
NetIron(config-ipv6-pim-router-vrf-blue)# ssm-enable ff02::200:2
```

Syntax: [**no**] **ssm-enable** [**range** <*address-range*>]

The **range** <*address-range*> option allows you to define the SSM range of IPv6 multicast addresses.

Modifying the Hop-Limit threshold

The Time To Live (TTL) defines the minimum value required in a packet in order for the packet to be forwarded out the interface. For example, if the Hop-Limit for an interface is set at 10, it means that only those packets that ingress with a TTL value of 11 or more will be forwarded out the TTL-10 interface. Thus, with a default Hop-Limit threshold of 1, only packets ingressing with a Hop-Limit of 2 or greater will be forwarded out. Note that the Hop-Limit threshold only applies to routed interfaces. Switched interfaces ignore the Hop-Limit threshold. Possible Hop-Limit values are from 1 through 64. The default Hop-Limit value is 1. To configure a Hop-Limit of 45, enter the following command.

```
NetIron(config-if-e10000-3/24)# ipv6 pim ttl-threshold 45
```

To configure a Hop-Limit of 45 on a virtual Ethernet interface, enter the following commands.

```
NetIron(config)# interface ve 10
NetIron(config-vif-10)# ipv6 pim ttl-threshold 45
```

Syntax: ipv6 pim ttl-threshold <1-64>

Configuring a DR priority

The DR priority option lets a network administrator give preference to a particular router in the DR election process by giving it a numerically higher DR priority. To set a DR priority higher than the default value of 1, use the **ipv6 pim dr-priority** command as shown in the example below.

```
NetIron(config-if-e10000-3/24)# ipv6 pim dr-priority 50
```

To set a DR priority higher than the default value of 1 on a virtual Ethernet interface, use the **ipv6 pim dr-priority** command as shown in the following.

```
NetIron(config)# interface ve 10
```

```
NetIron(config-vif-10)# ipv6 pim dr-priority 50
```

Syntax: [**no**] **ipv6 pim dr-priority** <*priority-value*>

The <*priority-value*> variable is the value that you want to set for the DR priority. The range of values is from 0 through 65535. The default value is 1.

The **no** option removes the command and sets the DR priority back to the default value of 1.

The following information may be useful for troubleshooting:

- If more than one router has the same DR priority on a subnet (as in the case of default DR priority on all), the router with the numerically highest IP address on that subnet will get elected as the DR.
- The DR priority information is used in the DR election *only if all* the PIM routers connected to the subnet support the DR priority option. If there is at least one PIM router on the subnet that does not support this option, then the DR election falls back to the backwards compatibility mode in which the router with the numerically highest IP address on the subnet is declared the DR regardless of the DR priority values.

Passive Multicast Route Insertion

To prevent unwanted multicast traffic from being sent to the CPU, IPv6 PIM routing and Passive Multicast Route Insertion (PMRI) can be used together to ensure that multicast streams are only forwarded out ports with interested receivers and unwanted traffic is dropped in hardware on Layer 3 routers.

PMRI enables a Layer 3 switch running IPv6 PIM Sparse to create an entry for a multicast route (for example, (S,G)), with no directly attached clients or when connected to another PIM router (transit network).

When a multicast stream has no output interfaces, the Layer 3 switch can drop packets in hardware if the multicast traffic meets the following conditions in IPv6 PIM-SM.

- The route has no OIF.
- The directly connected source passes source RPF check and completes data registration with the RP, or the non-directly connected source passes source RPF check.

If the OIF is inserted after the hardware-drop entries are installed, the hardware entries will be updated to include the OIFs.

NOTE
Disabling hardware-drop does not immediately take away existing hardware-drop entries, they will go through the normal route aging processing when the traffic stops.

Configuring PMRI

PMRI is enabled by default. To disable PMRI, enter the following commands.

```
NetIron(config)# ipv6 router pim
NetIron(config-ipv6-pim-router)# hardware-drop-disable
```

To disable PMRI for a specified VRF, enter the commands as shown in the following example.

```
NetIron(config)# ipv6 router pim vrf blue
NetIron(config-ipv6-pim-router-vrf-blue)# hardware-drop-disable
```

Syntax: [**no**] **hardware-drop-disable**

Displaying hardware-drop

Use the **show ipv6 pim sparse** command to display if the hardware-drop feature has been enabled or disabled.

```
NetIron# show ipv6 pim sparse
Global PIM Sparse Mode Settings
  Hello interval        : 30          Neighbor timeout                    : 105
  Bootstrap Msg interval: 60          Candidate-RP Advertisement interval: 60
  Join/Prune interval   : 60          SPT Threshold                       : 1
  SSM Enabled: Yes
  SSM Group Range: ff30::/12
  Hardware Drop Enabled : Yes
```

Displaying PIM Sparse configuration information and statistics

You can display the following PIM Sparse information:

- Basic PIM Sparse configuration information
- IPv6 interface information
- Group information
- BSR information
- Candidate RP information
- RP-to-group mappings
- RP information for an IPv6 PIM Sparse group
- RP set list
- Multicast neighbor information
- The IPv6 PIM multicast cache
- IPv6 PIM RPF
- IPv6 PIM counters
- IPv6 PIM resources
- IPv6 PIM traffic statistics

Displaying basic PIM Sparse configuration information

To display IPv6 PIM Sparse configuration information, enter the **show ipv6 pim sparse** command at any CLI level.

```
NetIron# show ipv6 pim sparse
Global PIM Sparse Mode Settings
  Hello interval            : 30       Neighbor timeout                    : 105
  Bootstrap Msg interval    : 60       Candidate-RP Advertisement interval: 60
  Register Suppress interval: 60       Register Stop Delay                 : 60
  Join/Prune interval       : 60       SPT Threshold                       : 1
  Inactivity interval       : 180      Hardware Drop Enabled               : Yes
  SSM Enabled               : Yes
```

Syntax: show ipv6 pim [**vrf** <*vrf-name*>] **sparse**

The **vrf** parameter allows you to configure IPv6 PIM on the virtual routing instance (VRF) specified by the <*vrf-name*> variable.

Table 369 displays the output from the **show ipv6 pim sparse** command.

TABLE 369 Output from the **show ipv6 pim sparse** command

Field	Description
Global PIM Sparse mode settings	
Hello interval	How frequently the device sends IPv6 PIM Sparse hello messages to its IPv6 PIM Sparse neighbors. This field shows the number of seconds between hello messages. IPv6 PIM Sparse routers use hello messages to discover one another.
Neighbor timeout	How many seconds the device will wait for a hello message from a neighbor before determining that the neighbor is no longer present and removing cached IPv6 PIM Sparse forwarding entries for the neighbor.
Bootstrap Msg interval	How frequently the BSR configured on the device sends the RP set to the RPs within the IPv6 PIM Sparse domain. The RP set is a list of candidate RPs and their group prefixes. The group prefix of a candidate RP indicates the range of IPv6 PIM Sparse group numbers for which it can be an RP. **NOTE:** This field contains a value only if an interface on the device is elected to be the BSR. Otherwise, the field is blank.
Candidate-RP Advertisement interval	How frequently the candidate PR configured on the device sends candidate RP advertisement messages to the BSR. **NOTE:** This field contains a value only if an interface on the device is configured as a candidate RP. Otherwise, the field is blank.
Join or Prune interval	How frequently the device sends IPv6 PIM Sparse Join or Prune messages for the multicast groups it is forwarding. This field shows the number of seconds between Join or Prune messages. The device sends Join or Prune messages on behalf of multicast receivers that want to join or leave an IPv6 PIM Sparse group. When forwarding packets from IPv6 PIM Sparse sources, the device sends the packets only on the interfaces on which it has received join requests in Join or Prune messages for the source group.
SPT Threshold	The number of packets the device sends using the path through the RP before switching to using the SPT path.
Inactivity Interval	How long a forwarding entry can remain unused before the router deletes it.
SSM Enabled	If yes, source-specific multicast is configured globally on this router.
IPv6 PIM Sparse interface information **NOTE:** You also can display IPv6 multicast interface information using the **show ipv6 pim interface** command.	
Interface	The type of interface and the interface number. The interface type can be one of the following: • Ethernet • VE The number is either a port number (and slot number if applicable) or the virtual interface (VE) number.

TABLE 369 Output from the **show ipv6 pim sparse** command (Continued)

Field	Description
TTL Threshold	Following the TTL threshold value, the interface state is listed. The interface state can be one of the following: • Disabled • Enabled
Local Address	Indicates the IP address configured on the port or virtual interface.

Displaying IPv6 PIM interface information

You can display IPv6 PIM multicast interface information using the **show ipv6 pim interface** command.

```
NetIron# show ipv6 pim
Interface v30
  PIM Version : V2 MODE : PIM SM
  TTL Threshold: 1, Enabled
  DR: fe80::20c:dbff:fef6:a00 on e3/2
  Link Local Address: fe80::20c:dbff:fef5:e900
  Global Address: 1e1e::4

Interface v167
  PIM Version : V2 MODE : PIM SM
  TTL Threshold: 1, Enabled
  DR: itself
  Link Local Address: fe80::20c:dbff:fef5:e900
  Global Address: a7a7::1
Interface l1
  PIM Version : V2 MODE : PIM SM
  TTL Threshold: 1, Enabled
  DR: itself
  Link Local Address: fe80::20c:dbff:fef5:e900
  Global Address: 8c8c::4
```

To display IPv6 PIM multicast interface information for a specified VRF, enter the following command as shown in the example.

```
NetIron# show ipv6 pim vrf2 interface

---------+-------------------------------------------------+----+---+---+---------+-------+------
Interface|Global Address                                    |Ver |St |TTL|Multicast|  VRF  | DR
         |  + Designated Router                         Port |    |   |Thr|Boundary |       | Prio
---------+-------------------------------------------------+----+---+---+---------+-------+------
     e3/6 101::1                                           SMv2 Ena   1 None      vrf2    1
          + Itself
    e3/16 102::1                                           SMv2 Ena   1 None      vrf2    1
          + Itself
       l1 100::1                                           SMv2 Ena   1 None      vrf2    1
          + Itself
```

Syntax: **show ipv6 pim** [**vrf** <*vrf-name*>] **interface** [**ethernet** <*slot/port*> | **loopback** <*number*> |**pos** <*slot/port*> | **ve** <*number*>]

The **vrf** parameter allows you to display IPv6 multicast interface information for the VRF instance identified by the <*vrf-name*> variable.

The **ethernet** <*slot*>/<*portnum*> | **loopback** <*num*> | **ve** <*num*> parameter specifies the IPv6 PIM multicast interface.

- Enter **ethernet** <*slot*>/<*portnum*> for a physical interface (port).
- Enter **loopback** <*num*> for a loopback interface.
- Enter **ve** <*num*> for a virtual interface.
- Enter **pos** <*slot/portnum*> specifies the individual POS interface described by the <slot/port> variable.

Displaying a list of multicast groups

To display IPv6 PIM group information, enter the **show ipv6 pim group** command at any CLI level.

```
NetIron# show ipv6 pim group
Total number of groups: 1
1    Group ff7e:a40:2001:3e8:27:0:1:2  Ports
     Group member at  e3/1: v31
```

Syntax: show ipv6 pim [**vrf** <*vrf-name*>] **group**

The **vrf** parameter allows you to display IPv6 PIM group information for the VRF instance identified by the <*vrf-name*> variable.

Table displays the output from the **show ipv6 pim group** command.

TABLE 370 Output from the **show ipv6 pim group** command

Field	Description
Total number of Groups	Lists the total number of IPv6 multicast groups the device is forwarding.
Group	The multicast group address.
Ports	The device ports connected to the receivers of the groups.

Displaying BSR information

To display information on a device that has been elected as the BSR, enter the **show ipv6 pim bsr** command at the CLI level.

```
NetIron# show ipv6 pim bsr
PIMv2 Bootstrap information

This system is the elected Bootstrap Router (BSR)
  BSR address: 2001:3e8:255:255::17
  Uptime: 00:12:09, BSR priority: 0, Hash mask length: 126
  Next bootstrap message in 00:00:30

Next Candidate-RP-advertisment in 00:00:30
  RP: 2001:3e8:255:255::17
    group prefixes:
    ff00:: / 8

  Candidate-RP-advertisement period: 60
```

The following example shows information displayed on a device that is not the BSR. Notice that some fields shown in the previous example do not appear in the following example.

```
NetIron# show ipv6 pim bsr
PIMv2 Bootstrap information
 BSR address  = 2001:3e8:255:255::17
 BSR priority = 0
```

Syntax: show ipv6 pim [**vrf** <*vrf-name*>] **bsr**

The **vrf** parameter allows you to display IPv6 PIM BSR information for the VRF instance identified by the <*vrf-name*> variable.

Table displays the output from the **show ipv6 pim bsr** command.

TABLE 371 Output from the **show ipv6 pim bsr** command

Field	Description
BSR address	The IPv6 address of the interface configured as the IPv6 PIM Sparse Bootstrap Router (BSR).
Uptime	The amount of time the BSR has been running. **NOTE:** This field appears only if this device is the BSR.
BSR priority	The priority assigned to the interface for use during the BSR election process. During BSR election, the priorities of the candidate BSRs are compared and the interface with the highest BSR priority becomes the BSR.
Hash mask length	The number of significant bits in the IPv6 multicast group comparison mask. This mask determines the IPv6 multicast group numbers for which the device can be a BSR. The default is 32 bits, which allows the device to be a BSR for any valid IPv6 multicast group number. **NOTE:** This field appears only if this device is a candidate BSR.
Next bootstrap message in	Indicates how many seconds will pass before the BSR sends its next Bootstrap message. **NOTE:** This field appears only if this device is the BSR.
Next Candidate-RP-advertisement message in	Indicates how many seconds will pass before the BSR sends its next candidate RP advertisement message. **NOTE:** This field appears only if this device is a candidate BSR.
RP	Indicates the IPv6 address of the Rendezvous Point (RP). **NOTE:** This field appears only if this device is a candidate BSR.
group prefixes	Indicates the multicast groups for which the RP listed by the previous field is a candidate RP. **NOTE:** This field appears only if this device is a candidate BSR.
Candidate-RP-advertisement period	Indicates how frequently the BSR sends candidate RP advertisement messages. **NOTE:** This field appears only if this device is a candidate BSR.

Displaying candidate RP information

To display candidate RP information, enter the **show ipv6 rp-candidate** command at any CLI level.

```
NetIron# show ipv6 pim rp-candidate

Next Candidate-RP-advertisement in 00:00:10
  RP: 1be::11:21
    group prefixes:
    ff00:: / 8

  Candidate-RP-advertisement period: 60
```

This example shows information displayed on a device that is a candidate RP. The following example shows the message displayed on a device that is not a candidate RP.

```
NetIron# show ipv6 pim rp-candidate

This system is not a Candidate-RP.
```

Syntax: show ipv6 pim [**vrf** <*vrf-name*>] **rp-candidate**

The **vrf** parameter allows you to display IPv6 candidate RP information for the VRF instance identified by the <*vrf-name*> variable.

Table displays the output from the **show ipv6 pim rp-candidate** command.

TABLE 372 Output from the **show ipv6 pim rp-candidate** command

Field	Description
Candidate-RP-advertisement in	Indicates how many seconds will pass before the BSR sends its next RP message. **NOTE:** This field appears only if this device is a candidate RP.
RP	Indicates the IPv6 address of the Rendezvous Point (RP). **NOTE:** This field appears only if this device is a candidate RP.
group prefixes	Indicates the multicast groups for which the RP listed by the previous field is a candidate RP. **NOTE:** This field appears only if this device is a candidate RP.
Candidate-RP-advertisement period	Indicates how frequently the BSR sends candidate RP advertisement messages. **NOTE:** This field appears only if this device is a candidate RP.

Displaying RP-to-group mappings

To display RP-to-group-mappings, enter the **show ipv6 pim rp-map** command at any CLI level.

```
NetIron# show ipv6 pim rp-map
Idx Group address                          RP address

  1ff1e::1:2 2001:3e8:255:255::17
  2              ff7e:a40:2001:3e8:27:0:1:2 2001:3e8:27::a
  3              ff7e:140:2001:3e8:16:0:1:2 2001:3e8:16::1
```

Syntax: show ipv6 pim [**vrf** <*vrf-name*>] **rp-map**

The **vrf** parameter allows you to display IPv6 RP-to-group-mappings for the VRF instance identified by the <*vrf-name*> variable.

Table displays the output from the **show ipv6 rp-map** command.

TABLE 373 Output from the show ipv6 pim rp-map command

Field	Description
Index	The index number of the table entry in the display.
Group address	Indicates the IPv6 PIM Sparse multicast group address using the listed RP.
RP address	Indicates the Iv6 address of the Rendezvous Point (RP) for the listed PIM Sparse group.

Displaying RP information for an IPv6 PIM Sparse group

To display RP information for an IPv6 PIM Sparse group, enter the following command at any CLI level.

```
NetIron# show ipv6 pim rp-hash ff1e::1:2
  RP: 2001:3e8:255:255::17, v2
    Info source: 2001:3e8:255:255::17, via bootstrap
```

Syntax: show ipv6 pim [**vrf** <*vrf-name*>] **rp-hash** <*group-addr*>

The **vrf** parameter allows you to display RP information for a PIM Sparse group for the VRF instance identified by the <*vrf-name*> variable.

The <*group-addr*> parameter is the address of an IPv6 PIM Sparse IP multicast group.

Table 374 displays the output from the **show ipv6 pim rp-hash** <*group-addr*> command.

Output from the show ipv6 pin rp-hash <group-addr> command

TABLE 374 Output from the **show ipv6 pin rp-hash** <*group-addr*> command

Field	Description
RP	Indicates the IPv6 address of the Rendezvous Point (RP) for the specified IPv6 PIM Sparse group. Following the IPv6 address is the port or virtual interface through which this device learned the identity of the RP.
Info source	Indicates the IPv6 address on which the RP information was received. Following the IPv6 address is the method through which this device learned the identity of the RP.

Displaying the RP set list

To display the RP set list, enter the **show ipv6 pim rp-set** command at any CLI level.

```
NetIron# show ipv6 pim rp-set
Static RP
---------
Static RP count: 1
100::1
Number of group prefixes Learnt from BSR: 0
No RP-Set present
```

Syntax: show ipv6 pim [**vrf** <*vrf-name*>] **rp-set**

The **vrf** parameter allows you to display the RP set for the VRF instance identified by the <*vrf-name*> variable.

Table displays the output from the **show ipv6 pim rp-set** command.

TABLE 375 Output from the **show ipv6 pim rp-set** command

Field	Description
Number of group prefixes	The number of IPv6 PIM Sparse group prefixes for which the RP is responsible.
Group prefix	Indicates the multicast groups for which the RP listed by the previous field is a candidate RP.
RPs expected or received	Indicates how many RPs were expected and received in the latest Bootstrap message.
RP <*num*>	Indicates the RP number. If there are multiple RPs in the IPv6 PIM Sparse domain, a line of information for each of them is listed, and they are numbered in ascending numerical order.
priority	The RP priority of the candidate RP. During the election process, the candidate RP with the highest priority is elected as the RP.
age	The age (in seconds) of this RP-set. **NOTE:** If this device is not a BSR, this field contains zero. Only the BSR ages the RP-set.

Displaying multicast neighbor information

To display information about IPv6 PIM neighbors, enter the **show ipv6 pim neighbor** command at any CLI level.

```
NetIron# show ipv6 pim neighbor
Port Phy_Port Neighbor                              Holdtime Age   UpTime Priority
                                                    sec      sec   sec
e11/15 e11/15 fe80::45:27:49:4                      105       20    1010   1
v312   e11/3  fe80::45:27:1:2                       105       10    1900   40
```

Syntax: show ipv6 pim [**vrf** <*vrf-name*>] **neighbor**

The **vrf** parameter allows you to display the IPv6 PIM neighbors for the VRF instance identified by the <*vrf-name*> variable.

Table 376 displays the output from the **show ipv6 pim neighbor** command.

TABLE 376 Output from the **show ipv6 pim neighbor** command

Field	Description
Port	The interface through which the device is connected to the neighbor.
Neighbor	The IPv6 interface of the IPv6 PIM neighbor interface.
Holdtime sec	Indicates how many seconds the neighbor wants this device to hold the entry for this neighbor in memory. The neighbor sends the Hold Time in its hello packets. • If the device receives a new hello packet before the Hold Time received in the previous packet expires, the device updates its table entry for the neighbor. • If the device does not receive a new hello packet from the neighbor before the Hold time expires, the device assumes the neighbor is no longer available and removes the entry for the neighbor.
Age sec	The number of seconds since the device received the last hello message from the neighbor.

TABLE 376 Output from the **show ipv6 pim neighbor** command (Continued)

Field	Description
UpTime sec	The number of seconds the PIM neighbor has been up. This timer starts when the device receives the first hello messages from the neighbor.
Priority	The DR priority that is used in the DR election process. This can be a configured value or the default value of 1.

Displaying the IPv6 PIM multicast cache

To display the IPv6 PIM multicast cache, enter the **show ipv6 pim mcache** command at any CLI level.

```
NetIron# show ipv6 pim mcache
Total 4 entries
Free mll entries: 766
1    (*, ff7e:140:2001:3e8:16:0:1:2) RP2001:3e8:16::1 in NIL, cnt=0

     Flags fast=1 slow=0 leaf=0 prun=0 frag=0 tag=0 needRte=0
     age=0 fid: 0406, mvid    312

Total number of mcache entries 4
```

Syntax: show ipv6 pim [**vrf** <*vrf-name*>] **mcache**

The **vrf** parameter allows you to display the IPv6 PIM multicast cache for the VRF instance identified by the <*vrf-name*> variable.

Displaying IPv6 PIM RPF

The **show ipv6 pim rpf** command displays what PIM sees as the reverse path to the source. While there may be multiple routes back to the source, the one displayed by the **show ipv6 pim rpf** command is the one that PIM thinks is best.

```
NetIron# show ipv6 pim vrf eng rpf 130.50.11.10
Source 130.50.11.10 directly connected on e4/1
```

Syntax: show ipv6 pim [**vrf** <*vrf-name*>] **rpf** <*ip-address*>

The **vrf** parameter allows you to display what PIM sees as the reverse path to the source for a VRF instance specified by the <*vrf-name*> variable.

The <*ip-address*> variable specifies the source address for RPF check.

Displaying IPv6 PIM counters

You can display the number of default-vlan-id changes that have occurred since the applicable VRF was created and how many times a tagged port was placed in a VLAN since the applicable VRF was created, as shown in the following example.

```
NetIron(config)# show ipv6 pim vrf eng counter
Event Callback:
   DFTVlanChange   :          0               VlanPort       :           2

LP to MP IPCs:
   SM_REGISTER    :           0               MCAST_CREATE     :          31
   S_G_AGEOUT      :          4               WRONG_IF       :           0
   ABOVE_THRESHOLD :          0               MCAST_FIRST_DATA :          31
```

Syntax: show ipv6 pim [**vrf** <*vrf-name*>] **counter**

The **vrf** parameter allows you to display IPv6 PIM counters for the VRF instance identified by the <*vrf-name*> variable.

Table displays the output from the **show ipv6 vrf eng counter** command.

TABLE 377 Output from the **show ipv6 pim vrf eng counter** command

Field	Description
DFTVlanChange	The number of default-vlan-id changes that have occurred since the applicable VRF was created.
VlanPort	The number of times that a tagged port was placed in a VLAN since the applicable VRF was created.

Displaying the IPv6 PIM resources

To display the hardware resource information, such as hardware allocation, availability, and limit for software data structure, enter the **show ipv6 pim resource** command.

```
NetIron# show ipv6 pim resource
                        allocated    in-use available allo-fail  up-limit
NBR list                   64         1        63         0       512
Static RP                  64         0        64         0        64
Anycast RP                 64         0        64         0        64
timer                      64         0        64         0  no-limit
prune                      32         0        32         0  no-limit
pimsm J/P elem          12240         0     12240         0     48960
pimsm OIF                  64        60         4         0  no-limit
mcache                     64        60         4         0  no-limit

graft if no mcache        197         0       197         0  no-limit
groups                     64         0        64         0  no-limit
group-memberships          64         0        64         0  no-limit
sources                   256         0       256         0  no-limit
client sources            256         0       256         0  no-limit
pim/dvm intf. group        64         0        64         0  no-limit
pim/dvm global group       64         0        64         0  no-limit
MLD Resources:
  groups                   64         0        64         0  no-limit
  phy-ports                64         0        64         0  no-limit
  exist-phy-port          256         0       256         0  no-limit
group-query              256         0       256         0  no-limit
  group-query              256         0       256         0  no-limit
Hardware-related Resources:
HW MVID: 0 allocated for MCAST6 of total allocated 1
Total (S,G) entries 30
Total SW FWD entries 0
  Total sw w/Tag MVID entries 0
```

Syntax: show ipv6 pim [**vrf** <*vrf-name*>] **resource**

The **vrf** parameter allows you to display IPv6 hardware resource information for the VRF instance identified by the <*vrf-name*> variable.

Table 378 displays the output from the **show ipv6 pim resource** command.

TABLE 378 Output from the **show ipv6 pim resource** command

Field	Description
alloc	Number of nodes of that data that are currently allocated in memory.
in-use	Number of allocated nodes in use.
avail	Number of allocated nodes are not in use.
allo-fail	Number of allocated notes that failed.
up-limit	Maximum number of nodes that can be allocated for a data structure. This may or may not be configurable, depending on the data structure

Displaying PIM traffic statistics

To display IPv6 PIM traffic statistics, enter the **show ipv6 pim traffic** command at any CLI level.

```
NetIron# show ipv6 pim traffic
Port    Hello           Join          Prune          Assert
     [Rx     Tx]    [Rx     Tx]    [Rx     Tx]    [Rx     Tx]
MLD Statistics:
  Total Recv/Xmit 356/161
  Total Discard/chksum  0/0
```

Syntax: show ipv6 pim [**vrf** <*vrf-name*>] **traffic**

The **vrf** parameter allows you to display IPv6 traffic statistics for the VRF instance identified by the <*vrf-name*> variable.

Table displays the output from the **show ipv6 pim traffic** command.

TABLE 379 Output from the **show ipv6 pim traffic** command

Field	Description
Port	The port or virtual interface on which the IPv6 PIM interface is configured.
Hello	The number of IPv6 PIM Hello messages sent or received on the interface.
J or P	The number of Join or Prune messages sent or received on the interface. **NOTE:** Unlike PIM dense, PIM Sparse uses the same messages for Joins and Prunes.
Register	The number of Register messages sent or received on the interface.
RegStop	The number of Register Stop messages sent or received on the interface.
Assert	The number of Assert messages sent or received on the interface.
Total Recv or Xmit	The total number of IGMP messages sent and received by the device.
Total Discard or chksum	The total number of IGMP messages discarded, including a separate counter for those that failed the checksum comparison.

Clearing the IPv6 PIM forwarding cache

You can clear the IPv6 PIM forwarding cache using the **clear ipv6 pim cache** command.

```
NetIron# clear ipv6 pim cache
```

Syntax: clear ipv6 pim [**vrf** <*vrf-name*>] **cache**

Use the **vrf** parameter to clear the IPv6 PIM forwarding cache for a VRF instance specified by the <*vrf-name*> variable.

Clearing the IPv6 PIM message counters

You can clear the IPv6 PIM message counters using the **clear ipv6 pim counters** command.

```
NetIron# clear ipv6 pim counters
```

Syntax: clear ipv6 pim [**vrf** <*vrf-name*>] **counters**

Use the **vrf** parameter to clear the IPv6 PIM message counters for a VRF instance specified by the <*vrf-name*> variable.

Updating PIM Sparse forwarding entries with a new RP configuration

If you make changes to your static RP configuration, the entries in the IPv6 PIM Sparse multicast forwarding table continue to use the old RP configuration until they are aged out.

The **clear IPv6 pim rp-map** command allows you to update the entries in the static multicast forwarding table immediately after making RP configuration changes. This command is meant to be used with **rp-address** command.

To update the entries in an IPv6 PIM Sparse static multicast forwarding table with a new RP configuration, enter the **clear ipv6 pim rp-map** command at the privileged EXEC level of the CLI.

```
NetIron(config)# clear ipv6 pim rp-map
```

Syntax: clear ipv6 pim [**vrf** <*vrf-name*>] **rp-map**

Use the **vrf** parameter to clear the IPv6 PIM Sparse static multicast forwarding table for a VRF instance specified by the <*vrf-name*> variable.

Clearing the IPv6 PIM traffic

To clear counters on IPv6 PIM traffic, enter the **clear ipv6 pim traffic** command.

```
NetIron# clear ipv6 pim traffic
```

Syntax: clear ipv6 pim [**vrf** <*vrf-name*>] **traffic**

Use the **vrf** par meter to clear counters on IPv6 PIM traffic for a VRF instance specified by the <*vrf-name*> variable.

Setting the maximum number of IPv6 multicast routes supported

You can use the **ipv6 max-mroute** command to define the maximum number of IPv6 multicast routes supported. The default VRF is defined using the **ipv6 max-mroute** command.

```
NetIron(config)# ipv6 router pim
NetIron(config-ipv6-pim-router)# ipv6 max-mroute
```

Syntax: [**no**] **ipv6 max-mroute** <*num*>

The <*num*> parameter specifies the maximum number of IPv6 multicast routes. If not defined by this command, the maximum value is determined by available system resources.

To define the maximum number of IPv6 multicast routes for a specified VRF, use the following commands.

```
NetIron(config)# ipv6 router pim vrf blue
NetIron(config-ipv6-pim-router-vrf-blue)# ipv6 max-mroute
```

Syntax: [**no**] **ipv6 router pim** [**vrf** <*vrf-name*>]

The **vrf** parameter specified with the **IPv6 router pim** command allows you to configure the **ipv6 max-mroute** command for a virtual routing instance (VRF) specified by the variable <*vrf-name*>.

Defining the maximum number of IPv6 PIM cache entries

You can use the **max-mcache** command to define the maximum number of repeated PIM traffic being sent from the same source address and being received by the same destination address. To define the maximum for the default VRF, enter the **max-mcache** command.

```
NetIron(config)# ipv6 router pim
NetIron(config-ipv6-pim-router)# max-mcache 999
```

Syntax: [**no**] **max-mcache** <*num*>

The <*num*> variable specifies the maximum number of IPv6 multicast cache entries for PIM in the default VRF. The maximum value and the default value that can be entered is 4K. If not defined by this command, the maximum value is determined by available system resources.

To define the maximum number of IPv6 PIM Cache entries for a specified VRF, use the following command.

```
NetIron(config)# ipv6 router pim vrf blue
NetIron(config-ipv6-pim-router-vrf-blue)# max-mcache 999
```

Syntax: [**no**] **ipv6 router pim** [**vrf** <*vrf-name*>]

The **vrf** parameter specified with the **IPv6 router pim** command allows you to configure the **max-mcache** command for a virtual routing instance (VRF) specified by the variable <*vrf-name*>.

Defining the maximum number of IPv6 multicast VRF CAM entries for all VRFs

You can use the following run-time command to define the maximum number of IPv6 multicast VRF CAM entries for all non-default VRF instances by entering a command such as the following.

```
NetIron(config-ipv6-pim-router-vrf-blue)# ipv6 multicast-max-all-vrf-cam 3072
```

Syntax: [**no**] **ipv6 multicast-max-all-vrf-cam** <*cam-size*>

The **ipv6 multicast-max-all-vrf-cam** command is configured at the global level. The <*cam-size*> variable specifies the maximum number of multicast VRF CAM entries for all non-default VRF instances. This setting does not affect the default VRF. The maximum possible value is 8000 and the default value is 2048.

Defining the maximum number of IPv6 multicast VRF CAM entries for a specified VRF

You can use the following run-time command to define the maximum number of IPv6 multicast VRF CAM entries for a specified non-default VRF by entering commands such as the following.

```
NetIron(config)# ipv6 router pim vrf blue
NetIron(config-ipv6-pim-router-vrf-blue)# ipv6 multicast-max-cam 3072
```

Syntax: [**no**] **ipv6 router pim** [**vrf** <*vrf-name*>]

Syntax: [**no**] **ipv6 multicast-max-cam** <*cam-size*>

The **vrf** parameter specified with the **IPv6 router pim** command allows you to configure the **ipv6 multicast-max-cam** command for a virtual routing instance (VRF) specified by the variable <*vrf-name*>.

The <*cam-size*> variable specifies the maximum number of IPv6 multicast VRF CAM entries for one or more non-default specified VRFs. This setting can be any number up to the limit set using the **ipv6 multicast-max-all-vrf-cam** command.

PIM Anycast RP

PIM Anycast RP is a method of providing load balancing and fast convergence to PIM RPs in an IPv6 multicast domain. The RP address of the Anycast RP is a shared address used among multiple PIM routers, known as PIM RP. The PIM RP routers create an Anycast RP set. Each router in the Anycast RP set is configured using two IP addresses: a shared RP address in their loopback address and a separate, unique IP address. The loopback address must be reachable by all PIM routers in the multicast domain. The separate, unique IP address is configured to establish static peering with other PIM routers and communication with the peers.

When the source is activated in a PIM Anycast RP domain, the PIM First Hop (FH) will register the source to the closet PIM RP. The PIM RP follows the same MSDP Anycast RP operation by decapsulating the packet and creating the (s,g) state. If there are external peers in the Anycast RP set, the router will re-encapsulate the packet with the local peering address as the source address of the encapsulation. The router will unicast the packet to all Anycast RP peers. The re-encapsulation of the data register packet to Anycast RP peers ensures source state distribution to all RPs in a multicast domain.

Configuring PIM Anycast RP

A new PIM CLI is introduced for PIM Anycast RP under the router pim submode. The PIM CLI specifies mapping of the RP and the Anycast RP peers.

To configure PIM Anycast RP, enter the following commands.

```
NetIron(config)# ipv6 router pim
NetIron(config-ipv6-pim-router)# rp-address 1001::1
NetIron(config-ipv6-pim-router)# anycast-rp 1001::1 my-anycast-rp-set-acl
```

To configure PIM Anycast RP for a specified VRF, enter the commands as shown in the following example.

```
NetIron(config)# ipv6 router pim vrf blue
NetIron(config-ipv6-pim-router-vrf-blue)# rp-address 1001::1
NetIron(config-ipv6-pim-router-vrf-blue)# anycast-rp 1001::1
my-anycast-rp-set-acl
```

Syntax: [**no**] **anycast-rp** <*rp-address*> <*my-anycast-rp-set-acl*>

The <*rp address*> parameter specifies a shared RP address used among multiple PIM routers.

The <*my-anycast-rp-set-acl*> parameter specifies a host-based simple ACL used to specify the address of the Anycast RP set, including a local address.

The following example is a configuration of PIM Anycast RP 1001:1.The example avoids using the loopback 1 interface when configuring PIM Anycast RP because the loopback 1 address could be used as a router-id. A PIM First Hop router will register the source with the closest RP. The first RP that receives the register will re-encapsulate the register to all other Anycast RP peers. Refer to Figure 221 as described in the configuration of PIM Anycast RP 1001:1.

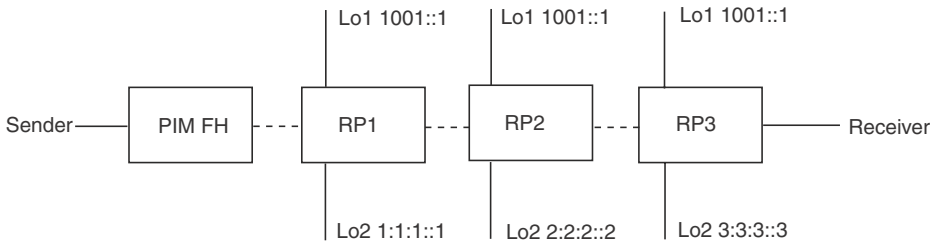
```
NetIron(config)# interface loopback 2
NetIron(config-lbif-2)# ipv address 1001::1/96
NetIron(config-lbif-2)# ipv pim-sparse
NetIron(config-lbif-2)# interface loopback 3
NetIron(config-lbif-3)# ipv address 1:1:1::1/96
NetIron(config-lbif-3)# ipv pim-sparse
NetIron(config-lbif-3)# ipv6 router pim
NetIron(config-ipv6-pim-router)# rp-address 1001::1
NetIron(config-ipv6-pim-router)# anycast-rp 1001::1 my-anycast-rp-set
NetIron(config-ipv6-pim-router)# ipv6 access-list my-anycast-rp-set
NetIron(config-std-nacl)# permit ipv6 host 1:1:1::1 any
NetIron(config-std-nacl)# permit ipv6 host 2:2:2::2 any
NetIron(config-std-nacl)# permit ipv6 host 3:3:3::3 any
```

The RP shared address 1001:1 is used in the PIM domain. IP addresses 1:1:1:1, 2:2:2:2, and 3:3:3:3 are listed in the ACL that forms the self-inclusive Anycast RP set. Multiple Anycast RP instances can be configured on a system; each peer with the same or different Anycast RP set.

NOTE
The PIM Anycast CLI applies to only PIM routers running RP. All deny statements in the anycast_rp_set ACL are ignored.

The example shown in Figure 221 is a PIM Anycast-enabled network with three RPs and one PIM-FH router connecting to its active source and local receiver. Loopback 2 in RP1, RP2, and RP3 each have the same IP addresses 1001:1. Loopback 3 in RP1, RP2, and RP3 each have separate IP address configured to communicate with their peers in the Anycast RP set.

FIGURE 221 Example of a PIM Anycast RP network



Displaying information for an IPv6 PIM Anycast RP interface

To display information for an IPv6 PIM Anycast RP interface, enter the **show ipv6 pim anycast-rp** command.

```
NetIron(config)# show ipv6 pim anycast-rp
Number of Anycast RP: 1
Anycast RP: 1001::1
  ACL ID: 200
  ACL Name: my-anycast-rp-set
  ACL Filter: SET
  Peer List:
   1:1:1::1
   2:2:2::2
   3:3:3::3
```

Syntax: show ipv6 pim [**vrf** <*vrf-name*>] <*anycast-rp*>

The **vrf** parameter allows you to display information for an IPv6 Anycast RP interface for the VRF instance identified by the <*vrf-name*> variable.

Table 380 describes the parameters of the **show ipv6 pim anycast-rp** command.

TABLE 380 Output from the **show ipv6 pim anycast-rp** command

Field	Description
Number of Anycast RP	Specifies the number of Anycast RP sets in the multicast domain.
Anycast RP	Specifies a shared RP address used among multiple PIM routers.
ACL ID	Specifies the ACL ID assigned.
ACL Name	Specifies the name of the Anycast RP set.
ACL Filter	Specifies the ACL filter state SET or UNSET.
Peer List	Specifies host addresses that are permitted in the Anycast RP set.

Multicast Listener Discovery and source-specific multicast protocols

Multicast Listener Discovery Version 2 (MLDv2) protocol is supported. IPv6 routers use the MLDv2 protocol to discover multicast listeners, or nodes that wish to receive multicast packets on directly attached links. MLDv2 supports source filtering, the ability of a node to send reports on traffic that is from a specific address source or from all multicast addresses except the specified address sources. The information is then provided to the source-specific multicast (SSM) routing protocols such as PIM-SSM.

The IPv6 router stores a list of multicast addresses for each attached link. For each multicast address, the IPv6 router stores a filter mode and a source list. The filter mode is set to INCLUDE if all nodes in the source list for a multicast address are in the INCLUDE state. If the filter mode is INCLUDE, then only traffic from the addresses in the source list is allowed. The filter mode is set to EXCLUDE if at least one of the nodes in the source list is in an EXCLUDE state. If the filter mode is EXCLUDE, traffic from nodes in the source list is denied and traffic from other sources is allowed.

The source list and filter mode are created when the IPv6 querier router sends a query. The querier router is the one with the lowest source IPv6 address. It sends out any of the following queries:

- **General query** – The querier sends this query to learn all multicast addresses that need to be listened to on an interface.

- **Address specific query** – The querier sends this query to determine if a specific multicast address has any listeners.
- **Address specific and source specific query** – The querier sends this query to determine if specified sources of a specific multicast address have any listeners.

In response to these queries, multicast listeners send the following reports:

- **Current state** – This report specifies the source list for a multicast address and whether the filter mode for that source list is INCLUDE or EXCLUDE.
- **Filter-mode change** – This report specifies if there has been a change to the filter mode for the source list and provides a new source list.
- **Source list change** – This report specifies the changes to the source list.

MLDv1 is compatible with IGMPv2 and MLDv2 is compatible with IGMPv3.

Enabling MLDv2

MLDv1 is enabled once PIM Sparse Mode (PIM-SM) is enabled on an interface. You then enable version 2 of MLD, the version that supports source filtering.

MLDv2 interoperates with MLDv1. MLDv1 messages are understood by MLDv2. When an IPv6 router detects that the node is operating in MLDv1 mode, the router switches to MLDv1 for that node even though queries are sent in MLDv2.

To enable IPv6 PIM-SM, enter the following command at the interface level.

```
NetIron(config)# ipv6 router pim
NetIron(config-if-e10000-1/1)# ipv6 pim-sparse
```

Syntax: [no] **ipv6 pim-sparse**

Configuring MLD parameters for default and non-default VRFs

MLD allows you to configure the following parameters on default and non-default VRFs:

- Group membership time - "Setting the group membership time" on page 1982
- Max group address - "Defining the maximum number of MLD group addresses" on page 1983
- Max response time - "Setting the maximum response time" on page 1983
- Query interval - "Setting the query interval" on page 1984
- Last listener query count - "Setting the last listener query interval" on page 1984
- Last listener query interval - "Setting the last listener query interval" on page 1984
- Robustness - "Setting the robustness" on page 1984
- Version - "Setting the version" on page 1985

Setting the group membership time

You can set the group membership time for the default VRF or for a specified VRF. Group membership time defines how long a group will remain active on an interface in the absence of a group report. Possible values are from 5 through 26,000 seconds and the default value is 260 seconds.

To define an MLD group membership time of 2000 seconds, enter the following command.

```
NetIron(config)# ipv6 mld group-membership-time 2000
```

Syntax: [**no**] **ipv6 mld group-membership-time** <5-26000>

To define an MLD group membership time of 2000 seconds for a specified VRF, enter the following commands.

```
NetIron(config)# ipv6 router pim vrf blue
NetIron(config-ipv6-pim-router-vrf-blue)# ipv6 mld group-membership-time 2000
```

Syntax: [**no**] **ipv6 router pim** [**vrf** <*vrf-name*>]

The **vrf** parameter specifies the virtual routing instance (VRF) specified by the variable <*vrf-name*>.

Defining the maximum number of MLD group addresses

You can use the following run-time command to set the maximum number of MLD addresses for the default VRF or for a specified VRF. To define this maximum for the default VRF, enter the following command.

```
NetIron(config)# ipv6 mld max-group-address 1000
```

Syntax: [**no**] **ipv6 mld max-group-address** <*num*>

The <*num*> variable specifies the maximum number of MLD group addresses you want to make available for the default VRF. If not defined by this command, the maximum value is determined by available system resources.

To define this maximum for a specified VRF, enter the following commands.

```
NetIron(config)# ipv6 router pim vrf blue
NetIron(config-ipv6-pim-router-vrf-blue)# ipv6 mld max-group-address 1000
```

Syntax: [**no**] **ipv6 router pim vrf** [<*vrf-name*>]

The **vrf** parameter specifies the virtual routing instance (VRF) specified by the variable <*vrf-name*>.

Setting the maximum response time

You can define the maximum amount of time a multicast listener has to respond to queries by entering a command such as the following.

```
NetIron(config)# ipv6 mld max-response-time 5
```

Syntax: [**no**] **ipv6 mld max-response-time** <*seconds*>

The <*seconds*> variable specifies the MLD maximum response time in seconds. You can specify from 1 through 10 seconds. The default is 5 seconds.

To define the maximum amount of time a multicast listener has to respond to queries for a specified VRF, enter the following commands.

```
NetIron(config)# ipv6 router pim vrf blue
NetIron(config-ipv6-pim-router-vrf-blue)# ipv6 mld max-response-time 5
```

Syntax: [**no**] **ipv6 router pim vrf** [<*vrf-name*>]

The **vrf** parameter specifies the virtual routing instance (VRF) specified by the variable <*vrf-name*>.

Setting the query interval

You can define the frequency at which MLD query messages are sent. For example, if you want queries to be sent every 50 seconds, enter a command such as the following.

```
NetIron(config)# ipv6 mld query-interval 50
```

Syntax: [**no**] **ipv6 mld query-interval** <*seconds*>

The <*seconds*> variable specifies the MLD query interval in seconds. You can specify from 1 through 3600 seconds. The default value is 125 seconds.

To define the frequency at which MLD query messages are sent for a specified VRF, enter the following commands.

```
NetIron(config)# ipv6 router pim vrf blue
NetIron(config-ipv6-pim-router-vrf-blue)# ipv6 mld query-interval 50
```

Syntax: [**no**] **ipv6 router pim** [**vrf** <*vrf-name*>]

The **vrf** parameter specifies the virtual routing instance (VRF) specified by the variable <*vrf-name*>.

Setting the last listener query interval

The Last Listener Query Interval is the Maximum Response Delay inserted into Multicast-Address-Specific Queries sent in response to Done messages, and is also the amount of time between Multicast- Address-Specific Query messages. When the device receives an MLDv1 leave message or an MLDv2 state change report, it sends out a query and expects a response within the time specified by this value. Using a lower value allows members to leave groups more quickly. You can set the last listener query interval by entering a command such as the following.

```
NetIron(config)# ipv6 mld llqi 5
```

Syntax: [**no**] **ipv6 mld llqi** <*seconds*>

The <*seconds*> variable sets the last listener query interval in seconds. You can specify from 1 through 10 seconds.

To set the last listener query interval for a specified VRF, enter the following commands.

```
NetIron(config)# ipv6 router pim vrf blue
NetIron(config-ipv6-pim-router-vrf-blue)# ipv6 mld llqi 5
```

Syntax: [**no**] **ipv6 router pim** [**vrf** <*vrf-name*>]

The **vrf** parameter specifies the virtual routing instance (VRF) specified by the variable <*vrf-name*>.

Setting the robustness

You can specify the number of times that the switch sends each MLD message from this interface. Use a higher value to ensure high reliability from MLD. You can set the robustness by entering a command such as the following.

```
NetIron(config)# ipv6 mld robustness 3
```

Syntax: ipv6 mld robustness <*seconds*>

The <*seconds*> variable sets the MLD robustness in seconds. You can specify from 2 through 7 seconds. The default is 2 seconds.

To set the robustness for a specified VRF, enter the following commands.

```
NetIron(config)# ipv6 router pim vrf blue
NetIron(config-ipv6-pim-router-vrf-blue)# ipv6 mld robustness 3
```

Syntax: [**no**] **ipv6 router pim** [**vrf** <*vrf-name*>]

The **vrf** parameter specifies the virtual routing instance (VRF) specified by the variable <*vrf-name*>.

Setting the version

You can use this command to set the MLD version (1 or 2) globally. You can select the version of MLD by entering a command such as the following.

```
NetIron(config)# ipv6 mld version 2
```

Syntax: **ipv6 mld version** <*version-number*>

The <*version-number*> variable sets the MLD version. You can specify 1 or 2 for the MLD version.The default version is 2.

To set the robustness for a specified VRF, enter the following commands.

```
NetIron(config)# pv6 router pim vrf blue
NetIron(config-ipv6-pim-router-vrf-blue)# ipv6 mld version 2
```

Syntax: [**no**] **ipv6 router pim** [**vrf** <*vrf-name*>]

The **vrf** parameter specifies the virtual routing instance (VRF) specified by the variable <*vrf-name*>.

Configuring MLD parameters at the interface level

The following MLD parameters can be configured at the interface level:

- Port- version - "Specifying a port version" on page 1985
- Static-group - "Specifying a static group" on page 1985
- Tracking - "Enabling MLD tracking on an interface" on page 1986
- Version - "Setting the version on an interface" on page 1986

Specifying a port version

To set the MLD version on a virtual Ethernet interface, enter the following commands as shown in the example.

```
NetIron(config)# interface ve 10
NetIron(config-vif-10)# ipv6 mld port-version 2
```

Syntax: **ipv6 mld port-version** <*version-number*>

Enter 1 or 2 for <*version-number*>. Be sure to enter 2 if you want to use source filtering.

Specifying a static group

A multicast group is usually learned when an MLDv1 report is received. You can configure static group membership without having to receive an MLDv1 report by entering a command such as the following at the interface level.

```
NetIron(config-if-e10000-1/1)# ipv6 mld static-group ff0d::1
```

To configure a static group membership without having to receive an MLDv1 report on a virtual Ethernet interface, enter the following commands.

```
NetIron(config)# interface ve 10
NetIron(config-vif-10)# ipv6 mld static-group ff0d::1
```

Syntax: **ipv6 mld static-group** <*multicast-group-address*> [**ethernet** <*port-number*> [**ethernet** <*port-number*> | **to** <*port-number*>]*]

Enter the IPv6 multicast group address for the <*multicast-group-address*>.

Enter the number of the port that will be included in this static group for the **ethernet** <*port-number*> parameter. The asterisk (*) in the syntax means that you can enter as many port numbers as you want to include in the static group. For a virtual routing interface (ve), specify the physical Ethernet ports on which to add the group address.

Enabling MLD tracking on an interface

When MLD tracking is enabled, a Layer 3 switch tracks all clients that send membership reports. When a Leave message is received from the last client, the device immediately stops forwarding to the physical port (without waiting 3 seconds to confirm that no other clients still want the traffic). To enable MLD tracking on a virtual interface, enter the following commands.

```
NetIron(config)# interface ve 10
NetIron(config-vif-10)# ipv6 mld tracking
```

Syntax: **ipv6 mld tracking**

Setting the version on an interface

You can use this command to set the MLD version (1 or 2) on an interface. You can select the version of MLD by entering a command such as the following.

```
NetIron(config)# interface ve 10
NetIron(config-vif-10)# ipv6 mld version 2
```

Syntax: **ipv6 mld version** <*version-number*>

The <*version-number*> variable sets the MLD version on an interface. You can specify 1 or 2 for the MLD version.The default version is 2.

Displaying MLD information

The sections below present the show commands for MLD.

Displaying MLD group information

To display the list of multicast groups, enter a command such as the following.

```
NetIron #show ipv6 mld group
Interface e6/18 has 11 groups
    group                                phy-port static querier life mode

1    ff33::6:b:1                          e6/18    no     yes     0    incl
2    ff33::6:a:1                          e6/18    no     yes     0    incl
3    ff33::6:9:1                          e6/18    no     yes     0    incl
4    ff33::6:8:1                          e6/18    no     yes     0    incl
5    ff33::6:7:1                          e6/18    no     yes     0    incl
6    ff33::6:6:1                          e6/18    no     yes     0    incl
7    ff33::6:5:1                          e6/18    no     yes     0    incl
8    ff33::6:4:1                          e6/18    no     yes     0    incl
9    ff33::6:3:1                          e6/18    no     yes     0    incl
10   ff33::6:2:1                          e6/18    no     yes     0    incl
11   ff33::6:1:1                          e6/18    no     yes     0    incl
```

Syntax: show ipv6 mld [**vrf** <*vrf-name*>] **group**

The **vrf** parameter allows you to display the list of IPv6 MLD groups for the VRF instance identified by the <*vrf-name*> variable.

Table displays the output from the **show ipv6 mld group** command.

TABLE 381 Output from the **show ipv6 mld group** command

Field	Description
Interface <*port-number*> has x groups	This message shows the ID of the interface and how many multicast groups it has.
#	Index for the MLD group.
group	IPv6 address of the multicast group.
phy-port	The physical port to which the group belongs.
static	Indicates if the group is a static group or not.
querier	Indicates if the multicast group is a querier or not.
life	The number of seconds the interface can remain in its current mode.
mode	Indicates if the filter mode of the multicast group is in INCLUDE or EXCLUDE.

Displaying MLD definitions for an interface

To display the MLD parameters on an interface, including the various timers, the current querying router, and whether or not MLD is enabled, enter the following command.

```
NetIron# show ipv6 mld interface
version = 2, query int = 60, max resp time = 5, group mem time = 140
e3/1: default V2, PIM sparse, addr=fe80::20c:dbff:fe82:833a
e3/2: default V2, PIM sparse, addr=fe80::20c:dbff:fe82:833b
e6/1: default V2, PIM sparse (port down), addr=::
e6/5: default V2, PIM sparse (port down), addr=::
e6/18: default V2, PIM sparse, addr=fe80::20c:dbff:fe82:840b
          has   11 groups, Querier, default V2
    group: ff33::6:b:1, include, permit 1
    group: ff33::6:a:1, include, permit 1
    group: ff33::6:9:1, include, permit 1
    group: ff33::6:8:1, include, permit 1
    group: ff33::6:7:1, include, permit 1
    group: ff33::6:6:1, include, permit 1
    group: ff33::6:5:1, include, permit 1
    group: ff33::6:4:1, include, permit 1
    group: ff33::6:3:1, include, permit 1
    group: ff33::6:2:1, include, permit 1
    group: ff33::6:1:1, include, permit 1
```

Syntax: show ipv6 mld [**vrf** <*vrf-name*>] **interface** [<*port-number*>]

The **vrf** parameter allows you to display MLD parameters on an interface for the VRF instance identified by the <*vrf-name*> variable.

Enter a port number in the <*port-number*> variable if you want to display MLD information for a specific interface.

Table displays the output from the **show ipv6 mld interface** command.

TABLE 382 Output from the **show ipv6 mld interface** command

Field	Description
version	Version of the MLD being used.
query int	Query interval in seconds.
max resp time	Number of seconds multicast groups have to respond to queries.
group mem time	Number of seconds multicast groups can be members of this group before aging out.
(details)	The following is displayed for each interface: • The port ID • The default MLD version being used • The multicast protocol used • IPV6 address of the multicast interface • If the interface has groups, the group source list, IPv6 multicast address, and the filter mode are displayed.

To display the MLD parameters on an interface for a specified VRF, enter the following command as shown in the example below.

```
NetIron(config)# show ipv mld vrf public interface
---------+------+---------+-----------------------------------------+---------+---
--+---------
Intf/Port|Groups| Version |Querier                                  |  Timer
|V1Rtr|Tracking
         |      | Oper  Cfg|                                        | OQrr GenQ|
|
---------+------+----+----+-----------------------------------------+----+----+---
--+---------
v6             0    2    -
Disabled
     e5/1           2    - fe80::20c:dbff:fee2:5000                 11    0 No
v61            0    2    -
Disabled
    e11/1           2    - Self                                      0  122 No
```

Displaying MLD settings

To display MLD settings for the “eng” VRF, enter the following command.

```
NetIron# show ipv6 mld vrf eng settings
MLD Global Configuration
  Query Interval            : 125s   Configured Interval    : 125s
  Max Response Time         : 10s
  Group Membership Time     : 260s
  Operating Version         : 2      Configured Version     : 0
  Robustness Variable       : 2
  Last Member Query Interval: 1s      Last Member Query Count: 2
  Older Host Present Timer  : 260s
```

Syntax: show ipv6 mld [**vrf** <*vrf-name*>] **settings**

The **vrf** parameter specifies that you want to display information for MLD settings for the VRF specified by the <*vrf-name*> variable.

Table displays the output from the **show ipv6 mld vrf eng settings** command.

TABLE 383 Output from the **show ipv6 mld vrf eng settings** command

Field	Description
Query Interval	How often the router will query an interface for group membership.
Configured Interval	The interval that has been configured for the router.
Max Response Time	The length of time in seconds that the router will wait for an IGMP (V1 or V2) response from an interface before concluding that the group member on that interface is down and removing it from the group.
Group Membership Time	The length of time in seconds that a group will remain active on an interface in the absence of a group report.
Operating Version	The IGMP version operating on the router.
Configured Version	The IGMP version configured on the router.
Robustness Variable	Used to fine-tune for unexpected loss on the subnet. The value is used to calculate the group interval.

TABLE 383 Output from the **show ipv6 mld vrf eng settings** command (Continued)

Field	Description
Last Member Query Interval	Indicates when a leave is received; a group-specific query is sent. The last member query count is the number of queries with a time interval of (LMQT) is sent.
Last Member Query Count	Specifies the number of group-specific queries when a leave is received.

Displaying static MLD groups

The following command displays static MLD groups for the “cs” VRF.

```
NetIron# show ipv6 mld vrf cs static
Group Address                                Interface Port List
-------------------------------------------+---------+---------
ff1e:1::1                                    v3       ethe 2/10
ff1e:a::7f                                   v3       ethe 2/10
```

Syntax: show ipv6 mld [**vrf** <*vrf-name*>] **static**

The **vrf** parameter specifies that you want to display static MLD group information for the VRF specified by the <*vrf-name*> variable.

Table displays the output from the **show ipv6 mld vrf cs static** command.

TABLE 384 Output from the show ipv6 mld vrf cs static command

Field	Description
Group Address	The address of the multicast group.
Interface Port List	The physical ports on which the multicast groups are received.

Displaying MLD traffic

To display information on MLD traffic, enter a command such as the following.

```
NetIron# show ipv6 mld traffic
Recv  QryV1 QryV2 G-Qry GSQry MbrV1 MbrV2 Leave IS_IN IS_EX 2_IN 2_EX ALLO  BLK
e3/1      0     0     0     0     0     0     0     0     0    0    0    0    0
e3/2      0     0     0     0     0     0     0     0     0    0    0    0    0
e6/18     0     0     0     0     0   176     0   110     0    0    0   66    0
e6/19     0     0     0     0     0   176     0   110     0    0    0   66    0
e6/20     0     0     0     0     0   176     0   110     0    0    0   66    0
e6/25     0     0     0     0     0   176     0   110     0    0    0   66    0
l1        0     0     0     0     0     0     0     0     0    0    0    0    0
Send  QryV1 QryV2 G-Qry GSQry
e3/1      0     0     0     0
e3/2      0     0     0     0
e6/18     0    10    10     0

l1        0     0     0     0
R2#
```

The report has a Receive and a Send section.

Syntax: show ipv6 mld [**vrf** <*vrf-name*>] **traffic**

The **vrf** parameter specifies that you want to display information on MLD traffic for the VRF specified by the <*vrf-name*> variable.

Table displays the output from the **show ipv6 mld traffic** command.

TABLE 385 Output from the **show ipv6 mld traffic** command

Field	Description
QryV1	Number of general MLDv1 queries received or sent by the virtual routing interface.
QryV2	Number of general MLDv2 queries received or sent by the virtual routing interface.
G-Qry	Number of group-specific queries received or sent by the virtual routing interface.
GSQry	Number of source specific queries received or sent by the virtual routing interface.
MbrV1	Number of MLDv1 membership reports received.
MbrV2	Number of MLDv2 membership reports received.
Leave	Number of MLDv1 “leave” messages on the interface. (See 2_Ex for MLDv2.)
Is_IN	Number of source addresses that were included in the traffic.
Is_EX	Number of source addresses that were excluded in the traffic.
2_IN	Number of times the interface mode changed from exclude to include.
2_EX	Number of times the interface mode changed from include to exclude.
ALLOW	Number of times that additional source addresses were allowed or denied on the interface.
BLK	Number of times that sources were removed from an interface.

Clearing IPv6 MLD traffic

To clear counters on IPv6 MLD traffic, enter the following command.

```
NetIron# clear ipv6 mld traffic
```

Syntax: clear ipv6 mld [**vrf** <*vrf-name*>] **traffic**

Use the **vrf** option to clear counters on IPv6 MLD traffic for a VRF instance specified by the <*vrf-name*> variable.

Clearing the IPv6 MLD group membership table cache

You can clear the IPv6 PIM group membership table cache using the following command.

```
NetIron# clear ipv6 pim cache
```

Syntax: clear ipv6 pim [**vrf** <*vrf-name*>] **cache**

Use the **vrf** option to clear the IPv6 PIM group membership table cache for a VRF instance specified by the <*vrf-name*> variable.

IPv6 Multicast Listener Discovery snooping

IPv6 Multicast Listener Discovery (MLD) snooping controls the amount of multicast traffic in a switched network. By default, a LAN switch floods the broadcast domain with multicast IPv6 packets. If many multicast servers are sending streams to the segment, this will consume a lot of bandwidth. MLD snooping identifies multicast-enabled router ports and multicast receiver ports in a given VLAN or a switched network and forwards multicast traffic only to those ports.

Configuring IPv6 multicast routing or snooping

IPv6 multicast snooping or routing can be enabled on a VE interface or VLAN, but not on both. This is because all of the multicast data and control packets received on the snooping VLAN are handled by multicast snooping and do not reach the multicast routing component. Similarly, any multicast data or control packets received on a VE interface enabled with PIM or Distance Vector Multicast Routing Protocol (DVMRP) routing are handled by the PIM or DVMRP routing component and are not seen by the MLD snooping component.

The following considerations apply when configuring concurrent operation of multicast routing and snooping.

- Either multicast snooping or routing can be enabled on a VE or VLAN but not both.
- Snooping can be enabled globally (**ipv6 multicast active** | **passive**).
- The global snooping configuration is inherited by all current VLANs that are not enabled for multicast routing.
- The global snooping configuration is also inherited by all new VLANs. To enable multicast routing on a newly configured VE or VLAN (when snooping is globally enabled), you must first disable snooping on the newly created VE or VLAN.
- Global snooping configuration must be configured first before VLAN configuration.
- A VLAN-level snooping configuration is displayed only if it is different from the global configuration.

Enabling IPv6 multicast traffic reduction

By default, the device forwards all IPv6 multicast traffic out to all ports except the port on which the traffic was received. To reduce multicast traffic through the device, you can enable IPv6 Multicast Traffic Reduction. This feature configures the device to forward multicast traffic only on the ports attached to multicast group members, instead of forwarding all multicast traffic to all ports. The device determines the ports that are attached to multicast group members based on entries in the MLD Snooping table. Each entry in the table consists of MAC addresses and the ports from which the device has received Group Membership reports for that group.

By default, the device broadcasts traffic addressed to an IPv6 multicast group that does not have any entries in the MLD Snooping table. When you enable IPv6 Multicast Traffic Reduction, the device determines the ports that are attached to multicast group members based on entries in the MLD Snooping table. The MLD Snooping table entries are created when the VLAN receives a Group Membership report for a group. Each entry in the table consists of an IPv6 multicast group address and the ports from which the device has received Group Membership reports.

When the device receives traffic for an IPv6 multicast group, the device looks in the MLD Snooping table for an entry corresponding to that group. If the device finds an entry, the device forwards the group traffic out to the ports listed in the corresponding entries, as long as the ports are members of the same VLAN. If the table does not contain an entry corresponding to the group or if the port is a member of the default VLAN, the device broadcasts the traffic.

When one or more devices are running Layer 2 IPv6 Multicast Traffic Reduction, configure one of the devices for active MLD and leave the other devices configured for passive MLD. However, if the IPv6 multicast domain contains a multicast-capable router, configure all the devices for MLD and allow the router to actively send the MLD queries.

Configuring IPv6 MLD snooping

To enable IPv6 Multicast Traffic Reduction, enter the following command.

```
NetIron(config)# ipv6 multicast active
```

Syntax: [no] ipv6 multicast active | passive

When you enable IPV6 multicast on a device, all ports on the device are configured for MLD.

If you are using passive MLD, all ports can send MLD queries and receive MLD reports. If you are using passive MLD, all ports can receive MLD queries.

IPv6 Multicast Traffic Reduction cannot be disabled on individual ports of a device. IPv6 Multicast Traffic Reduction can be disabled globally by entering the no ipv6 multicast command.

To verify that IPv6 Multicast Traffic Reduction is enabled, enter the following command at any level of the CLI.

```
NetIron(config)# show ipv6 multicast
IPv6 multicast is enabled - Active
```

Syntax: show ipv6 multicast

Changing the MLD mode

When you enable IPv6 Multicast Traffic Reduction on the device, MLD also is enabled. The device uses MLD to maintain a table of the Group Membership reports received by the device. You can use active or passive MLD mode. There is no default mode.

The active and passive MLD modes are described as follows:

- Active – When active MLD mode is enabled, the device actively sends out MLD queries to identify IPV6 multicast groups on the network and makes entries in the MLD table based on the Group Membership reports received from the network.

  NOTE
  Routers in the network generally handle this operation. Use the active MLD mode only when the device is in a standalone Layer 2 switched network with no external IPV6 multicast router attachments. In this case, enable the active MLD mode on only one of the devices and leave the other devices configured for passive MLD mode.

- Passive – When passive MLD mode is enabled, the device listens for MLD Group Membership reports but does not send MLD queries. The passive mode is sometimes called “MLD snooping”. Use this mode when another device in the network is actively sending queries.

Globally configuring the age interval

When the device receives a Group Membership report, the device makes an entry in the MLD group table for the group in the report. The age interval specifies how long the entry can remain in the table without the device receiving another Group Membership report.

To configure the age interval, enter a command such as the following.

```
NetIron(config)# ipv6 multicast age-interval 280
```

Syntax: [no] ipv6 multicast age-interval <*interval*>

The <*interval*> parameter specifies the interval between queries. You can specify a value from 10 through 1220 seconds. The default is 260 seconds.

Filtering multicast groups

By default, the device forwards multicast traffic for all valid multicast groups. You can configure a device to filter out all multicast traffic for groups other than the ones for which the device has received Group Membership reports.

When the device starts up, it forwards all multicast groups even though multicast traffic filters are configured. This process continues until the device receives a Group Membership report. Once the Group Membership report is received, the device drops all multicast packets for groups other than the ones for which the device has received the Group Membership report.

To enable IPv6 multicast filtering, enter the following command.

```
NetIron(config)# ipv6 multicast filter
```

Syntax: [no] ipv6 multicast filter

Setting PIM proxy interval

The PIM proxy interval specifies the time interval in seconds between the PIM proxy and join messages.

To set the time interval between PIM proxy messages, enter the following command.

```
NetIron(config)# ipv6 multicast pim-proxy-interval 10
```

Syntax: ipv6 multicast pim-proxy-interval <*interval*>

The <*interval*> parameter specifies the interval between PIM proxy messages. You can specify a value from 10 through 600 seconds.

PIM-SM traffic snooping

By default, when a device receives an IPv6 multicast packet, the device does not examine the multicast information in the packet. Instead, the device simply forwards the packet out to all ports except the port that received the packet. In some networks, this method can cause unnecessary traffic overhead in the network. For example, if the device is attached to only one group source and two group receivers, but has devices attached to every port, the device forwards group traffic out all ports in the same broadcast domain except the port attached to the source, even though there are only two receivers for the group.

PIM-SM traffic snooping eliminates the superfluous traffic by configuring the device to forward IPv6 multicast group traffic only on the ports that are attached to receivers for the group.

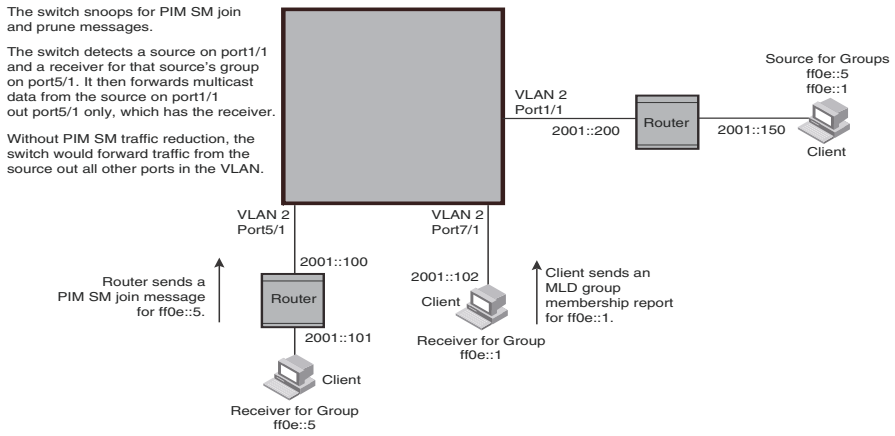
PIM-SM traffic snooping requires IPv6 Multicast Traffic Reduction to be enabled on the device. IPv6 Multicast Traffic Reduction configures the device to listen for MLD messages. PIM-SM traffic snooping provides a finer level of multicast traffic control by configuring the device to listen specifically for PIM-SM join and prune messages sent from one PIM-SM router to another through the device.

Application examples

Figure 222 shows an example application of the PIM-SM traffic snooping feature. In this example, a device is connected through an IP router to a PIM-SM group source that is sending traffic for two PIM-SM groups. The device also is connected to a receiver for each of the groups.

NOTE
PIM-SM traffic snooping applies only to PIM-SM version 2 (PIM V2).

FIGURE 222 PIM-SM IPv6 traffic reduction in enterprise network



When PIM-SM traffic snooping is enabled, the device starts listening for PIM-SM join and prune messages and MLD Snooping reports. Until the device receives a PIM-SM join message or an MLD report, the device forwards IPv6 multicast traffic out to all ports. Once the device receives a join message or Group Membership report for a group, the device forwards subsequent traffic for that group only on the ports from which the join messages or MLD reports were received.

In this example, the router connected to the receiver for group ff0e::1 sends a join message toward the source of the group. Since PIM-SM traffic snooping is enabled on the device, the device examines the join message to learn the group ID, then makes a forwarding entry for the group ID and the port connected to the router of the receiver. The next time the device receives traffic for ff0e::1 from the source of the group, the device forwards the traffic only on port 5/1, because that is the only port connected to a receiver for the group.

Notice that the receiver for group ff0e::5 is directly connected to the device. As a result, the device does not see a join message on behalf of the client. However, because IP Multicast Traffic Reduction also is enabled, the device uses the MLD Group Membership report from the client to select the port for forwarding traffic to group ff0e::5 receivers.

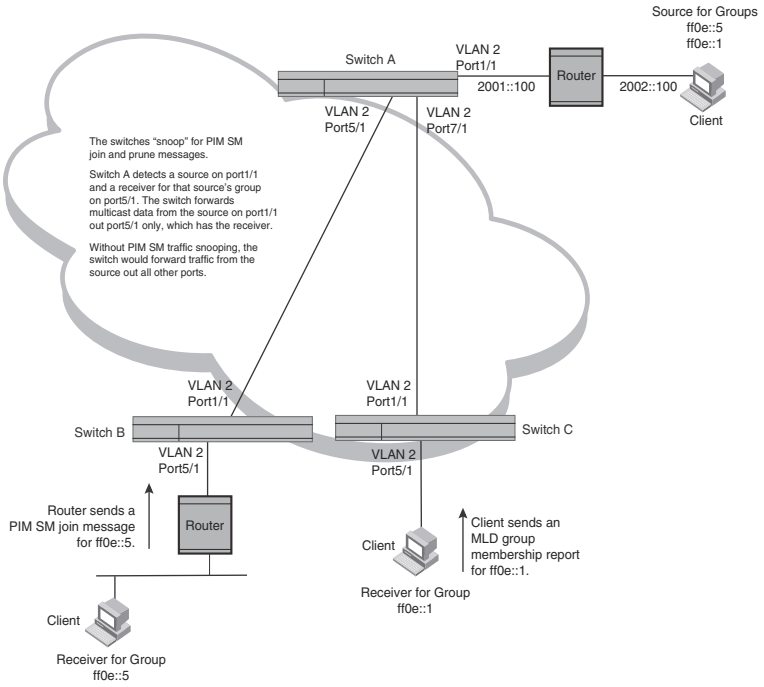
The IPv6 Multicast Traffic Reduction feature and the PIM-SM traffic snooping feature together build a list of groups and forwarding ports for the VLAN. The list includes PIM-SM groups learned through join messages as well as MAC addresses learned through MLD reports. In this case, even though the device never sees a join message for the receiver for group ff0e::5, the device nonetheless learns about the receiver and forwards group traffic to the receiver.

The device stops forwarding IPv6 multicast traffic on a port for a group if the port receives a prune message for the group.

Notice that the ports connected to the source and the receivers are all in the same port-based VLAN on the device. This is required for the PIM-SM traffic snooping feature. The feature also requires the source and the downstream router to be on different IP subnets, as shown in Figure 222.

Figure 223 shows another example application for PIM-SM traffic snooping. This example shows devices on the edge of a global Ethernet cloud (a Layer 2 Packet over SONET cloud). Assume that each device is attached to numerous other devices.

FIGURE 223 PIM-SM IPv6 traffic reduction in global Ethernet environment



The devices on the edge of the global Ethernet cloud are configured for IP Multicast Traffic Reduction and PIM-SM traffic snooping. Although this application uses multiple devices, the feature has the same requirements and works the same way as it does on a single device.

Configuration requirements

Consider the following configuration requirements:

- IPv6 Multicast Traffic Reduction must be enabled on the device that will be running PIM-SM snooping. The PIM-SM traffic snooping feature requires IPv6 Multicast Traffic Reduction.

NOTE
Use the passive mode of IPv6 Multicast Traffic Reduction instead of the active mode. The passive mode assumes that a router is sending group membership queries as well as join and prune messages on behalf of receivers. The active mode configures the device to send group membership queries.

- All the device ports connected to the source and receivers or routers must be in the same port-based VLAN.
- The PIM-SM snooping feature assumes that the group source and the device are in different subnets and communicate through a router. The source must be in a different IP subnet than the receivers. A PIM-SM router sends PIM join and prune messages on behalf of a multicast group receiver only when the router and the source are in different subnets. When the receiver and source are in the same subnet, they do not need the router in order to find one another. They find one another directly within the subnet.

  The device forwards all IPv6 multicast traffic by default. Once you enable IPv6 Multicast Traffic Reduction and PIM-SM traffic snooping, the device initially blocks all PIM-SM traffic instead of forwarding it. The device forwards PIM-SM traffic to a receiver only when the device receives a join message from the receiver. Consequently, if the source and the downstream router are in the same subnet, and PIM-SM traffic snooping is enabled, the device blocks the PIM-SM traffic and never starts forwarding the traffic. This is because the device never receives a join message from the downstream router for the group. The downstream router and group find each other without a join message because they are in the same subnet.

NOTE
If the “route-only” feature is enabled, PIM-SM traffic snooping is not supported.

Globally enabling IPv6 PIM SM traffic snooping

This feature is similar to PIM-SM traffic snooping but listens only for MLD snooping information, not PIM-SM information. You must enable both IPv6 Multicast Traffic Reduction and IPv6 PIM-SM traffic snooping to enable the device to listen for PIM-SM join and prune messages.

To enable IPv6 PIM-SM traffic snooping, enter the following commands at the global CONFIG level of the CLI.

```
NetIron(config)# ipv6 multicast active
NetIron(config)# ipv6 multicast pimsm-snooping
```

Syntax: [**no**] **ipv6 multicast** [**active** | **passive**]

When you enable IP multicast on device, all ports on the device are configured for IGMP.

If you are using **active** MLD, all ports can send MLD queries and receive MLD reports. If you are using **passive** MLD, all ports can receive MLD queries.

IPv6 Multicast Traffic Reduction cannot be disabled on individual ports of a device. IPv6 Multicast Traffic Reduction can be disabled globally by entering the **no ipv6 multicast** command.

Syntax: [**no**] **ipv6 multicast pimsm-snooping**

Use the **no** form of the command to disable IPv6 PIM-SM traffic snooping.

Globally configuring the query interval

If IPv6 Multicast Traffic Reduction is set to active mode, you can configure the query interval, which specifies how often a device is enabled for active IPv6 Multicast Traffic Reduction sends Group Membership queries.

NOTE
The query interval applies only to the active mode of IPv6 Multicast Traffic Reduction.

To configure the query interval, enter the following command.

```
NetIron(config)# ipv6 multicast query-interval 120
```

Syntax: [**no**] **ipv6 multicast query-interval** <*interval*>

The <*interval*> parameter specifies the interval between queries. You can specify a value from 10 through 600 seconds. The default is 125 seconds.

Setting the MLD version

You can use the **ipv6 multicast version** command to set the MLD version (1 or 2) globally for IPv6 multicast. You can select the version of MLD by entering the following command.

```
NetIron(config)# ipv6 multicast version 2
```

Syntax: **ipv6 multicast version** <*version-number*>

Enter 1 or 2 for the <*version-number*>. The default is version 1.

Configuring IPv6 multicast tracking and fast-leave

When IPv6 multicast tracking is configured, MLD fast-leave is enabled. MLD Leave Processing for MLDv1 is initiated by a receiver sending a Leave message. The router sends out a group-specific query to solicit reports from other receivers. The multicast group entry is maintained for 3 seconds to allow the processing of reports from any receivers on the LAN segment. If there are no receivers, the multicast stream is pruned.

MLD fast-leave allows a receiver to move from one multicast group to another instantly if it is the only receiver on the segment subscribed to the group. When a layer 3 switch receives a Leave message, it sends a group-specific query to see if any other receivers are present. The multicast group state is maintained for 3 seconds to process any MLD group reports from other receivers. If there are no other receivers, the multicast group entry prunes the receiver LAN segment, stopping traffic instantly.

MLDv2 also supports fast-leave processing. When an MLDv2 receiver changes the mode to Exclude, and there are no other receivers on that interface, the multicast group entry prunes the receiver LAN segment.

To enable IPv6 multicast tracking globally, enter the following command.

```
NetIron(config)# ipv6 multicast tracking
```

Syntax: [**no**] **ipv6 multicast tracking**

The **no** form of this command disables the tracking process globally.

Configuring IPv6 MLD snooping on a per-VLAN basis

The following IPv6 MLD snooping parameters can be configured on a per-VLAN basis:

- Active and passive - "Configuring IPv6 multicast snooping per VLAN" on page 1999
- MLD proxy - "Configuring MLD proxy per VLAN" on page 1999
- PIM-SM traffic snooping - "Configuring the PIM-SM traffic snooping per VLAN" on page 2000
- PIM proxy - "Configuring PIM proxy per VLAN" on page 2000
- Static-group uplink - "Configuring an IPv6 multicast static group uplink per VLAN" on page 2000
- Tracking - "Configuring IPv6 multicast tracking and fast-leave per VLAN" on page 2001

Configuring IPv6 multicast snooping per VLAN

The **multicast6** command allows you to configure IPv6 multicast snooping parameters per VLAN. To configure IPv6 multicast snooping to VLAN 2, enter the following commands as shown in the example below.

```
NetIron(config)# vlan 2
NetIron(config-vlan-2)# multicast6 active
```

To remove multicast traffic reduction configurations in VLAN 2, and take the global multicast traffic reduction configuration, enter the following command.

```
NetIron(config)# vlan 2
NetIron(config-vlan-2)# no multicast6 active
```

Syntax: [**no**] **multicast6 active** | **passive**

When you enable IPv6 multicast for a specific VLAN, MLD snooping is enabled. The device uses MLD to maintain a table of the Group Membership reports received by the device for the specified VLAN. You can use active or passive MLD mode. There is no default mode.

The description for the MLD modes is as follows:

- **Active** – When active MLD mode is enabled, the router actively sends out MLD queries to identify IPv6 multicast groups within the VLAN and makes entries in the MLD table based on the Group Membership reports received from the network.
- **Passive** – When passive MLD mode is enabled, the router listens for MLD Group Membership reports on the VLAN specified but does not send MLD queries. The passive mode is called "MLD snooping". Use this mode when another device in the VLAN is actively sending queries.

Configuring MLD proxy per VLAN

The **multicast6 mld-proxy-enable** command enables MLD proxy for IPv6. Using the MLD proxy function, the host is able send out MLD reports on behalf of the hosts behind the switch.

To configure a device to function as an MLD proxy on VLAN 2, enter the following commands as shown in this example.

```
NetIron(config)# vlan 2
NetIron(config-vlan-2)# multicast6 active
NetIron(config-vlan-2)# multicast6 mld-proxy-enable
```

Syntax: [**no**] **multicast6 mld-proxy-enable**

The **no** form of this command disables MLD proxy on a per-VLAN basis.

Configuring the PIM-SM traffic snooping per VLAN

In the following example, multicast traffic reduction is applied using PIM-SM traffic snooping to VLAN 2.

```
NetIron(config)# vlan 2
NetIron(config-vlan-2)# multicast6 active
NetIron(config-vlan-2)# multicast6 pimsm-snooping
```

Syntax: [**no**] **multicast6 pimsm-snooping**

The **no** form of this command disables PIM SM traffic snooping on a per-VLAN basis.

Configuring PIM proxy per VLAN

Using the PIM proxy function, multicast traffic can be reduced by configuring a device to issue PIM join and prune messages on behalf of hosts that the configured router discovers through standard PIM interfaces. The router is then able to act as a proxy for the discovered hosts and perform PIM tasks upstream of the discovered hosts. Where there are multiple PIM downstream routers, this removes the need to send multiple messages.

When configuring PIM proxy on a VLAN, you must first configure PIM-SM traffic snooping. To configure a device to function as a PIM proxy on VLAN 2, use the following commands.

```
NetIron(config)# vlan 2
NetIron(config-vlan-2)# multicast6 active
NetIron(config-vlan-2)# multicast6 pimsm-snooping
NetIron(config-vlan-2)# multicast6 pim-proxy-enable
```

Syntax: [**no**] **multicast6 pim-proxy-enable**

The **no** form of this command disables PIM proxy on a per-VLAN basis.

Configuring an IPv6 multicast static group uplink per VLAN

When the **multicast6 static-group uplink** command is enabled on a snooping VLAN, the snooping device behaves like an MLD host on ports connected to the multicast router. The snooping device will respond to MLD queries from the uplink multicast PIM router for the groups and sources configured. Upon the multicast router receiving the MLD join message, it will initiate the PIM join on its upstream path towards the source to pull the source traffic down. The source traffic will stop at the MLD snooping device. The traffic will then be forwarded to the multicast receiver and router ports or dropped in hardware if no other multicast receiver and routers are present in the VLAN.

The **multicast6 static-group uplink** command can be configured under the VLAN configuration only.

The **multicast6 static-group uplink** command must be used with the **multicast6 static-group** command in order to connect a remote multicast source with the snooping VLAN where the static group is configured.

When using MLDv2, you can use the **multicast6 static-group include** or **multicast6 static-group exclude** command to statically *include* or *exclude* multicast traffic, respectively for hosts that cannot signal group membership dynamically.

To configure the snooping device to statically join a multicast group on the uplink interface, enter the following commands.

```
NetIron(config)# vlan 10
```

```
NetIron(config-vlan-10)# multicast6 static-group active
NetIron(config-vlan-10)# multicast6 static-group ff2e::1 uplink
```

NOTE
The following error message will display if both static uplink MLDv1 and MLDv2 are configured for the same group: Error: Static v1 and v2 uplink configuration cannot co-exist for the same group.

To configure the physical interface Ethernet 1/1 to statically join a multicast group with an IPv6 group address of ff0e::1, enter commands such as the following.

```
NetIron(config)# vlan 10
NetIron(config-vlan-10)# multicast6 static-group ff0e::1 ethernet 1/1
```

To configure the snooping device to statically join a multicast stream on the uplink interface with the source address of 2003::1 in the MLDv2 include mode, enter commands such as the following.

```
NetIron(config)# vlan 10
NetIron(config-vlan-10)# multicast6 static-group ff1e::1 include 2003::1 uplink
```

To configure the snooping device to statically join all multicast streams on the uplink interface excluding the stream with source address 2002::1, enter commands such as the following.

```
NetIron(config)# vlan 10
NetIron(config-vlan-10)# multicast6 static-group active
NetIron(config-vlan-10)# multicast6 static-group ff1e::1 exclude 2002::1 uplink
```

Syntax: [**no**] **multicast6 static-group** <*group-address*> **uplink**

Syntax: [**no**] **multicast6 static-group** <*group-address*> [**include** | **exclude** <*source-address*>] **uplink**

The <*group-address*> variable specifies the group IPv6 multicast address.

The **include** or **exclude** keyword indicates a filtering action. You can specify which source (for a group) to include or exclude. The **include** or **exclude** keyword is only supported on MLDv2.

The <*source-address*> parameter specifies the IPv6 address of the multicast source. Each address must be added or deleted one line per source.

The **uplink** parameter specifies the port as an uplink port that can receive multicast data for the configured multicast groups. Upstream traffic will be sent to the router and will not use a port.

The **no** form of this command removes the static multicast definition. Each configuration must be deleted separately.

Configuring IPv6 multicast tracking and fast-leave per VLAN

The **multicast6 tracking** command enables IPv6 multicast tracking per VLAN. The **multicast6 tracking** command is similar to the **ipv6 multicast tracking** command. When the **multicast6 tracking** command is configured, MLD fast-leave is enabled. For more information on MLD fast-leave for IPv6 multicast tracking, refer to "Configuring IPv6 multicast tracking and fast-leave" on page 1998.

To enable IPv6 multicast tracking per VLAN, enter commands such as the following.

```
NetIron(config)# vlan 2
NetIron(config-vlan-2)# multicast6 active
NetIron(config-vlan-2)# multicast6 tracking
```

Syntax: [**no**] **multicast6 tracking**

The **no** form of this command disables the tracking process.

Displaying IPv6 multicast information

To display information for IPv6 multicast traffic reduction configuration, enter the following command.

```
NetIron(config)# show ipv6 multicast
Global Multicast Traffic Reduction Configuration
   MLD Snooping State :   Disabled    Version              :          1
   Group Interval     :        260    Query Interval       :        125
   Max Response Time  :         10    Robustness Var       :          1
   Last Member Qry Int:          5    Last Member Qry Count:          3

VLAN snooping configurations:

VLAN ID 2
 IPv6 Multicast snooping is enabled - Active. Entries 0
 IPv6 Multicast MLD tracking is disabled
VLAN ID 10
 IPv6 Multicast snooping is enabled - Active. Entries 0
IPv6 Multicast pimsm snooping is enabled
```

Syntax: **show ipv6 multicast** [**mldv2** <*vlan-id*> | **pim** <*vlan-id*> | **static** <*vlan-id*> | **statistics** <*vlan-id*> | **tracking** <*vlan-id*> | **vlan** <*vlan-id*>]

The **mldv2** <*vlan-id*> parameter displays IPv6 multicast information specific to MLDv2 for a specified port-based VLAN.

The **pim** <*vlan-id*> parameter displays IPv6 multicast information specific to PIM for a specified port-based VLAN.

The **static** <*vlan-id*> parameter displays information for the number of static MLD snooping entries configured in a specified port-based VLAN.

The **statistics** <*vlan-id*> parameter displays IPv6 multicast statistics for a specified port-based VLAN.

The **tracking** <*vlan-id*> parameter displays tracking information for MLDv2 hosts for a specified port-based VLAN.

The **vlan** <*vlan-id*> parameter displays IPv6 multicast PIM information for a specified port-based VLAN. The <*vlan-id*> variable is entered in decimal format.

Table 386 describes the fields displayed by the **show ipv6 multicast** command.

TABLE 386 Output from the **show ipv6 multicast** command

Field	Description
Global Multicast Traffic Reduction Configuration	Indicates all multicast traffic configuration displayed for all parameters.
MLD Snooping State:	Indicates whether MLD snooping is enabled or disabled. If enabled, it indicates if the feature is configured as passive or active.
Global Interval	Indicates the time until the groups time out if no reports are received.

TABLE 386 Output from the **show ipv6 multicast** command (Continued)

Field	Description
Max Response Time	The length of time in seconds that the router will wait for an IGMP (V1 or V2) response from an interface before concluding that the group member on that interface is down and removing it from the group.
Last Member Qry Int	Indicates when a leave is received; a group-specific query is sent. The last member query count is the number of queries with a time interval of (LMQT) is sent.
Querier Exp Tm	Indicates the time until the querier times out if no query is received.
MLD Proxy	Indicates whether MLD Proxy is enabled or disabled. If enabled, it indicates if the feature is configured as passive or active.
Filter	Indicates whether filtering is enabled or disabled. Filtering multicast groups allows the device to filter out all multicast traffic groups other than the ones for which the device has received Group Membership reports.
PIM Snooping	Indicates if PIM snooping is enabled. If disabled, this line does not appear.
PIM Prune Wait Time	The amount of time a PIM router will wait before stopping traffic to neighbor routers that do not want the traffic. The value can be from 0 to 3 seconds. The default is 3 seconds.
PIM Proxy	Indicates whether PIM proxy is enabled or disabled. If enabled, it indicates if the feature is configured as passive or active.
Version	The MLD version (1 or 2) operating on the router.
Query Interval	How often the router will query an interface for group membership.
Robustness Var	Used to fine tune for unexpected loss on the subnet. The value is used to calculate the group interval.
Last Member Qry Count	Specifies the number of group-specific queries when a leave is received.
Proxy Interval	Indicates the time interval in seconds between PIM proxy and join messages. You can specify a value from 10 through 600 seconds.
Tracking	Indicates whether tracking is enabled or disabled.
VLAN ID	The port-based VLAN to which the information listed below the ID applies.
IPv6 multicast traffic snooping	Indicates whether IPv6 multicast traffic snooping is enabled or disabled. If enabled, it indicates if the feature is configured as passive or active.
IPv6 Multicast MLD tracking	Indicates whether IPv6 multicast MLD tracking is enabled or disabled.
IPV6 Multicast pimsm snooping	Indicates whether pimsm snooping is enabled or disabled.

To display detailed IPv6 multicast traffic reduction information for a specified VLAN, enter the following command at any level of the CLI.

```
NetIron# show ipv6 multicast vlan 60
L2mdb port type: R-router port, V1-mld v1, V2-mld v2, P_SG-pim sg, P_G-pim g
VLAN ID 60
IPv6 Multicast snooping is running - Passive
IPv6 Multicast mld operating version  - 1 (7s)
 Router ports: 4/2 (9s)
 Number of Multicast Groups: 1

  1    Group: ff09::9
       Ports: 1/1 vlan 60 type  MLDv1  (7s)
              4/2 vlan 60 type  R (9s)
       1    Source: (2060::12,  4/2) FID 0x800a mvid none
            SG group ports: 1/1(1/1) vlan 60 type  MLDv1  (0s)
                            1/2(1/2) vlan 60 type  MLDv1  (0s)
```

Syntax: show ipv6 multicast [**vlan** <*vlan-id*>]

The **vlan** <*vlan-id*> parameter displays IPv6 multicast PIM information for a specified port-based VLAN. The <*vlan-id*> variable is entered in decimal format.

Table 387 displays the output from the **show ipv6 multicast vlan** command.

TABLE 387 Output from the **show ipv6 multicast** command

Field	Description
L2mdb port type	Specifies if it is a router port, or an S,G port, or G port.
VLAN ID	The VLAN to which the information listed below the ID applies. The VLAN ID displays IPv6 multicast PIM information.
IPv6 multicast snooping is running	Indicates whether IPv6 multicast snooping is running as enabled or disabled. If enabled, it indicates if the feature is configured as passive or active.
IPv6 Multicast mld operating version	Indicates whether IPv6 Multicast MLD version is 1 or 2.
Router Ports	The ports that are connected to routers that support IP multicast.
Number of Multicast Groups	The total number of groups for which the VLAN ports have received MLD group membership reports, join messages, or prune messages.
Group	An IPV6 multicast group.
Ports	Indicates outgoing ports of the group.
Source	The IPv6 address of each PIM SM source, and the device ports that are connected to the receivers of the source.
SG group ports	Indicates outgoing ports for an S,G entry.

Chapter

Managing a Device Over IPv6

47

The following ways to Manage a Device Over IPv6 features are supported by PowerConnect B-MLXe .Series devices.

- IPv6 copy Command
- Copying a File from an IPv6 TFTP Server
- Using the IPv6 ncopy Command
- IPv6 Ping Command
- IPv6 Traceroute Command
- IPv6 Telnet
- Secure Shell

You can perform system management tasks for the device using the **copy**, **ncopy**, **ping**, **telnet**, and **traceroute** commands and Secure Shell (SSH). These commands and SSH now function over IPv6.

This section describes the IPv6-related syntax added to the commands and SSH. It does not describe the already existing command syntax for IPv4.

Using the IPv6 copy command

The **copy** command for IPv6 allows you to do the following:

- Copy a file from a specified source to an IPv6 TFTP server.
- Copy a file from an IPv6 TFTP server to a specified destination.

Copying a file to an IPv6 TFTP server

You can copy a file from the following sources to an IPv6 TFTP server:

- Flash memory.
- Running configuration.
- Startup configuration.

Copying a file from flash memory

For example, to copy the primary or secondary boot image from the device's flash memory to an IPv6 TFTP server, enter a command such as the following.

```
NetIron# copy flash tftp 2001:7382:e0ff:7837::3 test.img secondary
```

This command copies the secondary boot image named test.img from flash memory to a TFTP server with the IPv6 address of 2001:7382:e0ff:7837::3.

Syntax: copy flash tftp <*ipv6-address*> <*source-file-name*> **primary | secondary**

The <*ipv6-address*> parameter specifies the address of the TFTP server. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The <*source-file-name*> parameter specifies the name of the file you want to copy to the IPv6 TFTP server.

The **primary** keyword specifies the primary boot image, while the **secondary** keyword specifies the secondary boot image.

Copying a file from the running or startup configuration

For example, to copy the running configuration to an IPv6 TFTP server, enter a command such as the following.

```
NetIron# copy running-config tftp 2001:7382:e0ff:7837::3 newrun.cfg
```

This command copies the running configuration to a TFTP server with the IPv6 address of 2001:7382:e0ff:7837::3 and names the file on the TFTP server newrun.cfg.

Syntax: copy running-config | startup-config tftp <*ipv6-address*> <*destination-file-name*>

Specify the **running-config** keyword to copy the running configuration file to the specified IPv6 TFTP server.

Specify the **startup-config** keyword to copy the startup configuration file to the specified IPv6 TFTP server.

The tftp <*ipv6-address*> parameter specifies the address of the TFTP server. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The <*destination-file-name*> parameter specifies the name of the file that is copied to the IPv6 TFTP server.

Copying a file from an IPv6 TFTP server

You can copy a file from an IPv6 TFTP server to the following destinations:

- Flash memory.
- Running configuration.
- Startup configuration.

Copying a file to flash memory

For example, to copy a boot image from an IPv6 TFTP server to the primary or secondary storage location in the device's flash memory, enter a command such as the following.

```
NetIron# copy tftp flash 2001:7382:e0ff:7837::3 test.img secondary
```

This command copies a boot image named test.img from an IPv6 TFTP server with the IPv6 address of 2001:7382:e0ff:7837::3 to the secondary storage location in the device's flash memory.

Syntax: copy tftp flash <*ipv6-address*> <*source-file-name*> **primary | secondary**

The <*ipv6-address*> parameter specifies the address of the TFTP server. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The <*source-file-name*> parameter specifies the name of the file you want to copy from the IPv6 TFTP server.

The **primary** keyword specifies the primary storage location in the device's flash memory, while the **secondary** keyword specifies the secondary storage location in the device's flash memory.

Copying a file to the running or startup configuration

For example, to copy a configuration file from an IPv6 TFTP server to the router's running or startup configuration, enter a command such as the following.

```
NetIron# copy tftp running-config 2001:7382:e0ff:7837::3 newrun.cfg overwrite
```

This command copies the newrun.cfg file from the IPv6 TFTP server and overwrites the router's running configuration file with the contents of newrun.cfg.

NOTE
To activate this configuration, you must reload (reset) the device.

Syntax: copy tftp running-config | startup-config <*ipv6-address*> <*source-file-name*> **[overwrite]**

Specify the **running-config** keyword to copy the running configuration from the specified IPv6 TFTP server.

Specify the **startup-config** keyword to copy the startup configuration from the specified IPv6 TFTP server.

The <*ipv6-address*> parameter specifies the address of the TFTP server. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The <*source-file-name*> parameter specifies the name of the file that is copied from the IPv6 TFTP server.

The **overwrite** keyword specifies that the device should overwrite the current configuration file with the copied file. If you do not specify this parameter, the device copies the file into the current running or startup configuration but does not overwrite the current configuration.

NOTE
You cannot use the overwrite option from non-console sessions, because it will disconnect the session.

Using the IPv6 ncopy command

The **ncopy** command for IPv6 allows you to do the following:

- Copy a primary or secondary boot image from flash memory to an IPv6 TFTP server.
- Copy the running configuration to an IPv6 TFTP server.
- Copy the startup configuration to an IPv6 TFTP server
- Upload various files from an IPv6 TFTP server.

Copying a primary or secondary boot image from flash memory to an IPv6 TFTP server

For example, to copy the primary or secondary boot image from the device's flash memory to an IPv6 TFTP server, enter a command such as the following.

```
NetIron# ncopy flash primary tftp 2001:7382:e0ff:7837::3 primary.img
```

This command copies the primary boot image named primary.img from flash memory to a TFTP server with the IPv6 address of 2001:7382:e0ff:7837::3.

Syntax: ncopy flash primary | secondary tftp <*ipv6-address*> <*source-file-name*>

The **primary** keyword specifies the primary boot image, while the **secondary** keyword specifies the secondary boot image.

The **tftp** <*ipv6-address*> parameter specifies the address of the TFTP server. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The <*source-file-name*> parameter specifies the name of the file you want to copy from flash memory.

Copying the running or startup configuration to an IPv6 TFTP server

For example, to copy a device's running or startup configuration to an IPv6 TFTP server, enter a command such as the following.

```
NetIron# ncopy running-config tftp 2001:7382:e0ff:7837::3 bakrun.cfg
```

This command copies a device's running configuration to a TFTP server with the IPv6 address of 2001:7382:e0ff:7837::3 and names the destination file bakrun.cfg.

Syntax: ncopy running-config | startup-config tftp <*ipv6-address*> <*destination-file-name*>

Specify the **running-config** keyword to copy the device's running configuration or the **startup-config** keyword to copy the device's startup configuration.

The **tftp** <*ipv6-address*> parameter specifies the address of the TFTP server. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The <*destination-file-name*> parameter specifies the name of the running configuration that is copied to the IPv6 TFTP server.

Uploading files from an IPv6 TFTP server

You can upload the following files from an IPv6 TFTP server:

- Primary boot image.
- Secondary boot image.
- Running configuration.
- Startup configuration.

Uploading a primary or secondary boot image from an IPv6 TFTP server

For example, to upload a primary or secondary boot image from an IPv6 TFTP server to a device's flash memory, enter a command such as the following.

```
NetIron# ncopy tftp 2001:7382:e0ff:7837::3 primary.img flash primary
```

This command uploads the primary boot image named primary.img from a TFTP server with the IPv6 address of 2001:7382:e0ff:7837::3 to the device's primary storage location in flash memory.

Syntax: ncopy tftp <*ipv6-address*> <*source-file-name*> **flash primary | secondary**

The **tftp** <*ipv6-address*> parameter specifies the address of the TFTP server. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The <*source-file-name*> parameter specifies the name of the file you want to copy from the TFTP server.

The **primary** keyword specifies the primary location in flash memory, while the **secondary** keyword specifies the secondary location in flash memory.

Uploading a running or startup configuration from an IPv6 TFTP server

For example to upload a running or startup configuration from an IPv6 TFTP server to a device, enter a command such as the following.

```
NetIron# ncopy tftp 2001:7382:e0ff:7837::3 newrun.cfg running-config
```

This command uploads a file named newrun.cfg from a TFTP server with the IPv6 address of 2001:7382:e0ff:7837::3 to the device.

Syntax: ncopy tftp <*ipv6-address*> <*source-file-name*> **running-config | startup-config**

The **tftp** <*ipv6-address*> parameter specifies the address of the TFTP server. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The <*source-file-name*> parameter specifies the name of the file you want to copy from the TFTP server.

Specify the **running-config** keyword to upload the specified file from the IPv6 TFTP server to the device. The device copies the specified file into the current running configuration but does not overwrite the current configuration.

Specify the **startup-config** keyword to upload the specified file from the IPv6 TFTP server to the device. The device copies the specified file into the current startup configuration but does not overwrite the current configuration.

Using the IPv6 ping command

The **ping** command allows you to verify the connectivity from a device to an IPv6 device by performing an ICMP for IPv6 echo test.

For example, to ping a device with the IPv6 address of 2001:3424:847f:a385:34dd::45 from the device, enter the following command.

```
NetIron# ping ipv6 2001:3424:847f:a385:34dd::45
```

Syntax: **ping ipv6** <*ipv6-address*> **[outgoing-interface** [<*port*> **| ve** <*number*>]] **[source** <*ipv6-address*>] **[count** <*number*>] **[timeout** <*milliseconds*>] **[ttl** <*number*>] **[size** <*bytes*>] **[quiet] [numeric] [no-fragment] [verify] [data <1-to-4 byte hex>] [brief]**

The <*ipv6-address*> parameter specifies the address of the router. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The **outgoing-interface** keyword specifies a physical interface over which you can verify connectivity. If you specify a physical interface, such as an Ethernet interface, you must also specify the port number of the interface. If you specify a virtual interface, such as a VE, you must specify the number associated with the VE.

The **source** <*ipv6-address*> parameter specifies an IPv6 address to be used as the origin of the ping packets.

The **count** <*number*> parameter specifies how many ping packets the router sends. You can specify from 1 - 4294967296. The default is 1.

The **timeout** <*milliseconds*> parameter specifies how many milliseconds the router waits for a reply from the pinged device. You can specify a timeout from 1 - 4294967296 milliseconds. The default is 5000 (5 seconds).

The **ttl** <*number*> parameter specifies the maximum number of hops. You can specify a TTL from 1 - 255. The default is 64.

The **size** <*bytes*> parameter specifies the size of the ICMP data portion of the packet. This is the payload and does not include the header. You can specify from 0 - 4000. The default is 16.

The **no-fragment** keyword turns on the "don't fragment" bit in the IPv6 header of the ping packet. This option is disabled by default.

The **quiet** keyword hides informational messages such as a summary of the ping parameters sent to the device and instead only displays messages indicating the success or failure of the ping. This option is disabled by default.

The **verify** keyword verifies that the data in the echo packet (the reply packet) is the same as the data in the echo request (the ping). By default the device does not verify the data.

The **data** <*1 - 4 byte hex*> parameter lets you specify a specific data pattern for the payload instead of the default data pattern, "abcd", in the packet's data payload. The pattern repeats itself throughout the ICMP message (payload) portion of the packet.

NOTE
For parameters that require a numeric value, the CLI does not check that the value you enter is within the allowed range. Instead, if you do exceed the range for a numeric value, the software rounds the value to the nearest valid value.

The **brief** keyword causes ping test characters to be displayed. The following ping test characters are supported:

! Indicates that a reply was received.

. Indicates that the network server timed out while waiting for a reply.

U Indicates that a destination unreachable error PDU was received.

I Indicates that the user interrupted ping.

Using the IPv6 traceroute command

The **traceroute** command allows you to trace a path from the device to an IPv6 host.

The CLI displays trace route information for each hop as soon as the information is received. Traceroute requests display all responses to a minimum TTL of 1 second and a maximum TTL of 30 seconds. In addition, if there are multiple equal-cost routes to the destination, the device displays up to three responses.

For example, to trace the path from the device to a host with an IPv6 address of 3301:23dd:349e:a384::34, enter the following command.

```
NetIron# traceroute ipv6 3301:23dd:349e:a384::34
```

Syntax: traceroute ipv6 *<ipv6-address>*

The *<ipv6-address>* parameter specifies the address of a host. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

Using Telnet

This section explains how to do the following:

- Use the **telnet** command to establish a Telnet session from the device to a remote IPv6 host.
- Establish a Telnet session from a remote IPv6 host to the device.

Using the IPv6 Telnet command

The **telnet** command allows a Telnet connection from a device to a remote IPv6 host using the console. Up to five read-access and one write-access inbound Telnet session are supported on the router at one time. Up to five simultaneous outbound Telnet sessions can also be supported from the console session, from inbound Telnet sessions, from inbound SSH sessions or from a Web session.

To see the Telnet sessions currently open on the device, enter the **show telnet** command; to see both the open Telnet and open SSH sessions, enter the **show who** command as shown below.

```
NetIron# show who
Console connections:
       established
       3 days 17 hours 31 minutes 27 seconds in idle
Telnet server status: Enabled
Telnet connections (inbound):
 1      established, client ip address 10.53.1.86
       you are connecting to this session
       1 seconds in idle
 2      established, client ip address 10.53.1.86
       7 seconds in idle
 3      closed
 4      closed
 5      closed
Telnet connections (outbound):
 6      established, server ip address 10.47.2.200, from Telnet session 1
       4 seconds in idle
 7      closed
 8      closed
 9      closed
 10     closed
SSH server status: Enabled
SSH connections:
 1      closed
 2      closed
 3      closed
 4      closed
...
```

Syntax: show who

To establish a Telnet connection to a remote host, use the **telnet** command. The following example will establish an outbound Telnet connection to a remote host with the IPv6 address of 3001:2837:3de2:c37::6.

```
NetIron# telnet 3001:2837:3de2:c37::6
```

Syntax: telnet <*ipv6-address*> [<*port-number*> **| outgoing-interface ethernet** <*port*> **| ve** <*number*>]

The <*ipv6-address*> parameter specifies the address of a remote host. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The <*port-number*> parameter specifies the port number on which the device establishes the Telnet connection. You can specify a value between 1 - 65535. If you do not specify a port number, the device establishes the Telnet connection on port 23.

If the IPv6 address you specify for the **telnet** <*ipv6-address*> command is a link-local address, you must specify the **outgoing-interface** ethernet <*port*> | ve <*number*> parameter. This parameter specifies the interface that must be used to reach the remote host. If you specify an Ethernet interface, also specify the port number associated with the interface. If you specify a VE interface, also specify the VE number.

Establishing a Telnet session from an IPv6 host

To establish a Telnet session from an IPv6 host to the device, open your Telnet application and specify the IPv6 address of the router.

Using Secure Shell

Secure Shell (SSH) is a mechanism that allows secure remote access to management functions on the device. SSH provides a function similar to Telnet. You can log into and configure the device using a publicly or commercially available SSH client program, just as you can with Telnet. However, unlike Telnet, which provides no security, SSH provides a secure, encrypted connection to the device.

To open an SSH session from an IPv6 host running an SSH client program to the device, open your SSH client program and specify the IPv6 address of the router.

Chapter

Configuring Secure Shell and Secure Copy 48

The following Secure Shell features are supported by PowerConnect B-MLXe Series devices.

- SSH Transport Layer Protocol
- SSH Authentication Protocol
- SSH Connection Protocol
- SSH Fingerprint Format
- SSH Protocol Assigned Numbers
- SCP for Copying code images
- SCP for Copying code images
- SSH Transport Layer Encryption Modes
- CP or SFTP or SSH URI Format
- DSA challenge-response authentication
- Password authentication
- 3DES as the encryption algorithm
- AES as the encryption algorithm
- SHA 1 as the MAC algorithm

Secure Shell (SSH) is a mechanism for allowing secure remote access to management functions on a PowerConnect. SSH provides a function similar to Telnet. Users can log into and configure the device using a publicly or commercially available SSH client program, just as they can with Telnet. However, unlike Telnet, which provides no security, SSH provides a secure, encrypted connection to the device.

SSH v2 is supported on the PowerConnect. Dell's SSHv2 implementation is compatible with all versions of the SSHv2 protocol (2.1, 2.2, and so on). At the beginning of an SSH session, the PowerConnect negotiates the version of SSHv2 to be used. The highest version of SSHv2 supported by both the PowerConnect and the client is the version that is used for the session. Once the SSHv2 version is negotiated, the encryption algorithm with the highest security ranking is selected to be used for the session.

The number of SSH client instances allowed is16.

Also, the PowerConnect support Secure Copy (SCP) for securely transferring files between a PowerConnect and an SCP-enabled remote hosts. Refer to "Using Secure Copy" on page 2026 for more information.

NOTE
SSH is disabled by default. To gain access to a PowerConnect router through SSH, you must enable it as described in this chapter.

SSH Version 2 support

SSHv2 is a substantial revision of Secure Shell, comprising the following hybrid protocols and definitions:

- SSH Transport Layer Protocol
- SSH Authentication Protocol
- SSH Connection Protocol
- SECSH Public Key File Format
- SSH Fingerprint Format
- SSH Protocol Assigned Numbers
- SSH Transport Layer Encryption Modes
- SCP or SFTP or SSH URI Format

If you are using redundant management modules, you can synchronize the DSA host key pair between the active and standby modules by entering the **sync-standby** command at the Privileged EXEC level of the CLI.

Tested SSHv2 clients

The following SSH clients have been tested with SSHv2:

- SSH Secure Shell 3.2.3
- Van Dyke SecureCRT 4.0 and 4.1
- F-Secure SSH Client 5.3 and 6.0
- PuTTY 0.54 and 0.56

NOTE
On the PuTTy client, under the options that control key re-exchange, it is recommended that the maximum minutes before rekey be set to 0 and the maximum data before rekey be set to 0.

- OpenSSH 3.5_p1 and 3.6.1p2
- Solaris Sun-SSH-1.0

Supported features

The SSH server allows secure remote access management functions on a device. SSH provides a function that is similar to Telnet, but unlike Telnet, SSH provides a secure, encrypted connection.

SSHv2 support includes the following:

- The following encryption cipher algorithm are supported. They are listed in order of preference:
  - **aes256-cbc:** AES in CBC mode with 256-bit key
  - **aes192-cbc:** AES in CBC mode with 192-bit key
  - **aes128-cbc:** AES in CBC mode with 128-bit key
  - **3des-cbc:** Triple-DES
- Key exchange methods, in the order of preference are:
  - **diffie-hellman-group1-sha1**

  - **diffie-hellman-group14-sha1**
- Public key algorithm is **ssh-dss**.
- Data integrity is ensured with **hmac-sha1** algorithm.
- Supported authentication methods are **Password** and **publickey**.
- Compression is not supported.
- TCP or IP port forwarding, X11 forwarding, and secure file transfer are not supported.
- SSH version 1 is not supported.
- SCP supports AES encryption

Configuring SSH

Dell's implementation of SSH supports two kinds of user authentication:

- ***DSA challenge-response authentication***, where a collection of public keys are stored on the device. Only clients with a private key that corresponds to one of the stored public keys can gain access to the device using SSH.
- ***Password authentication***, where users attempting to gain access to the device using an SSH client are authenticated with passwords stored on the device or on a TACACS or TACACS+ or RADIUS server

Both kinds of user authentication are enabled by default. You can configure the device to use one or both of them.

To configure Secure Shell on a PowerConnect, perform the tasks listed below.

1. Generate a host DSA public and private key pair for the device.
2. Configure DSA challenge-response authentication.
3. Set optional parameters.

You can also view information about active SSH connections on the device as well as terminate them.

Generating a host key pair

When SSH is configured, a public and private ***host DSA key pair*** is generated for the PowerConnect. The SSH server on the PowerConnect uses this host DSA key pair, along with a dynamically generated ***server DSA key pair***, to negotiate a session key and encryption method with the client trying to connect to it.

The host DSA key pair is stored in the PowerConnect's system-config file. Only the public key is readable. The public key should be added to a "known hosts" file (for example, $HOME/.ssh/known_hosts on UNIX systems) on the clients who want to access the device. Some SSH client programs add the public key to the known hosts file automatically; in other cases, you must manually create a known hosts file and place the PowerConnect's public key in it. Refer to "Providing the public key to clients" on page 2018 for an example of what to place in the known hosts file.

While the SSH listener exists at all times, sessions can't be started from clients until a key is generated. Once a key is generated, clients can start sessions. The keys are also not displayed in the configuration file by default. To display the keys, use the **ssh show-host-keys** command in Privileged EXEC mode. To generate a public and private DSA host key pair on a PowerConnect, enter the following commands.

```
NetIron(config)# crypto key generate
```

When a host key pair is generated, it is saved to the flash memory of all management modules.

To disable SSH in SSHv2 on a PowerConnect, enter the following commands.

```
NetIron(config)# crypto key zeroize
```

When SSH is disabled, it is deleted from the flash memory of all management modules.

Syntax: crypto key generate | zeroize

The **generate** keyword places an DSA host key pair in the flash memory and enables SSH on the device.

The **zeroize** keyword deletes the DSA host key pair from the flash memory and disables SSH on the device.

By default, public keys are hidden in the running configuration. You can optionally configure the PowerConnect to display the DSA host key pair in the running configuration file entering the following command.

```
NetIron# ssh show-host-keys
```

Syntax: ssh show-host-keys

To hide the public keys in the running configuration file, enter the following command.

```
NetIron# ssh no-show-host-keys
```

Syntax: ssh no-show-host-keys

Providing the public key to clients

If you are using SSH to connect to a PowerConnect from a UNIX system, you may need to add the PowerConnect's public key to a "known hosts" file; for example, $HOME/.ssh/known_hosts. The following is an example of an entry in a known hosts file.

```
AAAAB3NzaC1kc3MAAACBAPY8ZOHY2yFSJA6XYC9HRwNHxaehvx5wOJ0rzZdzoSOXxbET

```

Configuring DSA challenge-response authentication

With DSA challenge-response authentication, a collection of clients' public keys are stored on the PowerConnect. Clients are authenticated using these stored public keys. Only clients that have a private key that corresponds to one of the stored public keys can gain access to the device using SSH.

When DSA challenge-response authentication is enabled, the following events occur when a client attempts to gain access to the device using SSH.

1. The client sends its public key to the PowerConnect.
2. The PowerConnect compares the client's public key to those stored in memory.
3. If there is a match, the PowerConnect uses the public key to encrypt a random sequence of bytes.
4. The PowerConnect sends these encrypted bytes to the client.
5. The client uses its private key to decrypt the bytes.
6. The client sends the decrypted bytes back to the PowerConnect.
7. The PowerConnect compares the decrypted bytes to the original bytes it sent to the client. If the two sets of bytes match, it means that the client's private key corresponds to an authorized public key, and the client is authenticated.

Setting up DSA challenge-response authentication consists of the following steps.

1. Importing authorized public keys into the PowerConnect.
2. Enabling DSA challenge response authentication

Importing authorized public keys into the PowerConnect

SSH clients that support DSA authentication normally provide a utility to generate an DSA key pair. The private key is usually stored in a password-protected file on the local host; the public key is stored in another file and is not protected. You should collect one public key from each client to be granted access to the PowerConnect and place all of these keys into one file. This public key file is imported into the PowerConnect.

The following is an example of a public key file containing one public keys.

```
---- BEGIN SSH2 PUBLIC KEY ----
Comment: DSA Public Key
AAAAB3NzaC1kc3MAAACBAPY8ZOHY2yFSJA6XYC9HRwNHxaehvx5wOJ0rzZdzoSOXxbET
W6ToHv8D1UJ/z+zHo9Fiko5XybZnDIaBDHtblQ+Yp7StxyltHnXF1YLfKD1G4T6JYrdH YI14Om
1eg9e4NnCRleaqoZPF3UGfZia6bXrGTQf3gJq2e7Yisk/gF+1VAAAAFQDb8D5cv

sY29ouezv4Xz2PuMch5VGPP+CDqzCM4loWgV
---- END SSH2 PUBLIC KEY ----
```

NOTE
Make sure the key ends with the complete phrase "`---- END SSH2 PUBLIC KEY ----`" before importing the public key. Otherwise, a warning is displayed whenever the device is reloaded.

You can import the authorized public keys into the active configuration by loading them from a file on a TFTP server and are saved on the EEPROM of the chassis. If you import a public key file from a TFTP server, the file is automatically loaded into the active configuration the next time the device is booted.

To cause a public key file called pkeys.txt to be loaded from a TFTP server each time the PowerConnect is booted, enter a command such as the following.

```
NetIron(config)# ip ssh pub-key-file tftp 192.168.1.234 pkeys.txt
```

Syntax: ip ssh pub-key-file tftp ipv6 <*ipv6-addr*> **|** <*tftp-server-ip-addr*> <*filename*> **[remove]**

The <*tftp-server-ip-addr*> variable is the IP address of the tftp server that contains the public key file that you want to import into the device.

The <*filename*> variable is the name of the dsa public key file that you want to import into the device.

The **remove** parameter deletes the key from the system.

To display the currently loaded public keys, enter the following command.

```
NetIron# show ip client-pub-key
---- BEGIN SSH2 PUBLIC KEY ----
Comment: DSA Public Key
AAAAB3NzaC1kc3MAAACBAPY8ZOHY2yFSJA6XYC9HRwNHxaehvx5wOJ0rzZdzoSOXxbET

sY29ouezv4Xz2PuMch5VGPP+CDqzCM4loWgV
---- END SSH2 PUBLIC KEY ----
```

Syntax: show ip client-pub-key [| begin<*expression*> **| exclude** <*expression*> **| include** <*expression*>**]**

To clear the public keys from the buffers, enter the following command.

```
NetIron# clear public-key
```

Syntax: clear public-key

Use the **ip ssh pub-key remove** command to delete the public key from the system.

Enabling DSA challenge-response authentication

DSA challenge-response authentication is enabled by default. You can disable or re-enable it manually.

To enable DSA challenge-response authentication.

```
NetIron(config)# ip ssh key-authentication yes
```

To disable DSA challenge-response authentication.

```
NetIron(config)# ip ssh key-authentication no
```

Syntax: ip ssh key-authentication yes | no

Setting optional parameters

You can adjust the following SSH settings on the device:

- Number of SSH authentication retries
- User authentication method the device uses for SSH connections
- Whether or not the device allows users to log in without supplying a password

- Port number for SSH connections
- SSH login timeout value
- A specific interface to be used as the source for all SSH traffic from the device
- Maximum idle time for SSH sessions
- Disable 3-DES support

Setting the number of SSH authentication retries

By default, the PowerConnect attempts to negotiate a connection with the connecting host three times. The number of authentication retries can be changed to between 1 – 5.

For example, the following command changes the number of authentication retries to 5.

```
NetIron(config)# ip ssh authentication-retries 5
```

Syntax: ip ssh authentication-retries <*number*>

Deactivating user authentication

After the SSH server on the PowerConnect negotiates a session key and encryption method with the connecting client, user authentication takes place. Dell's implementation of SSH supports DSA challenge-response authentication and password authentication.

With DSA challenge-response authentication, a collection of clients' public keys are stored on the PowerConnect. Clients are authenticated using these stored public keys. Only clients that have a private key that corresponds to one of the stored public keys can gain access to the device using SSH.

With password authentication, users are prompted for a password when they attempt to log into the device (provided empty password logins are not allowed; refer to "Enabling empty password logins" on page 2022). If there is no user account that matches the user name and password supplied by the user, the user is not granted access.

You can deactivate one or both user authentication methods for SSH. Note that deactivating both authentication methods essentially disables the SSH server entirely.

To disable DSA challenge-response authentication.

```
NetIron(config)# ip ssh key-authentication no
```

Syntax: ip ssh key-authentication yes | no

The default is "yes".

To deactivate password authentication.

```
NetIron(config)# ip ssh password-authentication no
```

Syntax: ip ssh password-authentication no | yes

The default is "yes".

Enabling empty password logins

By default, empty password logins are not allowed. This means that users with an SSH client are always prompted for a password when they log into the device. To gain access to the device, each user must have a user name and password. Without a user name and password, a user is not granted access. Refer to "Setting up local user accounts" on page 31 for information on setting up user names and passwords on the PowerConnect.

If you enable empty password logins, users are ***not*** prompted for a password when they log in. Any user with an SSH client can log in without being prompted for a password.

To enable empty password logins.

```
NetIron(config)# ip ssh permit-empty-passwd yes
```

Syntax: ip ssh permit-empty-passwd no | yes

Setting the SSH port number

By default, SSH traffic occurs on TCP port 22. You can change this port number. For example, the following command changes the SSH port number to 2200.

```
NetIron(config)# ip ssh port 2200
```

Note that if you change the default SSH port number, you must configure SSH clients to connect to the new port. Also, you should be careful not to assign SSH to a port that is used by another service. If you change the SSH port number, it is recommended that you change it to a port number greater than 1024.

Syntax: ip ssh port <*number*>

Setting the SSH login timeout value

When the SSH server attempts to negotiate a session key and encryption method with a connecting client, it waits a maximum of 120 seconds for a response from the client. If there is no response from the client after 120 seconds, the SSH server disconnects. You can change this timeout value to between 1 – 120 seconds. For example, to change the timeout value to 60 seconds.

```
NetIron(config)# ip ssh timeout 60
```

Syntax: ip ssh timeout <*seconds*>

NOTE
The standard for the idle-timeout RADIUS attribute is for it to be implemented in seconds as opposed to the minutes that the PowerConnect router uses. If this attribute is used for setting idle time instead of this configuration, the value from the idle-timeout RADIUS attribute will be converted to seconds and truncated to the nearest minute. Designating an Interface as the Source for All SSH Packets

---

You can designate a loopback interface, virtual interface, or Ethernet port as the source for all SSH packets from the device. The software uses the IP address with the numerically lowest value configured on the port or interface as the source IP address for SSH packets originated by the device.

NOTE
When you specify a single SSH source, you can use only that source address to establish SSH management sessions with the PowerConnect.

To specify the numerically lowest IP address configured on a loopback interface as the device's source for all SSH packets, enter commands such as a the following.

```
NetIron(config)# int loopback 2
NetIron(config-lbif-2)# ip address 10.0.0.2/24
NetIron(config-lbif-2)# exit
NetIron(config)# ip ssh source-interface loopback 2
```

The commands in this example configure loopback interface 2, assign IP address 10.0.0.2/24 to the interface, then designate the interface as the source for all SSH packets from the PowerConnect.

Syntax: ip ssh source-interface ethernet <*slot/port*> **| loopback** <*num*> **| ve** <*num*>

The <*num*> parameter is a loopback interface or virtual interface number. The <*slot/port*> parameter specifies an ethernet port number.

Example

```
NetIron(config)# interface ethernet 1/4
NetIron(config-if-e10000-1/4)# ip address 209.157.22.110/24
NetIron(config-if-e10000-1/4)# exit
NetIron(config)# ip ssh source-interface ethernet 1/4
```

Configuring maximum idle time for SSH sessions

By default, SSH sessions do not time out. Optionally, you can set the amount of time an SSH session can be inactive before the PowerConnect closes it. For example, to set the maximum idle time for SSH sessions to 30 minutes.

```
NetIron(config)# ip ssh idle-time 30
```

Syntax: ip ssh idle-time <*minutes*>

If an established SSH session has no activity for the specified number of minutes, the PowerConnect closes it. An idle time of 0 minutes (the default value) means that SSH sessions never time out. The maximum idle time for SSH sessions is 240 minutes.

NOTE
The standard for the idle-timeout RADIUS attribute is for it to be implemented in seconds as opposed to the minutes that the PowerConnect router uses. If this attribute is used for setting idle time instead of this configuration, the value from the idle-timeout RADIUS attribute will be converted from seconds to minutes and truncated to the nearest minute.

Filtering SSH access using ACLs

You can permit or deny SSH access to the PowerConnect using ACLs. To configure an ACL that restricts SSH access to the device, enter commands such as the following.

```
NetIron(config)# access-list 12 deny host 209.157.22.98
NetIron(config)# access-list 12 deny 209.157.23.0 0.0.0.255
NetIron(config)# access-list 12 deny 209.157.24.0/24
NetIron(config)# access-list 12 permit any
NetIron(config)# ssh access-group 12
NetIron(config)# write memory
```

Syntax: ssh access-group {<*num*> | <*name*> | **ipv6** <*ipv6-acl-name*>}

Use the **ipv6** keyword if you are applying an IPv6 access list.

The <*num*> parameter specifies the number of a standard IPv4 ACL, 1 – 99.

The <*name*> parameter specifies a standard IPv4 access list name.

The <*ipv6-acl-name*> parameter specifies an IPv6 access list name.

These commands configure ACL 12, then apply the ACL as the access list for SSH access. The device denies SSH access from the IPv4 addresses listed in ACL 12 and permits SSH access from all other IP addresses. Without the last ACL entry for permitting all packets, this ACL would deny SSH access from all IP addresses.

NOTE
Access control lists are IP version specific. When both IPv4 and IPv6 ACLs are configured, the IPv4 ACL will be applied to sessions from IPv4 clients and the IPv6 ACL will be applied to sessions from IPv6 clients.

Refer to 21, "Access Control List" and Chapter 40, "Configuring an IPv6 Access Control List" for details on how to configure ACLs.

Disabling 3-DES

By default, both 3-DES and AES encryption algorithms are enabled on the NetIron device. You can disable 3-DES by entering the following command.

```
NetIron(config)# ip ssh encryption aes-only
```

Syntax: [no] ip ssh encryption aes-only

Displaying SSH connection information

Up to five SSH connections can be active on the PowerConnect. To display information about SSH connections, enter the following command.

```
NetIron# show ip ssh
Connection Version  Encryption    Username    IP Address
1           SSH-2   3des-cbc      Hanuma      10.43.2.4
2           SSH-2   aes128-cbc    Mikaila     10.50.3.7
3           SSH-2   aes192-cbc    Jenny       10.47.8.20
4           SSH-2   aes256-cbc    Mariah      10.55.3.9
5           SSH-2   3des-cbc      Logan       10.9.4.11
```

Syntax: show ip ssh [**| begin** <*expression*> **| exclude** <*expression*> **| include** <*expression*>]

This display shows the following information about the active SSH connections.

TABLE 388 SSH connection information

This field...	Displays...
Connection	The SSH connection ID. This can be from 1 – 16.
Version	The SSH version number. This should always be SSH-2.
Encryption	The encryption method used for the connection.
Username	The user name for the connection if password authentication is used. If public key authentication is used, username shows <*none*>.

The **show who** command also displays information about SSH connections.

Example

```
NetIron#show who
Console connections:
established, monitor enabled, in config mode
2 minutes 17 seconds in idle
Telnet connections (inbound):
1 closed
2 closed
3 closed
4 closed
5 closed
Telnet connection (outbound):
6 closed
SSH connections:
1 established, client ip address 10.43.2.4, user is hanuma
1 minutes 16 seconds in idle
2 established, client ip address 10.50.3.7, user is Mikaila
you are connecting to this session
18 seconds in idle
3 established, client ip address 10.47.8.20, user is Jenny
1 minutes 39 seconds in idle
4 established, client ip address 10.55.3.9, user is Mariah
41 seconds in idle
5 established, client ip address 10.9.4.11, user is Logan
23 seconds in idle
```

Syntax: show who [| **begin**<*expression*> | **exclude**<*expression*> | **include**<*expression*>]

Ending an SSH connection

To terminate one of the active SSH connections, enter the following command.

```
NetIron# kill ssh 1
```

Syntax: kill ssh <*connection-id*>

Using Secure Copy

Secure Copy (SCP) uses security built into SSH to transfer files between hosts on a network, providing a more secure file transfer method than Remote Copy (RCP), FTP, or TFTP. SCP automatically uses the authentication methods, encryption algorithm, and data compression level configured for SSH. For example, if password authentication is enabled for SSH, the user is prompted for a user name and password before SCP allows a file to be transferred. No additional configuration is required for SCP on top of SSH.

You can use SCP to copy files on the PowerConnect, including the startup configuration and running configuration files, to or from any other device running an SCP program (referred to here as an "SCP-enabled remote host").

SCP is enabled on the PowerConnect by default and can be disabled. To disable SCP, enter the following command.

```
NetIron(config)# ip ssh scp disable
```

Syntax: ip ssh scp disable | enable

NOTE
If you disable SSH, SCP is also disabled.

NOTE
When using SCP to transfer files, you enter the **scp** commands on the SCP-enabled remote host, rather than the console on the PowerConnect.

NOTE
Certain SCP client options, including -p and -r, are ignored by the SCP server on the PowerConnect. If an option is ignored, the client is notified.

NOTE
If password authentication is enabled for SSH, the user is prompted for user password before the file transfer takes place.

NOTE
All SCP features supported on the PowerConnect B-MLXe Series.

Outbound commands:

The following is the list of outbound SCP command options supported (Upload from device to host).

The general syntax of the outbound SCP commands is as follows.

Syntax: scp *<user>*@*<IP Address>*:*<Source>*:*<src-name> <dst-file>*

<src-name> can be abbreviated

To copy the running configuration file on a PowerConnect to a file on the SCP-enabled host.

```
C:\> scp <user>@<PowerConnect-IpAddress>:runConfig <dst-file>
```

NOTE
If you are copying the running configuration file from the PowerConnect to a PC or another machine (outbound), the command saves the running configuration file to the PC. If you are copying a configuration file from a PC to the PowerConnect, (inbound) the command appends the source file to the running configuration file on the PowerConnect.

To copy the startup configuration file on the PowerConnect to a file on the SCP-enabled client.

```
C:> scp <user>@<PowerConnect-IpAddress>:startConfig <dst-file>
```

To copy the MP primary image file from the PowerConnect to a file on the SCP-enabled client.

```
C:> scp <user>@<PowerConnect-IpAddress>:flash:primary <primary-image-file>
```

To copy the MP secondary image file from the PowerConnect to a file on the SCP-enabled client.

```
C:> scp <user>@<PowerConnect-IpAddress>:flash:secondary <secondary-image-file>
```

To copy a flash file from the PowerConnect to a file on the SCP-enabled client.

```
C:> scp <user>@<PowerConnect-IpAddress>:flash:<src-file> <dst-file>
```

To copy a file on PCMCIA slot from the PowerConnect to a file on the SCP-enabled client

```
C:> scp <user>@<PowerConnect-IpAddress>:slot1:/<src-file> <dst-file>
C:> scp <user>@<PowerConnect-IpAddress>:slot2:/<src-file> <dst-file>
```

Inbound commands:

The following is the list of inbound SCP command options supported (for downloading from an SCP-enabled client to the PowerConnect). The commands copy the files from the SCP-enabled client to the specified location on the PowerConnect.

The general syntax of the Inbound SCP commands is as follows.

Syntax: scp *<file-name>* *<user>***@***<IP Address>***:***<Destination>***:***<file-name>***[:***<additional-options>**]**

The last two tokens *<file-name>* and *<additional-options>* can be abbreviated. The others cannot be abbreviated.

PCMCIA command option

To download a file and store it in a PCMCIA (Slot 1 or Slot 2), enter the following command

```
C:> scp <src-file> <user>@<PowerConnect-IpAddress>:slot1:/<dst-file>
```

This commands transfers <*src-file*> to the PowerConnect and saves it as /slot1/<*dst-file*>.

Flash MP command options

To download a file and store in MP Flash , enter the following command.

```
C:> scp <src-file> <user>@<PowerConnect-IpAddress>:flash:<dst-file>
```

This command transfers <*src-file*> to the PowerConnect and saves it as <*dst-file*> in flash

To download and replace MP Monitor image in Flash , enter the following command.

```
C:> scp <monitor-image-file> <user>@<PowerConnect-IpAddress>:flash:monitor
```

This command transfers <monitor-image-file> to the PowerConnect and replaces MP monitor image in flash.

To download and replace MP Primary image in Flash , enter the following command.

```
C:> scp <primary-image-file> <user>@<PowerConnect-IpAddress>:flash:primary
```

This command transfers *<primary-image-file>* to the PowerConnect and replaces MP Primary image in flash.

To download and replace MP secondary image in Flash , enter the following command.

```
C:> scp <secondary-image-file> <user>@<PowerConnect-IpAddress>:flash:secondary
```

This command transfers <*secondary-image-file*> to the PowerConnect and replaces MP secondary image in flash.

To download and replace MP boot image in Flash, enter the following command.

```
C:> scp <boot-image-file> <user>@<PowerConnect-IpAddress>:flash:boot
```

This command transfers <*boot-image-file*> to the PowerConnect and replaces MP boot image in flash.

Running configuration command options

To download a configuration file and append to running configuration , enter the following command.

```
C:> scp <config-file> <user>@<PowerConnect-IpAddress>:config:run
```

This command transfers <*config-file*> to the PowerConnect and appends to the running configuration.

For backward compatibility, the following syntax is also supported for this command.

```
C:> scp <config-file> <user>@<PowerConnect-IpAddress>:runConfig
```

Startup configuration command options

To download a configuration file and replace startup configuration , enter the following command.

```
C:> scp <config-file> <user>@<PowerConnect-IpAddress>:config:start
```

This command transfers *<config-file>* to the PowerConnect and replaces the startup configuration in flash.

For backward compatibility, the following syntax is also supported for this command.

```
C:> scp <config-file> <user>@<PowerConnect-IpAddress>:startConfig
```

Combined image command options

To download a combined image file and replace LP and MP primary.

```
C:> scp <combined-image-file> <user>@<PowerConnect-IpAddress>:image:primary
```

This command transfers <*combined-image-file*> to the PowerConnect and replaces MP and LP Primary image in flash.

To download a combined image file and replace LP primary and MP secondary.

```
C:> scp <combined-image-file>   <user>@<PowerConnect-IpAddress>:image:mp-sec
```

This command transfers <*combined-image-file*> to the PowerConnect and replaces MP Secondary and LP Primary image in flash.

To download a combined image file and replace LP secondary and MP primary, enter the following command.

```
C:> scp <combined-image-file> <user>@<PowerConnect-IpAddress>:image:lp-sec
```

This command transfers <*combined-image-file*> to the PowerConnect and replaces MP Primary and LP Secondary image in flash.

To download a combined image file and replace LP and MP secondary, enter the following command.

```
C:> scp <combined-image-file> <user>@<PowerConnect-IpAddress>:image:secondary
```

This command transfers <*combined-image-file*> to the PowerConnect and replaces MP and LP Secondary image in flash.

MBRIDGE command options

To download and replace FPGA (mbridge) file in MP, enter the following command.

```
C:> scp <image-file> <user>@<PowerConnect-IpAddress>:mbridge
```

This command downloads <*image-file*> and replaces the mbridge image on the flash.

Switch fabric options

To download and replace switch fabric file to a single SNM or all in MP, enter the following command.

```
C:> scp <image-file> <user>@<PowerConnect-IpAddress>:snm:sbridge:
<snm-index>
```

This command downloads <*image-file*> and replaces sbridge image on the specified SNM.

To download and replace sbridge image on all SNMs, enter the following command.

```
C:> scp <image-file> <user>@<PowerConnect-IpAddress>:snm:sbridge:all
```

This command downloads <*image-file*> and replaces the sbridge image on all the SNMs.

LP command option

To download and over-write the LP boot image on one LP or all LPs, enter the following command.

```
C:> scp <lp-boot-image-file>
<user>@<PowerConnect-IpAddress>:lp:boot:<lp-slot-num>
```

This command transfers <*lp-boot-image-file*> to the PowerConnect and replaces the LP boot image in the specified LP slot.

```
C:> scp <lp-boot-image-file> <user>@<PowerConnect-IpAddress>:lp:boot:all
```

This command transfers <*lp-boot-image-file*> to the PowerConnect and replaces LP boot image in all the LP slots

To download and over-write the LP monitor image on one LP or all LPs, enter the following command.

```
C:> scp <lp-monitor-image-file>
<user>@<PowerConnect-IpAddress>:lp:monitor:<lp-slot-num>
```

This command transfers <*lp-monitor-image-file*> to the PowerConnect and replaces the LP monitor image in the specified LP slot.

```
C:> scp <lp-monitor-image-file> <user>@<PowerConnect-IpAddress>:lp:monitor:all
```

This command transfers <*lp-monitor-image-file*> to the PowerConnect and replaces LP monitor image in all LP slots.

To download and over-write LP primary image on one LP or all LPs, enter the following commands.

```
C:> scp <lp-primary-file>
<user>@<PowerConnect-IpAddress>:lp:primary:<lp-slot-num>
```

This command transfers <lp-primary-file> to the PowerConnect and replaces the LP Primary image in the specified LP slot.

```
C:> scp <lp-primary-file> <user>@<PowerConnect-IpAddress>:lp:primary:all
```

This command transfers <*lp-primary-file*> to the PowerConnect and replaces the LP Primary image in all the LP slots.

To download and over-write the LP secondary image on one LP or all LPs, enter the following commands.

```
C:> scp <lp-secondary-file>
<user>@<PowerConnect-IpAddress>:lp:secondary:<lp-slot-num>
```

This command transfers <*lp-secondary-file*> to the PowerConnect and replaces LP Secondary image in the specified LP slot.

```
C:> scp <lp-secondary-file> <user>@<PowerConnect-IpAddress>:lp:secondary:all
```

This command transfers <*lp-secondary-file*> to the PowerConnect and replaces the LP Secondary image in all the LP slots.

Bundled FPGA command options

NOTE
If force-overwrite is present in the command, the command skips compatibility checks and forcibly replaces the FPGA image, otherwise the command checks for compatibility of the FPGA image and if the check fails the FPGA image is not not replaced and error message is returned to the SCP client.

To download and over-write Bundled FPGA image, enter the following commands.

```
C:> scp <fpga-bundle-file>
<user>@<PowerConnect-IpAddress>:lp:fpga-all:<lp-slot-num>
```

This command downloads <*fpga-bundle-file*> and replaces all the FPGA images (PBIF, STATS, XGMAC and XPP) on the specified LP.

```
C:> scp <fpga-bundle-file> <user>@<PowerConnect-IpAddress>:lp:fpga-all:all
```

This command downloads <*fpga-bundle-file*> and replaces all the FPGA images (PBIF, STATS, XGMAC and XPP) on all the LPs.

To download and force overwrite Bundled FPGA image, enter the following.

```
C:> scp <fpga-bundle-file>
<user>@<PowerConnect-IpAddress>:lp:fpga-all:<lp-slot-num>:force-overwrite
```

This command downloads <*fpga-bundle-file*> and replaces all the FPGA images (PBIF, STATS, XGMAC and XPP) on the specified LP.

```
C:> scp <fpga-bundle-file>
<user>@<PowerConnect-IpAddress>:lp:fpga-all:all:force-overwrite
```

This command downloads <*fpga-bundle-file*> and replaces all the FPGA images (PBIF, STATS, XGMAC and XPP) on all the LPs.

PBIF FPGA command options

NOTE
If force-overwrite is present in the command, the command skips compatibility checks and forcibly replaces the FPGA image, otherwise the command checks for compatibility of the FPGA image and if the check fails, the FPGA image is not replaced and error message is returned to the SCP client.

To download and over-write PBIF FPGA image, enter the following command.

```
C:> scp <fpga-pbif-file>
<user>@<PowerConnect-IpAddress>:lp:fpga-pbif:<lp-slot-num>
```

This command downloads <*fpga-pbif-file*> and replaces the FPGA PBIF image on the specified LP.

```
C:> scp <fpga-pbif-file> <user>@<PowerConnect-IpAddress>:lp:fpga-pbif:all
```

This command downloads <*fpga-pbif-file*> and replaces FPGA PBIF image on all the LPs.

To download and force over-write PBIF FPGA image, enter the following command.

```
C:> scp <fpga-pbif-file>
<user>@<PowerConnect-IpAddress>:lp:fpga-pbif:<lp-slot-num>:force-overwrite
```

This command downloads <*fpga-pbif-file*> and replaces FPGA PBIF image on the specified LP.

```
C:> scp <fpga-pbif-file>
<user>@<PowerConnect-IpAddress>:lp:fpga-pbif:all:force-overwrite
```

This command downloads <*fpga-pbif-file*> and replaces the FPGA PBIF image on all the LPs.

STATS FPGA command options

NOTE
If force-overwrite is present in the command, the command skips compatibility checks and forcibly replaces the FPGA image, otherwise the command checks for compatibility of the FPGA image and if the check fails, the FPGA image is not replaced and error message is returned to the SCP client.

To download and over-write STATS FPGA image, enter the following.

```
C:> scp <fpga-stats-file>
<user>@<PowerConnect-IpAddress>:lp:fpga-stats:<lp-slot-num>
```

This command downloads <*fpga-stats-file*> and replaces FPGA STATS image on the specified LP.

```
C:> scp <fpga-stats-file> <user>@<PowerConnect-IpAddress>:lp:fpga-stats:all
```

This command downloads <*fpga-stats-file*> and replaces FPGA STATS image on all the LPs.

To download and force over-write STATS FPGA image, enter the following command.

```
C:> scp <fpga-stats-file>
<user>@<PowerConnect-IpAddress>:lp:fpga-stats:<lp-slot-num>:force-overwrite
```

This command downloads <*fpga-stats-file*> and replaces FPGA STATS image on the specified LP.

```
C:> scp <fpga-stats-file>
<user>@<PowerConnect-IpAddress>:lp:fpga-stats:all:force-overwrite
```

This command downloads <*fpga-stats-file*> and replaces FPGA STATS image on all the LPs.

XGMAC FPGA command options

NOTE
If force-overwrite is present in the command, the command skips compatibility checks and forcibly replaces the FPGA image, otherwise the command checks for compatibility of the FPGA image and if the check fails, the FPGA image is not replaced and error message is returned to the SCP client.

To download and over-write XGMAC FPGA image, enter the following commands.

```
C:> scp <fpga-xgmac-file>
<user>@<PowerConnect-IpAddress>:lp:fpga-xgmac:<lp-slot-num>
```

This command downloads <*fpga-xgmac-file*> and replaces FPGA XGMAC image on the specified LP.

```
C:> scp <fpga-xgmac-file> <user>@<PowerConnect-IpAddress>:lp:fpga-xgmac:all
```

This command downloads <*fpga-xgmac-file*> and replaces FPGA XGMAC image on all the LPs.

To download and force over-write XGMAC FPGA image, enter the following commands.

```
C:> scp <fpga-xgmac-file> <user>@<PowerConnect-IpAddress>:lp:
fpga-xgmac:<lp-slot-num>:force-overwrite
```

This command downloads <*fpga-xgmac-file*> and replaces FPGA XGMAC image on the specified LP.

```
C:> scp <fpga-xgmac-file>
<user>@<PowerConnect-IpAddress>:lp:fpga-xgmac:all:force-overwrite
```

This command downloads <*fpga-xgmac-file*> and replaces FPGA XGMAC image on all the LPs.

XPP FPGA command options

NOTE
If force-overwrite is present in the command, the command skips compatibility checks and forcibly replaces the FPGA image, otherwise the command checks for compatibility of the FPGA image and if the check fails, the FPGA image is not replaced and error message is returned to the SCP client.

To download and over-write an XPP FPGA image, enter the following commands.

```
C:> scp <fpga-xpp-file> <user>@<PowerConnect-IpAddress>:lp:fpga-xpp:<lp-slot-num>
```

This command downloads <*fpga-xpp-file*> and replaces FPGA XPP image on the specified LP.

```
C:> scp <fpga-xpp-file> <user>@<PowerConnect-IpAddress>:lp:fpga-xpp:all
```

This command downloads <*fpga-xpp-file*> and replaces FPGA XPP image on all the LPs.

To download and force over-write XPP FPGA image, enter the following commands.

```
C:> scp <fpga-xpp-file> <user>@<PowerConnect-IpAddress>:lp:fpga-xpp:<
lp-slot-num>:force-overwrite
```

This command downloads <*fpga-xpp-file*> and replaces FPGA XPP image on the specified LP.

```
C:> scp <fpga-xpp-file> <user>@<MLXe-IpAddress>:lp:fpga-xpp:all:force-overwrite
```

This command downloads <*fpga-xpp-file*> and replaces FPGA XPP image on all the LPs.

Delete old file first option

NOTE
The delete file first option only applies to inbound SCP commands; its purpose is make room in the MP flash by deleting old image files prior to an image download.

An option "delete-first" is provided in the third or fourth token position in the following commands."

```
C:> scp <image-file>
<user>@<PowerConnect-IpAddress>:image:<primary|secondary|mp-sec|lp-sec>:delete-first
C:> scp <image-file>
<user>@<PowerConnect-IpAddress>:flash:<primary|secondary|monitor>:delete-first
C:> scp <image-file>
<user>@<PowerConnect-IpAddress>:lp:<primary|secondary|monitor>:all:delete-first
```

Without **delete-first** option, if the flash is full these commands should display the following message.

"There is not enough space on MP flash. Please clean up MP flash and retry, or use \"delete-first\" option."

When the **delete-first** option is specified, these commands clear space in the MP flash by removing the following files first.

```
image:primary, "primary", "lp-primary-0"
image:secondary, "secondary", "lp-secondary-0"
image:lp-sec, "primary", "lp-secondary-0"
image:mp-sec, "secondary", "lp-primary-0"
flash:primary, "primary"
flash: secondary, "secondary"
flash: monitor, "monitor"
lp:primary:all, "lp-primary-0"
lp:secondary:all, "lp-secondary-0"
lp:monitor:all, "lp-monitor-0"
```

Before deleting the file the system will check to see if deleting the file or files will create enough space in the flash. If it can create enough space to accommodate the download, the files will be deleted. Otherwise, the command will fail with the following error message.

```
"There will not be enough space on MP flash even after deleting the target files.
Please clean up MP flash and retry."
```

NOTE
Other commands will not check for available space in the flash or delete the file before downloading. In other words, the delete-first option is not supported for commands not mentioned above.

Chapter

Configuring Multi-Device Port Authentication 49

The following Multi-Device Port Authenticationt features supported by PowerConnect B-MLXe Series.

- Multi-Device Port Authentication
- Authentication Method List for 802.1x
- RADIUS Parameters
- Authentication-Failure Action
- Authenticated MAC Addresses
- MAC Address Filters
- Authenticating Multiple MAC Addresses on an Interface
- Multi-Device Port Authentication and 802.1x on the Same Interface
- Aging Time for Blocked MAC Addresses

Multi-device port authentication is a way to configure a PowerConnect router to forward or block traffic from a MAC address based on information received from a RADIUS server.

How multi-device port authentication works

The multi-device port authentication feature is a mechanism by which incoming traffic originating from a specific MAC address is switched or forwarded by the device only if the source MAC address is successfully authenticated by a RADIUS server. The MAC address itself is used as the username and password for RADIUS authentication; the user does not need to provide a specific username and password to gain access to the network. If RADIUS authentication for the MAC address is successful, traffic from the MAC address is forwarded in hardware.

If the RADIUS server cannot validate the user's MAC address, then it is considered an authentication failure, and a specified authentication-failure action can be taken. The default authentication-failure action is to drop traffic from the non-authenticated MAC address in hardware. You can also configure the device to move the port on which the non-authenticated MAC address was learned into a restricted or “guest” VLAN, which may have limited access to the network.

RADIUS authentication

The multi-device port authentication feature communicates with the RADIUS server to authenticate a newly found MAC address. The PowerConnect devices support multiple RADIUS servers; if communication with one of the RADIUS servers times out, the others are tried in sequential order. If a response from a RADIUS server is not received within a specified time (by default, 3 seconds) the RADIUS session times out, and the device retries the request up to three times. If no response is received, the next RADIUS server is chosen, and the request is sent for authentication.

The RADIUS server is configured with the usernames and passwords of authenticated users. For multi-device port authentication, the username and password is the MAC address itself; that is, the device uses the MAC address for both the username and the password in the request sent to the RADIUS server. For example, given a MAC address of 0007e90feaa1, the users file on the RADIUS server would be configured with a username and password both set to 0007e90feaa1. When traffic from this MAC address is encountered on a MAC-authentication-enabled interface, the device sends the RADIUS server an Access-Request message with 0007e90feaa1 as both the username and password. The format of the MAC address sent to the RADIUS server is configurable through the CLI.

The request for authentication from the RADIUS server is successful only if the username and password provided in the request matches an entry in the users database on the RADIUS server. When this happens, the RADIUS server returns an Access-Accept message back to the PowerConnect router. When the RADIUS server returns an Access-Accept message for a MAC address, that MAC address is considered authenticated, and traffic from the MAC address is forwarded normally by the PowerConnect router.

Authentication-failure actions

If the MAC address does not match the username and password of an entry in the users database on the RADIUS server, then the RADIUS server returns an Access-Reject message. When this happens, it is considered an authentication failure for the MAC address. When an authentication failure occurs, the PowerConnect devices can either drop traffic from the MAC address in hardware (the default), or move the port on which the traffic was received to a restricted VLAN.

PowerConnect devices support multi-device port authentication on untagged ports only.

Supported RADIUS attributes

The PowerConnect devices support the following RADIUS attributes for multi-device port authentication:

- Username (1) – RFC 2865
- FilterId (11) – RFC 2865
- Vendor-Specific Attributes (26) – RFC 2865
- Tunnel-Type (64) – RFC 2868
- Tunnel-Medium-Type (65) – RFC 2868
- EAP Message (79) – RFC 3579
- Tunnel-Private-Group-Id (81) – RFC 2868

Dynamic VLAN and ACL assignments

The multi-device port authentication feature supports ***dynamic VLAN assignment***, where a port can be placed in a VLAN based on the MAC address learned on that interface. When a MAC address is successfully authenticated, the RADIUS server sends the PowerConnect router a RADIUS Access-Accept message that allows the PowerConnect router to forward traffic from that MAC address. The RADIUS Access-Accept message can also contain attributes set for the MAC address in its access profile on the RADIUS server.

If one of the attributes in the Access-Accept message specifies a VLAN identifier, and this VLAN is available on the PowerConnect router, the port is moved from its default VLAN to the specified VLAN.

To enable dynamic VLAN assignment for authenticated MAC addresses, you must add the following attributes to the profile for the MAC address on the RADIUS server. Dynamic VLAN assignment on multi-device port authentication-enabled interfaces is enabled by default.

Attribute name	Type	Value
Tunnel-Type	064	13 (decimal) – VLAN
Tunnel-Medium-Type	065	6 (decimal) – 802
Tunnel-Private-Group-ID	081	<*vlan-name*> (string) – either the name or the number of a VLAN configured on the PowerConnect device.

In addition to dynamic VLAN assignment, PowerConnect devices also support dynamic ACL assignment as is the case with 802.1x port security.

Support for authenticating multiple MAC addresses on an interface

The multi-device port authentication feature allows multiple MAC addresses to be authenticated or denied authentication on each interface. The maximum number of MAC addresses that can be authenticated on each interface is 256. The default is 32.

Support for multi-device port authentication and 802.1x on the same interface

On the PowerConnect devices, multi-device port authentication and 802.1x security can be enabled on the same port. However, only one of them can authenticate a MAC address or 802.1x client. If an 802.1x client responds, the software assumes that the MAC should be authenticated using 802.1x protocol mechanisms and multi-device port authentication for that MAC is aborted. Also, at any given time, a port can have either 802.1x clients or multi-device port authentication clients but not both.

Configuring multi-device port authentication

Configuring multi-device port authentication on the PowerConnect devices consists of the following tasks:

- Enabling multi-device port authentication globally and on individual interfaces
- Configuring an Authentication Method List for 802.1x
- Setting RADIUS Parameters
- Specifying the format of the MAC addresses sent to the RADIUS server (optional)
- Specifying the authentication-failure action (optional)
- Defining MAC address filters (optional)
- Configuring dynamic VLAN assignment (optional)

- Specifying to which VLAN a port is moved after its RADIUS-specified VLAN assignment expires (optional)
- Saving dynamic VLAN assignments to the running configuration file (optional)
- Clearing authenticated MAC addresses (optional)
- Disabling aging for authenticated MAC addresses (optional)
- Specifying the aging time for blocked MAC addresses (optional)

Enabling multi-device port authentication

You globally enable multi-device port authentication on the PowerConnect router.

To globally enable multi-device port authentication on the device, enter the following command.

```
NetIron(config)# mac-authentication enable
```

Syntax: [no] mac-authentication enable

Syntax: [no] mac-authentication enable <*slot*>/<*portnum*> **| all**

The **all** option enables the feature on all interfaces at once.

You can enable the feature on an interface at the interface CONFIG level.

Configuring an authentication method list for 802.1x

To use 802.1x port security, you must specify an authentication method to be used to authenticate Clients. The PowerConnect device supports RADIUS authentication with 802.1x port security. To use RADIUS authentication with 802.1x port security, you create an authentication method list for 802.1x and specify RADIUS as an authentication method, then configure communication between the PowerConnect router and the RADIUS server.

Example

```
NetIron(config)# aaa authentication dot1x default radius
```

Syntax: [no] aaa authentication dot1x default <*method-list*>

For the <*method-list*>, enter at least one of the following authentication methods:

radius – Use the list of all RADIUS servers that support 802.1x for authentication.

none – Use no authentication. The Client is automatically authenticated without the device using information supplied by the Client.

NOTE
If you specify both **radius** and **none**, make sure **radius** comes before **none** in the method list.

Setting RADIUS parameters

To use a RADIUS server to authenticate access to a PowerConnect router, you must identify the server to the PowerConnect router.

Example

```
NetIron(config)# radius-server host 209.157.22.99 auth-port 1812 acct-port 1813
default key mirabeau dot1x
```

Syntax: **radius-server host** <*ip-addr*> **|** <*server-name*> **[auth-port** <*number*> **acct-port** <*number*> **[authentication-only | accounting-only | default [key 0 | 1** <*string*> **[dot1x]]]]**

The **host** <*ip-addr*> | <*server-name*> parameter is either an IP address or an ASCII text string.

The **auth-port** <*number*> parameter specifies what port to use for RADIUS authentication.

The **acct-port** <*number*> parameter specifies what port to use for RADIUS accounting.

The **dot1x** parameter indicates that this RADIUS server supports the 802.1x standard. A RADIUS server that supports the 802.1x standard can also be used to authenticate non-802.1x authentication requests.

NOTE
To implement 802.1x port security, at least one of the RADIUS servers identified to the router must support the 802.1x standard.

Supported RADIUS attributes

Many IEEE 802.1x Authenticators will function as RADIUS clients. Some of the RADIUS attributes may be received as part of IEEE 802.1x authentication. The PowerConnect devices support the following RADIUS attributes for IEEE 802.1x authentication:

- Username (1) – RFC 2865
- FilterId (11) – RFC 2865
- Vendor-Specific Attributes (26) – RFC 2865
- Tunnel-Type (64) – RFC 2868
- Tunnel-Medium-Type (65) – RFC 2868
- EAP Message (79) – RFC 2579
- Tunnel-Private-Group-Id (81) – RFC 2868

Specifying the format of the MAC addresses sent to the RADIUS server

When multi-device port authentication is configured, the PowerConnect router authenticates MAC addresses by sending username and password information to a RADIUS server. The username and password is the MAC address itself; that is, the device uses the MAC address for both the username and the password in the request sent to the RADIUS server.

By default, the MAC address is sent to the RADIUS server in the format *xxxxxxxxxxxx*. You can optionally configure the device to send the MAC address to the RADIUS server in the format *xx-xx-xx-xx-xx-xx*, or the format *xxxx.xxxx.xxxx*. To do this, enter a command such as the following.

```
NetIron(config)# mac-authentication auth-passwd-format xxxx.xxxx.xxxx
```

Syntax: **[no] mac-authentication auth-passwd-format xxxx.xxxx.xxxx | xx-xx-xx-xx-xx-xx | xxxxxxxxxxxx**

Specifying the authentication-failure action

When RADIUS authentication for a MAC address fails, you can configure the device to perform one of two actions:

- Drop traffic from the MAC address in hardware (the default)
- Move the port on which the traffic was received to a restricted VLAN

To configure the device to move the port to a restricted VLAN when multi-device port authentication fails, enter commands such as the following.

```
NetIron(config)# interface e 3/1
NetIron(config-if-e100-3/1)# mac-authentication auth-fail-action restrict-vlan
100
```

Syntax: [no] mac-authentication auth-fail-action restrict-vlan [<*vlan-id*>]

If the ID for the restricted VLAN is not specified at the interface level, the global restricted VLAN ID applies for the interface.

To specify the VLAN ID of the restricted VLAN globally, enter the following command.

```
NetIron(config)# mac-authentication auth-fail-vlan-id 200
```

Syntax: [no] mac-authentication auth-fail-vlan-id <*vlan-id*>

The command above applies globally to all MAC-authentication-enabled interfaces.

Note that the restricted VLAN must already exist on the device. You cannot configure the restricted VLAN to be a non-existent VLAN.

To configure the device to drop traffic from non-authenticated MAC addresses in hardware, enter commands such as the following.

```
NetIron(config)# interface e 3/1
NetIron(config-if-e100-3/1)# mac-authentication auth-fail-action block-traffic
```

Syntax: [no] mac-authentication auth-fail-action block-traffic

Dropping traffic from non-authenticated MAC addresses is the default behavior when multi-device port authentication is enabled.

Defining MAC address filters

You can specify MAC addresses that do not have to go through multi-device port authentication. These MAC addresses are considered pre-authenticated, and are not subject to RADIUS authentication. To do this, you can define MAC address filters that specify the MAC addresses to exclude from multi-device port authentication.

You should use a MAC address filter when the RADIUS server itself is connected to an interface where multi-device port authentication is enabled. If a MAC address filter is not defined for the MAC address of the RADIUS server and applied on the interface, the RADIUS authentication process would fail since the device would drop all packets from the RADIUS server itself.

For example, the following command defines a MAC address filter for address 0010.dc58.aca4.

```
NetIron(config)# mac-authentication mac-filter 1 permit 0010.dc58.aca4
```

Syntax: [no] mac-authentication mac-filter <*filter*>

The following commands apply the MAC address filter on an interface so that address 0010.dc58.aca4 is excluded from multi-device port authentication.

```
NetIron(config)# interface e 3/1
NetIron(config-if-e100-3/1)# mac-authentication apply-mac-auth-filter 1
```

Syntax: [no] mac-authentication apply-mac-auth-filter <*filter-id*>

Configuring dynamic VLAN assignment

An interface can be dynamically assigned to a VLAN based on the MAC address learned on that interface. When a MAC address is successfully authenticated, the RADIUS server sends the PowerConnect router a RADIUS Access-Accept message that allows the PowerConnect router to forward traffic from that MAC address. The RADIUS Access-Accept message can also contain attributes set for the MAC address in its access profile on the RADIUS server.

If one of the attributes in the Access-Accept message specifies a VLAN identifier, and this VLAN is available on the PowerConnect router, the port is moved from its default VLAN to the specified VLAN.

To enable dynamic VLAN assignment for authenticated MAC addresses, you must add the following attributes to the profile for the MAC address on the RADIUS server (dynamic VLAN assignment on multi-device port authentication-enabled interfaces is enabled by default and can be disabled). Refer to "Dynamic VLAN and ACL assignments" on page 2036 for a list of the attributes that must be set on the RADIUS server

Dynamic VLAN assignment on a multi-device port authentication-enabled interface is enabled by default. If it is disabled, enter commands such as the following command to enable it.

```
NetIron(config)# interface e 3/1
NetIron(config-if-e100-3/1)# mac-authentication enable-dynamic-vlan
```

Syntax: [no] mac-authentication enable-dynamic-vlan

If a previous authentication attempt for a MAC address failed, and as a result the port was placed in the restricted VLAN, but a subsequent authentication attempt was successful, the RADIUS Access-Accept message may specify a VLAN for the port. By default, the PowerConnect router moves the port out of the restricted VLAN and into the RADIUS-specified VLAN. You can optionally configure the device to ignore the RADIUS-specified VLAN in the RADIUS Access-Accept message, and leave the port in the restricted VLAN.

To do this, enter the following command.

```
NetIron(config)# mac-authentication no-override-restrict-vlan
```

Syntax: [no] mac-authentication no-override-restrict-vlan

NOTES:

- For untagged ports, if the VLAN ID provided by the RADIUS server is valid, then the port is removed from its current VLAN and moved to the RADIUS-specified VLAN as an untagged port.
- If you configure dynamic VLAN assignment on a multi-device port authentication enabled interface, and the Access-Accept message returned by the RADIUS server does not contain a Tunnel-Private-Group-ID attribute, then it is considered an authentication failure, and the configured authentication failure action is performed for the MAC address.

- If the <*vlan-name*> string does not match either the name or the ID of a VLAN configured on the device, then it is considered an authentication failure, and the configured authentication failure action is performed for the MAC address.
- If an untagged port had previously been assigned to a VLAN though dynamic VLAN assignment, and then another MAC address is authenticated on the same port, but the RADIUS Access-Accept message for the second MAC address specifies a different VLAN, then it is considered an authentication failure for the second MAC address, and the configured authentication failure action is performed. Note that this applies only if the first MAC address has not yet aged out. If the first MAC address has aged out, then dynamic VLAN assignment would work as expected for the second MAC address.

Specifying the VLAN to which a port is moved after the RADIUS-specified VLAN assignment expires

When a port is dynamically assigned to a VLAN through the authentication of a MAC address, and the MAC session for that address is deleted on the PowerConnect router, then by default the port is removed from its RADIUS-assigned VLAN and placed back in the VLAN where it was originally assigned.

A port can be removed from its RADIUS-assigned VLAN when any of the following occur:

- The link goes down for the port
- The MAC session is manually deleted with the **mac-authentication clear-mac-session** command
- The MAC address that caused the port to be dynamically assigned to a VLAN ages out

For example, say port 1/1 is currently in VLAN 100, to which it was assigned when MAC address 0007.eaa1.e90f was authenticated by a RADIUS server. The port was originally configured to be in VLAN 111. If the MAC session for address 0007.eaa1.e90f is deleted, then port 1/1 is moved from VLAN 100 back into VLAN 111.

You can optionally specify an alternate VLAN to which to move the port when the MAC session for the address is deleted. For example, to place the port in the restricted VLAN, enter commands such as the following.

```
NetIron(config)# interface e 3/1
NetIron(config-if-e100-3/1)# mac-auth move-back-to-old-vlan port-restrict-vlan
```

Syntax: [no] **mac-authentication move-back-to-old-vlan disable | port-configured-vlan | port-restrict-vlan | system-default-vlan**

The **disable** keyword disables moving the port back to its original VLAN. The port would stay in its RADIUS-assigned VLAN.

The **port-configured-vlan** keyword removes the port from its RADIUS-assigned VLAN and places it back in the VLAN where it was originally assigned. This is the default.

The **port-restrict-vlan** keyword removes the port from its RADIUS-assigned VLAN and places it in the restricted VLAN.

The **system-default-vlan** keyword removes the port from its RADIUS-assigned VLAN and places it in the DEFAULT-VLAN.

Saving dynamic VLAN assignments to the running configuration file

You can configure the PowerConnect router to save the RADIUS-specified VLAN assignments to the device's running configuration file. To do this, enter the following command.

```
NetIron(config)# mac-authentication save-dynamicvlan-to-config
```

Syntax: [no] mac-authentication save-dynamicvlan-to-config

By default, the dynamic VLAN assignments are not saved to the running configuration file. Entering the **show running-config** command does not display dynamic VLAN assignments, although they can be displayed with the **show vlan** and **show auth-mac-address detail** commands.

Clearing authenticated MAC addresses

The PowerConnect router maintains an internal table of the authenticated MAC addresses (viewable with the **show authenticated-mac-address** command). You can clear the contents of the authenticated MAC address table either entirely, or just for the entries learned on a specified interface. In addition, you can clear the MAC session for an address learned on a specific interface.

To clear the entire contents of the authenticated MAC address table, enter the following command.

```
NetIron(config)# clear auth-mac-table
```

Syntax: clear auth-mac-table

To clear the authenticated MAC address table of entries learned on a specified interface, enter a command such as the following.

```
NetIron(config)# clear auth-mac-table e 3/1
```

Syntax: clear auth-mac-table *<slot>/<portnum>*

To clear the MAC session for an address learned on a specific interface, enter commands such as the following.

```
NetIron(config)# interface e 3/1
NetIron(config-if-e100-3/1)# mac-authentication clear-mac-session 00e0.1234.abd4
```

Syntax: mac-authentication clear-mac-session *<mac-address>*

This command removes the Layer 2 CAM entry created for the specified MAC address. If the PowerConnect router receives traffic from the MAC address again, the MAC address is authenticated again.

Disabling aging for authenticated MAC addresses

MAC addresses that have been authenticated or denied by a RADIUS server are aged out if no traffic is received from the MAC address for a certain period of time:

- Authenticated MAC addresses or non-authenticated MAC addresses that have been placed in the restricted VLAN are aged out if no traffic is received from the MAC address over the device's normal MAC aging interval.
- Non-authenticated MAC addresses that are blocked by the device are aged out if no traffic is received from the address over a fixed hardware aging period (70 seconds), plus a configurable software aging period. (Refer to the next section for more information on configuring the software aging period).

You can optionally disable aging for MAC addresses subject to authentication, either for all MAC addresses or for those learned on a specified interface.

To disable aging for all MAC addresses subject to authentication on all interfaces where multi-device port authentication has been enabled, enter the following command.

```
NetIron(config)# mac-authentication disable-aging
```

To disable aging for all MAC addresses subject to authentication on a specific interface where multi-device port authentication has been enabled, enter commands such as the following.

```
NetIron(config)# interface e 3/1
NetIron(config-if-e100-3/1)# mac-authentication disable-aging
```

Syntax: [no] mac-authentication disable-aging [denied-mac-only | permitted-mac-only]

denied-mac-only disables aging of denied sessions and enables aging of permitted sessions.

permitted-mac-only disables aging of permitted (authenticated and restricted) sessions and enables aging of denied sessions.

Specifying the aging time for blocked MAC addresses

When the PowerConnect router is configured to drop traffic from non-authenticated MAC addresses, traffic from the blocked MAC addresses is dropped in hardware, without being sent to the CPU. A Layer 2 CAM entry is created that drops traffic from the blocked MAC address in hardware. If no traffic is received from the blocked MAC address for a certain amount of time, this Layer 2 CAM entry is aged out. If traffic is subsequently received from the MAC address, then an attempt can be made to authenticate the MAC address again.

Aging of the Layer 2 CAM entry for a blocked MAC address occurs in two phases, known as ***hardware aging*** and ***software aging***. The hardware aging period is fixed at 70 seconds and is non-configurable. The software aging time is configurable through the CLI.

Once the PowerConnect router stops receiving traffic from a blocked MAC address, the hardware aging begins and lasts for a fixed period of time. After the hardware aging period ends, the software aging period begins. The software aging period lasts for a configurable amount of time (by default 120 seconds). After the software aging period ends, the blocked MAC address ages out, and can be authenticated again if the PowerConnect router receives traffic from the MAC address.

To change the length of the software aging period for blocked MAC addresses, enter a command such as the following.

```
NetIron(config)# mac-authentication max-age 180
```

Syntax: [no] mac-authentication max-age <*seconds*>

You can specify from 1 – 65535 seconds. The default is 120 seconds.

Displaying multi-device port authentication information

You can display the following information about the multi-device port authentication configuration:

- Information about authenticated MAC addresses
- Information about the multi-device port authentication configuration

- Authentication Information for a specific MAC address or port
- Multi-device port authentication settings and authenticated MAC addresses for each port where the multi-device port authentication feature is enabled
- The MAC addresses that have been successfully authenticated
- The MAC addresses for which authentication was not successful

Displaying authenticated MAC address information

To display information about authenticated MAC addresses on the ports where the multi-device port authentication feature is enabled, enter the following command.

```
NetIron# show auth-mac-address
------------------------------------------------------------------------
Port           Vlan  Accepted MACs    Rejected MACs    Attempted-MACs
------------------------------------------------------------------------
1/18           100   1                  100              0
1/20           40    0                  0                0
1/22           100   0                  0                0
4/5            30    0                  0                0
```

Syntax: show auth-mac-address

The following table describes the information displayed by the **show auth-mac-address** command.

TABLE 389 Output from the **show auth-mac-address command**

This field...	Displays...
Port	The port number where the multi-device port authentication feature is enabled.
Vlan	The VLAN to which the port has been assigned.
Accepted MACs	The number of MAC addresses that have been successfully authenticated
Rejected MACs	The number of MAC addresses for which authentication has failed.
Attempted-MACs	The rate at which authentication attempts are made for MAC addresses.

Displaying multi-device port authentication configuration information

To display a summary of multi-device port authentication that have been configured on the device, enter the following command.

```
NetIron# show auth-mac configuration
Feature enabled                 : Yes
Global Fail-VLAN Id             : None
Username/Password format        : xxxx.xxxx.xxxx
Maximum Age                     : 120
Save dynamic VLAN configuration : No
Number of Ports enabled         : 25
-------------------------------------------------------------------------------
Port  Aging     Fail       Fail DynVLAN Override   Revert      MAC    DoS Protectn
                Action     VLAN Support Restricted VLAN        Filter Enable Limit
-------------------------------------------------------------------------------
1/1   All       Blocked    N/A  Yes     Yes        Configured  No     No     512
1/2   Permitted Blocked    101  No      Yes        Restricted  No     No     512
1/3   All       Blocked    N/A  Yes     Yes        Configured  No     No     512
1/4   Denied    Blocked    N/A  Yes     Yes        Configured  No     No     512
1/5   All       Blocked    N/A  Yes     Yes        Configured  No     No     512
1/6   None      Blocked    N/A  Yes     Yes        Sys.Default No     No     512
1/7   All       Blocked    N/A  Yes     Yes        Configured  No     No     512
1/8   All       Blocked    N/A  Yes     Yes        Configured  No     No     512
1/9   All       Blocked    N/A  Yes     Yes        Configured  No     No     512
1/10  All       Blocked    N/A  Yes     Yes        Configured  No     No     512
```

The following table describes the information displayed by the **show authenticated-mac-address configuration** command.

TABLE 390 Output from the **show auth-mac-addres**s configuration c**ommand**

This field...	Displays...
Feature enabled	Whether the multi-device port authentication feature is enabled on the PowerConnect device.
Number of Ports enabled	The number of ports on which the multi-device port authentication feature is enabled.
Aging	Shows which MAC addresses are aged out. Denied – Only denied MAC addresses are aged out Permitted – Only permitted MAC addresses are aged out All – Both denied and permitted MAC addresses are aged out None – None of the MAC addresses are aged out
Port	Information for each multi-device port authentication-enabled port.
Fail-Action	What happens to traffic from a MAC address for which RADIUS authentication has failed: either block the traffic or assign the MAC address to a restricted VLAN.
Fail VLAN	The restricted VLAN to which non-authenticated MAC addresses are assigned, if the Fail-Action is to assign the MAC address to a restricted VLAN.
DynVLAN Support	Whether RADIUS dynamic VLAN assignment is enabled for the port.
Override Restricted	Whether or not a port in a restricted VLAN (due to a failed authentication) is removed from the restricted VLAN on a subsequent successful authentication on the port.

TABLE 390 Output from the **show auth-mac-address** configuration **command** (Continued)

This field...	Displays...
Revert VLAN	The VLAN that the port reverts to when the RADIUS-assigned dynamic VLAN expires.
MAC-filter	Whether a MAC filter has been applied to this port to specify pre-authenticated MAC addresses.
DOS Enable	Denial of Service status. This column will always show "No" since DOS is not supported.
Protectn Limit	This is not applicable to the PowerConnect, but the output always show "512".

Syntax: show auth-mac-address configuration

To display detailed information about the multi-device port authentication configuration and authenticated MAC addresses for a port where the feature is enabled, enter the following command.

```
NetIron# show auth-mac-address detail
Port 1/18
 Dynamic-Vlan Assignment          : Enabled
 RADIUS failure action            : Block Traffic
 Override-restrict-vlan           : Yes
 Port VLAN                        : 4090 (Configured)
 DOS attack protection            : Disabled
 Accepted Mac Addresses           : 0
 Rejected Mac Addresses           : 0
 Aging of MAC-sessions            : Enable-All
 Port move-back vlan              : Port-Configured
 MAC Filter applied               : No
                                1 : 0000.0010.2000

MAC TABLE
-------------------------------------------
MAC Address    Port    VLAN Access     Age

-------------------------------------------
00A1.0010.2000 1/18    1    Allowed    0
00A1.0010.2001 1/18    1    Blocked    120
00A1.0010.2002 1/18    1    Init       0
```

The following table describes the information displayed by the **show authenticated-mac-address** command.

TABLE 391 Output from the **show authenticated-mac-address** c**ommand**

This field...	Displays...
Port	The port to which this information applies.
Dynamic-Vlan Assignment	Whether RADIUS dynamic VLAN assignment has been enabled for the port.
RADIUS failure action	What happens to traffic from a MAC address for which RADIUS authentication has failed: either block the traffic or assign the MAC address to a restricted VLAN.
Override-restrict-vlan	Whether a port can be dynamically assigned to a VLAN specified by a RADIUS server, if the port had been previously placed in the restricted VLAN because a previous attempt at authenticating a MAC address on that port failed.

TABLE 391 Output from the **show authenticated-mac-address command** (Continued)

This field...	Displays...
Port VLAN	The VLAN to which the port is assigned, and whether the port had been dynamically assigned to the VLAN by a RADIUS server.
DOS attack protection	Whether denial of service attack protection has been enabled for multi-device port authentication, limiting the rate of authentication attempts sent to the RADIUS server.
Accepted MAC Addresses	The number of MAC addresses that have been successfully authenticated.
Rejected MAC Addresses	The number of MAC addresses for which authentication has failed.
Aging of MAC-sessions	Whether software aging of MAC addresses is enabled.
Max-Age of MAC-sessions	The configured software aging period.
Port move-back VLAN	The VLAN that the port reverts to when the RADIUS-assigned dynamic VLAN expires.
MAC Filter applied	Whether a MAC filter has been applied to this port to specify pre-authenticated MAC addresses.
MAC Table	The MAC addresses learned on the port.

Syntax: show auth-mac-address detail

Displaying multi-device port authentication information for a specific MAC address or port

To display authentication information for a specific MAC address or port, enter a command such as the following.

```
NetIron# show auth-mac-address 0007.e90f.eaa1
--------------------------------------------------------------------------------
MAC/IP Address     Port        Vlan    Access      Age
--------------------------------------------------------------------------------
00A1.0010.2000     1/18        1       Allowed     0
```

Syntax: show auth-mac-address <*mac-address*> | <*ip-address*> | <*slot*>/<*portnum*>

The <*ip-address*> parameter lists the MAC address associated with the specified IP address.

The <*slot*>/<*portnum*> parameter lists the MAC addresses on the specified port.

The following table describes the information displayed by the **show auth-mac-address** command for a specified MAC address or port.

TABLE 392 Output from the **show auth-mac-address** <*address*> **command**

This field...	Displays...
MAC or IP Address	The MAC address for which information is displayed. If the packet for which multi-device port authentication was performed also contained an IP address, then the IP address is displayed as well.
Port	The port on which the MAC address was learned.
VLAN	The VLAN to which the MAC address was assigned.

TABLE 392 Output from the **show auth-mac-address** <*address*> **command** (Continued)

This field...	Displays...
Access	Whether or not the MAC address was allowed or denied access into the network.
Age	The age of the MAC address entry in the authenticated MAC address list.

Displaying the authenticated MAC addresses

To display the MAC addresses that have been successfully authenticated, enter the following command.

```
NetIron# show auth-mac-addresses authorized-mac
MAC TABLE
-------------------------------------------
MAC Address    Port    VLAN Access     Age

-------------------------------------------
00A1.0010.2000 1/18    1    Allowed      0
00A1.0010.2001 1/18    1    Allowed    120
00A1.0010.2002 1/18    1    Allowed      0
```

Syntax: show auth-mac-addresses authorized-mac

Displaying the non-authenticated MAC addresses

To display the MAC addresses for which authentication was not successful, enter the following command.

```
NetIron# show auth-mac-addresses unauthorized-mac
MAC TABLE
-------------------------------------------
MAC Address    Port    VLAN Access     Age

-------------------------------------------
00A1.0010.2000 1/18    1    Blocked       0
00A1.0010.2001 1/18    1    Blocked     120
00A1.0010.2002 1/18    1    Blocked       0
```

Syntax: show auth-mac-addresses unauthorized-mac

Chapter

Using the MAC Port Security Feature 50

The following MAC Port Security features are supported by PowerConnect B-MLXe Series.

- MAC Port Security
- Port Security Age Timer
- Denying Specific MAC Addresses
- Port Security MAC Violation Limit
- MAC Port Security on VPLS endpoints
- MAC Port Security on Vll endpoints

Overview

MAC Port Security allows you to configure the PowerConnect router to learn a limited number of "secure" MAC addresses on an interface. The interface will forward only packets with source MAC addresses that match these secure addresses. The secure MAC addresses can be specified manually, or the PowerConnect router can learn them automatically. After the device reaches the limit for the number of secure MAC addresses it can learn on the interface, if the interface then receives a packet with a source MAC address that is different from any of the secure learned addresses, it is considered a security violation.

When a security violation occurs, a Syslog entry and an SNMP trap are generated. In addition, the device takes one of two actions: it either drops packets from the violating address (but allows packets from the secure addresses), or it disables the port for a specified amount of time. You specify which of these actions takes place.

The secure MAC addresses are not flushed when an interface is disabled and brought up again. The secure addresses can be kept secure permanently (the default), or can be configured to age out, at which time they are no longer secure. You can configure the device to automatically save the list of secure MAC addresses to the startup-config file at specified intervals, allowing addresses to be kept secure across system restarts.

The port security feature applies only to Ethernet interfaces.

Configuration Considerations

When using the MAC port security feature, the following should be considered.

- If there is no port security configuration at the interface level, global level port security configuration is inherited.
- If a port security attribute is configured at the interface level, interface level configuration for that attribute takes precedence over global level configuration for the same attribute.The rest of the port security attributes that are not configured at the interface level will be inherited from the global level configuration.

Local and global resources

The port security feature uses a concept of local and global “resources” to determine how many MAC addresses can be secured on each interface. In this context, a “resource” is the ability to store one secure MAC address entry. Each interface is allocated 64 local resources. When the port security feature is enabled, the interface can store up to 64 secure MAC addresses using local resources.

Besides the maximum of 64 local resources available to an interface, there are 4096 global resources available. When an interface has secured enough MAC addresses to reach its limit for local resources, it can secure additional MAC addresses by using global resources. Global resources are shared among all the interfaces on a first-come, first-served basis.

The maximum number of MAC addresses any single interface can secure is 64 (the maximum number of local resources available to the interface), plus the number of global resources not allocated to other interfaces.

Configuring the MAC port security feature

To configure the MAC port security feature, you perform the following tasks:

- Enable the MAC port security feature
- Set the maximum number of secure MAC addresses for an interface
- Set the port security age timer
- Specify secure MAC addresses
- Configure the device to automatically save secure MAC addresses to the startup-config file
- Specify the action taken when a security violation occurs
- Deny specific MAC addresses
- Port Security MAC Violation Limits

Enabling the MAC port security feature

By default, the MAC port security feature is disabled on all interfaces. You can enable or disable the feature globally on all interfaces or on an individual interface.

To enable the feature globally, first go to the level for global port security and then enter **enable**, as follows.

```
NetIron(config)# global-port-security
NetIron(config-global-port-security)# enable
```

To disable the feature on all interfaces at once, do the following.

```
NetIron(config)# global-port-security
NetIron(config-global-port-security)#disable
```

Syntax: global-port-security

This command is for global enable port security.

To enable port security on a specific interface, first go to the level of a specific interface and then security level.

```
NetIron(config)# interface ethernet 7/11
NetIron(config-if-e100-7/11)# port security
NetIron(config-port-security-e100-7/11)# enable
```

Syntax: enable

This command applies to a specific interface or global configuration. The interface level take precedence over the global configuration.

Syntax: disable

This command applies to a specific interface or global configuration. The interface level take precedence over the global configuration.

Setting the maximum number of secure MAC addresses for an interface

When the port security feature is enabled, the interface can store 1 secure MAC address. You can increase the number of MAC addresses that can be secured to a maximum of 64, plus the total number of global resources available.

For example, to configure interface 7/11 to have a maximum of 10 secure MAC addresses.

```
NetIron(config)# interface ethernet 7/11
NetIron(config-if-e100-7/11)# port security
NetIron(config-if-e100-7/11)# maximum 10
```

Syntax: maximum <*number-of-addresses*>

The <*number-of-addresses*> parameter can be set to a number from 0 – (64 + the total number of global resources available) The total number of global resources is 4096. Setting the parameter to 0 prevents any addresses from being learned. The default is 1.

Setting the port security age timer

By default, a learned MAC address stays secure indefinitely. You can configure the device to age out secure MAC addresses after a specified amount of time and can do so for all timers globally of for a specific interface.

To set the port security age timer to 10 minutes on all interfaces, first go to the level for global security.

```
NetIron(config)# global-port-security
NetIron(config-global-port-security)# age 10
```

Syntax: global-port-security

Syntax: [no] age <*minutes*>

The default is 0 (never age out secure MAC addresses).

To set the port security age timer to 10 minutes on a specific interface, go to the interface level and then the port security level for that interface.

```
NetIron(config)# interface ethernet 7/11
NetIron(config-if-e100-7/11)# port security
NetIron(config-port-security-e100-7/11)# age 10
```

Syntax: port security

Syntax: [no] age <*minutes*>

The default is 0 (never age out secure MAC addresses).

Specifying secure MAC addresses

To specify a secure MAC address on an interface, enter commands such as the following.

```
NetIron(config)# interface ethernet 7/11
NetIron(config-if-e100-7/11)# port security
NetIron(config-port-security-e100-7/11)# secure 0050.DA18.747C
```

Syntax: [no] secure <*mac-address*>

Autosaving secure MAC addresses to the startup-config file

The learned MAC addresses can automatically be saved to the startup-config file at specified intervals. You can specifiy the autosave interval at the global level or for a specific interface. For example, to set a 20-minute autosave interval globally for learned secure MAC addresses on the router, enter the following commands.

```
NetIron(config)# global-port-security
NetIron(config-port-security)# autosave 20
```

Syntax: global-port-security

Syntax: [no] autosave <*minutes*>

The interval range is 15 – 1440 minutes. By default, secure MAC addresses are not autosaved to the startup-config file. To remove autosave intervals, use the **no** form of the **autosave** command.

To specifiy the interval or MAC address autosave on a port, first go to the level of that port and then the port security level for that port, as follows.

```
NetIron(config)# interface ethernet 7/11
NetIron(config-if-e100-7/11)# port security
NetIron(config-port-security-e100-7/11)#autosave 20
```

Syntax: port security

Syntax: [no] autosave <*minutes*>

The interval range is 15 – 1440 minutes. By default, secure MAC addresses are not autosaved to the startup-config file. To remove autosave intervals, use the **no** form of the **autosave** command.

Specifying the action taken when a security violation occurs

A security violation can occur when a user tries to plug into a port where a MAC address is already locked, or the maximum number of secure MAC addresses has been exceeded. When a security violation occurs, an SNMP trap and Syslog message are generated.

In addition, you configure the device to take one of two actions when a security violation occurs: either drop packets from the violating address (and allow packets from secure addresses), or disable the port altogether for a specified amount of time.

To configure the device to drop packets from a violating address and allow packets from secure addresses.

```
NetIron(config)# interface ethernet 7/11
NetIron(config-if-e100-7/11)# port security
NetIron(config-port-security-e100-7/11)# violation restrict
```

Syntax: violation restrict

To shut down the port for 5 minutes when a security violation occurs.

```
NetIron(config)# interface ethernet 7/11
NetIron(config-if-e100-7/11)# port security
NetIron(config-port-security-e100-7/11)# violation shutdown 5
```

Syntax: violation shutdown <*minutes*>

To specific the mac-addresses that will be denied. All other mac-addresses no specificed will be allowed.

```
NetIron(config)# interface ethernet 7/11
NetIron(config-if-e100-7/11)# port security
NetIron(config-port-security-e100-7/11)# deny-mac-address
```

Syntax: deny-mac-address

NOTE
When using this feature with a 24-port 10/100 module (part number B24E) only the **shutdown** option is supported. The **restrict** option is not supported on the B24E.

Denying specific MAC addresses

You can configure the *violation deny mode*. The violation deny mode allows you to deny MAC addresses on a global level or on a per port level.

Denying MAC addresses globally

To deny a specific MAC address globally, enable the violation deny mode, then specify the MAC address to be denied.

```
NetIron(config)# global-port-security
NetIron(config-port-security)# violation deny
NetIron(config-port-security)# deny-mac-address 0000.0000.0001 2
```

Global denied secure MAC addresses are denied system-wide. These MAC entries are added to the MAC table as deny entries, when a flow is received and are the only MAC addresses that are denied. All other MAC addresses are allowed.

A maximum of 512 deny MAC addresses can be configured on a global level.

Denying MAC addresses on an interface

You can specify which MAC addresses can be denied on an interface.

```
NetIron(config)# internet ethernet 7/11
NetIron(config-if-e100-7/11)# port security
NetIron(config-port-security-e100-7/11)# violation deny
NetIron(config-port-security-e100-7/11)# deny-mac-addr 0000.1111.2222 4
```

Only the configured MAC addresses are denied on the specified interface. All other MAC addresses are allowed.

A maximum of 64 deny MAC addresses can be configured at an interface level.

Displaying MAC addresses that have been denied

Use the **show port security global-deny** command to display all the MAC addresses that have been denied globally. Use the **show port security denied-macs** command to display all the denied MAC addresses

Port security MAC violation limit

Use the **violation restrict** command to specify how many packets the system can receive in a one-second interval from denied MAC address before the system shuts the port down.

Configuring port security

To enable this new mode, enter a command such as the following.

```
NetIron(config)# global-port-security
NetIron(config-port-security)# violation restrict 12
```

Syntax: violation restrict [#-denied-packets processed]

Enter 0 – 64000. This parameter has no default.

NOTE
With the introduction of this command, packets from denied MAC addresses are now processed in software by the LP. They are no longer programmed in the hardware.

In addition to the new processing of packets from denied MAC addresses, these packets can now be logged in the Syslog. And to prevent the Syslog from being overwhelmed with messages for denied packets, you can specify how many messages will be logged per second, based on a packet's IP address.

```
NetIron(config)# global-port-security
NetIron(config-port-security)# violation restrict 12
NetIron(config-port-security)# deny-log-rate <7>
```

Syntax: deny-log-rate [<#-*logs*>]

The #-logs parameter specifies the count per line card. Enter 1 – 10. There is no default.

The logged message contains the packet's IP address and the MAC address of the denied packet. For example, the following configuration shows that violation restrict is configured;

```
interface ethernet 14/1
 port security
  enable
  maximum 5
  violation restrict 1000
  secure-mac-address 0000.0022.2222 10
  secure-mac-address 0000.0022.2223 10
  secure-mac-address 0000.0022.2224 10
  secure-mac-address 0000.0022.2225 10
  secure-mac-address 0000.0022.2226 10
```

When packet from MAC address 000.0022.2227, an address that is not a secured MAC address, the following Syslog message is generated.

```
SYSLOG: Mar 10 17:36:12:<12>3-RW-Core-3, Interface e14/1 shutdn due to high rate
of denied mac 0000.0022.2227, vlan 10
SYSLOG: Mar 10 17:36:12:<14>3-RW-Core-3, Interface ethernet14/1, state
down - disabled
```

However, when **deny-log-rate** is configured,

```
interface ethernet 14/1
 disable
 port security
  enable
  maximum 5
  violation restrict 1000
  deny-log-rate 4
  secure-mac-address 0000.0022.2222 10
  secure-mac-address 0000.0022.2223 10
  secure-mac-address 0000.0022.2224 10
  secure-mac-address 0000.0022.2225 10
  secure-mac-address 0000.0022.2226 10
```

The following Syslog messages are generated.

```
Mar 10 17:38:51:I:Port security denied pkt: 0000.0022.2224 -> 0000.0011.1111
198.19.1.2 -> 198.19.1.1 [Protocol:114]
Mar 10 17:38:51:I:Port security denied pkt: 0000.0022.2224 -> 0000.0011.1111
198.19.1.2 -> 198.19.1.1 [Protocol:114]
Mar 10 17:38:51:I:Port security denied pkt: 0000.0022.2224 -> 0000.0011.1111
198.19.1.2 -> 198.19.1.1 [Protocol:114]
Mar 10 17:38:51:I:Port security denied pkt: 0000.0022.2224 -> 0000.0011.1111
198.19.1.2 -> 198.19.1.1 [Protocol:114]
Mar 10 17:38:51:I:Port security denied pkt: 0000.0022.2224 -> 0000.0011.1111
198.19.1.2 -> 198.19.1.1 [Protocol:114]
```

Displaying port security information

You can display the following information about the port security feature:

- The secure MAC addresses that have been saved to the startup-config file by the autosave feature
- The port security settings for an individual port or for all the ports on a specified module
- The secure MAC addresses configured on the device
- Port security statistics for an interface or for a module

Displaying port security settings

You can display the port security settings for an individual port or for all the ports on a specified module. For example, to display the port security settings for port 7/11, enter the following command.

```
NetIron# show port security e 1/1
```

```
Port  Security   MacAddrs          Violation  PortShutdn(minutes) SecureMac Learn
                Learnt/Max  Total/Count/Type   Status/Time/Remain   AgeTime
----- -------- ----------- ------------------ ------------------ ---------
------
 1/1  disabled    0/1         0/   0/shutdown    no/permanent         permanent
yes
```

Syntax: show port security <*module*> | <*portnum*>

This command displays the following information

TABLE 393 Output from the show port security <*module*> command

This field...	Displays...
Port	The slot and port number of the interface.
Security	Whether the port security feature has been enabled on the interface.
MacAddrs Learnt or Max	Learnt – The number of secure MAC addresses that have been learned on the interface. Max – The maximum number of secure MAC addresses that can be learned on the interface.
Violation Total or Count or Type	Total – The total number of violations that have occurred on the interface. Count – The count of the current violation on the interface. Type – The action to be undertaken when a security violation occurs, either “shutdown” or “restrict”.
PortShutdn (minutes) Status or Time or Remain	Status – Whether the interface has been shut down due to a security violation. Time – The number of seconds a port is shut down following a security violation, if the port is set to “shutdown” when a violation occurs. Remain – The number of seconds before the port is enabled again.
SecureMac AgeTime	The amount of time, in minutes, MAC addresses learned on the port will remain secure.
Learn	Whether the port is able to learn MAC addresses.

Displaying the secure MAC addresses on the device

To list the secure MAC addresses configured on the device, enter the following command.

```
NetIron(config)# show port security mac
Port  Num-Addr Secure-Src-Addr Resource Age-Left  Shutdown/Time-Left
----- -------- -------------- -------- --------- ------------------
 7/11        1  0050.da18.747c    Local        10       no
```

Syntax: show port security mac

This command displays the following information.

TABLE 394 Output from the show port security mac command

This field...	Displays...
Port	The slot and port number of the interface.
Num-Addr	The number of MAC addresses secured on this interface.
Secure-Src-Addr	The secure MAC address.
Resource	Whether the address was secured using a local or global resource. Refer to “Local and global resources” on page 2052 for more information.

TABLE 394 Output from the show port security mac command (Continued)

This field...	Displays...
Age-Left	The number of minutes the MAC address will remain secure.
Shutdown or Time-Left	Whether the interface has been shut down due to a security violation and the number of seconds before it is enabled again.

Displaying port security statistics

You can display port security statistics for an interface or for a module.

For example, to display port security statistics for interface 7/11.

```
NetIron# show port security statistics e 7/11
Port  Total-Addrs Maximum-Addrs Violation Shutdown/Time-Left
----- ----------- ------------- --------- ------------------
 7/11           1             1         0       no
```

Syntax: show port security statistics <*portnum*>

TABLE 395 Output from the show port security statistics <*portnum*> command

This field...	Displays...
Port	The slot and port number of the interface.
Total-Addrs	The total number of secure MAC addresses on the interface.
Maximum-Addrs	The maximum number of secure MAC addresses on the interface.
Violation	The number of security violations on the port.
Shutdown or Time-Left	Whether the port has been shut down due to a security violation and the number of seconds before it is enabled again.

To display port security statistics for a module, enter the following command.

```
NetIron# show port security statistics 7
Module 7:
  Total ports: 0
  Total MAC address(es): 0
  Total violations: 0
  Total shutdown ports 0
```

Syntax: show port security statistics <*module*>

TABLE 396 Output from the show port security statistics <*module*> command

This field...	Displays...
Total ports:	The number of ports on the module.
Total MAC address(es):	The total number of secure MAC addresses on the module.
Total violations:	The number of security violations encountered on the module.
Total shutdown ports:	The number of ports on the module shut down as a result of security violations.

Chapter

Configuring 802.1x Port Security 51

PowerConnect B-MLXe supports the following 802.1x Port Security features:

- 802.1x Port Security
- 802.1x Port Security and sFlow
- Dynamic VLAN Assignment for 802.1x Ports
- Strict Security Mode for Dynamic Filter Assignment
- Dynamically Applying Existing ACLs or MAC Address Filter
- Per-User IP ACLs or MAC Address Filters
- Periodic Re-Authentication
- Re-Authenticating a Port Manually
- Quiet Periods
- EAP-Request or Identity Frame Retransmissions
- Timeouts for Retransmission of Messages to the Authentication Server
- Timeout for Retransmission of EAP-Request Frames to the client
- Allowing Multiple 802.1x clients to Authenticate

Overview of 802.1x port security

The Multi-Service IronWare software supports the IEEE 802.1x standard for authenticating devices attached to LAN ports. Using 802.1x port security, you can configure a device to grant access to a port based on information supplied by a client to an authentication server.

When a user logs on to a network that uses 802.1x port security, the device grants (or does not grant) access to network services after the user is authenticated by an authentication server. The user-based authentication in 802.1x port security provides an alternative to granting network access based on a user's IP address, MAC address, or subnetwork.

IETF RFC support

The implementation of 802.1x port security supports the following RFCs:

- RFC 2284 PPP Extensible Authentication Protocol (EAP)
- RFC 2865 Remote Authentication Dial In User Service (RADIUS)
- RFC 2869 RADIUS Extensions

How 802.1x port security works

This section explains the basic concepts behind 802.1x port security, including device roles, how the devices communicate, and the procedure used for authenticating clients.

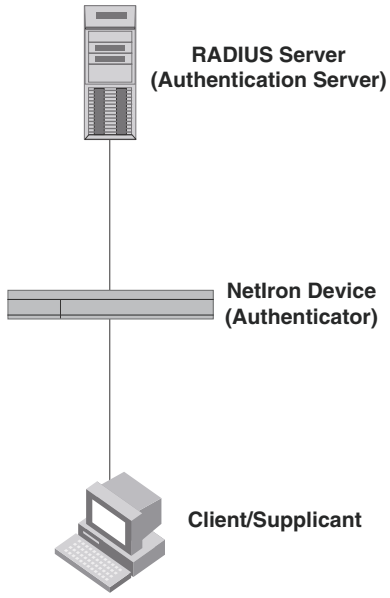
Device roles in an 802.1x configuration

The 802.1x standard defines the roles of **client or Supplicant**, **Authenticator**, and **Authentication Server** in a network.

The client (known as a **Supplicant** in the 802.1x standard) provides username or password information to the Authenticator. The Authenticator sends this information to the Authentication Server. Based on the client's information, the Authentication Server determines whether the client can use services provided by the Authenticator. The Authentication Server passes this information to the Authenticator, which then provides services to the client, based on the authentication result.

Figure 224 illustrates these roles.

FIGURE 224 Authenticator, client or supplicant, and authentication server in an 802.1x configuration



Authenticator – The device that controls access to the network. In an 802.1x configuration, the device serves as the Authenticator. The Authenticator passes messages between the client and the Authentication Server. Based on the identity information supplied by the client, and the authentication information supplied by the Authentication Server, the Authenticator either grants or does not grant network access to the client.

client or supplicant – The device that seeks to gain access to the network. clients must be running software that supports the 802.1x standard (for example, the Windows XP operating system). clients can either be directly connected to a port on the Authenticator, or can be connected by way of a hub.

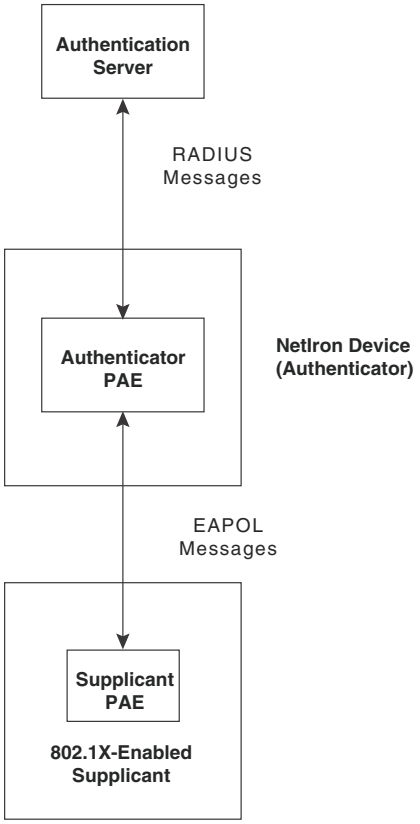
Authentication server – The device that validates the client and specifies whether or not the client may access services on the device. The device supports Authentication Servers running RADIUS.

Communication between the devices

For communication between the devices, 802.1x port security uses the Extensible Authentication Protocol (AP), defined in RFC 2284. The 802.1x standard specifies a method for encapsulating EAP messages so that they can be carried over a LAN. This encapsulated form of EAP is known as EAP over LAN (EAPOL). The standard also specifies a means of transferring the EAPOL information between the client or Supplicant, Authenticator, and Authentication Server.

EAPOL messages are passed between the Port Access Entity (PAE) on the Supplicant and the Authenticator. Figure 225 shows the relationship between the Authenticator PAE and the Supplicant PAE.

FIGURE 225 Authenticator PAE and supplicant PAE



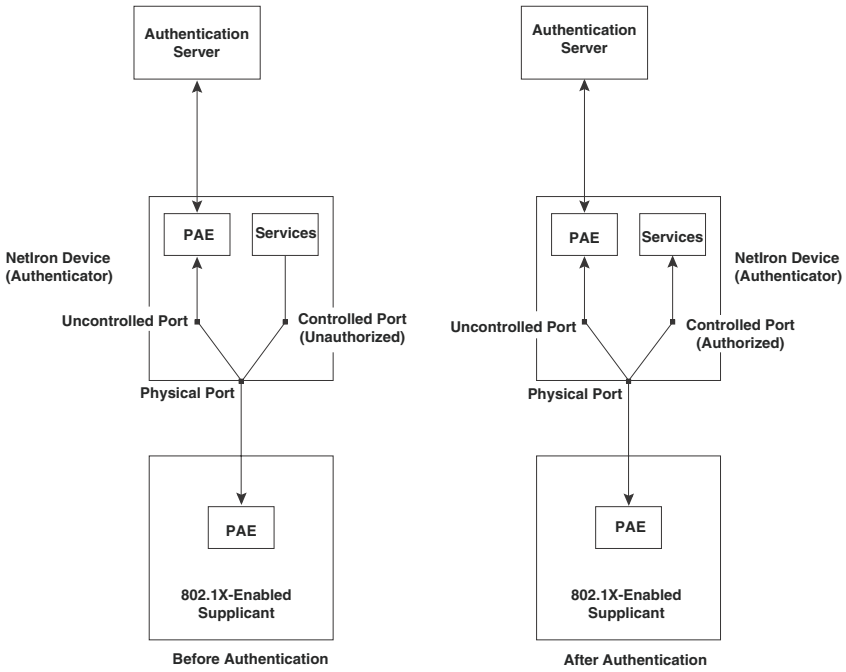
Authenticator PAE – The Authenticator PAE communicates with the Supplicant PAE, receiving identifying information from the Supplicant. Acting as a RADIUS client, the Authenticator PAE passes the Supplicant's information to the Authentication Server, which decides whether the Supplicant can gain access to the port. If the Supplicant passes authentication, the Authenticator PAE grants it access to the port.

Supplicant PAE – The Supplicant PAE supplies information about the client to the Authenticator PAE and responds to requests from the Authenticator PAE. The Supplicant PAE can also initiate the authentication procedure with the Authenticator PAE, as well as send logoff messages.

Controlled and uncontrolled ports

A physical port on the device used with 802.1x port security has two virtual access points: a controlled port and an uncontrolled port. The controlled port provides full access to the network. The uncontrolled port provides access only for EAPOL traffic between the client and the Authentication Server. When a client is successfully authenticated, the controlled port is opened to the client. Figure 226 illustrates this concept.

FIGURE 226 Controlled and uncontrolled ports before and after client authentication



Before a client is authenticated, only the uncontrolled port on the Authenticator is open. The uncontrolled port allows only EAPOL frames to be exchanged between the client and the Authentication Server. The controlled port is in the unauthorized state and allows no traffic to pass through.

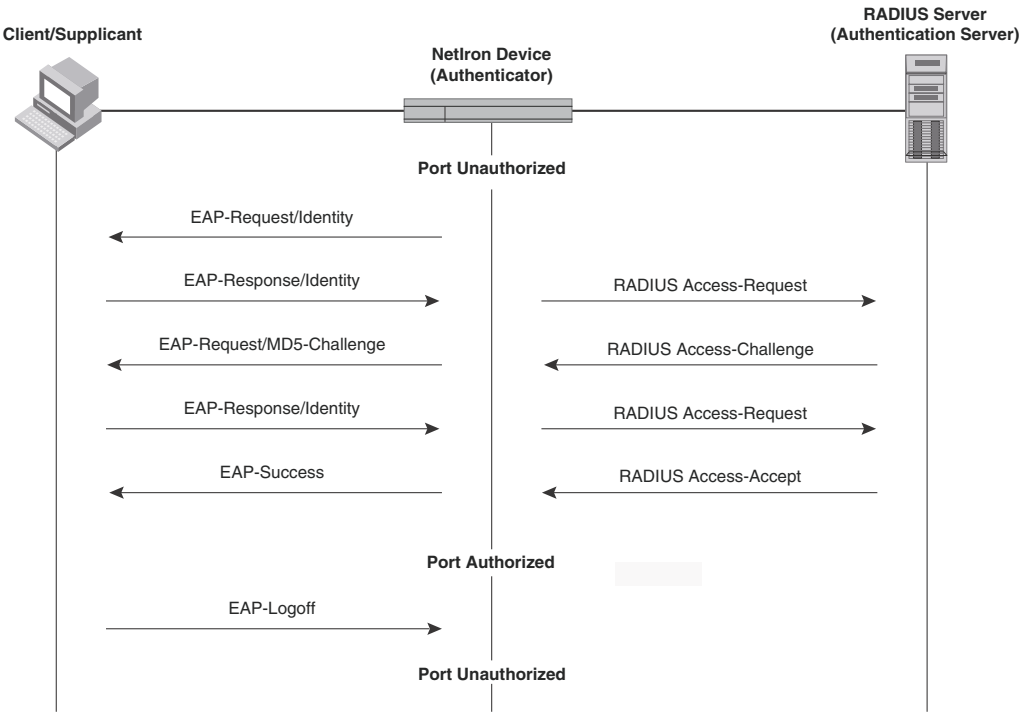
During authentication, EAPOL messages are exchanged between the Supplicant PAE and the Authenticator PAE, and RADIUS messages are exchanged between the Authenticator PAE and the Authentication Server. Refer to "Message exchange during authentication" on page 2065 for an example of this process. If the client is successfully authenticated, the controlled port becomes authorized, and traffic from the client can flow through the port normally.

By default, all controlled ports on the device are placed in the authorized state, allowing all traffic. When authentication is activated on an 802.1x-enabled interface, the controlled port on the interface is placed initially in the unauthorized state. When a client connected to the port is successfully authenticated, the controlled port is then placed in the authorized state until the client logs off. Refer to "Enabling 802.1x port security" on page 2074 for more information.

Message exchange during authentication

Figure 227 illustrates a sample exchange of messages between an 802.1x-enabled client, a device acting as Authenticator, and a RADIUS server acting as an Authentication Server.

FIGURE 227 Message exchange during authentication



In this example, the Authenticator (the device) initiates communication with an 802.1x-enabled client. When the client responds, it is prompted for a username (255 characters maximum) and password. The Authenticator passes this information to the Authentication Server, which determines whether the client can access services provided by the Authenticator. When the client is successfully authenticated by the RADIUS server, the port is authorized. When the client logs off, the port becomes unauthorized again.

Dell's 802.1x implementation supports dynamic VLAN assignment. If one of the attributes in the Access-Accept message sent by the RADIUS server specifies a VLAN identifier, and this VLAN is available on the device, the client's port is moved from its default VLAN to the specified VLAN. When the client disconnects from the network, the port is placed back in its default VLAN. Refer to "Configuring dynamic VLAN assignment for 802.1x ports" on page 2070 for more information.

Dell's 802.1x implementation supports dynamically applying an IP ACL or MAC address filter to a port, based on information received from the Authentication Server.

If a client does not support 802.1x, authentication cannot take place. The device sends EAP-Request or Identity frames to the client, but the client does not respond to them.

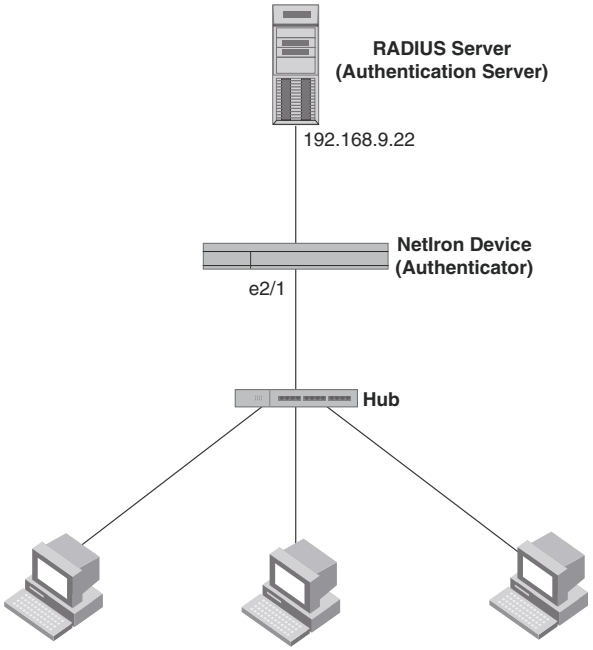
When a client that supports 802.1x attempts to gain access through a non-802.1x-enabled port, it sends an EAP start frame to the device. When the device does not respond, the client considers the port to be authorized, and starts sending normal traffic.

Dell routers and switches support MD5-challenge TLS and any other EAP-encapsulated authentication types in EAP Request or Response messages. In other words, the devices are transparent to the authentication scheme used.

Authenticating multiple clients connected to the same port

Dell routers and switches support 802.1x authentication for ports with more than one client connected to them. Figure 228 illustrates a sample configuration where multiple clients are connected to a single 802.1x port.

FIGURE 228 Multiple clients connected to a single 802.1x-enabled port



If there are multiple clients connected to a single 802.1x-enabled port, the device authenticates each of them individually. Each client's authentication status is independent of the others, so that if one authenticated client disconnects from the network, it has no effect on the authentication status of any of the other authenticated clients.

By default, traffic from clients that cannot be authenticated by the RADIUS server is dropped in hardware. You can optionally configure the device to assign the port to a "restricted" VLAN if authentication of the client is unsuccessful.

How 802.1x multiple client authentication works

When multiple clients are connected to a single 802.1x-enabled port on a router (as in Figure 228), 802.1x authentication is performed in the following ways.

1. One of the 802.1x-enabled clients attempts to log into a network in which a device serves as an Authenticator.
2. The device creates an internal session (called a ***dot1x-mac-session***) for the client. A dot1x-mac-session serves to associate a client's MAC address and username with its authentication status.
3. The device performs 802.1x authentication for the client. Messages are exchanged between the device and the client, and between the device and the Authentication Server (RADIUS server). The result of this process is that the client is either successfully authenticated or not authenticated, based on the username and password supplied by the client.
4. If the client is successfully authenticated, the client's dot1x-mac-session is set to "access-is-allowed". This means that traffic from the client can be forwarded normally.
5. If authentication for the client is unsuccessful the first time, multiple attempts to authenticate the client will be made as determined by the **attempts** variable in the **auth-fail-max-attempts** command.
    - Refer to "Specifying the number of authentication attempts the device makes before dropping packets" on page 2080 for information on how to do this.
6. If authentication for the client is unsuccessful more than the number of times specified by the **attempts** variable in the **auth-fail-max-attempts** command, an ***authentication-failure*** action is taken. The authentication-failure action can be either to drop traffic from the client, or to place the port in a "restricted" VLAN:
    - If the authentication-failure action is to drop traffic from the client, then the client's dot1x-mac-session is set to "access-denied", causing traffic from the client to be dropped in hardware.
    - If the authentication-failure action is to place the port in a "restricted" VLAN, If the client's dot1x-mac-session is set to "access-restricted" then the port is moved to the specified restricted VLAN, and traffic from the client is forwarded normally.
7. When the client disconnects from the network, the device deletes the client's dot1x-mac-session. This does not affect the dot1x-mac-session or authentication status (if any) of the other clients connected on the port.

NOTES:

- The client's dot1x-mac-session establishes a relationship between the username and MAC address used for authentication. If a user attempts to gain access from different clients (with different MAC addresses), he or she would need to be authenticated from each client.
- If a client has been denied access to the network (that is, the client's dot1x-mac-session is set to "access-denied"), then you can cause the client to be re-authenticated by manually disconnecting the client from the network, or by using the **clear dot1x mac-session** command. Refer to "Clearing a dot1x-mac-session for a MAC address" on page 2080 for information on this command.
- When a client has been denied access to the network, its dot1x-mac-session is aged out if no traffic is received from the client's MAC address over a fixed hardware aging period (70 seconds), plus a configurable software aging period. You can optionally change the software aging period for dot1x-mac-sessions or disable aging altogether. After the denied client's dot1x-mac-session is aged out, traffic from that client is no longer blocked, and the client can be re-authenticated.

802.1x port security and sFlow

sFlow is a system for observing traffic flow patterns and quantities within and among a set of the devices. sFlow works by taking periodic samples of network data and exporting this information to a collector.

When you enable sFlow forwarding on an 802.1x-enabled interface, the samples taken from the interface include the user name string at the inbound or outbound port, if that information is available.

For more information on sFlow, refer to Chapter 57, "sFlow".

Configuring 802.1x port security

Configuring 802.1x port security on a device consists of the following tasks.

1. Configuring device interaction with the Authentication Server:
   - "Configuring an authentication method list for 802.1x" on page 2069
   - "Setting RADIUS parameters" on page 2069
   - "Configuring dynamic VLAN assignment for 802.1x ports" on page 2070 (optional)
2. Configuring the device role as the Authenticator:
   - "Enabling 802.1x port security" on page 2074
   - "Initializing 802.1x on a port" on page 2079 (optional)
3. Configuring device interaction with clients:
   - "Configuring periodic re-authentication" on page 2076 (optional)
   - "Re-authenticating a port manually" on page 2077 (optional)
   - "Setting the quiet period" on page 2077 (optional)
   - "Setting the interval for retransmission of EAP-request or identity frames" on page 2077 (optional)
   - "Specifying the number of EAP-request or identity frame retransmissions" on page 2078 (optional)
   - "Specifying a timeout for retransmission of EAP-request frames to the client" on page 2078 (optional)
   - "Allowing multiple 802.1x clients to authenticate" on page 2079 (optional)

NOTE
Multi-Device Port Authentication and 802.1x authentication can both be enabled on a port; however only one of them can authenticate a MAC address or 802.1x client. Refer to "Support for multi-device port authentication and 802.1x on the same interface" on page 2037.

Configuring an authentication method list for 802.1x

To use 802.1x port security, you must specify an authentication method to be used to authenticate clients. The device supports RADIUS authentication with 802.1x port security. To use RADIUS authentication with 802.1x port security, you create an authentication method list for 802.1x and specify RADIUS as an authentication method, then configure communication between the device and RADIUS server.

Example

```
NetIron(config)# aaa authentication dot1x default radius
```

Syntax: [**no**] **aaa authentication dot1x default** <*method-list*>

For the <*method-list*>, enter at least one of the following authentication methods:

radius – Use the list of all RADIUS servers that support 802.1x for authentication.

none – Use no authentication. The client is automatically authenticated without the device using information supplied by the client.

NOTE
If you specify both **radius** and **none**, make sure **radius** comes before **none** in the method list.

Setting RADIUS parameters

To use a RADIUS server to authenticate access to a device, you must identify the server to the device.

```
NetIron(config)# radius-server host 209.157.22.99 auth-port 1812 acct-port 1813
default key mirabeau dot1x
```

Syntax: **radius-server host** <*ip-addr*> | <*server-name*> [**auth-port** <*number*> **acct-port** <*number*> [**authentication-only** | **accounting-only** | **default** [**key 0** | 1 <*string*> [**dot1x**]]]]

The **host** <*ip-addr*> | <*server-name*> parameter is either an IP address or an ASCII text string.

The **auth-port** <*number*> parameter specifies what port to use for RADIUS authentication.

The **acct-port** <*number*> parameter specifies what port to use for RADIUS accounting.

The **dot1x** parameter indicates that this RADIUS server supports the 802.1x standard. A RADIUS server that supports the 802.1x standard can also be used to authenticate non-802.1x authentication requests.

NOTE
To implement 802.1x port security, at least one of the RADIUS servers identified to the device must support the 802.1x standard.

Supported RADIUS attributes

Many IEEE 802.1x Authenticators will function as RADIUS clients. Some of the RADIUS attributes may be received as part of IEEE 802.1x authentication. The device supports the following RADIUS attributes for IEEE 802.1x authentication:

- Username (1) – RFC 2865
- FilterId (11) – RFC 2865
- Vendor-Specific Attributes (26) – RFC 2865
- Tunnel-Type (64) – RFC 2868
- Tunnel-Medium-Type (65) – RFC 2868
- EAP Message (79) – RFC 2579
- Tunnel-Private-Group-Id (81) – RFC 2868

Configuring dynamic VLAN assignment for 802.1x ports

Dell's 802.1x implementation supports assigning a port to a VLAN dynamically, based on information received from an Authentication (RADIUS) Server. If one of the attributes in the Access-Accept message sent by the RADIUS server specifies a VLAN identifier, and this VLAN matches a VLAN on the device, the client's port is moved from its default VLAN to the specified VLAN. When the client disconnects from the network, the port is placed back in its default VLAN.

When a client or supplicant successfully completes the EAP authentication process, the Authentication Server (the RADIUS server) sends the Authenticator (the device) a RADIUS Access-Accept message that grants the client access to the network. The RADIUS Access-Accept message contains attributes set for the user in the user's access profile on the RADIUS server.

If one of the attributes in the Access-Accept message specifies a VLAN identifier, and this VLAN is available on the device, the client's port is moved from its default VLAN to the specified VLAN. When the client disconnects from the network, the port is placed back in its default VLAN.

NOTE
This feature is supported on port-based VLANs only. This feature cannot be used to place an 802.1x-enabled port into a Layer 3 protocol VLAN.

To enable 802.1x VLAN ID support on the device, you must add the following attributes to a user's profile on the RADIUS server.

TABLE 397 802.1x VLAN attributes required from the RADIUS server

Attribute name	Type	Value
Tunnel-Type	064	13 (decimal) – VLAN
Tunnel-Medium-Type	065	6 (decimal) – 802
Tunnel-Private-Group-ID	081	<*vlan-name*> (string) – either the name or the number of a VLAN configured on the device.

The device reads the attributes as follows:

- If the Tunnel-Type or the Tunnel-Medium-Type attributes in the Access-Accept message do not have the values specified above, the device ignores the three Attribute-Value pairs. The client becomes authorized, but the client's port is not dynamically placed in a VLAN.
- If the Tunnel-Type or the Tunnel-Medium-Type attributes in the Access-Accept message do have the values specified above, but there is no value specified for the Tunnel-Private-Group-ID attribute, the client will not become authorized.

- When the device receives the value specified for the Tunnel-Private-Group-ID attribute, it checks whether the <*vlan-name*> string matches the name of a VLAN configured on the device. If there is a VLAN on the device whose name matches the <*vlan-name*>, then the client's port is placed in the VLAN whose ID corresponds to the VLAN name.
- If the <*vlan-name*> string does not match the name of a VLAN, the device checks whether the string, when converted to a number, matches the ID of a VLAN configured on the device. If it does, then the client's port is placed in the VLAN with that ID.
- If the <*vlan-name*> string does not match either the name or the ID of a VLAN configured on the device, then the client will not become authorized.

The **show interface** command displays the VLAN to which an 802.1x-enabled port has been dynamically assigned, as well as the port from which it was moved (that is, the port's default VLAN). Refer to "Displaying dynamically assigned VLAN information" on page 2084 for sample output indicating the port's dynamically assigned VLAN.

Considerations for dynamic VLAN assignment in an 802.1x multiple client configuration

The following considerations apply when a client in a 802.1x multiple client configuration is successfully authenticated, and the RADIUS Access-Accept message specifies a VLAN for the port:

- If the port is not already a member of a RADIUS-specified VLAN, and the RADIUS Access-Accept message specifies the name or ID of a valid VLAN on the device, then the port is placed in that VLAN.
- If the port is already a member of a RADIUS-specified VLAN, and the RADIUS Access-Accept message specifies the name or ID of a different VLAN, then it is considered an authentication failure. The port's VLAN membership is not changed.
- If the port is already a member of a RADIUS-specified VLAN, and the RADIUS Access-Accept message specifies the name or ID of that same VLAN, then traffic from the client is forwarded normally.
- If the RADIUS Access-Accept message specifies the name or ID of a VLAN that does not exist on the device, then it is considered an authentication failure.
- If the RADIUS Access-Accept message does not contain any VLAN information, the client's dot1x-mac-session is set to "access-is-allowed". If the port is already in a RADIUS-specified VLAN, it remains in that VLAN.

Disabling and enabling strict security mode for dynamic filter assignment

By default, 802.1x dynamic filter assignment operates in strict security mode. When strict security mode is enabled, 802.1x authentication for a port fails if the Filter-ID attribute contains invalid information, or if insufficient system resources are available to implement the per-user IP ACLs or MAC address filters specified in the Vendor-Specific attribute.

When strict security mode is enabled:

- If the Filter-ID attribute in the Access-Accept message contains a value that does not refer to an existing filter (that is, a MAC address filter or IP ACL configured on the device), then the client will not be authenticated, regardless of any other information in the message (for example, if the Tunnel-Private-Group-ID attribute specifies a VLAN to which to assign the port).

- If the Vendor-Specific attribute specifies the syntax for a filter, but there are insufficient system resources to implement the filter, then the port will not be authenticated.
- If the device does not have the system resources available to dynamically apply a filter to a port, then the port will not be authenticated.

NOTE
If the Access-Accept message contains values for both the Filter-ID and Vendor-Specific attributes, then the value in the Vendor-Specific attribute (the per-user filter) takes precedence.
Also, if authentication for a port fails because the Filter-ID attribute referred to a non-existent filter, or there were insufficient system resources to implement the filter, then a Syslog message is generated.

When strict security mode is disabled:

- If the Filter-ID attribute in the Access-Accept message contains a value that does not refer to an existing filter (that is, a MAC address filter or IP ACL configured on the device), then the port is still authenticated, but no filter is dynamically applied to it.
- If the Vendor-Specific attribute specifies the syntax for a filter, but there are insufficient system resources to implement the filter, then the port is still authenticated, but the filter specified in the Vendor-Specific attribute is not applied to the port.

By default, strict security mode is enabled for all 802.1x-enabled interfaces, but you can manually disable or enable it, either globally or for specific interfaces.

To disable strict security mode globally, enter the following commands.

```
NetIron(config)# dot1x-enable
NetIron(config-dot1x)# no global-filter-strict-security
```

After you have globally disabled strict security mode on the device, you can re-enable it by entering the following command.

```
NetIron(config-dot1x)# global-filter-strict-security
```

Syntax: [no] **global-filter-strict-security**

To disable strict security mode for a specific interface, enter commands such as the following.

```
NetIron(config)# interface e 1
NetIron(config-if-e10000-1)# no dot1x filter-strict-security
```

To re-enable strict security mode for an interface, enter the following command.

```
NetIron(config-if-e10000-1)# dot1x filter-strict-security
```

Syntax: [no] **dot1x filter-strict-security**

The output of the **show dot1x** and **show dot1x config** commands has been enhanced to indicate whether strict security mode is enabled or disabled globally and on an interface.

Dynamically applying existing ACLs or MAC address filter

When a port is authenticated using 802.1x security, an IP ACL or MAC address filter that exists in the running configuration on the device can be dynamically applied to the port. To do this, you configure the Filter-ID (type 11) attribute on the RADIUS server. The Filter-ID attribute specifies the name or number of the IP ACL or MAC address filter.

The following table shows the syntax for configuring the Filter-ID attribute to refer to a IP ACL or MAC address filter.

Value	Description
ip.<*number*>.in	Applies the specified numbered ACL to the 802.1x authenticated port in the inbound direction.
ip.<*name*>.in	Applies the specified named ACL to the 802.1x authenticated port in the inbound direction.
ip.<*number*>.out	Applies the specified numbered ACL to the 802.1x authenticated port in the outbound direction.
ip.<*name*>.out	Applies the specified named ACL to the 802.1x authenticated port in the outbound direction.
mac.<*number*>.in	Applies the specified MAC address filter to the 802.1x authenticated port in the inbound direction.

The following table lists examples of values you can assign to the Filter-ID attribute on the RADIUS server to refer to IP ACLs and MAC address filters configured on a device.

Possible values for the filter ID attribute on the RADIUS server	ACL or MAC address filter configured on the device
ip.2.in	access-list 2 permit host 36.48.0.3 access-list 2 permit 36.0.0.0 0.255.255.255
ip.102.in	access-list 102 permit ip 36.0.0.0 0.255.255.255 any
ip.fdry_filter.in	ip access-list standard fdry_filter permit host 36.48.0.3
mac.401.in	access-list 401 permit 3333.3333.3333 ffff.ffff.ffff any etype any
mac.402.in mac.403.in	access-list 402 permit 3333.3333.3333 ffff.ffff.ffff any etype any access-list 403 permit 2222.2222.2222 ffff.ffff.ffff any etype any

NOTES:

- The <*name*> in the Filter ID attribute is case-sensitive.
- You can specify only numbered MAC address filters in the Filter ID attribute. Named MAC address filters are not supported.
- Dynamic ACL filters are supported for the inbound and outbound direction.
- MAC address filters are supported only for the inbound direction. Outbound MAC address filters are not supported.
- Dynamically assigned IP ACLs and MAC address filters are subject to the same configuration restrictions as non-dynamically assigned IP ACLs and MAC address filters.

- Multiple IP ACLs and MAC address filters can be specified in the Filter ID attribute, allowing multiple address filters to be simultaneously applied to an 802.1x authenticated port. Use commas, semicolons, or carriage returns to separate the address filters (for example: ip.3.in,mac.402.in).
- If 802.1x is enabled on a VE port, ACLs, dynamic (802.1x assigned) or static (user configured), cannot be applied to the port.

Configuring per-user IP ACLs or MAC address filters

Per-user IP ACLs and MAC address filters make use of the Vendor-Specific (type 26) attribute to dynamically apply filters to ports. Defined in the Vendor-Specific attribute are Dell ACL or MAC address filter statements. When the RADIUS server returns the Access-Accept message granting a client access to the network, the device reads the statements in the Vendor-Specific attribute and applies these IP ACLs or MAC address filters to the client's port. When the client disconnects from the network, the dynamically applied filters are no longer applied to the port. If any filters had been applied to the port previous to the client connecting, then those filters are reapplied to the port.

The following is the syntax for configuring the PowerConnect Vendor-Specific attribute with ACL or MAC address filter statements.

Value	Description
ipacl.e.in=<*extended-acl-entries*>	Applies the specified extended ACL entries to the 802.1x authenticated port in the inbound direction.
ipacl.e.out=<*extended-acl-entries*>	Applies the specified extended ACL entries to the 802.1x authenticated port in the outbound direction.
macfilter.in=<*mac-accesslist-entries*>	Applies the specified MAC address filter entries to the 802.1x authenticated port in the inbound direction.

The following table shows examples of IP ACLs and MAC address filters configured in the Dell Vendor-Specific attribute on a RADIUS server. These IP ACLs and MAC address filters follow the same syntax as other Dell ACLs and MAC address filters. Refer to 21, "Access Control List" or Chapter 40, "Configuring an IPv6 Access Control List" for information on syntax.

IP ACL or MAC address filter	Vendor-specific attribute on RADIUS server
Extended ACL with one entry (outbound direction)	ipacl.e.out=permit ip 36.0.0.0 0.255.255.255 any
Mac address filter with one entry	macfilter.in= deny any any
Mac address filter with two entries	macfilter.in= permit 0000.0000.3333 ffff.ffff.0000 any, macfilter.in= permit 0000.0000.4444 ffff.ffff.0000 any

The RADIUS server allows one instance of the Vendor-Specific attribute to be sent in an Access-Accept message. However, the Vendor-Specific attribute can specify multiple IP ACLs or MAC address filters. You can use commas, semicolons, or carriage returns to separate the filters (for example: ipacl.e.in= permit ip any any,ipacl.e.in = deny ip any any).

Enabling 802.1x port security

By default, 802.1x port security is disabled on devices. To enable the feature on the device and enter the dot1x configuration level, enter the following command.

```
NetIron(config)# dot1x-enable
NetIron(config-dot1x)#
```

Syntax: [**no**] **dot1x-enable**

At the dot1x configuration level, you can enable 802.1x port security on all interfaces at once, on individual interfaces, or on a range of interfaces.

For example, to enable 802.1x port security on all interfaces on the device, enter the following command.

```
NetIron(config-dot1x)# enable all
```

Syntax: [**no**] **enable all**

To enable 802.1x port security on interface 3/11, enter the following command.

```
NetIron(config-dot1x)# enable ethernet 3/11
```

Syntax: [**no**] **enable** <*portnum*>

To enable 802.1x port security on interfaces 3/11 through 3/16, enter the following command.

```
NetIron(config-dot1x)# enable ethernet 3/11 to 3/16
```

Syntax: [**no**] **enable** <*portnum*> **to** <*portnum*>

Setting the port control

To activate authentication on an 802.1x-enabled interface, you specify the kind of ***port control*** to be used on the interface. An interface used with 802.1x port security has two virtual access points:

- The controlled port can be either the authorized or unauthorized state. In the authorized state, it allows normal traffic to pass between the client and the authenticator. In the unauthorized state, it allows no traffic to pass through.
- The uncontrolled port allows only EAPOL traffic between the client and the authentication server.

Refer to Figure 226 on page 2064 for an illustration of this concept.

By default, all controlled ports on the device are in the authorized state, allowing all traffic. When you activate authentication on an 802.1x-enabled interface, its controlled port is placed in the unauthorized state. When a client connected to the interface is successfully authenticated, the controlled port is then placed in the authorized state for that client. The controlled port remains in the authorized state until the client logs off.

To activate authentication on an 802.1x-enabled interface, you configure the interface to place its controlled port in the authorized state when a client is authenticated by an authentication server. To do this, enter commands such as the following.

```
NetIron(config)# interface e 3/1
NetIron(config-if-e10000-3/1)# dot1x port-control auto
```

Syntax: [**no**] **dot1x port-control** [**force-authorized** | **force-unauthorized** | **auto**]

When an interface's control type is set to **auto**, its controlled port is initially set to unauthorized, but is changed to authorized when the connecting client is successfully authenticated by an Authentication Server.

The port control type can be one of the following:

force-authorized – The port's controlled port is placed unconditionally in the authorized state, allowing all traffic. This is the default state for ports on the device. Also, this parameter allows connection from multiple clients.

force-unauthorized – The controlled port is placed unconditionally in the unauthorized state.

auto – The controlled port is unauthorized until authentication takes place between the client and Authentication Server. Once the client passes authentication, the port becomes authorized. This has the effect of activating authentication on an 802.1x-enabled interface.

Notes

You cannot enable 802.1x port security on ports that have any of the following features enabled:

- Static MAC configurations
- Link aggregation
- Metro Ring Protocol (MRP)
- Tagged port
- Mirror port
- LAG port
- MAC port security
- Management Port
- VE members

Configuring periodic re-authentication

You can configure the device to periodically re-authenticate clients connected to 802.1x-enabled interfaces. When you enable periodic re-authentication, the device re-authenticates clients every 3,600 seconds by default. You can optionally specify a different re-authentication interval of between 1 – 4294967295 seconds.

To configure periodic re-authentication using the default interval of 3,600 seconds, enter the following command.

```
NetIron(config)#dot1x-enable
NetIron(config-dot1x)# re-authentication
```

Syntax: [**no**] **re-authentication**

To configure periodic re-authentication with an interval of 2,000 seconds, enter the following commands.

```
NetIron(config)#dot1x-enable
NetIron(config-dot1x)# re-authentication
NetIron(config-dot1x)# timeout re-authperiod 2000
```

Syntax: [**no**] **timeout re-authperiod** <*seconds*>

The re-authentication interval is a global setting, applicable to all 802.1x-enabled interfaces. If you want to re-authenticate clients connected to a specific port manually, use the **dot1x re-authenticate** command. Refer to "Re-authenticating a port manually".

Re-authenticating a port manually

When periodic re-authentication is enabled, by default the device re-authenticates clients connected to an 802.1x-enabled interface every 3,600 seconds (or the time specified by the **dot1x timeout re-authperiod** command). You can also manually re-authenticate clients connected to a specific port.

For example, to re-authenticate clients connected to interface 3/1, enter the following command.

```
NetIron# dot1x re-authenticate e 3/1
```

Syntax: [**no**] **dot1x re-authenticate** <*portnum*>

Setting the quiet period

If the device is unable to authenticate the client, the device waits a specified amount of time before trying again. The amount of time the device waits is specified with the **quiet-period** parameter. This timer also indicates how long a client that failed authentication would have its blocked entry programmed into the hardware.The **quiet-period** parameter can be from 0 – 4294967295 seconds. The default is 60 seconds.

For example, to set the quiet period to 30 seconds, enter the following command.

```
NetIron(config-dot1x)# timeout quiet-period 30
```

Syntax: [**no**] **timeout quiet-period** <*seconds*>

Setting the interval for retransmission of EAP-request or identity frames

When the device sends a client an EAP-request or identity frame, it expects to receive an EAP-response or identity frame from the client. If the client does not send back an EAP-response or identity frame, the device waits a specified amount of time and then retransmits the EAP-request or identity frame. You can specify the amount of time the device waits before retransmitting the EAP-request or identity frame to the client. This amount of time is specified with the **tx-period** parameter. The **tx-period** parameter can be from 1 – 65535 seconds. The default is 30 seconds.

For example, to cause the device to wait 60 seconds before retransmitting an EAP-request or identity frame to a client, enter the following command.

```
NetIron(config-dot1x)# timeout tx-period 60
```

Syntax: [**no**] **timeout tx-period** <*seconds*>

If the client does not send back an EAP-response or identity frame within 60 seconds, the device will transmit another EAP-request or identity frame.

Specifying the number of EAP-request or identity frame retransmissions

If the device does not receive a EAP-response or identity frame from a client, the device waits 30 seconds (or the amount of time specified with the **timeout tx-period** command), then retransmits the EAP-request or identity frame. By default, the device retransmits the EAP-request or identity frame a maximum of two times. If no EAP-response or identity frame is received from the client after two EAP-request or identity frame retransmissions, the device restarts the authentication process with the client.

You can optionally specify between 1 – 10 frame retransmissions. For example, to configure the device to retransmit an EAP-request or identity frame to a client a maximum of three times, enter the following command.

```
NetIron(config-dot1x)# maxreq 3
```

Syntax: maxreq <*value*>

Specifying a timeout for retransmission of messages to the Authentication Server

When performing authentication, the device receives EAPOL frames from the client and passes the messages on to the RADIUS server. The device expects a response from the RADIUS server within 30 seconds. If the RADIUS server does not send a response within 30 seconds, the device retransmits the message to the RADIUS server. The time constraint for retransmission of messages to the Authentication Server can be between 1 – 4294967295 seconds.

For the device, the possible values are: 1 - 4294967295.

For example, to configure the device to retransmit a message if the Authentication Server does not respond within 45 seconds, enter the following command.

```
NetIron(config-dot1x)# servertimeout 45
```

Syntax: servertimeout <*seconds*>

Specifying a timeout for retransmission of EAP-request frames to the client

Acting as an intermediary between the RADIUS Authentication Server and the client, the device receives RADIUS messages from the RADIUS server, encapsulates them as EAPOL frames, and sends them to the client. When the device relays an EAP-Request frame from the RADIUS server to the client, it expects to receive a response from the client within 30 seconds. If the client does not respond within the allotted time, the device retransmits the EAP-Request frame to the client. The time constraint for retransmission of EAP-Request frames to the client can be between 1 – 4294967295 seconds.

For example, to configure the device to retransmit an EAP-Request frame if the client does not respond within 45 seconds, enter the following command.

```
NetIron(config-dot1x)# supptimeout 45
```

Syntax: supptimeout <*seconds*>

Initializing 802.1x on a port

To initialize 802.1x port security on a port, or to flush all of its information on that port and start again, enter a command such as the following.

```
NetIron# dot1x initialize e 3/1
```

Syntax: dot1x initialize <*portnum*>

Allowing multiple 802.1x clients to authenticate

If there are multiple clients connected to a single 802.1x-enabled port, the device authenticates each of them individually. When multiple clients are connected to the same 802.1x-enabled port, the functionality described in "How 802.1x multiple client authentication works" on page 2066 is enabled by default. You can optionally do the following:

- Specify the authentication-failure action
- Specify the number of authentication attempts the device makes before dropping packets
- Disabling aging for dot1x-mac-sessions
- Configure aging time for blocked clients
- Clear the dot1x-mac-session for a MAC address

Specifying the authentication-failure action

In an 802.1x multiple client configuration, if RADIUS authentication for a client is unsuccessful, traffic from that client is either dropped in hardware (the default), or the client's port is placed in a "restricted" VLAN. You can specify which of these two authentication-failure actions is to be used. If the authentication-failure action is to place the port in a restricted VLAN, you can specify the ID of the restricted VLAN.

To specify that the authentication-failure action is to place the client's port in a restricted VLAN, enter the following command.

```
NetIron(config)# dot1x-enable
NetIron(config-dot1x)# auth-fail-action restricted-vlan
```

Syntax: [**no**] **auth-fail-action restricted-vlan**

To specify the ID of the restricted VLAN as VLAN 300, enter the following command.

```
NetIron(config-dot1x)# auth-fail-vlanid 300
```

Syntax: [**no**] **auth-fail-vlanid** <*vlan-id*>

Specifying the number of authentication attempts the device makes before dropping packets

When the initial authentication attempt made by the device to authenticate the client is unsuccessful, the device immediately retries to authenticate the client. After three unsuccessful authentication attempts, the client's802.1x MAC authentication session is set to either "access-denied" or the port is moved to restricted VLAN.

You can optionally configure the number of authentication attempts the device makes. To do so, enter a command such as the following.

```
NetIron(config-dot1x)# auth-fail-max-attempts 2
```

Syntax: [**no**] **auth-fail-max-attempts** <*attempts*>

By default, the device makes 3 attempts to authenticate a client. You can specify between 1 – 10 authentication attempts.

Display commands

The **show port security global-deny** command lists all the configured global deny MAC addresses.

The **show port security denied-macs** command lists all the denied MAC addresses in the system.

Clearing a dot1x-mac-session for a MAC address

You can clear the dot1x-mac-session for a specified MAC address, so that the client with that MAC address can be re-authenticated by the RADIUS server.

```
NetIron# clear dot1x mac-session 00e0.1234.abd4
```

Syntax: **clear dot1x mac-session** <*mac-address*>

Displaying 802.1x information

You can display the following 802.1x-related information:

- Information about the 802.1x configuration on the device and on individual ports
- Statistics about the EAPOL frames passing through the device
- Information about 802.1x-enabled ports dynamically assigned to a VLAN
- Information about the user-defined and dynamically applied Mac address and IP ACLs currently active on the device
- Information about the 802.1x multiple client configuration

Displaying 802.1x configuration information

To display information about the 802.1x configuration on the device, enter the following command.

```
NetIron# show dot1x
PAE Capability                : Authenticator Only
system-auth-control           : Enable
Number of ports enabled       : 25
re-authentication             : Disable
global-filter-strict-security: Enable
quiet-period                  : 60 Seconds
tx-period                     : 30 Seconds
supptimeout                   : 30 Seconds
servertimeout                 : 30 Seconds
maxreq                        : 3
re-authperiod                 : 3600 Seconds
Protocol Version              : 1
auth-fail-action              : Block Traffic
MAC Session Aging             : All
MAC Session Max Age           : 120 Seconds
Maximum Failed Attempts       : 3
```

Syntax: show dot1x

The following table describes the information displayed by the **show dot1x** command.

TABLE 398 Output from the **show dot1x command**

This field...	Displays...
PAE Capability	The Port Access Entity (PAE) role for the device. This is always “Authenticator Only”.
system-auth-control	Whether system authentication control is enabled on the device. The **dot1x-enable** command enables system authentication control on the device.
Number of ports enabled	Number of interfaces on the devices that have been enabled for 802.1x.
re-authentication	Whether periodic re-authentication is enabled on the device. Refer to “Configuring periodic re-authentication” on page 2076. When periodic re-authentication is enabled, the device automatically re-authenticates clients every 3,600 seconds by default.
global-filter-strict-security	Whether or not strict security mode is enabled globally.
quiet-period	When the device is unable to authenticate a client, the amount of time the device waits before trying again (default 60 seconds). Refer to “Setting the quiet period” on page 2077 for information on how to change this setting.
tx-period	When a client does not send back an EAP-response or identity frame, the amount of time the device waits before retransmitting the EAP-request or identity frame to a client (default 30 seconds). Refer to “Setting the interval for retransmission of EAP-request or identity frames” on page 2077 for information on how to change this setting.
supp-timeout	When a client does not respond to an EAP-request frame, the amount of time before the device retransmits the frame. Refer to “Specifying a timeout for retransmission of EAP-request frames to the client” on page 2078 for information on how to change this setting.
server-timeout	When the Authentication Server does not respond to a message sent from the client, the amount of time before the device retransmits the message. Refer to “Specifying a timeout for retransmission of messages to the Authentication Server” on page 2078 for information on how to change this setting.

TABLE 398 Output from the **show dot1x command** (Continued)

This field...	Displays...
max-req	The number of times the device retransmits an EAP-request or identity frame if it does not receive an EAP-response or identity frame from a client (default 2 times). Refer to "Specifying the number of EAP-request or identity frame retransmissions" on page 2078 for information on how to change this setting.
re-authperiod	How often the device automatically re-authenticates clients when periodic re-authentication is enabled (default 3,600 seconds). Refer to "Configuring periodic re-authentication" on page 2076 for information on how to change this setting.
security-hold-time	This field is not supported.
Protocol Version	The version of the 802.1x protocol in use on the device.
Auth-fail-action	The configured authentication-failure action. This can be Restricted VLAN or Block Traffic.
Mac Session Aging	Whether aging for dot1x-mac-sessions has been enabled or disabled for permitted or denied dot1x-mac-sessions.
Mac Session max-age	The configured software aging time for dot1x-mac-sessions.
Maximum Failed Attempts	The number of failed authentication attempts, if the authentication-failure action shows Restricted VLAN,

To display information about the 802.1x configuration on an individual port, enter a command such as the following.

```
NetIron# show dot1x config e 1/3

Port 1/3 Configuration:
AuthControlledPortControl    : Auto
max-clients                  : 32
multiple-clients             : Enable
filter-strict-security       : Enable
```

Syntax: show dot1x config ethernet <*slot/port*>

The following additional information is displayed in the **show dot1x config** command for an interface.

TABLE 399 Output from the **show dot1x config command** for an interface

This field...	Displays...
AuthControlledPortControl	The port control type configured for the interface. If set to auto, authentication is activated on the 802.1x-enabled interface.
multiple-hosts	Whether the port is configured to allow multiple Supplicants accessing the interface on the device through a hub. Refer to "Allowing multiple 802.1x clients to authenticate" on page 2079 for information on how to change this setting.
max-clients	The maximum number of clients that can be authenticated on this interface.
multiple-clients	Shows if the interface is enabled or disabled for multiple client authentication.
filter-strict-security	Shows if the interface is enabled or disabled for strict security mode.

Displaying 802.1x statistics

To display 802.1x statistics for an individual port, enter a command such as the following.

```
NetIron# show dot1x statistics e 3/3

Port 1/3 Statistics:
RX EAPOL Start:                 0
RX EAPOL Logoff:                0
RX EAPOL Invalid:               0
RX EAPOL Total:                 2
RX EAP Resp/Id:                 1
RX EAP Resp other than Resp/Id: 1
RX EAP Length Error:            0
Last EAPOL Version:             1
Last EAPOL Source:              0050.da0b.8bef
TX EAPOL Total:                 3
TX EAP Req/Id:                  1
TX EAP Req other than Req/Id:   1
Num Sessions:                   1
Num Restricted Sessions:        0
Num Authorized Sessions:        1
```

Syntax: show dot1x statistics [**all** | **ethernet** <*slot/port*>]

The following table describes the information displayed by the **show dot1x statistics** command for an interface.

TABLE 400 Output from the **show dot1x statistics command**

This field...	Displays...
RX EAPOL Start	The number of EAPOL-Start frames received on the port.
RX EAPOL Logoff	The number of EAPOL-Logoff frames received on the port.
RX EAPOL Invalid	The number of invalid EAPOL frames received on the port.
RX EAPOL Total	The total number of EAPOL frames received on the port.
RX EAP Resp or Id	The number of EAP-Response or Identity frames received on the port
RX EAP Resp other than Resp or Id	The total number of EAPOL-Response frames received on the port that were not EAP-Response or Identity frames.
RX EAP Length Error	The number of EAPOL frames received on the port that have an invalid packet body length.
Last EAPOL Version	The version number of the last EAPOL frame received on the port.
Last EAPOL Source	The source MAC address in the last EAPOL frame received on the port.
TX EAPOL Total	The total number of EAPOL frames transmitted on the port.
TX EAP Req or Id	The number of EAP-Request or Identity frames transmitted on the port.
TX EAP Req other than Req or Id	The number of EAP-Request frames transmitted on the port that were not EAP-Request or Identity frames.
Num sessions	Total number of dot1x sessions, which include authenticated, restricted, denied and sessions in the initial state.

TABLE 400 Output from the **show dot1x statistics command** (Continued)

This field...	Displays...
Num Restricted Sessions	Number of current 802.1x sessions that failed authentication. The user configuration was moved into a restricted VLAN.
Num Authorized Sessions	Number of current 802.1x authenticated sessions that are authorized.

Clearing 802.1x statistics

You can clear the 802.1x statistics counters on all interfaces at once, on individual interfaces, or on a range of interfaces.

For example, to clear the 802.1x statistics counters on all interfaces on the device, enter the following command.

```
NetIron# clear dot1x statistics all
```

Syntax: clear dot1x statistics all

To clear the 802.1x statistics counters on interface e 3/11, enter the following command.

```
NetIron# clear dot1x statistics e 3/11
```

Syntax: clear dot1x statistics [**mac-address** | **ethernet** *<slot>/<portnum>*]

Displaying dynamically assigned VLAN information

The **show interface** command displays the VLAN to which an 802.1x-enabled port has been dynamically assigned, as well as the port from which it was moved (that is, the port's default VLAN).

The following is an example of the **show interface** command indicating the port's dynamically assigned VLAN. Information about the dynamically assigned VLAN is shown in bold type.

```
NetIron# show interface e 12/2
GigabitEthernet1/3 is up, line protocol is up
  Hardware is GigabitEthernet, address is 000c.dbe2.5800 (bia 000c.dbe2.5800)
  Configured speed auto, actual 100Mbit, configured duplex fdx, actual fdx
  Configured mdi mode AUTO, actual MDIX
  Member of L2 VLAN ID 4094 (dot1x-RADIUS assigned), original L2 VLAN ID is 1,
  port is untagged, port state is Forwarding
  STP configured to ON, Priority is level0, flow control enabled
  Force-DSCP disabled
  mirror disabled, monitor disabled
  Not member of any active trunks
  Not member of any configured trunks
  No port name
  Internet address is 12.12.12.250/24, MTU 1522 bytes, encapsulation ethernet
  300 second input rate: 810 bits/sec, 0 packets/sec, 0.00% utilization
  300 second output rate: 1253 bits/sec, 1 packets/sec, 0.00% utilization
  70178 packets input, 7148796 bytes, 0 no buffer
  Received 0 broadcasts, 0 multicasts, 70178 unicasts
  0 input errors, 0 CRC, 0 frame, 0 ignored
  0 runts, 0 giants, DMA received 70178 packets
  91892 packets output, 10081165 bytes, 0 underruns
  Transmitted 9853 broadcasts, 13330 multicasts, 68709 unicasts
  0 output errors, 0 collisions, DMA transmitted 91892 packets
```

In this example, the 802.1x-enabled port has been moved from VLAN 1 to VLAN 4094. When the client disconnects, the port will be moved back to VLAN 1.

Displaying information on MAC address filters and IP ACLs on an interface

You can display information about the user-defined and dynamically applied MAC address filters and IP ACLs currently active on an interface.

Displaying MAC address filters applied to an 802.1x-enabled port

Use the **show dot1x mac-address** command to display information about MAC filters applied to an interface. If the MAC address filter is dynamically assigned by 802.1x, the display shows the following.

```
NetIron#show dot1x mac-address ethernet 1/1
Port 1/1 MAC Address Filter information:
  802.1x dynamic MAC Filter (user defined) :
    mac access-list 401 in
  Port default MAC Filter :
    mac access-list 400 in
```

The “Port default MAC Filter” appears if a default MAC filter has been configured on the port. This default MAC filter is the MAC filter that will be applied to the port once the dynamically assigned MAC filter is removed. If a default MAC filter has not been configured, the message “No Port default MAC is displayed.

When the dynamically assigned MAC address filter is removed, the display shows the following information.

```
NetIron#show dot1x mac-address ethernet 1/1
```

```
Port 1/1 MAC Address Filter information:
  Port default MAC Filter :
    mac access-list 400 in
```

Syntax: **show dot1x mac-address-filter** [**all** | **ethernet** <*slot/port*> | | **begin** <*expression*> | **exclude** <*expression*> | **include** <*expression*>]

The **all** keyword displays all dynamically applied MAC address filters active on the device.

Use the **ethernet** <*slot*>/<*port*> parameter to display information for one port.

Displaying IP ACLs applied to an 802.1x-enabled port

Use the **show dot1x ip-acl** command to display the information about what IP ACLs have been applied to an 802.1x-enabled port. If the IP ACL was dynamically applied by 802.1x, the following information is displayed.

```
NetIron# show dot1x ip-acl ethernet 1/1
Port 1/1 IP ACL information:
  802.1x dynamic IP ACL (user defined) in:
    ip access-list extended Port_1/1_E_IN in
  Port default IP ACL in:
    ip access-list 100 in
  No outbound ip access-list is set
```

The “Port default IP ACL” appears if a default IP ACL has been configured on the port. The default IP ACL is the IP ACL that will be applied to the port once the dynamically assigned IP ACL is removed. If a default IP ACL has not been configured, the message “No Port default IP ACL” is displayed.

When the dynamically assigned IP ACL is removed from the port, the display shows the following information.

```
NetIron# show dot1x ip-acl ethernet 1/1
Port 1/1 IP ACL information:
  Port default IP ACL in:
    ip access-list 100 in
  No outbound ip access-list is set
```

Syntax: **show dot1x ip-acl [all | ethernet** <*slot/port*> | | **begin** <*expression*> | **exclude** <*expression*> | **include** <*expression*>]

The **all** keyword displays all dynamically applied IP ACLs active on the device.

Use the **ethernet** <*slot*>/<*port*> parameter to display information for one port.

Displaying information about the dot1x-mac-sessions on each port

To display information about the dot1x-mac-sessions on each port on the device, enter the following command.

```
NetIron# show dot1x mac-session
Port  MAC             Username                      VLAN Auth State ACL|MAC  Age
                                                                    i|o|f
-------------------------------------------------------------------------------
1/1   0050.da0b.8cd7  Mary M                          1    DENIED  n|n|n   0
1/2   0050.da0b.8cb3  adminmorn                    4094 PERMITTED  y|n|n   0
1/3   0050.da0b.8bef  reports                      4094 PERMITTED  y|n|n   0
1/4   0010.5a1f.6a63  testgroup                    4094 PERMITTED  y|n|n   0
1/5   0050.da1a.ff7e  admineve                     4094 PERMITTED  y|n|n   0
```

Syntax: **show dot1x mac-session** [**brief** | [**begin** <*expression*> | **exclude** <*expression*> | **include** <*expression*>]]

Table 401 describes the information displayed by the **show dot1x mac-session** command.

TABLE 401 Output from the **show dot1x mac-session** command

This field...	Displays...
Port	The port on which the dot1x-mac-session exists.
MAC	The MAC address of the client
Username	The username used for RADIUS authentication.
Vlan	The VLAN to which the port is currently assigned.
Auth-State	The authentication state of the dot1x-mac-session. This can be one of the following: permit – The client has been successfully authenticated, and traffic from the client is being forwarded normally. blocked – Authentication failed for the client, and traffic from the client is being dropped in hardware. restricted – Authentication failed for the client, but traffic from the client is allowed in the restricted VLAN only. init - The client is in is in the process of 802.1x authentication, or has not started the authentication process.
ACL	Whether or not an IP ACL is applied to incoming (i) and outgoing (o) traffic on the interface
MAC	Whether or not a MAC filter is applied to the port.
Age	The software age of the dot1x-mac-session.

Displaying information about the ports in an 802.1x multiple client configuration

To display information about the ports in an 802.1x multiple client configuration, enter the following command.

```
NetIron# show dot1x mac-session brief
Port             Number of users      Dynamic Dynamic     Dynamic
          Restricted Authorized Total VLAN    ACL (In/Out)MAC-Filt
---------+----------+----------+-----+-------+-----------+--------
1/1               0          0     1 no          no/no   no
1/2               0          1     1 yes        yes/no   no
1/3               0          1     1 yes        yes/no   no
1/4               0          1     1 yes        yes/no   no
1/5               0          1     1 yes        yes/no   no
```

Syntax: **show dot1x mac-session brief** [| **begin** <*expression*> | **exclude** <*expression*> | **include** <*expression*>]

The following table describes the information displayed by the **show dot1x mac-session brief** command.

TABLE 402 Output from the **show dot1x mac-session brief** command

This field...	Displays...
Port	Information about the users connected to each port.
Number of users	The number of restricted and authorized (those that were successfully authenticated) users connected to the port.
Dynamic VLAN	Whether or not the port is a member of a RADIUS-specified VLAN.
Dynamic ACL	Whether or not a RADIUS-specified ACL has been applied to the port for incoming (in) and outgoing (out) traffic.
Dynamic MAC Filters	Whether or not a RADIUS-specified MAC Filter has been applied to the port.

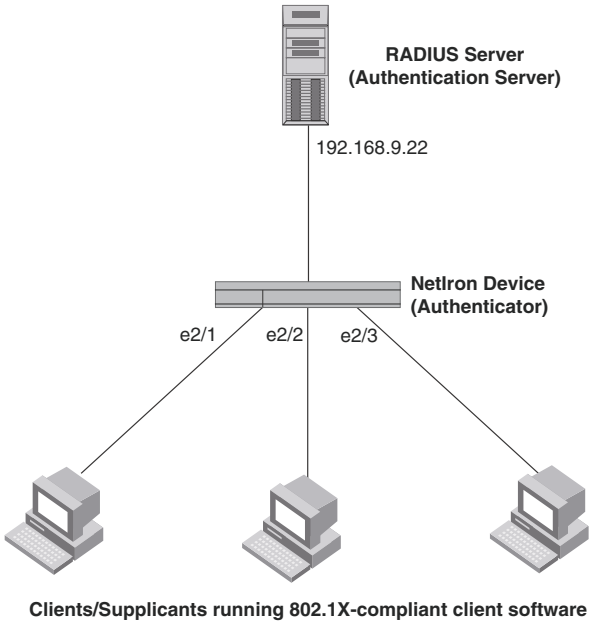
Sample 802.1x configurations

This section illustrates a sample point-to-point configuration and a sample hub configuration that use 802.1x port security.

Point-to-point configuration

Figure 229 illustrates a sample 802.1x configuration with clients connected to three ports on the device. In a point-to-point configuration, only one 802.1x client can be connected to each port.

FIGURE 229 **Sample point-to-point 802.1x configuration**



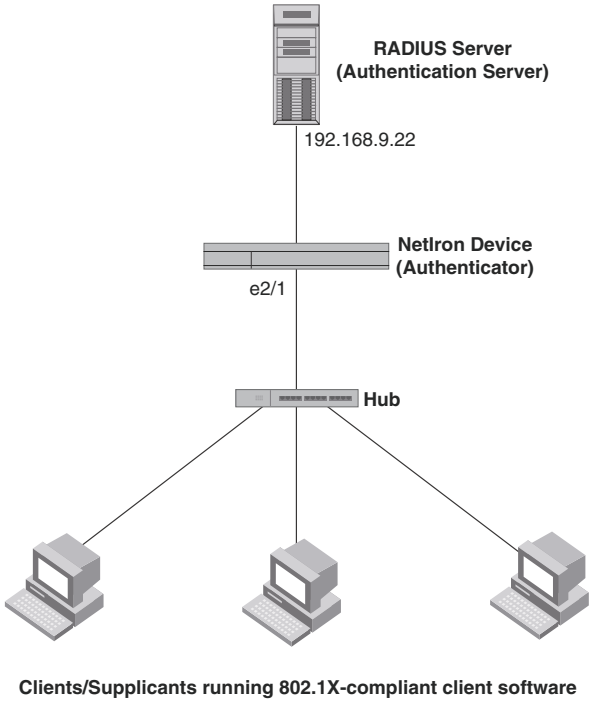
The following commands configure the device in Figure 229.

```
NetIron(config)# aaa authentication dot1x default radius
NetIron(config)# radius-server host 192.168.9.22 auth-port 1812 acct-port 1813
default key mirabeau dot1x
NetIron(config)# dot1x-enable e 2/1 to 2/3
NetIron(config-dot1x)# re-authentication
NetIron(config-dot1x)# timeout re-authperiod 2000
NetIron(config-dot1x)# timeout quiet-period 30
NetIron(config-dot1x)# timeout tx-period 60
NetIron(config-dot1x)# max-req 6
NetIron(config-dot1x)# exit
NetIron(config)# interface e 2/1
NetIron(config-if-e100-1)# dot1x port-control auto
NetIron(config-if-e100-1)# exit
NetIron(config)# interface e 2/2
NetIron(config-if-e100-2)# dot1x port-control auto
NetIron(config-if-e100-2)# exit
NetIron(config)# interface e 2/3
NetIron(config-if-e100-3)# dot1x port-control auto
NetIron(config-if-e100-3)# exit
```

Hub configuration

Figure 230 illustrates a configuration where three 802.1x-enabled clients are connected to a hub, which is connected to a port on the device. The configuration is similar to that in Figure 229, except that 802.1x port security is enabled on only one port, and the **multiple-hosts** command is used to allow multiple clients on the port.

FIGURE 230 Sample 802.1x configuration using a hub



The following commands configure the device in Figure 230.

```
NetIron(config)# aaa authentication dot1x default radius
NetIron(config)# radius-server host 192.168.9.22 auth-port 1812 acct-port 1813
default key mirabeau dot1x
NetIron(config)# dot1x-enable e 2/1
NetIron(config-dot1x)# re-authentication
NetIron(config-dot1x)# timeout re-authperiod 2000
NetIron(config-dot1x)# timeout quiet-period 30
NetIron(config-dot1x)# timeout tx-period 60
NetIron(config-dot1x)# max-req 6
NetIron(config-dot1x)# exit
NetIron(config)# interface e 2/1
NetIron(config-if-e100-1)# dot1x port-control auto
NetIron(config-if-e100-1)# exit
```

Chapter

Protecting against Denial of Service Attacks 52

PowerConnect B-MLXe supports the following Denial of Service (DoS) attack features they support.

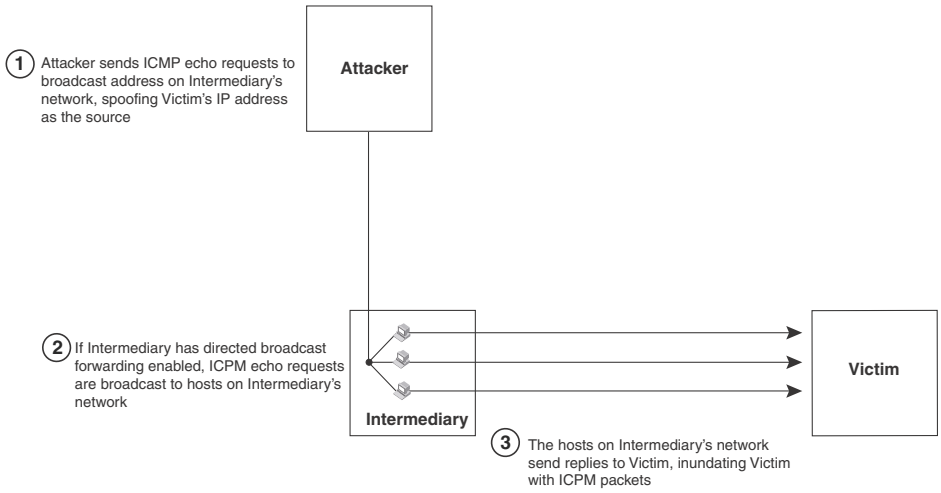
- Denial of Service (DoS)
- Protection Against smurf Attacks
- Protection Against TCP SYN Attacks
- Protection Against TCP Reset Attacks

In a DoS attack, a router is flooded with useless packets for the purpose of slowing down or stopping normal operation. Dell devices include measures to defend against two types of DoS attacks: Smurf attacks and TCP SYN attacks.

Protecting against smurf attacks

A ***smurf attack*** is a kind of DoS attack where an attacker causes a victim to be flooded with ICMP echo (pPing) replies sent from another network. Figure 231 illustrates how a smurf attack works.

FIGURE 231 How a smurf attack floods a victim with ICMP replies



The attacker sends an ICMP echo request packet to the broadcast address of an intermediary network. The ICMP echo request packet contains the spoofed address of a victim network as its source. When the ICMP echo request reaches the intermediary network, it is converted to a Layer 2 broadcast and sent to the hosts on the intermediary network. The hosts on the intermediary network then send ICMP replies to the victim network.

For each ICMP echo request packet sent by the attacker, a number of ICMP replies equal to the number of hosts on the intermediary network are sent to the victim. If the attacker generates a large volume of ICMP echo request packets, and the intermediary network contains a large number of hosts, the victim can be overwhelmed with ICMP replies.

Avoiding being an intermediary in a smurf attack

A smurf attack relies on the intermediary to broadcast ICMP echo request packets to hosts on a target subnet. When the ICMP echo request packet arrives at the target subnet, it is converted to a Layer 2 broadcast and sent to the connected hosts. This conversion takes place only when directed broadcast forwarding is enabled on the device.

To avoid being an intermediary in a smurf attack, make sure forwarding of directed broadcasts is disabled on the device. Directed broadcast forwarding is disabled by default. To disable directed broadcast forwarding, enter this command.

```
NetIron(config)# no ip directed-broadcast
```

Syntax: [**no**] **ip directed-broadcast**

Avoiding being a victim in a smurf attack

You can configure the device to drop ICMP packets when excessive numbers are encountered, as is the case when the device is the victim of a smurf attack. The following example sets threshold values for ICMP packets targeted at the router and drop them when the thresholds are exceeded.

```
NetIron(config)# ip icmp burst-normal 5000 burst-max 10000 lockup 300
```

Syntax: ip icmp burst-normal <*value*> **burst-max** <*value*> **lockup** <*seconds*>

The **burst-normal** value can be from 1 – 100000.

The **burst-max** value can be from 1 – 100000.

The **lockup** value can be from 1 – 10000.

The number of incoming ICMP packets per second are measured and compared to the threshold values, as follows:

- If the number of ICMP packets exceeds the **burst-normal** value, the excess ICMP packets are dropped.
- If the number of ICMP packets exceeds the **burst-max** value, all ICMP packets are dropped for the number of seconds specified by the lockup value. When the lockup period expires, the packet counter is reset and measurement is restarted.

  In this example, if the number of ICMP packets received per second exceeds 5,000, the excess packets are dropped. If the number of ICMP packets received per second exceeds 10,000, the device drops all ICMP packets for the next 300 seconds (five minutes).

When incoming ICMP packets exceed the **burst-max** value, the following message is logged.

```
<date> <time>:N:Local ICMP exceeds <burst-max> burst packets, stopping for
<lockup> seconds!!
```

IPv6 traffic not subject to DOS attack filtering

The following IPv6 traffic exceptions (per section 4.4 of RFC 4890) are not subject to DoS attack filtering.

Error messages that are essential to the establishment and maintenance of communications:

- Destination unreachable (Type 1) - All codes
- Packet Too Big (Type 2)
- Time Exceeded (Type 3) - Code 0 only
- Parameter Problem (Type 4) - Codes 1 and 2 only

Address configuration and router selection messages:

- Router Solicitation (Type 133)
- Router Advertisement (Type 134)
- Neighbor Solicitation (Type 135)
- Neighbor Advertisement (Type 136)
- Inverse Neighbor Discovery Solicitation (Type 141)
- Inverse Neighbor Discovery Advertisement (Type 142)

Link-local multicast receiver notification messages:

- Listener Query (Type 130)
- Listener Report (Type 131)
- Listener Done (Type 132)
- Listener Report v2 (Type 143)

Multicast Router Discovery messages:

- Multicast router advertisement (Type 151)
- Multicast router solicitation (Type 152)
- Multicast router termination (Type 153)

Section 4.4 of RFC 4890 also recommends that the following traffic types must not be dropped, however these traffic types will continue to be subject to DoS attack filtering:

- Echo request (Type 128)
- Echo response (Type 129)
- Certificate path solicitation (Type 148)
- Certificate path advertisement (Type 149)

Protecting against TCP SYN attacks

TCP SYN attacks disrupt normal traffic flow by exploiting the way TCP connections are established. When a TCP connection starts, the connecting host sends a TCP SYN packet to the destination host. The destination host responds with a SYN ACK packet, and the connecting host sends back an ACK packet. This process, known as a “TCP three-way handshake”, establishes the TCP connection.

While waiting for the connecting host to send an ACK packet, the destination host keeps track of the as-yet incomplete TCP connection in a connection queue. When the ACK packet is received, information about the connection is removed from the connection queue. Usually there is not much time between the destination host sending a SYN ACK packet and the source host sending an ACK packet, so the connection queue clears quickly.

In a TCP SYN attack, an attacker floods a host with TCP SYN packets that have random source IP addresses. For each of these TCP SYN packets, the destination host responds with a SYN ACK packet and adds information to the connection queue. However, since the source host does not exist, no ACK packet is sent back to the destination host, and an entry remains in the connection queue until it ages out (after approximately one minute). If the attacker sends enough TCP SYN packets, the connection queue can fill up, and service can be denied to legitimate TCP connections.

To protect against TCP SYN attacks, you can configure Dell devices to drop TCP SYN packets when excessive numbers are encountered. You can set threshold values for TCP SYN packets that are targeted at the device and drop them when the thresholds are exceeded, as shown in this example.

```
NetIron(config)# ip tcp burst-normal 10 burst-max 100 lockup 300
```

Syntax: **ip tcp burst-normal** <*value*> **burst-max** <*value*> **lockup** <*seconds*>

The **burst-normal** value can be from 1 – 100000.

The **burst-max** value can be from 1 – 100000.

The **lockup** value can be from 1 – 10000.

The number of incoming TCP SYN packets per second is measured and compared to the threshold values as follows:

- If the number of TCP SYN packets exceeds the **burst-normal** value, the excess TCP SYN packets are dropped.
- If the number of TCP SYN packets exceeds the **burst-max** value, all TCP SYN packets are dropped for the number of seconds specified by the **lockup** value. When the lockup period expires, the packet counter is reset and measurement is restarted.

  In this example, if the number of TCP SYN packets received per second exceeds 10, the excess packets are dropped. If the number of TCP SYN packets received per second exceeds 100, the device drops all TCP SYN packets for the next 300 seconds (five minutes).

When incoming TCP SYN packets exceed the burst-max value, the following message is logged.

```
<date> <time>:N:Local TCP exceeds <burst-max> burst packets, stopping for <lockup>
seconds!!
```

TCP security enhancement

A TCP security enhancement improves the way TCP inbound segments are handled. This enhancement eliminates or minimizes the possibility of a TCP reset attack, in which a perpetrator attempts to prematurely terminate an active TCP session, and a data injection attack, where an attacker injects or manipulates data in a TCP connection.

In both cases, the attack is blind, meaning the perpetrator does not have visibility into the content of the data stream between two devices, but blindly injects traffic. The attacker also does not see the direct effect (the continuing communications between the devices and the impact of the injected packet) but may see the indirect impact of a terminated or corrupted session.

The TCP security enhancement prevents and protects against the following types of attacks:

- Blind TCP reset attack using the reset (RST) bit.
- Blind TCP reset attack using the synchronization (SYN) bit
- Blind TCP packet injection attack

The TCP security enhancement is automatically enabled. If necessary, you can disable this feature. Refer to "Disabling the TCP security enhancement" on page 2095.

Protecting against a blind TCP reset attack using the RST bit

In a blind TCP reset attack using the RST bit, a perpetrator attempts to guess the RST segments to prematurely terminate an active TCP session.

To prevent a user from using the RST bit to reset a TCP connection, the RST bit is subject to the following rules when receiving TCP segments:

- If the RST bit is set and the sequence number is outside the expected window, the device silently drops the segment.
- If the RST bit is exactly the next expected sequence number, the device resets the connection.
- If the RST bit is set and the sequence number does not exactly match the next expected sequence value, but is within the acceptable window, the device sends an acknowledgement (ACK).

The TCP security enhancement is enabled by default. To disable it, refer to "Disabling the TCP security enhancement" on page 2095.

Protecting against a blind TCP reset attack using the SYN bit

For a blind TCP reset attack, the attacker tries to guess the SYN bits to terminate an active TCP session.To protect against this type of attack, the SYN bit is subject to the following rules during arrival of TCP segments:

- If the SYN bit is set and the sequence number is outside the expected window, the device sends an ACK to the peer.
- If the SYN bit is set and the sequence number is an exact match to the next expected sequence, the device sends an ACK segment to the peer. Before sending the ACK segment, the software subtracts a 1 from the value being acknowledged.
- If the SYN bit is set and the sequence number is acceptable, the device sends an ACK segment to the peer.

This TCP security enhancement is enabled by default. To disable it, refer to "Disabling the TCP security enhancement" on page 2095.

Protecting against a blind injection attack

In a blind TCP injection attack, the attacker tries to inject or manipulate data in a TCP connection. To reduce the chances of a blind injection attack, an additional check is performed on all incoming TCP segments.

This TCP security enhancement is enabled by default. To disable it, refer to "Disabling the TCP security enhancement" on page 2095.

Disabling the TCP security enhancement

The TCP security enhancement is enabled by default. If necessary, you can disable this feature. When you disable this feature, the device reverts to the original behavior.

To disable the TCP security enhancement, enter the following command at the Global CONFIG level of the CLI.

```
NetIron(config)# no ip tcp tcp-security
```

To re-enable the TCP security enhancement after it has been disabled, enter the following command.

```
NetIron(config)# ip tcp tcp-security
```

Syntax: [**no**] **ip tcp tcp-security**

Displaying statistics from a DoS attack

You can display statistics about ICMP and TCP SYN packets that were dropped, passed, or blocked because burst thresholds were exceeded using the **show statistics dos-attack** command.

```
NetIron# show statistics dos-attack
------ Local Attack Statistics ------
ICMP Drop Count     Port Block Count    SYN Drop Count    SYN Block Count
---------------     ----------------    --------------    ---------------
              0                   0                 0                  0
```

Syntax: **show statistics dos-attack** [| **begin** <*expression*> | **exclude** <*expression*> | **include** <*expression*>]

Table 403 describes this output.

TABLE 403 Output from the **show statistics dos-attack** command

This field...	Displays...
Packet drop count	Number of packets that are dropped when the port is in lockup mode.
Packet Pass Count	Number of packets that are forwarded when the port is in rate-limiting mode.
Packet BLock Count	Number of times the port was shut down for a traffic flow that matched the ACL.

Clear DoS attack statistics

To clear statistics about ICMP and TCP SYN packets, enter the **clear statistics dos-attack** command.

```
NetIron(config)# clear statistics dos-attack
```

Syntax: **clear statistics dos-attack**

Chapter

Reverse Path Forwarding 53

The following Reverse Path Forwarding features are supported by PowerConnect B-MLXe Series.

- Reverse Path Forwarding (RPF)
- RPF Support for IP over MPLS Routes
- Suppressing RPF for Packets Using inbound ACLs
- Excluding Packets that Match the Routers Default Route

A number of common types of denial-of-service (DoS) attacks, including Smurf and Tribe Flood Network (TFN), can take advantage of forged or rapidly changing source IP addresses to allow attackers to thwart efforts to locate or filter the attacks. Reverse Path Forwarding (RPF) is designed to prevent such a malicious user from spoofing a source IP address by checking that the source address specified for a packet is received from a network that the PowerConnect has access to. Packets with invalid source addresses are not forwarded. Optionally, you can log packets that fail the RPF test.

RPF is supported for IPv6 packets. Differences in RPF support in IPv4 and IPv6 are noted within this chapter where necessary.

Configuration of RPF

To configure the PowerConnect for RPF, you must perform the following steps:

- Considerations for Configuring RPF
- Special Considerations for Configuring RPF with ECMP routes
- RPF Support for IP over MPLS routes
- RPF Compatible CAM profiles
- Configure the global command: **reverse-path-check**
- Enable RPF mode individually on ports that you want it to run.
- Suppressing RPF for Packets with Specified Address Prefixes

Configuration considerations for RPF

You must consider the following when configuring RPF:

- IP packets with source IP address of 0.0.0.0 will always fail RPF check
- If you attempt to enable the global RPF command on a system with incompatible CAM settings, the command will be rejected and you will receive a console message describing this.
- Since the RPF feature requires that the entire IP route table is available in hardware, the feature must work in conjunction with Foundry Direct Routing (FDR). FDR is the default mode of operation for the PowerConnect. For more information about enabling and disabling FDR refer to “Foundry Direct Routing” on page 40-1.

- You cannot configure RPF on a physical port that has VRF configured on it or if the physical port belongs to a virtual interface with a VRF configuration.
- Only RPF loose mode is supported for GRE routes.
- If a default route is present on the router, loose mode will permit all traffic.
- RPF can only be configured at the physical port level. It should not be configured on virtual interfaces.
- IPv6 packets with a link-local source address are not subject to IPv6 RPF check.
- IPv6 RPF check is not supported for 6-to-4 tunnel routes.

Special considerations for configuring RPF with ECMP routes

RPF for IPv6 is not subject to the special considerations for configuring RPF with ECMP routes described here.

For a source IP address matching an ECMP route, RPF will permit the packet if it arrives on any of the next-hop interfaces for that route. For example, if there are two best next-hops for a network route 11.11.11.0/24, one pointing to 10.10.10.1 (Gigabit Ethernet 7/1) and the other to 10.10.30.1 (Gigabit Ethernet 7/12), then incoming packets with source address matching 11.11.11.0/24 will be permitted on either Gigabit Ethernet 7/1 or Gigabit Ethernet 7/12.

A disadvantage of this configuration is that if some other route shares any of these next-hops, the packets with a source IP address matching that route will also be permitted from any of the interfaces associated with those next hops. For example, say 12.12.12.0/24 has the next-hop 10.10.10.1, then packets from 12.12.12.0/24 will also be be permitted on either Gigabit Ethernet 7/1 or Gigabit Ethernet 7/12.

RPF support for IP over MPLS routes

For IPv4 routes over MPLS tunnels, the physical interface for an outgoing tunnel on which a route is assigned may not be the same as the one from which we receive packets. Consequently, only RPF loose mode is supported on MPLS uplinks. IPv6 is not currently supported over MPLS. When it is supported, it will only support RPF loose mode on MPLS uplinks.

RPF compatible CAM profiles

Not all CAM profiles are compatible with RPF. Table 404 lists all of the RPF Compatible CAM profiles by software release. Refer to "CAM partition profiles" on page 2240 for a description of each of the available CAM profiles.

TABLE 404 RPF compatible and non-compatible CAM profiles

Configuring the global RPF command

Before you can enable RPF to operate on a PowerConnect you must first configure RPF globally. There are separate command for IPv4 and IPv6, as shown in the following.

For IPv4.

```
NetIron(config)# reverse-path-check
```

Syntax: reverse-path-check

```
NetIron(config)# ipv6 reverse-path-check
```

For IPv6.

Syntax: ipv6 reverse-path-check

Enable RPF on individual ports

After RPF has been configured globally for a PowerConnect, it must be configured on every interface that you want it to operate. The RPF feature can only be configured on physical ethernet interfaces. There are two modes "strict" and "loose" that can be configured to enforce RPF on IP addresses for packets arriving on a given interface, as described in the following:

- In **loose** mode, RPF will permit a packet as long as the source address matches a known route entry in the routing table. It will drop a packet if it does not match a route entry. Please note that if a default route is present, loose mode will permit all traffic.
- In **strict** mode, RPF requires that a packet matches a known route entry as described in loose mode and also that it arrives at the interface as described in the router table's next hop information. It will drop a packet that does not match both of these criteria.

Configuring RPF on a port requires a separate command for IPv4 and IPv6. To configure RPF on a port, use the IPv4 or IPv6 command, as shown in the following.

For IPv4.

```
NetIron(config)# interface ethernet 3/1
NetIron(config-if-e1000-3/1)# rpf-mode strict log
```

Syntax: [no] rpf-mode [loose | strict] [log]

For IPv6.

```
NetIron(config)# interface ethernet 3/1
NetIron(config-if-e1000-3/1)# rpf-mode-ipv6 strict log
```

Syntax: [no] rpf-mode-ipv6 [loose | strict] [log]

There are two modes in which you can enforce RPF on IP sources address for packets that arrive on a configured interface: **loose** mode and **strict** mode as described previously.

The **log** parameter directs RPF to log packets that fail the RPF test. Enabling RPF logging may lead to high CPU utilization on the interface module because packets that fail the RPF check test are dropped in software. Only syslog entries are created by this option. No SNMP traps are issued by this option.

The ACL or RPF logging mechanism on the Interface modules log a maximum of 256 messages per minute, and send these messages to the Management module. A rate-limiting mechanism has been added to rate-limit the number of messages from the Interface module CPU to the Management module CPU to 5 messages per second. Because this delays the delivery of messages to the Management module, in the worst case scenario with all 256 packets arriving at the same time on the Interface module, the time values stamped by the Management module on the messages will vary by as much as 60 seconds.

Configuring a timer interval for IPv6 session logging

You can use the **ipv6 session-logging-age** command to globally configure a timer interval for IPv6 session logging. The timer interval is set for 3 minutes in the following example.

```
NetIron(config)# ipv6 session-logging-age 3
```

Syntax: [no] ipv6 session-logging-age <*minutes*>

The <*minutes*> variable sets the timer interval for logging. Configurable variables are 1 - 10 minutes. The default value is 5 minutes.

You can use the **show syslog** command to view RPF messages as shown in the following.

```
NetIron# show syslog
Dec 18 19:32:52:I:IPv6 RPF: Denied 1 packet(s) on port 1/2 tcp fec0:1::2(0) ->
4500:1::2(0)
```

Suppressing RPF for packets with specified address prefixes

You can suppress RPF packet drops for a specified set of packets using inbound ACLs. To do this.

Create an IPv4 or IPv6 ACL that identifies the address range that you do not want dropped and specify the flag **suppress-rpf-drop** to the ACL clause. When a packet that fails the RPF check and matches the specified ACL permit clause with the suppress-rpf-drop flag set, it is forwarded as a normal packet and it is accounted as a **unicast RPF suppressed drop packet** as described in Table 405.

The following example demonstrates the configuration of the IPv4 ACL named **access-list 135** which permits traffic from the source network 4.4.4.0/24 even if the RPF check test fails.

```
NetIron(config)# access-list 135 permit ip 4.4.4.0.0.0.255 any
suppress-rpf-drop
NetIron(config)# access-list 135 permit ip any any
```

The following example demonstrates the configuration of the IPv6 ACL named **rpf1** which permits traffic from the source host 2002::1 even if the RPF check test fails.

```
NetIron(config)# ipv6 access-list rpf1
NetIron(config-ipv6-access-list rpf1)# permit tcp host 2002::1 any
suppress-rpf-drop
```

Syntax: suppress-rpf-drop

In the following example, the IPv4 ACL 135 is applied as an inbound filter on ethernet interface 7/5.

```
NetIron(config)# interface ethernet 7/5
NetIron(config-if-e1000-7/5)# rpf-mode strict
NetIron(config-if-e1000-3/1)# ip access-group 135 in
```

In the following example, the IPv6 ACL named “rpf1” is applied as an inbound filter on ethernet interface 7/5.

```
NetIron(config)# interface ethernet 7/5
NetIron(config-if-e1000-7/5)# ipv6-rpf-mode strict
NetIron(config-if-e1000-3/1)# ipv6 traffic-filter rpf1 in
```

NOTE
If the physical port is a member of a virtual interface, the ACL will have to be applied to the virtual interface instead of the physical port.

Excluding packets that match the routers default route

A new command was introduced that directs the PowerConnect router to drop packets whose source address match the routers default route and increment the RPF drop counter. Using this feature requires that RPF be configured globally first. This feature is configured separately for IPv4 and IPv6 as described in the following.

For IPv4.

```
NetIron(config)# reverse-path-check
NetIron(config)# urpf-exclude-default
```

Syntax: urpf-exclude-default

For IPv6.

```
NetIron(config)# ipv6 reverse-path-check
NetIron(config)# ipv6 urpf-exclude-default
```

Syntax: ipv6 urpf-exclude-default

Displaying RPF statistics

To display information about RPF configuration and packets that have been dropped because they failed the RPF check, use the **show ip interface** or the **show ipv6 interface** command as shown.

For IPv4.

```
NetIron# show ip interface ethernet 7/1
Interface Ethernet 7/1 (384)
    port enabled
    port state: UP
    ip address: 1.2.3.4/8
    Port belongs to VRF: default
    encapsulation: Ethernet, mtu: 1500
    MAC Address 000c.db24.a6c0
    directed-broadcast-forwarding: disabled
    No inbound ip access-list is set
    No outbound ip access-list is set
    No Helper Addresses are configured
    RPF mode: strict RFP Log: Disabled
    376720 unicast RPF drop 36068 unicast RPF suppressed drop
```

For IPv6:

```
NetIron#show ipv6 interface ethernet 3/1
Interface Ethernet  3/1 is down, line protocol is down
  IPv6 is enabled, link-local address is
  Global unicast address(es):
  Joined group address(es):
    ff02::2
    ff02::1
  MTU is 1500 bytes
  ICMP redirects are disabled
  ND DAD is enabled, number of DAD attempts: 3
  ND reachable time is 30 seconds
  ND advertised reachable time is 0 seconds
  ND retransmit interval is 1 seconds
  ND advertised retransmit interval is 0 seconds
  ND router advertisements are sent every 200 seconds
```

```
ND router advertisements live for 1800 seconds
No Inbound Access List Set
No Outbound Access List Set
IPv6 RPF mode: Strict  IPv6 RPF Log: Enabled
RxPkts:       0                      TxPkts:   0
RxBytes:      0                      TxBytes:  0
IPv6 unicast RPF drop: 0
IPv6 unicast RPF suppressed drop: 0
```

NOTE
The RPF accounting information is always available through the physical interface, even if the physical port belongs to one or more VE's

Table 405 describes the RPF statistics displayed when using the **show ip interface** or **show ipv6 interface** command. They are displayed in **bold**.

TABLE 405 RPF statistics by port

This field...	Displays...
RPF Mode:	This display parameter can have one of the following two values: • loose – RPF will permit a packet as long as the source address matches a known route entry in the routing table. It will drop a packet if it does not match a route entry. • strict – RPF requires that a packet matches a known route entry as described for loose mode and also that it arrives at the configured interface as described in the router table's next hop information. It will drop a packet that does not match both of these criteria.
RPF Log:	This display parameter displays the RPF Log Configuration Status: • Enabled – the RPF log feature has been configured. • Disabled – the RPF log feature has not been configured
<*number*> unicast RPF drop	The number of packets that have been dropped due to failure of the RPF test.
<*number*> unicast RPF suppressed drop	The number of packets would have been dropped due to failure of the RPF test but were not dropped because they matched conditions set in an ACL with the **suppress-rpf-drop** flag set.

Clearing RPF statistics for a specified IPv4 interface

To clear RPF statistics on a specific IPv4 physical interface use the following command.

Syntax: **clear ip interface ethernet** <*slot/port*> **| pos** <*slot/port*>

Use the **ethernet** or **pos** parameters to specify whether the port is Ethernet or Packet-over-Sonet.

The slot/port variables specify the interface that you want to clear RPF statistics for.

Clearing RPF statistics for all IPv4 interfaces within a router

To clear RPF statistics on all IPv4 physical interfaces within a router, use the following command.

Syntax: **clear ip interface counters**

Clearing RPF statistics for a specified IPv6 interface

To clear RPF statistics on a specific IPv6 physical interface use the following command.

Syntax: clear ipv6 interface ethernet <*slot/port*> **| pos** <*slot/port*>

Use the **ethernet** or **pos** parameters to specify whether the port is Ethernet or Packet-over-Sonet.

The slot/port variables specify the interface that you want to clear RPF statistics for.

Clearing RPF statistics for all IPv6 interfaces within a router

To clear RPF statistics on all IPv6 physical interfaces within a router, use the following command.

Syntax: clear ipv6 interface counters

Displaying RPF logging

If you set the log option of the rpf-mode command, the packets are saved to the system log. To display the log, enter the following.

```
NetIron## show logging
Syslog logging: enabled (0 messages dropped, 0 flushes, 1305 overruns)
    Buffer logging: level ACDMEINW, 50 messages logged
    level code: A=alert C=critical D=debugging M=emergency E=error
                I=informational N=notification W=warning
Dynamic Log Buffer (50 lines):
May 11 12:12:54:I:RPF: Denied 1 packets on port 7/5 tcp 4.4.4.1(0) -> 5.6.7.8(0)
```

NOTE
A maximum of 256 RPF log messages are logged per minute.

Chapter

Securing SNMP Access 54

Table displays the SNMPv3 features supported by PowerConnect B-MLXe Series.

- SNMP v3
- User-Based Security Mode
- Community Strings to Authenticate SNMP Access
- New encryption code for passwords, authentication keys, and community strings
- Defining an SNMP User Account
- AES for SNMPv3

Simple Network Management Protocol (SNMP) is a set of protocols for managing complex networks. SNMP sends messages, called protocol data units (PDUs), to different parts of a network. An SNMP-compliant device, called an agent, stores data about itself in Management Information Bases (MIBs) and SNMP requesters or managers.

NOTE
SNMP agent is disabled by default. Use the **snmp-server** command to enable the agent.

Establishing SNMP community strings

SNMP versions 1 and 2c use community strings to restrict SNMP access. The default passwords for SNMP access are the SNMP community strings configured on the device:

- The default read-only community string is “public”. Use this community string for any SNMP Get, GetNext, or GetBulk request.
- By default, you cannot perform any SNMP Set operations since a read-write community string is not configured.

You can configure as many additional read-only and read-write community strings as you need. The number of strings you can configure depends on the memory on the device. There is no practical limit.

If you delete the startup configuration file, the device automatically re-adds the default “public” read-only community string the next time you load the software.

Encryption of SNMP community strings

Encryption is enabled by default. The software automatically encrypts SNMP community strings. Users with read-only access or who do not have access to management functions in the CLI cannot display the strings. For users with read-write access, the strings are encrypted in the CLI but are shown in the clear in the Web Management Interface.

To display the community strings in the CLI, first use the **enable password-display** command and then use the **show snmp server** command. This will display both the read-only and read-write community strings in the clear.

Adding an SNMP community string

By default, the string is encrypted. To add a community string, enter commands such as the following.

```
NetIron(config)# snmp-server community private rw
```

The command adds the read-write SNMP community string “private”.

Syntax: [no] **snmp-server community** <*string*>
ro | rw [**view** <*viewname*>] [<*standard-acl-name*> | <*standard-acl-id*> | **ipv6** <*ipv6-acl-name*>]

The <*string*> parameter specifies the community string name. The string can be up to 32 characters long.

The system modifies the configuration to `session 1.1.1.1 key 2 $XkBTb24tb0RuXA==`

By default, the community string is encrypted. If you want the community string to be in clear text, insert a **0** between **community** and <*string*>. For example,

```
NetIron(config)# snmp-server community 0 nightadmin rw
```

The software adds a prefix to the community string in the configuration. For example, the following portion of the code has the encrypted code “2”.

```
snmp-server community 2 $D?@d=8 rw
```

The prefix can be one of the following:

- 0 = the community string is not encrypted and is in clear text
- 2 = the community string uses proprietary base64 crytographic 2-way algorithm.
- The **ro | rw** parameter specifies whether the string is read-only (**ro**) or read-write (**rw**).

The **view** <*viewstring*> parameter is optional. It allows you to associate a view to the members of this community string. Enter up to 32 alphanumeric characters. If no view is specified, access to the full MIB is granted. The view that you want must exist before you can associate it to a community string. Here is an example of how to use the view parameter in the community string command.

```
NetIron(config)# snmp-s community myread ro view sysview
```

The command in this example associates the view “sysview” to the community string named “myread”. The community string has read-only access to “sysview”. For information on how create views, refer to the section “Defining SNMP views” on page 2113.

The <*standard-acl-name*> | <*standard-acl-id*> | **ipv6** <*ipv6-acl-name*> parameter is optional. It allows you to specify which ACL is used to filter the incoming SNMP packets. You can enter either the ACL name or its ID for an IPv4 ACL; for an IPv6 ACL, you must enter the keyword **ipv6** followed by the name of the IPv6 ACL. Here are examples.

```
NetIron(config) # snmp-s community myread ro view sysview 2
NetIron(config) # snmp-s community myread ro view sysview myacl
```

The command in the first example specifies that ACL group 2 filters incoming SNMP packets, whereas the command in the second example uses the IPv4 ACL group called “myacl” to filter incoming packets.

Displaying the SNMP community strings

To display the community strings in the CLI, first use the **enable password-display** command and then use the **show snmp server** command. This will display both the read-only and read-write community strings in the clear.

To display the configured community strings, enter the following command at any CLI level.

```
NetIron(config)# show snmp server
```

Syntax: show snmp server

NOTE
If display of the strings is encrypted, the strings are not displayed. Encryption is enabled by default.

Using the User-Based Security model

SNMP version 3 (RFC 2570 through 2575) introduces a User-Based Security model (RFC 2574) for authentication and privacy services.

SNMP version 1 and version 2 use community strings to authenticate SNMP access to management modules. This method can still be used for authentication. In SNMP version 3, the User-Based Security model of SNMP can be used to secure against the following threats:

- Modification of information
- Masquerading the identity of an authorized entity
- Message stream modification
- Disclosure of information

Furthermore, SNMP version 3 supports View-Based Access Control Mechanism (RFC 2575) to control access at the PDU level. It defines mechanisms for determining whether or not access to a managed object in a local MIB by a remote principal should be allowed. (Refer to the section "Defining SNMP views" on page 2113.)

Configuring your NMS

To be able to use the SNMP version 3 features.

1. Make sure that your Network Manager System (NMS) supports SNMP version 3.
2. Configure your NMS agent with the necessary users.
3. Configure the SNMP version 3 features in the PowerConnect.

Configuring SNMP version 3 on the PowerConnect

To configure SNMP version 3 on the PowerConnect, perform the tasks listed below.

1. Enter an engine ID for the management module using the **snmp-server engineid** command if you will not use the default engine ID. Refer to "Defining the engine ID" on page 2108.
2. Create views that will be assigned to SNMP user groups using the **snmp-server view** command. Refer to the "Defining SNMP views" on page 2113 for details.

3. Create ACL groups that will be assigned to SNMP user groups using the **access-list** command. Refer to 21, "Access Control List" for details.
4. Create user groups using the **snmp-server group** command. Refer to "Defining an SNMP group" on page 2109.
5. Create user accounts and associate these accounts to user groups using the **snmp-server user** command. Refer to "Defining an SNMP user account" on page 2110.

If SNMP version 3 is not configured, then community strings by default are used to authenticate access.

Even if SNMP version 3 users are configured on the device, the system will still accept SNMP version 1, 2c and 3 PDUs from the remote manager.

Defining the engine ID

A default engine ID is generated during system start up.The format of the default engine ID is derived from RFC 2571 (Architecture for SNMP frameworks) within the MIB description for object SnmpEngineID.

To determine what the default engine ID of the device is, enter the **show snmp engineid** command and find the following line.

```
Local SNMP Engine ID: 800007c70300e05290ab60
```

Refer to the section "Displaying the engine ID" on page 2111 for details.

The default engine ID guarantees the uniqueness of the engine ID for SNMP version 3. If you want to change the default engine ID, enter a command such as the following.

```
NetIron(config)# snmp-server engineid local 800007c70300e05290ab60
```

Syntax: [no] snmp-server engineid local <*hex-string*>

The **local** parameter indicates that engine ID to be entered is the ID of this device, representing an SNMP management entity.

NOTE
Since the current implementation of SNMP version 3 does not support Notification, remote engine IDs cannot be configured at this time.

The <*hex-string*> variable consists of 11 octets, entered as hexadecimal values. Each octet has two hexadecimal characters. The engine ID should contain an even number of hexadecimal characters.

The default engine ID has a maximum of 11 octets:

- Octets 1 through 4 represent the agent's SNMP management private enterprise number as assigned by the Internet Assigned Numbers Authority (IANA). The most significant bit of Octet 1 is "1". For example, "000007c7" is the ID for Brocade in hexadecimal. With Octet 1 always equal to "1", the first four octets in the default engine ID is always "800007c7" (which is 1991 in decimal).
- Octet 5 is always 03 in hexadecimal and indicates that the next set of values represent a MAC address.
- Octets 6 through 11 form the MAC address of the lowest port in the management module.

NOTE
Engine ID must be a unique number among the various SNMP engines in the management domain. Using the default engine ID ensures the uniqueness of the numbers.

Defining an SNMP group

SNMP groups map SNMP users to SNMP views. For each SNMP group, you can configure a read view, a write view, or both. Users who are mapped to a group will use its views for access control.

To configure an SNMP user group, enter a command such as the following.

```
NetIron(config)# snmp-server group admin v3 auth read all write all
```

Syntax: [no] **snmp-server group** <*groupname*>
v1 | v2c | v3
auth | noauth | priv
[**access** <*standard-acl-id*>] [**read** <*viewstring*>] [**write** <*viewstring*>] [**notify** <*viewname*>]

NOTE
The **snmp-server group** command has been enhanced to include the [notify <*viewname*>] keyword.

NOTE
This command is not used for SNMP version 1 and SNMP version 2. In these versions, groups and group views are created internally using community strings. (Refer to "Establishing SNMP community strings" on page 2105.) When a community string is created, two groups are created, based on the community string name. One group is for SNMP version 1 packets, while the other is for SNMP version 2 packets.

The **group** <*groupname*> parameter defines the name of the SNMP group to be created.

The **v1**, **v2c**, or **v3** parameter indicates which version of SNMP is used. In most cases, you will be using v3, since groups are automatically created in SNMP versions 1 and 2 from community strings.

The **auth** | **noauth** parameter determines whether authentication is required for accessing the supported views. If auth is selected, then only authenticated packets are allowed to access the view specified for the user group. Selecting **noauth** means that no authentication is required to access the specified view. Selecting **priv** means that an authentication password is required from the users.

The auth | noauth | priv parameter is available when you select v3, not v1 or v2.

The **access** <*standard-acl-id*> parameter is optional. It allows incoming SNMP packets to be filtered based on the standard ACL attached to the group.

The **read** <*viewstring*> | **write** <*viewstring*> parameter is optional. It indicates that users who belong to this group have either read or write access to the MIB.

The **notify** <*viewname*> parameter is optional. It allows trap notifications to be encrypted and sent to target hosts.

The <*viewstring*> variable is the name of the view to which the SNMP group members have access. If no view is specified, then the group has no access to the MIB.

The value of <*viewstring*> is defined by using the **snmp-server view** command. The SNMP agent comes with the "all" view, the default view that provides access to the entire MIB; however, it must be specified when creating the group. The "all" view also lets SNMP version 3 be backwards compatibility with SNMP version 1 and version 2.

NOTE
If you plan to use a view other than the "all" view, that view must have been configured before you create the user group. Refer to "Defining SNMP views" on page 2113, for details on the **include | exclude** parameters.

Defining an SNMP user account

The **snmp-server user** command does the following:

- Creates an SNMP user.
- Defines the group to which the user will be associated.
- Defines the type of authentication to be used for SNMP access by this user.

Here is an example of how to create the account.

```
NetIron(config)# snmp-s user bob admin v3 access 2 auth md5 bobmd5 priv des bobdes
```

The CLI for creating SNMP version 3 users has been updated as follows.

Syntax: **[no] snmp-server user** <*name*> <*groupname*> **v3**
[[access <*standard-acl-id*>**]**
[[encrypted] auth md5 <*md5-password*> **| sha** <*sha-password*>
[priv [encrypted] des <*des-password-key*> **| aes** <*aes-password-key*>**]]]**

The <*name*> parameter defines the SNMP user name or security name used to access the management module.

The <*groupname*> parameter identifies the SNMP group to which this user is associated or mapped. All users must be mapped to an SNMP group. Groups are defined using the **snmp-server group** command.

NOTE
The SNMP group to which the user account will be mapped should be configured before creating the user accounts; otherwise, the group will be created without any views. Also, ACL groups must be configured before configuring user accounts.

The **v3** parameter is required.

The **access** <*standard-acl-id*> parameter is optional. It indicates that incoming SNMP packets are filtered based on the ACL attached to the user account.

NOTE
The ACL specified in a user account overrides the ACL assigned to the group to which the user is mapped. If no ACL is entered for the user account, the ACL configured for the group is used to filter packets.

The encrypted parameter means that the MD5 or SHA password will be a digest value. MD5 has 16 octets in the digest. SHA has 20. The digest string has to be entered as a hexadecimal string. In this case, the agent need not generate any explicit digest. If the encrypted parameter is not used, the user is expected to enter the authentication password string for MD5 or SHA. The agent converts the password string to a digest, as described in RFC 3414.

The optional **auth md5 | sha** parameter defines the type of encryption the user must have to be authenticated. The choices are MD5 and SHA encryption (the two authentication protocols used in SNMP version 3).

The <*md5-password*> and <*sha-password*> define the password the user must use to be authenticated. These password must have a minimum of 8 characters. If the encrypted parameter is used, then the digest has 16 octets for MD5 or 20 octets for SHA.

NOTE
Once a password string is entered, the generated configuration displays the digest (for security reasons), not the actual password.

The **priv** [encrypted] parameter is optional after you enter the md5 or sha password. The **priv** parameter specifies the encryption that is used to encrypt the privacy password. If the **encrypted** keyword is used, do the following:

- If DES is the privacy protocol to be used, enter **des** <*des-password-key*> and enter a 16-octet DES key in hexadecimal format for the <*des-password-key*>. If you include the **encrypted** keyword, enter a password string of at least 8 characters.
- If AES is the privacy protocol to be used, enter **aes** and an <*aes-password-key*>. Enter either 12 (for a small key) or 16 (for a big key) characters for the <*aes-password-key*>. If you include the **encrypted** keyword, enter a password string containing 32 hexadecimal characters.

Displaying the engine ID

To display the engine ID of a management module, enter a command such as the following.

```
NetIron(config)# show snmp engineid
Local SNMP Engine ID: 800007c70300e05290ab60
Engine Boots: 3
Engine time: 5
```

Syntax: show snmp engineid

The engine ID identifies the source or destination of the packet.

The engine boots represents the number of times that the SNMP engine reinitialized itself with the same engine ID. If the engineID is modified, the boot count is reset to 0.

The engine time represents the current time with the SNMP agent.

Displaying SNMP groups

To display the definition of an SNMP group, enter a command such as the following.

```
NetIron(config)# show snmp group
groupname = exceptifgrp
security model = v3
security level = authNoPriv
ACL id = 2
readview = exceptif
writeview = <none>
```

Syntax: show snmp group

The value for security level can be one of the following.

Security level	Authentication
<none>	If the security model shows v1 or v2, then security level is blank. User names are not used to authenticate users; community strings are used instead.
noauthNoPriv	Displays if the security model shows v3 and user authentication is by user name only.
authNoPriv	Displays if the security model shows v3 and user authentication is by user name and the MD5 or SHA algorithm.
authPriv	Authentication uses MD5 or SHA. Encryption uses DES and AES protocol.

Displaying user information

To display the definition of an SNMP user account, enter a command such as the following.

```
NetIron(config)# show snmp user
username = bob
acl id = 0
group = bobgroup
security model = v3
group acl id = 0
authtype = md5
authkey = ad172674ebc09cd9448c8276db0d12f8
privtype = aes
privkey = 3c154b47996534b22b22758e23f9a71a
engine ID= 800007c703000cdbf48a00
```

Syntax: show snmp user

Interpreting varbinds in report packets

If an SNMP version 3 request packet is to be rejected by an SNMP agent, the agent sends a report packet that contains one or more varbinds. The varbinds contain additional information, showing the cause of failures. An SNMP manager application decodes the description from the varbind. The following table presents a list of varbinds supported by the SNMP agent.

Varbind object identifier	Description
1. 3. 6. 1. 6. 3. 11. 2. 1. 3. 0	Unknown packet data unit.
1. 3. 6. 1. 6. 3. 12. 1. 5. 0	The value of the varbind shows the engine ID that needs to be used in the snmp-server engineid command

Varbind object identifier	Description
1. 3. 6. 1. 6. 3. 15. 1. 1. 1. 0	Unsupported security level.
1. 3. 6. 1. 6. 3. 15. 1. 1. 2. 0	Not in time packet.
1. 3. 6. 1. 6. 3. 15. 1. 1. 3. 0	Unknown user name. This varbind can also be generated if either the: • Configured ACL for the user filters out the packet. • Group associated with the user is unknown.
1. 3. 6. 1. 6. 3. 15. 1. 1. 4. 0	Unknown engine ID. The value of this varbind would be the correct authoritative engineID that should be used.
1. 3. 6. 1. 6. 3. 15. 1. 1. 5. 0	Wrong digest.
1. 3. 6. 1. 6. 3. 15. 1. 1. 6. 0	Decryption error.

Defining SNMP views

SNMP views are named groups of MIB objects that can be associated with user accounts to allow limited access for viewing and modification of SNMP statistics and system configuration. SNMP views can also be used with other commands that take SNMP views as an argument. SNMP views reference MIB objects using object names, numbers, wildcards, or a combination of the three. The numbers represent the hierarchical location of the object in the MIB tree. You can reference individual objects in the MIB tree or a subset of objects from the MIB tree.

You can create up to 10 views on the PowerConnect. This number cannot be changed.

To create an SNMP view, enter one of the following commands.

```
NetIron(config)# snmp-server view Maynes system included
NetIron(config)# snmp-server view Maynes system.2 excluded
NetIron(config)# snmp-server view Maynes 2.3.*.6 included
NetIron(config)# write mem
```

NOTE
The **snmp-server view** command supports the MIB objects as defined in RFC 1445.

Syntax: [no] snmp-server view <*name*> <*mib_tree*> **included | excluded**

The <*name*> parameter can be any alphanumeric name you choose to identify the view. The names cannot contain spaces.

The <*mib_tree*> parameter is the name of the MIB object or family. MIB objects and MIB sub-trees can be identified by a name or by the numbers called Object Identifiers (OIDs) that represent the position of the object or sub-tree in the MIB hierarchy. You can use a wildcard (*) in the numbers to specify a sub-tree family.

The **included | excluded** parameter specifies whether the MIB objects identified by the <*mib_family*> parameter are included in the view or excluded from the view.

NOTE
All MIB objects are automatically excluded from any view unless they are explicitly included; therefore, when creating views using the **snmp-server view** command, indicate which portion of the MIB you want users to access.
For example, you may want to assign the view called “admin” a community string or user group. The “admin” view will allow access to the IronWare MIBs objects that begin with the 1.3.6.1.4.1.1991

object identifier. Enter the following command.
NetIron(config)# snmp-server view admin 1.3.6.1.4.1.1991 included
You can exclude portions of the MIB within an inclusion scope. For example, if you want to exclude the snAgentSys objects, which begin with 1.3.6.1.4.1.1991.1.1.2 object identifier from the admin view, enter a second command such as the following.
NetIron(config)# snmp-server view admin 1.3.6.1.4.1.1991.1.1.2 excluded
Note that the exclusion is within the scope of the inclusion.

To delete a view, use the no parameter before the command.

SNMP v3 configuration examples

The examples below shows how to configure SNMP v3.

Simple SNMP v3 configuration

```
NetIron(config)#snmp-s group admingrp v3 priv read all write all notify all
NetIron(config)#snmp-s user adminuser admingrp v3 auth md5 <auth password> priv
<privacy password>
NetIron(config)#snmp-s host <dest-ip> adminuser
```

More detailed SNMP v3 configuration

```
NetIron(config)#snmp-server view internet internet included
NetIron(config)#snmp-server view system system included
NetIron(config)#snmp-server community ..... ro
NetIron(config)#snmp-server community ..... rw
NetIron(config)#snmp-server contact isc-operations
NetIron(config)#snmp-server location sdh-pillbox
NetIron(config)#snmp-server host 128.91.255.32 .....
NetIron(config)#snmp-server group ops v3 priv read internet write system
NetIron(config)#snmp-server group admin v3 priv read internet write internet
NetIron(config)#snmp-server group restricted v3 priv read internet

Chapter

Remote Network Monitoring 55

The following Remote Network Monitoring features are supported by PowerConnect B-MLXe Series.

- Remote Network Monitoring
- Statistics (RMON Group 1)
- History (RMON Group 2)
- Alarms (RMON Group 3)
- Events (RMON Group 9)

This chapter describes the remote monitoring features available on PowerConnect products:

- **Remote Monitoring (RMON) statistics** – All PowerConnect products support RMON statistics on the individual port level. Refer to "RMON support" on page 2116.
- **sFlow** – sFlow collects interface statistics and traffic samples from individual interfaces on a PowerConnect and exports the information to a monitoring server. Refer to Chapter 57, "sFlow".

Basic management

The following sections contain procedures for basic system management tasks.

Viewing system information

You can access software and hardware specifics for a PowerConnect.

To view the software and hardware details for the system, enter the **show version** command.

```
NetIron# show version
```

Syntax: show version

Viewing configuration information

You can view a variety of configuration details and statistics with the show option. The **show** option provides a convenient way to check configuration changes before saving them to flash.

The show options available will vary for the PowerConnect and by configuration level.

To determine the available show commands for the system or a specific level of the CLI, enter the following command.

```
NetIron# show ?
```

Syntax: show <*option*>

You also can enter "show" at the command prompt, then press the TAB key.

Viewing port statistics

Port statistics are polled by default every 10 seconds.

You can view statistics for ports by entering the following **show** commands:

- show interfaces
- show configuration

Viewing STP statistics

You can view a summary of STP statistics for the PowerConnect. STP statistics are by default polled every 10 seconds.

To view spanning tree statistics, enter the **show span** command. To view STP statistics for a VLAN, enter the **span vlan** command.

Clearing statistics

You can clear statistics for many parameters with the clear option.

To determine the available **clear** commands for the system, enter the following command.

```
NetIron# clear ?
```

Syntax: clear <*option*>

You also can enter “clear” at the command prompt, then press the TAB key.

NOTE
Clear commands are found at the Privileged EXEC level.

RMON support

The RMON agent supports the following groups. The group numbers come from the RMON specification (RFC 1757):

- Statistics (RMON Group 1)
- History (RMON Group 2)
- Alarms (RMON Group 3)
- Events (RMON Group 9)

The CLI allows you to make configuration changes to the control data for these groups, but you need a separate RMON application to view and display the data graphically.

Statistics (RMON group 1)

Count information on multicast and broadcast packets, total packets sent, undersized and oversized packets, CRC alignment errors, jabbers, collision, fragments and dropped events is collected for each port on a PowerConnect.

No configuration is required to activate collection of statistics for the PowerConnect. This activity is by default automatically activated at system start-up.

NOTE
The PowerConnect system provides limited MIB counters. Dell uses "rmon_giant" to represent oversized packet, i.e 9216 and above.

You can view a textual summary of the statistics for all ports by entering the following CLI command.

```
NetIron(config)# show rmon statistics
Ethernet statistics 1 is active, owned by monitor
 Interface 1/1 (ifIndex 1) counters
                  Octets          0
              Drop events         0                  Packets          0
           Broadcast pkts         0            Multicast pkts         0
     CRC alignment errors         0            Undersize pkts         0
            Oversize pkts         0                 Fragments         0
                  Jabbers         0               Collisions         0
           64 octets pkts         0     65 to 127 octets pkts         0
   128 to 255 octets pkts         0    256 to 511 octets pkts         0
  512 to 1023 octets pkts         0  1024 to 1518 octets pkts         0
```

Syntax: show rmon statistics [<*num*> | **ethernet** <*slot/port*> | **management** <*num*> | | **begin** <*expression*> | **exclude** <*expression*> | **include** <*expression*>]

The <*portnum*> parameter specifies the port number. You can use the physical port number or the SNMP port number. The physical port number is based on the product.

- The ports are numbered according to slot and port. For example, the first port in slot 1 is 1/1. The third port in slot 7 is 7/3.

The SNMP numbers of the ports start at 1 and increase sequentially. For example, if you are using a Chassis device and slot 1 contains an 8-port module, the SNMP number of the first port in slot 2 is 9. The physical port number of the same port is 2/1.

This command shows the following information.

TABLE 406 Export configuration and statistics

This line...	Displays...
Octets	The total number of octets of data received on the network. This number includes octets in bad packets. This number does not include framing bits but does include Frame Check Sequence (FCS) octets.
Drop events	Indicates an overrun at the port. The port logic could not receive the traffic at full line rate and had to drop some packets as a result. The counter indicates the total number of events in which packets were dropped by the RMON probe due to lack of resources. This number is not necessarily the number of packets dropped, but is the number of times an overrun condition has been detected.
Packets	The total number of packets received. This number includes bad packets, broadcast packets, and multicast packets.
Broadcast pkts	The total number of good packets received that were directed to the broadcast address. This number does not include multicast packets.

TABLE 406 Export configuration and statistics (Continued)

This line...	Displays...
Multicast pkts	The total number of good packets received that were directed to a multicast address. This number does not include packets directed to the broadcast address.
CRC alignment errors	The total number of packets received that were from 64 – 1518 octets long, but had either a bad FCS with an integral number of octets (FCS Error) or a bad FCS with a non-integral number of octets (Alignment Error). The packet length does not include framing bits but does include FCS octets.
Undersize pkts	The total number of packets received that were less than 64 octets long and were otherwise well formed. This number does not include framing bits but does include FCS octets.
Fragments	The total number of packets received that were less than 64 octets long and had either a bad FCS with an integral number of octets (FCS Error) or a bad FCS with a non-integral number of octets (Alignment Error). It is normal for this counter to increment, since it counts both runts (which are normal occurrences due to collisions) and noise hits. This number does not include framing bits but does include FCS octets.
Oversize packets	The total number of packets received that were longer than 1518 octets and were otherwise well formed. This number does not include framing bits but does include FCS octets.
Jabbers	The total number of packets received that were longer than 1518 octets and had either a bad FCS with an integral number of octets (FCS Error) or a bad FCS with a non-integral number of octets (Alignment Error). **NOTE:** This definition of jabber is different from the definition in IEEE-802.3 section 8.2.1.5 (10BASE5) and section 10.3.1.4 (10BASE2). These documents define jabber as the condition where any packet exceeds 20 ms. The allowed range to detect jabber is between 20 ms and 150 ms. This number does not include framing bits but does include FCS octets.
Collisions	The best estimate of the total number of collisions on this Ethernet segment.
64 octets pkts	The total number of packets received that were 64 octets long. This number includes bad packets. This number does not include framing bits but does include FCS octets.
65 to 127 octets pkts	The total number of packets received that were 65 – 127 octets long. This number includes bad packets. This number does not include framing bits but does include FCS octets.
128 to 255 octets pkts	The total number of packets received that were 128 – 255 octets long. This number includes bad packets. This number does not include framing bits but does include FCS octets.
256 to 511 octets pkts	The total number of packets received that were 256 – 511 octets long. This number includes bad packets. This number does not include framing bits but does include FCS octets.
512 to 1023 octets pkts	The total number of packets received that were 512 – 1023 octets long. This number includes bad packets. This number does not include framing bits but does include FCS octets.
1024 to 1518 octets pkts	The total number of packets received that were 1024 – 1518 octets long. This number includes bad packets. This number does not include framing bits but does include FCS octets.

NOTE
The number of entries in a RMON statistics table directly corresponds to the number of ports on a system. For example, if the system is a 26 port device, there will be 26 entries in the statistics display.

History (RMON group 2)

All active ports by default will generate two history control data entries per active PowerConnect interface. An active port is defined as one with a link up. If the link goes down the two entries are automatically be deleted.

Two history entries are generated for each device:

- a sampling of statistics every 30 seconds
- a sampling of statistics every 30 minutes

The history data can be accessed and displayed using any of the popular RMON applications

A sample RMON history command and its syntax is shown below.

```
NetIron(config)# rmon history 1 interface 1 buckets 10 interval 10 owner nyc02
```

Syntax: **rmon history** <*entry-number*> **interface ethernet** <*slot/port*> | **management** <*num*> **buckets** <*number*> **interval** <*sampling-interval*> **owner** <*text-string*>

You can modify the sampling interval and the bucket (number of entries saved before overwrite) using the CLI. In the above example, owner refers to the RMON station that will request the information.

NOTE
To review the control data entry for each port or interface, enter the **show rmon history** command.

Alarm (RMON group 3)

Alarm is designed to monitor configured thresholds for any SNMP integer, time tick, gauge or counter MIB object. Using the CLI, you can define what MIB objects are monitored, the type of thresholds that are monitored (falling, rising or both), the value of those thresholds, and the sample type (absolute or delta).

An alarm event is reported each time that a threshold is exceeded. The alarm entry also indicates the action (event) to be taken if the threshold be exceeded.

A sample CLI alarm entry and its syntax is shown below.

```
NetIron(config)# rmon alarm 1 ifInOctets.6 10 delta rising-threshold 100 1 falling
threshold 50 1 owner nyc02
```

Syntax: **rmon alarm** <*entry-number*> <*MIB-object.interface-num*> <*sampling-time*> <*sample-type*>
<*threshold-type*> <*threshold-value*> <*event-number*> <*threshold-type*> <*threshold-value*> <*event-number*>
owner <*text-string*>

The <*sample-type*> can be absolute or delta.

The <*threshold-type*> can be falling-threshold or rising-threshold.

Event (RMON group 9)

There are two elements to the Event Group—the ***event control table*** and the ***event log table***.

The event control table defines the action to be taken when an alarm is reported. Defined events can be found by entering the CLI command, show event. The Event Log Table collects and stores reported events for retrieval by an RMON application.

A sample entry and syntax of the event control table is shown below.

```
NetIron(config)# rmon event 1 description ‘testing a longer string’ log-and-trap
public owner nyc02
```

Syntax: **rmon event** <*event-entry*> **description** <*text-string*> **log | trap | log-and-trap | owner** <*rmon-station*>

Chapter

Configuring Management VRF 56

The following management Virtual Routing and Forwarding (VRF) features are supported by the NetIron MLX Series devices:

- IPv4 management VRF
- IPv6 management VRF

Management VRF overview

The management VRF is used to provide secure management access to the device by sending inbound and outbound management traffic through the VRF specified as a global management VRF and through the out-of-band management port, thereby isolating management traffic from the network data traffic.

By default, the inbound traffic is unaware of VRF and allows incoming packets from any VRF, including the default VRF. The outbound traffic is only through the default VRF. The default VRF consists of out-of-band management port and all the LP ports that do not belong to any other VRFs.

Any VRF, except the default VRF, can be configured as a management VRF. When a management VRF is configured, the management traffic is allowed through the ports belonging to the specified VRF and the out-of-band management port. The management traffic through the ports belonging to the other VRFs and the default VRF are dropped and the rejection statistics are incremented.

If the management VRF is not configured, the management applications will follow the default behavior. The management VRF configuration is applicable for both IPv4 and IPv6 management traffic.

The management VRF is supported by the following management applications:

- SNMP server
- SNMP trap generator
- Telnet server
- SSH server
- Telnet client
- RADIUS client
- TACACS+ client
- TFTP
- SCP
- Syslog

NOTE
The management VRF is not applicable to inbound and outbound traffic of the **ping** and **traceroute** commands. These commands use the VRF specified in the command or the default VRF, if no VRF is specified.

Source interface and management VRF compatibility

There is a source interface configuration associated with the management applications. When a source interface is configured, the management applications use the lowest configured IP address of the specified interface as source IP address in all the outgoing packets. If the configured interface is not part of the management VRF, the response packet will not reach the destination. If the compatibility check fails while configuring either the management VRF or the source interface, the following warning message will be displayed. However, the configuration command will be accepted.

```
The source-interface for Telnet, TFTP is not part of the management-vrf
```

Supported management applications

This section explains the management VRF support provided by the management applications.

SNMP server

When the management VRF is configured, the SNMP server receives SNMP requests and sends SNMP responses only through the ports belonging to the management VRF and through the out-of-band management port.

Any change in the management VRF configuration becomes immediately effective for the SNMP server.

SNMP trap generator

When the management VRF is configured, the SNMP trap generator sends traps to trap hosts through the ports belonging to the management VRF and through the out-of-band management port.

Any change in the management VRF configuration becomes immediately effective for the SNMP trap generator.

NOTE
The SNMP source interface configuration command **snmp-server trap-source** must be compatible with the management VRF configuration. Refer to "Source interface and management VRF compatibility" on page 2122.

Telnet server

When the management VRF is configured, the incoming Telnet connection requests are allowed only from the ports belonging to the management VRF and from the out-of-band management port. Management VRF enforcement is only done during the establishment of a connection. Once the connection is established, no further management VRF enforcement is done.

To allow the incoming Telnet connection requests only from the management VRF and not from the out-of-band management port, enter the following command.

```
NetIron(config)# telnet strict-management-vrf
```

The previous command is applicable only when the management VRF is configured. If not, the command issues the following warning message.

```
Warning - Management-vrf is not configured.
```

For the Telnet server, changes in the management VRF configuration or configuring the **telnet strict-management-vrf** command will not affect the existing Telnet connections and the changes will be applied only to the new incoming connection requests.

SSH server

When the management VRF is configured, the incoming SSH connection requests are allowed only from the ports belonging to the management VRF and from the out-of-band management port. Management VRF enforcement is only done during the establishment of a connection. Once the connection is established, no further management VRF enforcement is done.

To allow the incoming SSH connection requests only from the management VRF and not from the out-of-band management port, enter the following command.

```
NetIron(config)# ip ssh strict-management-vrf
```

The previous command is applicable only when the management VRF is configured. If not, the command issues the following warning message.

```
Warning - Management-vrf is not configured.
```

For the SSH server, changes in the management VRF configuration or configuring the **ip ssh strict-management-vrf** command will not affect the existing SSH connections and the changes will be applied only to the new incoming connection requests.

Telnet client

When the VRF name is specified in the **telnet vrf** command, the Telnet client initiates Telnet requests only from the ports belonging to the specified VRF.

To configure the VRF name in outbound Telnet sessions, enter the following command.

```
NetIron(config)# telnet vrf red 209.157.22.39
```

Syntax: telnet vrf <*vrf-name*> <*IPv4 address*> | **ipv6** <*IPv6 address*>

The <*vrf-name*> variable specifies the name of the pre-configured VRF.

RADIUS client

When the management VRF is configured, the RADIUS client will sends RADIUS requests or receives responses only through the ports belonging to the management VRF and through the out-of-band management port.

Any change in the management VRF configuration will be immediately effective for the RADIUS client.

NOTE
The RADIUS source interface configuration command **ip radius source-interface** must be compatible with the management VRF configuration. Refer to "Source interface and management VRF compatibility" on page 2122.

TACACS+ client

When the management VRF is configured, the TACACS+ client establishes connections with TACACS+ servers only through the ports belonging to the management VRF and the out-of-band management port.

For the TACACS+ client, any change in the management VRF configuration will not affect the existing TACACS+ connections and the changes will be applied only to the new TACACS+ connections.

NOTE
The TACACS+ source interface configuration command **ip tacacs source-interface** must be compatible with the management VRF configuration. Refer to "Source interface and management VRF compatibility" on page 2122.

TFTP

When the management VRF is configured, TFTP will send or receive the data and acknowledgements only through the ports belonging to the management VRF and through the out-of-band management port.

Any change in the management VRF configuration will be immediately effective for TFTP. You cannot change in the management VRF configuration while TFTP is in progress.

NOTE
The TFTP source interface configuration command **ip tftp source-interface** must be compatible with the management VRF configuration. Refer to "Source interface and management VRF compatibility" on page 2122.

SCP

SCP uses SSH as underlying transport. The behavior of SCP is similar to the SSH server. For more information, refer to "SSH server" on page 2123.

Syslog

When the management VRF is configured, the Syslog module sends log messages only through the ports belonging to the management VRF and the out-of-band management port.

Any change in the management VRF configuration will be immediately effective for Syslog.

NOTE
The Syslog source interface configuration command **ip syslog source-interface** must be compatible with the management VRF configuration. Refer to "Source interface and management VRF compatibility" on page 2122.

Configuring a global management VRF

To configure a VRF as a global management VRF, enter the following command.

```
NetIron(config)# management-vrf mvrf
```

Syntax: [no] management-vrf <*vrf-name*>

The <*vrf-name*> parameter specifies the name of the pre-configured VRF. If the VRF is not pre-configured, the command execution fails and displays the following error message.

```
Error - VRF <vrf-name> doesn't exist
```

When the management VRF is configured, the software generates the following Syslog message.

```
SYSLOG: VRF <vrf-name> has been configured as management-vrf
```

Enter the **no** form of the command to remove the management VRF. When the management VRF is deleted, the software generates the following Syslog message.

```
SYSLOG: VRF <vrf-name> has been un-configured as management-vrf
```

Configuration notes

Consider the following configuration notes:

- If there is a management VRF already configured, you must remove the existing management VRF configuration before configuring a new one. If not, the system displays the following error message.

  ```
  NetIron(config)# management-vrf  red
  Error - VRF mvrf already configured as management-vrf
  ```

- If you try to delete a management VRF that was not configured, the system displays the following error message.

  ```
  NetIron(config)# no management-vrf red
  Error - VRF red is not the current management-vrf
  ```

- The deletion or modification of the VRF will fail if the specified VRF is currently configured as the management VRF. Attempting to do so causes the system to return the following error message.

  ```
  NetIron(config)# no ip vrf mvrf
  Error - Cannot modify/delete a VRF which is configured as management-vrf
  ```

Displaying the management VRF information

To display IP Information for a specified VRF, enter the following command at any level of the CLI.

```
NetIron(config)# show vrf mvrf
VRF mvrf, default RD 1:1, Table ID 1 IFL ID 131071
Label: 500000,  Label-Switched Mode: OFF
Configured as management-vrf
IP Router-Id: 2.2.2.2
  Interfaces:
    e2/2
  No Export VPN route-target communities
  No Import VPN route-target communities
```

```
No import route-map
  No export route-map
  Address Family IPv4
    Max Routes: 5120
    No Export VPN route-target communities
    No Import VPN route-target communities
 Address Family IPv6
    Max Routes: 128
    No Export VPN route-target communities
    No Import VPN route-target communities
```

Syntax: show vrf <*vrf-name*>

The <*vrf-name*> parameter specifies the VRF for which you want to display IP information.

Table 407 displays a description of the output from the **show vrf** command.

TABLE 407 Output from the **show vrf** command

This field...	Displays...
VRF <*name*>	The name of the VRF.
default RD	The default route distinguisher for the VRF.
Table ID	The table ID for the VRF.
IFL ID	The Internal Forwarding Lookup Identifier (IFL-ID) for ports in the VRF instance.
Label	The unique VRF label that has been assigned to the specified VRF.
Label-Switched Mode	Indicates whether Label-Switched Mode is ON or OFF.
Configured as management-vrf	Indicates that the specified VRF is configured as a management VRF.
IP Router-Id	The 32-bit number that uniquely identifies the router.
import route-map	The name of the import route-map, if any, that is configured for this management VRF.
export route-map	The name of the export route-map if a route-map has been configured for this management VRF.

The **show who** command displays information about the management VRF from which the Telnet and SSH connection has been established.

```
NetIron(config)# show who
Console connections:
        established, monitor enabled, privilege super-user, in config mode
        1 minutes 47 seconds in idle
Telnet server status: Enabled
Telnet connections (inbound):
 1      established, client ip address 10.53.1.181, user is lab, privilege
super-user
        using vrf default-vrf.
        2 minutes 46 seconds in idle
 2      established, client ip address 20.20.20.2, user is lab, privilege
super-user
        using vrf mvrf.
        16 seconds in idle
 3      closed
```

```
 4      closed
 5      closed
Telnet connections (outbound):
 6      established, server ip address 20.20.20.2, from Telnet session 2, ,
privilege super-user
        using vrf mvrf.
        12 seconds in idle
 7      closed
 8      closed
 9      closed
 10     closed
SSH server status: Enabled
SSH connections:
 1      established, client ip address 10.53.1.181, privilege super-user
        using vrf default-vrf.
        you are connecting to this session
        3 seconds in idle
 2      established, client ip address 20.20.20.2, privilege super-user
        using vrf mvrf.
        48 seconds in idle
 3      closed
 4      closed
 5      closed
 6      closed
 7      closed
 8      closed
 9      closed
 10     closed
 11     closed
 12     closed
 13     closed
 14     closed
 15     closed
 16     closed
```

Syntax: show who

To display the packets and sessions rejection statistics due to failure in management VRF validation, enter the following command.

```
NetIron(config)# show management-vrf

Management VRF name : mvrf
Management Application Rx Drop Pkts Tx Drop Pkts
SNMP Engine             36        0
RADIUS Client           0         8
TFTP Client             0         4
SNMP Notifications      -         55
SysLogs                 -         78

TCP Connection rejects:
Telnet           : 1
SSH              : 1
TACACS+ Client   : 8
```

Syntax: show management-vrf

Table 408 displays a description of the output from the **show management-vrf** command.

TABLE 408 Output from the **show management-vrf** command

This field...	Displays...
Management VRF name	Displays the configured management VRF name.
Management Application	Displays the management application names.
Rx Drop Pkts	Displays the number of packets dropped in the inbound traffic.
Tx Drop Pkts	Displays the number of packets dropped in the outbound traffic.
TCP Connection rejects	Displays the number of TCP connections per application rejected due to management VRF validation.

Make sure that the management VRF is configured before executing the **show management-vrf** command. If not, the system will display the following error message.

```
Error - Management VRF is not configured.
```

To clear the management VRF rejection statistics, enter the following command.

```
NetIron(config)# clear management-vrf-stats
```

Syntax: clear management-vrf-stats

Chapter

sFlow 57

The following sFlow features are supported by PowerConnect B-MLXe Series.

- sFlow (RFC 3176)
- sFlow (v5 Support)
- sFlow Support on MPLS L2/3 VPN Endpoints
- sFlow Support on MPLS Uplinks
- ACL-based sFlow

sFlow is a system for observing traffic flow patterns and quantities within and among a set of PowerConnect devices. To support sFlow, the system:

- Samples the packet flows
- Collects the packet headers from sampled packets to gather ingress-egress information on these packets
- Composes the collected information into flow sample messages
- Relays these messages to an external device known as a collector

Participating devices also relay byte and packet counter data (counter samples) for ports to the collector.

sFlow is described in RFC 3176, “InMon Corporation's sFlow: A Method for Monitoring Traffic in Switched and Routed Networks”. Refer to this RFC to determine the contents of the sampled packet..

Dell also support sFlow v5 which replaces version outlined in RFC 3176.

Configuration considerations

Sample data is collected from inbound traffic on ports enabled for sFlow. However, byte and packet counters that are sent to the collector include traffic statistics for both the ingress and egress directions.The actual IP source address of the IP header is decided from the router port address of the best route to the sFlow collector IP address.

NOTE
Interface module processors directly forward sFlow packets to the specified sFlow collectors. The sFlow collector is reachable via ports on any of the Interface modules. We do not recommend that an sFlow collector be connected to a Management module’s Ethernet port.

NOTE
sFlow is implemented in the default VRF only. Therefore, sFlow data is only accessible by the sFlow collector (sFlow destination host(s)) defined in the default VRF.

Source address

The sampled sFlow data sent to the collectors includes an agent_address field. This field identifies the IP address of the device that sent the data.

sFlow looks for an IP address in following order, and uses the first address found:

- The router ID configured by the **ip router-id** command
- The first IP address on the lowest-numbered loopback interface
- The first IP address on the lowest-numbered virtual interface
- The first IP address on any interface

NOTE
If an IP address in not already configured when you enable sFlow, the feature uses the source address 0.0.0.0. To display the agent_address, enable sFlow, then enter the **show sflow** command. Refer to "Enabling sFlow forwarding" on page 2134 and "Displaying sFlow information" on page 2138.

NOTE
If you change the address sFlow will use for the agent_address, you must disable and re-enable sFlow to enable the feature to use the changed address.

Sampling rate

The ***sampling rate*** is the average ratio of the number of packets incoming on an sflow enabled port, to the number of flow samples taken from those packets. PowerConnect ports send only the sampled traffic to the CPU. sFlow sampling requires high LP CPU usage, which can affect performance in some configurations especially if a high sampling rate is implemented.

Configured rate and actual rate

When you enter a sampling rate value, this value is the configured rate. The software rounds the value you enter to the next higher odd power of 2 to obtain the actual rate. This value becomes the actual sampling rate. For example, if the configured sampling rate is 1000, then the actual rate is 2048 and 1 in 2048 packets are sampled by the hardware.

Extended router information

Extended router information contains information for the next hop router. This information includes the next hop router's IP address and the outgoing VLAN ID. Extended router information also includes the source IP address prefix length and the destination IP address prefix length.

Note that in IPv4, prefix length of source and destination IP addresses is collected only if BGP is configured on the devices.

Extended gateway information

Extended gateway information is included in an sFlow sampled packet if BGP is enabled. The extended gateway information includes the following BGP information about the packet's destination route:

- This router's autonomous system (AS) number

- The route's source IP AS
- The route's source peer AS
- The AS path to the destination

In BGP configured routers AS-Path information is collected from each node traversed by the sFlow packets.

NOTE
AS communities and local preferences are not included in the sampled packets.

To obtain extended gateway information use "struct extended_gateway" as described in RFC 3176.

sFlow support for MPLS

In addition to the regular Layer 2 or Layer 3 information export supported across devices, the PowerConnect supports the exporting of MPLS or VPN information in sFlow when sFlow sampling is configured on VPN endpoint interfaces. This includes VLL, VPLS, and VRF customer endpoint interfaces. This functionality allows service providers to collect sFlow information from VPN customers.

For incoming packets to an endpoint interface sampled by sFlow, the following additional information is collected and exported in the sFlow packets:

- **MPLS VC information:** including VC name, VC index, and VC label COS
- **MPLS tunnel information:** including the LSP tunnel name, the tunnel index as assigned by the router, and the tunnel COS used

NOTE
IP over MPLS (non-L3VPN or VRF) packets are not supported for sFlow processing.

Enhancements to support MPLS in sFlow packet export format are described in "sFlow Version 5" which is available at *www.sflow.org*.

sFlow with VPLS local switching

This feature allows sFlow to carry the original VLAN ID of the incoming traffic under scenarios where a VPLS has multiple endpoints and different endpoints with different VLAN IDs – implementing automatic VLAN ID translation.

When VPLS CPU protection is enabled in conjunction with sFlow, hardware flooded unknown unicast packets will be marked with a source VLAN ID of 0. Please note that this behavior is not specific to VPLS local switching but is applicable to all VPLS traffic.

NOTE
You have to configure MAs with different MD levels to monitor the different endpoints with different VLAN IDs in the same VPLS instance.

Configuring and enabling sFlow

To configure sFlow:

- Specify collector information. The collector is the external device to which you are exporting the sFlow data. You can specify up to four collectors.
- **Optional** – Change the polling interval.
- **Optional** – Change the sampling rate.
- Enable sFlow globally.
- Enable sFlow forwarding on individual interfaces.

NOTE
If you change the router ID or other IP address value that sFlow uses for its agent_address, you need to disable and then re-enable sFlow to cause the feature to use the new source address.

Specifying the collector

sFlow exports traffic statistics to an external collector. You can specify up to four collectors. You can specify more than one collector with the same IP address if the UDP port numbers are unique. You can have up to four unique combinations of IP address and UDP port number.

NOTE
sFlow is implemented in the default VRF only. Therefore, sFlow data is only accessible by the sFlow collector (sFlow destination host(s)) defined in the default VRF.

To specify sFlow collectors, enter a command such as the following.

```
NetIron(config)# sflow destination 10.10.10.1
```

This command specifies a collector with IP address 10.10.10.1, listening for sFlow data on UDP port 6343.

Syntax: [no] sflow destination <*ip-addr*> [<*dest-udp-port*>]

The <*ip-addr*> parameter specifies the collector's IP address.

The <*dest-udp-port*> parameter specifies the UDP port on which the sFlow collector will be listening for exported sFlow data. The default port number is 6343.

The sampled sFlow data sent to the collectors includes an agent_address field. This field identifies the device that sent the data. Refer to "Source address" on page 2130.

Changing the polling interval

The polling interval defines how often sFlow byte and packet counter data for a port are sent to the sFlow collectors. If multiple ports are enabled for sFlow, the PowerConnect staggers transmission of the counter data to smooth performance. For example, if sFlow is enabled on two ports and the polling interval is 20 seconds, the PowerConnect sends counter data every ten seconds. The counter data for one of the ports are sent after ten seconds, and counter data for the other port are sent after an additional ten seconds. Ten seconds later, new counter data for the first port are sent. Similarly, if sFlow is enabled on five ports and the polling interval is 20 seconds, the PowerConnect sends counter data every four seconds.

The default polling interval is 20 seconds. You can change the interval to a value from 1 to any higher value. The interval value applies to all interfaces on which sFlow is enabled. If you set the polling interval to 0, counter data sampling is disabled.

To change the polling interval, enter a command such as the following at the global CONFIG level of the CLI.

```
NetIron(config)# sflow polling-interval 30
```

Syntax: [no] sflow polling-interval *<secs>*

The *<secs>* parameter specifies the interval and can be from 1 to any higher value. The default is 20 seconds. If you specify 0, counter data sampling is disabled.

Changing the sampling rate

The sampling rate is the average ratio of the number of packets incoming on an sFlow-enabled port, to the number of flow samples taken from those packets. By default, all sFlow-enabled ports use the default sampling rate, which is 2048. With a sampling rate of 2048, on average, one in every 2048 packets forwarded on an interface is sampled.

You can change the default (global) sampling rate. You also can change the rate on an individual port, overriding the default sampling rate.

NOTE
sFlow uses CPU resources to send sFlow samples to the collector. If you set a low sampling value on a high rate interface (for example 10 GE), the Interface module CPU utilization can become high.

Configuration considerations

The sampling rate is a fraction in the form 1/N, meaning that, on average, one out of every N packets will be sampled. The **sflow sample** command at the global level or port level specifies N, the denominator of the fraction. Thus a higher number for the denominator means a lower sampling rate since fewer packets are sampled. Likewise, a lower number for the denominator means a higher sampling rate because more packets are sampled. For example, if you change the denominator from 2,000 to 512, the sampling rate increases because four times as many packets will be sampled.

NOTE
It is recommended that you do not change the denominator to a value lower than the default. Sampling requires CPU resources. Using a low denominator for the sampling rate can cause high CPU utilization.

Change to global rate

If you change the global sampling rate, the change is applied to all sFlow-enabled ports ***except*** those ports on which you have already explicitly set the sampling rate. For example, suppose that sFlow is enabled on ports 1/1, 1/2, and 5/1. If you configure the sampling rate on port 1/1 but leave the other two ports using the default rate, then a change to the global sampling rate applies to ports 1/2 and 5/1 but not port 1/1. sFlow assumes that you want to continue using the sampling rate you explicitly configured on an individual port even if you globally change the sampling rate for the other ports.

Sampling rate for new ports

When you enable sFlow on a port, the port's sampling rate is set to the global default sampling rate. This also applies to ports on which you disable and then re-enable sFlow. The port does not retain the sampling rate it had when you disabled sFlow on the port, even if you had explicitly set the sampling rate on the port.

Changing the default sampling rate

To change the default (global) sampling rate, enter a command such as the following at the global CONFIG level of the CLI.

```
NetIron(config)# sflow sample 2048
```

Syntax: [no] sflow sample <*num*>

The <*num*> parameter specifies the average number of packets from which each sample will be taken. In PowerConnect, the sampling rate you configure is the actual sampling rate. You can enter 512 – 2147483648. The default is 2048.

Changing the sampling rate on a port

You can configure an individual port to use a different sampling rate than the global default sampling rate. This is useful in cases where ports have different bandwidths. For example, if you are using sFlow on 10/100 ports and Gigabit Ethernet ports, you might want to configure the Gigabit ports to use a higher sampling rate (and thus gather fewer samples per number of packets) than the 10/100 ports.

To change the sampling rate on an individual port, enter a command such as the following at the configuration level for the port.

```
NetIron(config-if-e10000-1/1)# sflow sample 8192
```

Syntax: [no] sflow sample <*num*>

The <*num*> parameter specifies the average number of packets from which each sample will be taken. The software rounds the value you enter up to the next odd power of 2. The actual sampling rate becomes one of the values listed in "Changing the default sampling rate" on page 2134.

Enabling sFlow forwarding

sFlow exports data only for the interfaces on which you enable sFlow forwarding. You can enable sFlow forwarding on Ethernet or POS interfaces

To enable sFlow forwarding:

- Globally enable the sFlow feature.
- Enable sFlow forwarding on individual interfaces.

NOTE
Before you enable sFlow, make sure the device has an IP address that sFlow can use as its source address. Refer to "Source address" on page 2130 for the source address requirements.

Enabling sFlow forwarding

To enable sFlow forwarding, enter commands such as the following.

```
NetIron(config)# sflow enable
NetIron(config)# interface ethernet 1/1 to 1/8
NetIron(config-mif-1/1-1/8)# sflow forwarding
```

These commands globally enable sFlow, then enable sFlow forwarding on Ethernet ports 1/1 – 1/8. You must use both the **sflow enable** and **sflow forwarding** commands to enable the feature.

Syntax: [no] sflow enable

Syntax: [no] sflow forwarding

NOTE
Data for POS ports is sampled using Ethernet format. PPP or HDLC header of the sampled POS packet is replaced with an Ethernet header. PPP or HDLC control packets or ISIS packets transmitted or received at a POS port are not sampled. Such packets are not included in the number of packets from which each sample is taken.

NOTE
sFlow packets cannot be forwarded from a management interface. You must configure an IP interface on an Interface module to forward sFlow packets.

ACL-based Inbound sFlow

With this release, the Multi-Service IronWare software supports using an IPv4 or IPv6 ACL to select sample traffic to be sent to an sFlow collector. The data matching an ACL clause can be collected to observe traffic flow patterns and quantities between a set of switches and routers. To accommodate collecting sFlow through standard procedures and using ACL-filtered traffic, Dell created the Proprietary Tag Type 1991 that encapsulates the sFlow samples obtained through ACL-based sFlow and separates them from the sequence flow of other sFlow samples. Figure 232 shows the format of an sFlow packet which illustrates the differences between a standard sFlow payload and an ACL-based payload.

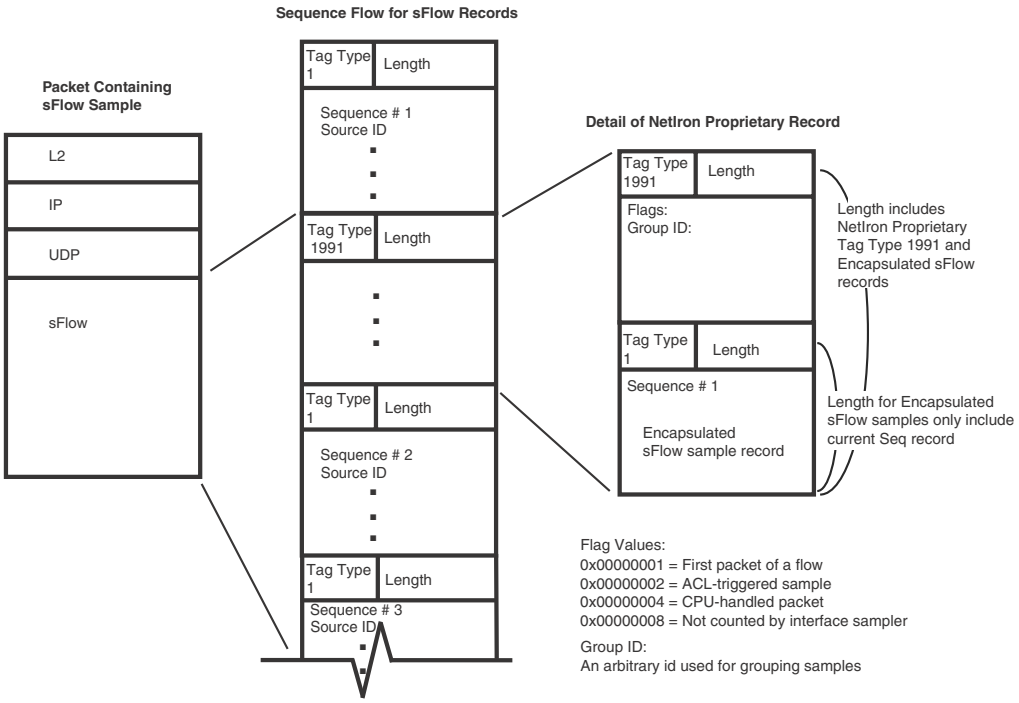
As shown in Figure 232, sFlow is carried in a UDP packet. Within the UDP packet, the sFlow contents are carried in individual samples that are identified by a Tag Type and a Length variable. The standard values for the Tag Types are: 1 = sampled packet and 2 = counter sample. The length variable describes the length of the sample. Within the sample are other variables including the Sequence number and the Source ID.

Dell has introduced the proprietary Tag Type 1991 to identify ACL-based sFlow samples. For these samples, standard Tag Type 1 samples collected using ACL-based Inbound sFlow are encapsulated in a Tag Type 1991 sample. The length variable identifies the entire length of the Tag Type 1991 sample including the encapsulated Tag Type 1 sample.The encapsulated sample has a length variable of its own that only identifies the length of that sample.

The Tag Type 1991 samples are sequenced separately from the unencapsulated Tag Type 1 samples. For instance in the packet detail described in the "Sequence Flow for sFlow Records" in Figure 232, the top sFlow record with Tag Type 1 begins with the sequence number 1. The next sFlow record is of Tag Type 1991 which indicates that the sample contained is from ACL-based sFlow. Encapsulated within this ACL-based sFlow sample is an sFlow sample record of Tag Type 1. The ACL-based sFlow sample (which contains the Type 1 sample) is followed by an unencapsulated Tag Type 1 sFlow sample. That unencapsulated Tag Type 1 sFlow sample follows the sequence numbering of the first unencapsulated Tag Type 1 sFlow sample which gives it a sequence number of 2.

This is useful in cases where an sFlow collector does not recognize Tag Type 1991. In these situations, the Tag Type 1991 samples can be ignored without disrupting the sFlow sequence numbers. It is also useful for indentifying samples obtained using ACL-based sFlow on which other processing might be performed.

FIGURE 232 sFlow packet format



Configuring ACL-based Inbound sFlow

The followings sections describe how to configure ACL-based Inbound sFlow:

- "Configuration considerations for ACL-based Inbound sFlow"
- "Creating an ACL with an sFlow clause"
- "Specifying an sFlow collector"

Configuration considerations for ACL-based Inbound sFlow

The followings sections describe the configuration considerations for ACL-based Inbound sFlow:

- sFlow must be enabled on the router.
- **ACL-based mirroring:** The **mirror** and **copy-sflow** keywords are mutually exclusive on a per ACL clause basis.
- **Port-based monitoring:** Port-based monitoring and ACL-based sFlow can co-exist on the same interface.
- **Port-based sFlow:** Port and ACL-based sFlow can co-exist on the same interface. When both features are configured on an interface, packets that qualify as ACL-based sFlow packets are sent to the collector as ACL sample packets. Also, the user can configure ACL-based sFlow on an interface without configuring port-based sFlow.

- **IP Receive ACLs:** IP Receive ACLs are used for filtering or rate-limiting management traffic. The keyword **copy-sflow** is also supported for IP Receive ACLs.
- **Policy Based Routing:** The **copy-sflow** keyword is applicable for PBR ACLs.
- **IPv4 ACL based Rate-Limiting:** When the **copy-sflow** keyword is used in an IPv4 Rate Limiting ACL, only traffic permitted by the Rate Limiting engine is copied to the CPU for forwarding to the sFlow collector.
- **IPv4 ACLs on VRF endpoints:** You can apply ACL-based sFlow for VRF endpoints however such packets are treated as regular sampled sFlow packets and do not carry proprietary encapsulation. This can create a minor skew of statistics projection.
- **L2 ACLs:** The **copy-sflow** keyword is not supported for L2 ACLs.
- If the **copy-sflow** keyword is used for a clause that is applied to the outbound direction, it is ignored.

Creating an ACL with an sFlow clause

The **copy-sflow** keyword has been added for inclusion in IPv4 and IPv6 ACL clauses to direct traffic that meets the criteria in the clause to be sent to the sFlow collector. In the following example, the ACL is used to direct syn-ack packets sent from a server at address 10.10.10.1.

```
access-list 151 permit tcp host 10.10.10.1 any established syn copy-sflow
access-list 151 permit any any
```

The **copy-sflow** parameter directs selected traffic to the sFlow collector. Traffic can only be selected using the **permit** clause.

You must apply the ACL to an interface using the **ip access-group command** as shown in the following.

```
NetIron(config)# int eth 1/1
NetIron(config-if-e10000-1/1)# ip access-group 151 in
```

Specifying an sFlow collector

sFlow exports traffic statistics to an external collector. You can specify up to four collectors. You can specify more than one collector with the same IP address if the UDP port numbers are unique. You can have up to four unique combinations of IP address and UDP port number.

NOTE
sflow is implemented in the default VRF only. Therefore, sflow data is only accessible by the sflow collector (sflow destination host(s)) defined in the default VRF.

To specify sFlow collectors, enter a command such as the following.

```
NetIron(config)# sflow destination 10.10.10.1
```

This command specifies a collector with IP address 10.10.10.1, listening for sFlow data on UDP port 6343.

Syntax: [no] sflow destination <*ip-addr*> [<*dest-udp-port*>]

The <*ip-addr*> parameter specifies the collector's IP address.

The <*dest-udp-port*> parameter specifies the UDP port on which the sFlow collector will be listening for exported sFlow data. The default port number is 6343.

Only inbound traffic is selected using sFlow. This applies to both standard sFlow and ACL-based sFlow.

NOTE
The sampling rate is the average ratio of the number of packets incoming on an sFlow-enabled port, to the number of flow samples taken from those packets. However for ACL based sFlow, every matching packet is sent to the CPU. Consequently, configured sampling rates do not affect ACL based sFlow.

Displaying sFlow information

To display sFlow configuration information and statistics, enter the following command at any level of the CLI.

```
NetIron(config)# show sflow
sFlow services are enabled.
sFlow agent IP address: 30.30.30.2
Collector IP 10.10.10.1, UDP 6343
Polling interval is 20 seconds.
Configured default sampling rate: 1 per 2048 packets.
0 UDP packets exported
0 sFlow samples collected.
sFlow ports   Global Sample Rate   Port Sample Rate   Hardware Sample Rate
        3/1                2048               2048   2048
        3/2                2048               2048   2048
        3/3                2048               2048   2048
        3/4                2048               2048   2048
```

Syntax: show sflow

This command shows the following information.

TABLE 409 sFlow information

This field...	Displays...
sFlow services	The feature state, which can be one of the following: • disabled • enabled
sFlow agent IP address	The IP address that sFlow is using in the agent_address field of packets sent to the collectors. Refer to "Source address" on page 2130.
Collector	The collector information. The following information is displayed for each collector: • IP address • UDP port If more than one collector is configured, the line above the collectors indicates how many have been configured.
Polling interval	The port counter polling interval.
Configured default sampling rate	The configured global sampling rate. If you changed the global sampling rate, the value you entered is shown here. The actual rate calculated by the software based on the value you entered is listed on the next line, "Actual default sampling rate".
UDP packets exported	The number of sFlow export packets the PowerConnect has sent. **NOTE:** Each UDP packet can contain multiple samples.

TABLE 409 sFlow information (Continued)

This field...	Displays...
sFlow samples collected	The number of sampled packets that have been sent to the collectors.
sFlow ports	The ports on which you enabled sFlow.
Global Sample Rate	The global sampling rate for the PowerConnect.
Port Sampling Rates	The sampling rates of a port on which sFlow is enabled.
Hardware Sample Rate	The actual sampling rate. This is the same as the Global Sample Rate

Displaying ACL-based sFlow statistics

Use the show sflow command to display the number of sFlow samples collected for ACL-based sFlow. These statistics are shown in bold in the following display.

```
NetIron# show sflow
sFlow services are disabled.
sFlow agent IP address: 10.10.10.254
Collector IP 10.10.10.1, UDP 6343
Polling interval is 30 seconds.
Configured default sampling rate: 1 per 1024 packets.
0 UDP packets exported
0 sFlow samples collected.
5 ACL sFlow samples collected
sFlow ports   Global Sample Rate   Port Sample Rate   Hardware Sample Rate
        4/1                1024               8192   8192
```

All other display parameters are unchanged as documented in the PowerConnect User Guide.

Clearing sFlow statistics

To clear the UDP packet and sFlow sample counters in the **show sflow** display, enter the following command.

```
NetIron(config)# clear statistics
```

Syntax: clear statistics

This command clears the values in the following fields of the **show sflow** display:

- UDP packets exported
- sFlow samples collected

NOTE
This command also clears the statistics counters used by other features.

Chapter

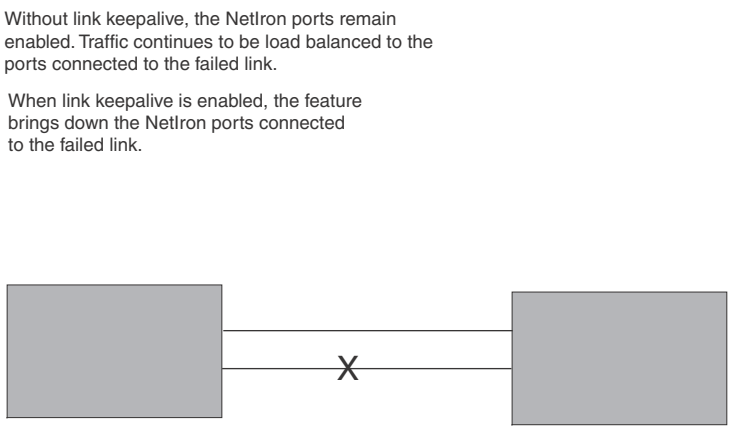
Configuring Uni-Directional Link Detection (UDLD) 58

The following Uni-Directional Link Detection (UDLD) features are supported by PowerConnect B-MLXe Series.

- Uni-Directional Link Detection (UDLD)
- UDLD for Tagged Ports

Uni-directional Link Detection (UDLD) monitors a link between two PowerConnect devices and provides a fast detection of link failures. UDLD brings the ports on both ends of the link down if the link goes down at any point between the two devices. This feature is useful for links that are individual ports and for LAG links. Figure 233 shows an example.

FIGURE 233 UDLD example



By default, ports enabled for UDLD exchange proprietary health-check packets once every 500 ms (the keepalive interval). If a port does not receive a health-check packet from the port at the other end of the link within the keepalive interval, the port waits for four more intervals. If the port still does not receive a health-check packet after waiting for five intervals, the port concludes that the link has failed and takes the port down.

The Keepalive Interval and Keepalive Retries can be configured to values other than the default, as shown in "Changing the keepalive interval" on page 2142 and "Changing the keepalive retries" on page 2142.

Configuration considerations

This section describes the configuration considerations:

- The feature is supported only on Ethernet ports.
- To configure UDLD on a LAG group, you must configure the feature on each port of the group individually. Configuring UDLD on a LAG group's primary port enables the feature on that port only.

- Dynamic LAG is not supported. If you want to configure a LAG group that contains ports on which UDLD is enabled, you must remove the UDLD configuration from the ports. After you create the LAG group, you can re-add the UDLD configuration.

Configuring UDLD

To enable UDLD on a port, enter a command such as the following at the global CONFIG level of the CLI.

```
NetIron(config)# link-keepalive ethernet 1/1
```

Syntax: [no] link-keepalive ethernet <*slot*>/<*portnum*> **[ethernet** <*slot*>/<*portnum*>**]**

To enable the feature on a LAG group, enter commands such as the following.

```
NetIron(config)# link-keepalive ethernet 1/1 ethernet 1/2
NetIron(config)# link-keepalive ethernet 1/3 ethernet 1/4
```

These commands enable UDLD on ports 1/1 – 1/4. You can specify up to two ports on the same command line.

Changing the keepalive interval

By default, ports enabled for UDLD send a link health-check packet once every 500 ms. You can change the interval to a value from 1 – 60, where 1 is 100 ms, 2 is 200 ms, and so on. To change the interval, enter a command such as the following.

```
NetIron(config)# link-keepalive interval 3
```

Syntax: [no] link-keepalive interval <*num*>

The <*num*> parameter specifies how often the ports send a UDLD packet. You can specify from 1 – 60, in 100 ms increments. The default is 5 (500 ms).

Changing the keepalive retries

You can change the maximum number of keepalive attempts to a value from 3 – 10. To change the maximum number of attempts, enter a command such as the following.

```
NetIron(config)# link-keepalive retries 4
```

Syntax: [no] link-keepalive retries <*num*>

The <*num*> parameter specifies the maximum number of times the port will try the health check. You can specify a value from 3 – 10. The default is 5.

UDLD for tagged ports

The default implementation of UDLD sends the packets untagged, even across tagged ports. If the untagged UDLD packet is received by a third-party switch, that switch may reject the packet. As a result, UDLD may be limited only to Dell devices, since UDLD may not function on third-party switches.

Beginning with Multi-Service IronWare release 04.1.00, you can configure ports to send out UDLD control packets that are tagged with a specific VLAN ID as tagged UDLD control packets. The enhancement also allows third party switches to receive the control packets that are tagged with the specified VLAN.

To allow ports to receive and send UDLD control packets tagged with a specific VLAN ID, enter commands such as the following:

```
NetIron(config)# link-keepalive ethernet 1/18 vlan 22
```

This commands enables UDLD on port 1/18 and allows UDLD control packet tagged with VLAN 22 to be received and sent on port 1/18.

Syntax: [no] link-keepalive ethernet <portnum> [vlan <vlan-ID>]

Enter the slot number (if applicable) and the port number of the Ethernet port.Enter the ID of the VLAN that the UDLD control packets can contain to be received and sent on the port. If a VLAN ID is not specified, then UDLD control packets are sent out of the port as untagged packets.

NOTE
You must configure the same VLANs that will be used for UDLD on all devices across the network; otherwise, the UDLD link cannot be maintained

Displaying UDLD information

Displaying information for all ports

.In the following example, port 1/1 is tagged in VLAN 2 and is configured for tagged UDLD. Port 1/2 is not configured for tagged UDLD:

```
PowerConnect#show link-keepalive
Total link-keepalive enabled ports: 2
Keepalive Retries: 5    Keepalive Interval: 5 * 100 MilliSec.

Port    Physical Link   Link-keepalive  Logical link    Link-vlan
1/1         down            down                down              2
1/2         down            down                down
PowerConnect#
```

Syntax: show link-keepalive [ethernet <*slot*>/<*portnum*>**]**

TABLE 410 CLI display of UDLD information

This field...	Displays...
Total link-keepalive enabled ports	The total number of ports on which UDLD is enabled.
Keepalive Retries	The number of times a port will attempt the health check before concluding that the link is down.
Keepalive Interval	The number of seconds between health check packets.
Port	The port number.
Physical Link	The state of the physical link. This is the link between the PowerConnect port and the directly connected device.
Link-keepalive	Show if the keepalive link is up or down.

TABLE 410 CLI display of UDLD information (Continued)

This field...	Displays...
Logical Link	The state of the logical link. This is the state of the link between this PowerConnect port and the PowerConnect port on the other end of the link. If the states of both Physical Link and Link-keepalive are up, then Logical link is up. If either or both Physical Link and Link-keepalive states are down, then Logical Link displays "down".
Link-vlan	The VLAN that the port is configured to tag the UDLD packets with.

If a port is disabled by UDLD, the change also is indicated in the output of the **show interfaces brief** command. Here is an example.

```
NetIron(config)# show interface brief

Port  Link State      Dupl Speed Trunk Tag Priori MAC            Name
1/1   Up   LK-DISABLE None None  None  No  level0 00e0.52a9.bb00
1/2   Down None       None None  None  No  level0 00e0.52a9.bb01
1/3   Down None       None None  None  No  level0 00e0.52a9.bb02
1/4   Down None       None None  None  No  level0 00e0.52a9.bb03
```

If the port was already down before you enabled UDLD for the port, the port's state is listed as None.

Syntax: show interface brief

The **show link-keepalive** command shows the following.

```
NetIron(config)# show link-keepalive ethernet
Current State   : down          Remote MAC Addr  : 0000.0000.0000
Local Port      : 1/1           Remote Port      : n/a
Local System ID : e0eb8e00      Remote System ID : 00000000
Packets sent    : 0             Packets received : 0
Transitions     : 0
```

Syntax: show link-keepalive ethernet

Displaying information for a single port

To display detailed UDLD information for a specific port, the command **show link-keepalive ethernet 4/1** is valid for a port that is not configured for Tagged UDLD. For a Tagged UDLD port VLAN information is also included. In the following example, port 1/1 is tagged in VLAN 2 and is configured for tagged UDLD. Port 1/2 is not configured for tagged UDLD.

```
PowerConnect#show link-keepalive ethernet 1/1

Current State   : down          Remote MAC Addr  : 0000.0000.0000
Local Port      : 1/1           Remote Port      : n/a
Local System ID : 1bb3d340      Remote System ID : 00000000
Packets sent    : 0             Packets received : 0
Transitions     : 5             Link-Vlan        :2

PowerConnect#show link-keepalive ethernet 1/2

Current State   : down          Remote MAC Addr  : 0000.0000.0000
Local Port      : 1/2           Remote Port      : n/a
```

```
Local System ID : 1bb3d340      Remote System ID : 00000000
Packets sent    : 0             Packets received : 0
Transitions     : 6

PowerConnect#
```

TABLE 411 CLI display of detailed UDLD information

This field...	Displays...
Current State	The state of the logical link. This is the link between this PowerConnect port and the PowerConnect port on the other end of the link.
Remote MAC Addr	The MAC address of the port or device at the remote end of the logical link.
Local Port	The port number on this PowerConnect router.
Remote Port	The port number on the PowerConnect router at the remote end of the link. **NOTE:** The Remote Port number shown in this parameter reflects the port ID sent by the other router or switch and interpreted by this local router. In cases where this router interprets the port ID different than the router that sent the port ID, the port shown can be incorrect.
Local System ID	A unique value that identifies this PowerConnect router. The ID can be used by Dell technical support for troubleshooting.
Remote System ID	A unique value that identifies the PowerConnect router at the remote end of the link.
Packets sent	The number of UDLD health-check packets sent on this port.
Packets received	The number of UDLD health-check packets received on this port.
Transitions	The number of times the logical link state has changed between up and down.
Link-vlan	The VLAN that the port is configured to tag the UDLD packets with.

The **show interface ethernet** <*slot*>/<*portnum*> command also displays the UDLD state for an individual port. In addition, the line protocol state listed in the first line will say “down” if UDLD has brought the port down. Here is an example.

```
NetIron(config)# show interface ethernet 1/1
GigabitEthernet2/1 is disabled, line protocol is down, link keepalive is enabled
  Hardware is GigabitEthernet, address is 000c.dbe2.5900 (bia 000c.dbe2.5900)
  Configured speed 1Gbit, actual unknown, configured duplex fdx, actual unknown
  Configured mdi mode AUTO, actual unknown
  Member of 2 L2 VLANs, port is tagged, port state is Disabled
  STP configured to ON, Priority is level7, flow control enabled
  Force-DSCP disabled
  mirror disabled, monitor disabled
  Not member of any active trunks
  Not member of any configured trunks
  No port name
  MTU 1522 bytes, encapsulation ethernet
  300 second input rate: 0 bits/sec, 0 packets/sec, 0.00% utilization
  300 second output rate: 0 bits/sec, 0 packets/sec, 0.00% utilization
  0 packets input, 0 bytes, 0 no buffer
  Received 0 broadcasts, 0 multicasts, 0 unicasts
  0 input errors, 0 CRC, 0 frame, 0 ignored
  0 runts, 0 giants, DMA received 0 packets
  0 packets output, 0 bytes, 0 underruns
  Transmitted 0 broadcasts, 0 multicasts, 0 unicasts
  0 output errors, 0 collisions, DMA transmitted 0 packets
```

In this example, the port has been brought down by UDLD. Notice that in addition to the information in the first line, the port state on the fourth line of the display is listed as DISABLED.

Clearing UDLD statistics

To clear UDLD statistics, enter the following command.

```
NetIron# clear link-keepalive statistics
```

Syntax: clear link-keepalive statistics

This command clears the Packets sent, Packets received, and Transitions counters in the **show link keepalive ethernet** *<slot>/<portnum>* display.

Chapter

BiDirectional Forwarding Detection (BFD) 59

PowerConnect B-MLXe supports the following BiDirectional Forwarding Detection (BFD) features:

- BiDirectional Forwarding Detection (BFD)
- BFD for IPv4 IS-IS
- BFD for IPv6 IS-IS
- BFD for OSPFv2
- BFD for OSPFv3
- BFD for IPv4 BGP
- Configuring BFD for RSVP-TE LSPs
- IP router alert option
- MPLS BFD

Multi-Service IronWare software provides support for Bidirectional Forwarding Detection (BFD). BFD provides rapid detection of the failure of a forwarding path by checking that the next-hop device is alive. Without BFD enabled, it can take from 3 to 30 seconds to detect that a neighboring device is not operational causing packet loss due to incorrect routing information at a level unacceptable for real-time applications such as VOIP and video over IP. Using BFD, you can detect a forwarding path failure in 300 milliseconds or less depending on your configuration.

A BFD session is automatically established when a neighbor is discovered for a protocol provided that BFD is enabled on the interface on which the neighbor is discovered and BFD is also enabled for the protocol (by interface or globally). Once a session is set-up, each device transmits control messages at a high rate of speed that is negotiated by the devices during the session setup. To provide a detection time of 150 milliseconds, it is necessary to process 20 messages per second of about 70 to 100 bytes each per each session. A similar number of messages also need to be transmitted out per each session. Once a session is set-up, that same message is continuously transmitted at the negotiated rate and a check is made that the expected control message is received at the agreed frequency from the neighbor. If the agreed upon messages are not received from the neighbor within a short period of time, the neighbor is considered to be down.

NOTE
BFD session establishment on an interface does not start until 90 seconds after the interface comes up. The reason for this delay is to ensure that the link is not effected by unstable link conditions which could cause BFD to flap. This delay time is not user configurable.

The BFD Control Message is an UDP message with destination port 3784.

NOTE
BFD version 0 is not supported in this implementation and BFD version 1 is not compatible with BFD version 0.

NOTE
BFD supports multi-slot LAGs in cases where all BFD packet are transmitted only on a single path which does not change unless the LAG active membership changes. BFD is not be supported on multi-slot LAGs where per-packet switching is used such that the path taken by the BFD packets will vary per packet.

NOTE
When BFD is configured with stringent values of 100/300 msec, BFD may flap when learning a large number of routes.

Number of BFD sessions supported

The devices have a set limit of 250 BFD sessions per system with a maximum number of 40 sessions per Interface Module. This number is inclusive of the fact that IS-IS and OSPF sessions on an Interface Module will include both Tx and Rx sessions. Consequently, the 40 sessions per Interface Module actually corresponds to 80 sessions where each OSPF and IS-IS session consumes 2 sessions (1 Tx and 1 Rx).

Unlike IS-IS and OSPF however, the Tx and Rx sessions for MPLS BFD can reside on different interface modules. This means that when counting MPLS BFD sessions against the Interface Module maximum, the Tx and Rx sessions must be counted separately. In practice this means that the maximum number of sessions per-Interface Module is 80; where each Tx and Rx session for MPLS BFD is counted as 1 and IS-IS and OSPF BFD sessions are counted as 2 towards a per-Interface Module maximum number of sessions of 80.

Configuring BFD parameters

When you configure BFD you must set timing and interval parameters. These are configured on each interface. When two adjacent interfaces with BFD are configured, they negotiate the conditions for determining if the connection between them is still active. The following command is used to set the BFD parameters:

```
NetIron(config-if-e1000-3/1)# bfd interval 100 min-rx 100 multiplier 3
```

Syntax: [**no**] **bfd interval** <*transmit-time*> **min-rx** <*receive-time*> **multiplier** <*number*>

The <*transmit-time*> variable is the interval in milliseconds between which this device will send a BFD message to its peer informing it that it is still operational. This value is specified in milliseconds. Acceptable values are: 50 - 30000.

The <*receive-time*> variable is the interval in milliseconds that this device waits to receive a BFD message from its peer. The device waits for this interval for the number of times specified in the <*number*> variable before determining that the connection to its peer in not operational. Acceptable values are: 50 - 30000.

NOTE
The **transit-time** and **receive-time** variables are the intervals desired by the local device. The actual values in use will be the negotiated values.

The <*number*> variable specifies the number of times in a single sequence that this device will wait to receive a BFD message from its peer before determining that the connection to that peer is not operational. Acceptable values are: 3 - 50.

Disabling BFD Syslog messages

Syslog messages are generated for BFD operations. These messages are described in "Syslog messages BFD". Logging of these messages is enabled by default. To disable logging of BFD messages use the following command:

```
NetIron(config)# no logging enable bfd
```

Syntax: [no] **logging enable bfd**

BFD logging is enabled by default. If you disable BFD logging as shown, you can re-enable it by using the **logging enable bfd** command.

Displaying BFD information

You can display BFD information for the device you are logged-in to and for BFD-configured neighbors as described in the following sections.

Displaying BFD information

The following example illustrates the output from the **show bfd** command:

```
NetIron# show bfd
 BFD State: ENABLED Version: 1
Current Registered Protocols: ospf/0  ospf6/0
All Sessions: Current: 4 Maximum Allowed: 100 Maximum Exceeded Count: 0
LP Sessions: Maximum Allowed on LP: 40  Maximum Exceeded Count for LPs: 0
LP Tx/Rx Sessions LP Tx/Rx Sessions LP Tx/Rx Sessions LP Tx/Rx Sessions
1   4/4           2   2/2           3  0/0           4  0/0
5   0/0           6   0/0           7  0/0           8  0/0
9   0/0           10  0/0           11 0/0           12 0/0
13  0/0           14  0/0           15 0/0           16 0/0
BFD Enabled ports count: 2
Port       MinTx       MinRx       Mult Sessions
eth 2/1    100         100         3    2
pos 3/1    100         100         3    2
```

Syntax: show bfd

This display shows the following information.

TABLE 412 Display of BFD information

This field...	Displays...
BFD State	Specifies if BFD is Enabled or Disabled on the device.
Version	Specifies the version of the BFD protocol operating on the device.
Current Registered Protocols	Specifies which protocols are registered to use BFD on the device. Possible values are mpls/0, ospf/0, ospf6/0, or isis_task/0
All Sessions	

TABLE 412 Display of BFD information (Continued)

This field...	Displays...
Current:	The number of BFD sessions currently operating on the device.
Maximum Allowed	The maximum number of BFD sessions that are allowed on the device.
Maximum Exceeded Count	The number of times the request to set up a BFD session was declined because it would have resulted in exceeding the maximum number of BFD sessions allowed on the device.
LP Sessions:	
Maximum Allowed on LP	The maximum number of BFD sessions that are allowed on an interface module.
Maximum Exceeded Count for LPs	The number of times the request to set up a BFD session was declined because it would have resulted in exceeding the maximum number of BFD sessions allowed on an interface module.
LP	The number of the interface module that the Current Session Count is displayed for.
Sessions	The number of Transmit (Tx) and Receive (Rx) BFD sessions currently operating on the specified interface module.
BFD Enabled ports count	The number of ports on the device that have been enabled for BFD.
Port	The port that BFD is enabled on.
MinTx	The interval in milliseconds between which the device desires to send a BFD message from this port to its peer.
MinRx	The interval in milliseconds that this device desires to receive a BFD message from its peer on this port.
Mult	The number of times that the device will wait for the MinRx time on this port before it determines that its peer device is non-operational.
Sessions	The number of BFD sessions originating on this port.

Displaying BFD neighbor information

The following example illustrates the output from the **show bfd neighbor** command.

```
NetIron# show bfd neighbor
Total number of Neighbor entries: 2
NeighborAddress                         State   Interface Holddown  Interval  RH
12.14.1.1                               UP      eth 3/1   300000    100000    1
12.2.1.1                                UP      eth 2/1   300000    100000    1
```

Syntax: **show bfd neighbor** [**interface ethernet** <*slot/port*> | **interface pos** <*slot/port*> | **interface ve** <*port-no*>]

The **interface ethernet** option displays BFD neighbor information for the specified ethernet interface only.

The **interface ve** option displays BFD neighbor information for the specified virtual interface only.

This display shows the following information.

TABLE 413 Display of BFD information

This field...	Displays...
Total number of Neighbor entries	The number of neighbors that have established BFD sessions with ports on this device.
NeighborAddress	The IPv4 or IPv6 address of the remote peer.
State	The current state of the BFD session: Up Down A.DOWN – The administrative down state. INIT – The Init state. UNKNOWN – The current state is unknown.
Interface	The logical port (physical or virtual port) on which the peer is known. The physical port can be either Ethernet or POS.
Holddown	The interval in microseconds after which the session will transition to the down state if no message is received.
Interval	The interval in microseconds at which the local device sends BFD messages to the remote peer.
RH	Heard from remote.

To display BFD Neighbor information in the detailed format use the following command.

```
NetIron# show bfd neighbor details
Total number of Neighbor entries: 1
NeighborAddress                         State   Interface Holddown  Interval  RH
12.14.1.1                               UP      ve 50     300000    100000    1
  Registered Protocols(Protocol/VRFID): ospf/0
  Local: Disc: 1, Diag: 0, Demand: 0 Poll: 0
         MinTxInterval: 100000, MinRxInterval: 100000, Multiplier: 3
  Remote: Disc: 22, Diag: 7, Demand: 0 Poll: 0
          MinTxInterval: 100000, MinRxInterval: 100000, Multiplier: 3
  Stats: RX: 72089 TX: 72101 SessionUpCount: 1 at SysUpTime: 0:1:30:54.775
  Session Uptime: 0:1:30:6.375, LastSessionDownTimestamp: 0:0:0:0.0
  Physical Port: eth 4/1, Vlan Id: 50
```

Syntax: show bfd neighbor details [<*ip-address*> | <*ipv6-address*>]

This display shows the following information.

TABLE 414 Display of BFD neighbor detail information

This field...	Displays...
Total number of Neighbor entries	Total number of BFD sessions.
NeighborAddress	IPv4 or IPv6 address of the remote peer.
State	The current state of the BFD session: Up Down A.DOWN – The administrative down state. INIT – The Init state. UNKNOWN – The current state is unknown.
Interface	The logical port on which the peer is known.

TABLE 414 Display of BFD neighbor detail information (Continued)

This field...	Displays...
Holddown	The interval in microseconds after which the session will transition to the down state if no message is received.
Interval	The interval in microseconds at which the local device sends BFD messages to the remote peer.
RH	Heard from remote.
Registered Protocols	Specifies which protocols are registered to use BFD on this port.
Local:	
Disc	Value of the “local discriminator” field in the BFD Control Message as used by the local device in the last message sent.
Diag	Value of the “diagnostic” field in the BFD Control Message as used by the local device in the last message sent.
Demand	Value of the “demand” bit in the BFD Control Message as used by the local device in the last message sent.
Poll	Value of the “poll” bit in the BFD Control Message as used by the local device in the last message sent.
MinTxInterval	The interval in microseconds between which the device will send a BFD message from this local neighbor port to its peer.
MinRxInterval	The interval in microseconds that the neighbor device waits to receive a BFD message from its peer on this local port.
Multiplier	The number of times that the neighbor device will wait for the MinRxInterval time on this port before it determines that its peer device is non-operational.
Remote:	
Disc	Value of the “local discriminator” field in the BFD Control Message as received in the last message sent by the remote peer.
Diag	Value of the “diagnostic” field in the BFD Control Message as received in the last message sent by the remote peer.
Demand	Value of the “demand” bit in the BFD Control Message as received in the last message sent by the remote peer.
Poll	Value of the “poll” bit in the BFD Control Message as received in the last message sent by the remote peer.
MinTxInterval	The interval in milliseconds between which the device will send a BFD message from the remote neighbor port to its peer.
MinRxInterval	The interval in milliseconds that the neighbor device waits to receive a BFD message from its peer on this remote port.
Multiplier	The number of times that the remote neighbor device will wait for the MinRxInterval time on this port before it determines that its peer device is non-operational.
Stats: Rx	Total number of BFD control messages received from the remote peer.
Stats: Tx	Total number of BFD control messages sent to the remote peer.
Stats: SessionUpCount	The number of times the session has transitioned to the UP state.
Stats: SysUpTime	The amount of time that the system has been up.

TABLE 414 Display of BFD neighbor detail information (Continued)

This field...	Displays...
Session Uptime	The amount of time the session has been in the UP state.
LastSessionDownTimestamp	The system time at which the session last transitioned from the UP state to some other state.
Physical Port	The physical port on which the peer is known.
Vlan Id	The VLAN ID of the VLAN that the physical port is resident on.

Clearing BFD neighbor sessions

You can clear all BFD neighbor sessions or a specified BFD neighbor session using the following command.

```
NetIron# clear bfd neighbor
```

Syntax: clear bfd neighbor [<*ip-address*> | <*ipv6-address*>]

The <*ip-address*> variable specifies the IPv4 address of a particular neighbor whose session you want to clear BFD.

The <*ipv6-address*> variable specifies the IPv6 address of a particular neighbor whose session you want to clear BFD.

Executing this command without specifying an IP or IPv6 address clears the sessions of all BFD neighbors.

Configuring BFD for the specified protocol

BFD can be configured for use with the following protocols:

- OSPFv2
- OSPFv3
- IS-IS
- BGP

NOTE
BFD is not supported for OSPF v2 or v3 virtual links.

NOTE
BFD brings ISIS and OSPF down with it when RSTP path-cost changes are made to the switch Alt Discarding port.

Configuring BFD for OSPFv2

You can configure your device for BFD on the OSPFv2 protocol for all OSPFv2 enabled interfaces or for specific interfaces as shown in the following sections.

Enabling BFD for OSPFv2 for all interfaces

You can configure BFD for OSPFv2 on all of a device's OSPFv2 enabled interfaces using the command shown in the following"

```
NetIron# device ospf
NetIron(config-ospf-device)# bfd all-interfaces
```

Syntax: [**no**] **bfd all-interfaces**

Although this command configures BFD for OSPFv2 on all of the OSPFv2 enabled interfaces for a device, it is not required if you use the **ip ospf bfd** command to configure specific interfaces. It can be used independently or together with the **ip ospf bfd** command.

Enabling or disabling BFD for OSPFv2 for a specific interface

You can selectively enable or disable BFD on any OSPFv2 interface as shown.

```
NetIron# (config-if-e1000-3/1)# ip ospf bfd disable
```

Syntax: ip ospf bfd [**disable** | **enable**]

The **disable** option disables BFD for OSPFv3 on the interface. The enable option enables BFD for OSPFv3 on the interface

Configuring BFD for OSPFv3

You can configure your device for BFD on the OSPFv3 protocol for all OSPFv3 enabled interfaces or for specific interfaces as shown in the following sections.

Enabling BFD for OSPFv3 for all interfaces

You can configure BFD for OSPFv3 on all OSPFv3 enabled interfaces using the command shown in the following.

```
NetIron(config)# ipv6 router ospf
NetIron(config-ospf6-router)# bfd all-interfaces
```

Syntax: [**no**] **bfd all-interfaces**

Although this command configures BFD for OSPFv3 on all of the OSPFv3 enabled interfaces on a device, it is not required if you use the **ipv6 ospf bfd** command to configure specific interfaces. It can be used independently or together with the **ipv6 ospf bfd** command.

Enabling or disabling BFD for OSPFv3 for a specific interface

You can selectively enable or disable BFD on any OSPFv3 interface as shown in the following.

```
NetIron#(config-if-e1000-3/1)# ipv6 ospf bfd enable
```

Syntax: ipv6 ospf bfd [**disable** | **enable**]

The **disable** option disables BFD for OSPFv3 on the interface. The **enable** option enables BFD for OSPFv2 on the interface.

Configuring BFD for IS-IS

You can configure your device for BFD (for both IPv4 ad IPv6 IS-IS neighbors) for the IS-IS protocol for all IS-IS enabled interfaces, or for specific interfaces as shown in the following sections.

Enabling BFD for IS-IS for all interfaces

You can configure IS-IS for IS-IS on all S-IS enabled interfaces for a device using this command.

```
NetIron# router isis
NetIron(config-isis-router)# bfd all-interfaces
```

Syntax: [**no**] **bfd all-interfaces**

Although this command configures BFD for IS-IS on all IS-IS enabled interfaces on the device, it is not required if you use the **isis bfd** command to configure specific interfaces. It can be used independently or together with the **isis bfd** command.

Enabling or disabling BFD for IS-IS for a specific interface

You can selectively enable or disable BFD on any IS-IS interface as shown in the following.

```
NetIron#(config-if-e1000-3/1)# isis bfd enable
```

Syntax: [**no**] **isis bfd** [**enable** | **disable**]

The **enable** option enables IS-IS on the interface. The **disable** option disables BFD for IS-IS on the interface.

Configuring BFD for BGP4

You can configure your device for BFD for BGP4. BGP4 supports IPv4 and IPv6 IBGP and EBGP peers. These peers can be directly connected or multihop. BFD for BGP4 supports single hop and multihop BFD on Ethernet, POS and Virtual Interfaces. BFD for BGP4 is not supported on loopback, tunnel (including IGP shortcut) and management interfaces.

BFD for BGP4 global configuration – Using this configuration, you can enable and disable BFD BGP4 on a global level. In addition, you can use the global command to set revised default values for the transmit interval, receive interval, and for the detection time multiplier for all BFD multihop BGP4 sessions.

BFD for BGP4 at global, peer, and peer group configuration – Using this configuration, you can enable and disable BFD for individual peers or peer groups. You can also change the values for the transmit interval, receive interval, and for the detection time multiplier. If these values are not specified at this level, they are obtained from the values configured at the global level.

BFD for BGP4, which is disabled by default, can be enabled or disabled at the global BGP router level or for each individual peer or peer group. The hierarchy for BFD for BGP4 is as follows:

- Peer and peer group parameters can be configured but will not take effect until BFD for BGP4 has been enabled.
- Peer configurations will override global and peer group configurations.
- Peer group configurations will override global configurations
- The **bfd-enable** command under **router bgp** overrides all other BGP4 BFD configurations

Enabling BFD for BGP4 globally

By default, BFD for BGP4 is disabled and can be first enabled globally and then on each peer. To enable BFD for BGP4 globally, enter commands such as the following.

```
NetIron# router bgp
NetIron(config-bgp)# bfd-enable
```

To disable BFD for BGP globally and terminate all BFD sessions used by BGP4, enter commands such as the following

```
NetIron# router bgp
NetIron(config-bgp)# no bfd-enable
```

Syntax: [**no**] **bfd-enable**

NOTE
If BFD for BGP4 is globally disabled and then enabled, the original BFD sessions for BGP4 may not be available, depending on whether or not the maximum BFD sessions limit has been reached. When a BFD session for BGP4 is disabled, the session will be removed but BGP4 peering will not go down. The remote BFD peer will be informed that BFD use is disabled.

Setting the transmit, receive, and detection time multiplier at the global level

When using BFD for BGP4, you must configure BFD globally at the **router BGP** level. You can also use this configuration to set new default values for the transmit interval, receive interval, and for the detection time multiplier.

For a single hop EBGP session, the BFD parameters configured under interface will be used because the BFD session for single hop is also shared with other applications. To create a BFD session for a single hop BGP4 session, you must have BFD enabled and the timers configured for the interface on which single hop BGP4 peering is established.

NOTE
For multihop BFD sessions, BFD does not have to be enabled for any of the interfaces, and the BFD timers need not be configured, since the default values can be used.

The timers parameters **min-tx**, **min-rx** and **multiplier** can also be configured for each peer and peer group and will override the global configuration.

To configure a multi hop EBGP or IBGP session, enter a command such as the following.

```
NetIron(config)# router bgp
NetIron(config-bgp)# bfd-enable
NetIron(config-bgp)# bfd min-tx 500 min-rx 500 multiplier 5
```

Syntax: [**no**] **bfd** [**min-tx** <*transmit-time*> **min-rx** <*receive-time*> **multiplier** <*number*>]

The <*transmit-time*> variable is the interval in milliseconds between which this device will send a BFD message to its peer informing it that it is still operational. Acceptable values are: 50 - 30000. Default value: 1000 (unless changed at the global level

The <*receive-time*> variable is the interval in milliseconds that this device waits to receive a BFD message from its peer. The device will wait for this interval for the number of times specified in the <*number*> variable before determining that the connection to its peer in not operational. Acceptable values are 50 - 30000. The default value is 1000 (unless changed at the global level)

The **multiplier** option allows you to specify a value for the number of times in a single sequence that this device will wait to receive a BFD message from its peer before determining that the connection to that peer is not operational. This value is set at the <*number*> variable. Acceptable values are 3 - 50. The default value is 3.

The **no** option globally removes the BFD for BGP4 configuration from the device.

Holdover interval

The BFD holdover interval is supported for both single hop and multihop sessions. It sets the time by which the BFD session DOWN notification to BGP4 is delayed. If within that holdover time, the BFD session is UP then BGP4 is not notified of the BFD session flap.

The holdover interval can be configured globally, on each peer, or peer-group.

If the **bfd holdover-interval** is set to 20 seconds, when a notification is received from BFD that the BFD session has moved to DOWN state, the system waits for 20 seconds before sending the BFD session down notification to BGP4 state machine. If the BFD session returns to UP state before the 20 seconds expires, the BGP4 state machine is not notified that the BFD session flapped. Otherwise, after 20 seconds the BFD session down notification is passed to the BGP4 state machine. If BFD for BGP4 is disabled, the request to not use BFD for BGP4 is passed to BFD by BGP4, BFD acknowledges this request, and the BFD session is removed. If BFD is disabled, BGP4 is notified and asks BFD to remove the single hop BFD session on the interface.

To configure the BFD down notification delay, enter a command such as the following.

```
NetIron(config-bgp)# bfd holdover-interval 20
```

Syntax: [**no**] **bfd holdover-interval** <*time-seconds*>

The <*time-seconds*> variable is a number between 0 and 30 seconds. The default is 0 seconds.

The **no** option removes the BFD for BGP4 holdover interval from the configuration.

Enabling BFD for a BGP4 peer group

To enable BFD and create a peer group for BGP4, you must first create the peer group, then enable BFD for the peer group by entering commands such as the following.

```
NetIron(config-bgp)# neighbor pg1 peer-group
NetIron(config-bgp)neighbor pg1 fail-over bfd-enable
```

Syntax: [**no**] **neighbor** <*name*> **peer group**

Syntax: [**no**] **neighbor** <*name*> **fail-over bfd-enable**

The <*name*> variable specifies peer-group name of a particular neighbor.
The **no** option removes the BFD for BGP4 peer group from the configuration.

Enabling BFD timers for a BGP4 peer group

To enable BFD timers for a BGP4 peer group, you must first create the peer group, then enable BFD timers for the peer group by entering commands such as the following.

```
NetIron(config-bgp)# neighbor pg1 peer-group
NetIron(config-bgp)neighbor pg1 bfd min-tx 500 min-rx 500 multiplier 5
```

Syntax: [**no**] **neighbor** <*name*> **peer group**

Syntax: [**no**] **neighbor** <*name*> **bfd min-tx** <*transmit-time* > **min-rx** <*receive-time*> **multiplier** <*number*>

The <*name*> variable specifies peer-group name of a particular neighbor.

The <*transmit-time*> variable is the interval in milliseconds during which this device will send a BFD message to its peer informing it that it is still operational. Acceptable values are 50 - 30000. The default value is 1000 (unless changed at the global level).

The <*receive-time*> variable is the interval in milliseconds that this device waits to receive a BFD message from its peer. The device waits for this interval for the number of times specified in the <*number*> variable before determining that the connection to its peer in not operational. Acceptable values are 50 - 30000. The default value is 1000 (unless changed at the global level).

The **multiplier** option allows you to specify a value for the number of times in a single sequence that the device waits to receive a BFD message from its peer before determining that the connection to that peer is not operational. This value is set at the <*number*> variable. Acceptable values are 3 - 50. The default value is 3.

The **no** option removes the BFD timers for the peer group from the configuration.

Enabling BFD for a specific BGP4 peer

To enable BFD for BGP4 for a specific neighbor or peer, enter a command such as the following

```
NetIron(config-bgp)# neighbor 12.14.1.1 fail-over bfd-enable
```

Syntax: [**no**] **neighbor** <*ipv4-address* | *ipv6-address*> **fail-over bfd-enable**

The <*ipv4-address* | *pv6-address*> variables specify the IPv4 or IPv6 address of a particular neighbor or peer.

The **no** option removes the BFD for BGP4 peer from the configuration.

Disabling BFD for a specific BGP4 peer

To disable BFD for BGP4 for a specific peer, enter a command such as the following.

```
NetIron(config-bgp)# neighbor 12.14.1.1 fail-over bfd-disable
```

Syntax: [**no**] **neighbor** <*ipv4-address* l *ipv6-address*> **fail-over bfd-disable**

The <*ipv4-address* l *ipv6-address*> variables specify the IPv4 or IPv6 address of a particular neighbor or peer.

The **no** option removes the BFD specific peer from the configuration.

Enabling BFD timers for a specific BGP4 peer

To enable BFD timers for a specific neighbor or peer for BGP4, you must first configure the bfd timers, and set the holdover interval by entering commands such as the following.

```
NetIron(config-bgp)# neighbor 12.14.1.1 bfd min-tx 500 min-rx 500 multiplier 5
NetIron(config-bgp)# bfd holdover-interval 20
```

Syntax: [**no**] **neighbor** <*ipv4-address* l *ipv6-address*> **bfd min-tx** <*transmit-time* > **min-rx** <*receive-time*> **multiplier**

Syntax: [**no**] **bfd holdover-interval** <*time-seconds*>

The <*ipv4-address* l *ipv6-address*> variables specify the IPv4 or IPv6 address of a particular neighbor or peer.

The <*time-seconds*> variable is a number between 0 and 30 seconds. The default is 0 seconds.

The <*transmit-time*> variable is the interval in milliseconds between which this device will send a BFD message to its peer informing it that it is still operational. Acceptable values are 50 - 30000. The default value is 1000 (unless changed at the global level).

The <*receive-time*> variable is the interval in milliseconds that this device waits to receive a BFD message from its peer. The device will wait for this interval for the number of times specified in the <*number*> variable before determining that the connection to its peer is not operational. Acceptable values are 50 - 30000. The default value is 1000 (unless changed at the global level).

The **multiplier** option allows you to specify a value for the number of times in a single sequence that this device will wait to receive a BFD message from its peer before determining that the connection to that peer is not operational. This value is set at the <*number*> variable. Acceptable values are 3 - 50. The default value is 3.

The **no** option removes the BFD for BGP configuration for the peer.

Displaying BFD for BGP4

You can display BFD for BGP4 information for the device you are logged in to and for BFD configured neighbors as described in the following sections.

Displaying BFD information

The following example illustrates the output from the **show bfd** command:

```
NetIron# show bfd
 BFD State: ENABLED Version: 1
 Current Registered Protocols: bgp/1 ospf6/0 ospf/0 bgp/0
 All Sessions: Current: 0 Maximum Allowed: 100 Maximum Exceeded Count: 0
 LP Sessions: Maximum Allowed on LP: 20 Maximum Exceeded Count for LPs: 0
   LP Tx/Rx Sessions LP Tx/Rx Sessions LP Tx/Rx Sessions LP Tx/Rx Sessions
   1   0/0           2   0/0           3   0/0           4   0/0
   5   0/0           6   0/0           7   0/0           8   0/0
   9   0/0           10  0/0           11  0/0           12  0/0
   13  0/0           14  0/0           15  0/0           16  0/0
 BFD Enabled ports count: 0
```

Syntax: show bfd

This display shows the following information.

TABLE 415 Display of BFD information

This field...	Displays...
BFD State	Specifies if BFD is Enabled or Disabled on the device.
Version	Specifies the version of the BFD protocol operating on the device.
Current Registered Protocols	Specifies which protocols are registered to use BFD on the device. Possible values are mpls/0, ospf/0, ospf6/0, or isis_task/0 or bgp/0
All Sessions	
Current:	The number of BFD sessions currently operating on the device.
Maximum Allowed	The maximum number of BFD sessions that are allowed on the device.
Maximum Exceeded Count	The number of times the request to set up a BFD session was declined because it would have exceeded the maximum number of BFD sessions allowed on the device.
LP Sessions:	
Maximum Allowed on LP	The maximum number of BFD sessions allowed on an interface module.
Maximum Exceeded Count for LPs	The number of times the request to set up a BFD session was declined because it would have exceeded the maximum number of BFD sessions allowed on an interface module.
LP	The number of the interface modules for which the Current Session Count is displayed.
Sessions	The number of Transmit (Tx) and Receive (Rx) BFD sessions currently operating on the specified interface module.
BFD Enabled ports count	The number of ports that have been enabled for BFD.
Port	The port on which BFD is enabled.
MinTx	The interval in milliseconds during which the device sends a BFD message from this port to its peer.
MinRx	The interval in milliseconds during which this device can receive a BFD message from its peer on this port.

TABLE 415 Display of BFD information (Continued)

This field...	Displays...
Mult	The number of times the device will wait for the MinRx time on this port before it determines that the peer device is non-operational.
Sessions	The number of BFD sessions originating on this port.

Displaying BFD applications

The following example illustrates the output from the **show bfd applications** command.

```
NetIron# show bfd applications
  Registered Protocols Count: 4
     Protocol  VRFID     Parameter
     bgp       1          0
     ospf6     0          0
     ospf      0          0
     bgp       0          0
```

TABLE 416 Display of BFD applications information

This field...	Displays...
Protocol	Which protocols are registered to use BFD on the device.
VRFID	The VRFID of the protocol.
Parameter	The parameter value passed by the protocol during registration with BFD.

Displaying BFD for BGP neighbor information

The following example illustrates the output from the **show bfd neighbor bgp detail** command.

```
NetIron# show bfd neighbor bgp detail

NetIron#
```

Syntax: show bfd neighbor bgp [<*ipv4-address*> | <*ipv6-address*>| **detail**]

The <*ipv4-address*> | <*ipv6-address*> options display BFD neighbor information for the BGP specified IPv4 or IPv6 neighbor only.

The **detail** option displays BFD neighbor information for all BGP neighbors.

This display contains the following information.

TABLE 417 Display of BFD neighbor detail information

This field...	Displays...
Total number of Neighbor entries	Total number of BFD sessions.
NeighborAddress	IPv4 or IPv6 address of the remote peer.
State	The current state of the BFD session: Up Down A.DOWN – The administrative down state. INIT – The Init state. UNKNOWN – The current state is unknown.
Interface	The logical port on which the peer is known.
Holddown	The interval in microseconds after which the session will transition to the down state if no message is received.
Interval	The interval in microseconds at which the local device sends BFD messages to the remote peer.
RH	Heard from remote, values: Y or N where Y stand for Yes and N stand for No; H- Single hop/Multihop Values are S and M where S stand for Single Hop and M stand for MultiHop.
Registered Protocols	Specifies which protocols are registered to use BFD on this port.
Local:	
Disc	Value of the local discriminator field in the BFD Control Message as used by the local device in the last message sent.
Diag	Value of the diagnostic field in the BFD Control Message as used by the local device in the last message sent.

TABLE 417 Display of BFD neighbor detail information (Continued)

This field...	Displays...
Demand	Value of the demand bit in the BFD Control Message as used by the local device in the last message sent.
Poll	Value of the poll bit in the BFD Control Message as used by the local device in the last message sent.
MinTxInterval	The interval in microseconds during which the device will send a BFD message from this local neighbor port to the peer.
MinRxInterval	The interval in microseconds that the neighbor device waits to receive a BFD message from the peer on this local port.
Multiplier	The number of times the neighbor device will wait for the MinRxInterval time on this port before it determines the peer device is non-operational.
Remote:	
Disc	Value of the local discriminator field in the BFD Control Message as received in the last message sent by the remote peer.
Diag	Value of the diagnostic field in the BFD Control Message as received in the last message sent by the remote peer.
Demand	Value of the demand bit in the BFD Control Message as received in the last message sent by the remote peer.
Poll	Value of the poll bit in the BFD Control Message as received in the last message sent by the remote peer.
MinTxInterval	The interval in milliseconds during which the device will send a BFD message from the remote neighbor port to the peer.
MinRxInterval	The interval in milliseconds that the neighbor device waits to receive a BFD message from the peer on this remote port.
Multiplier	The number of times that the remote neighbor device will wait for the MinRxInterval time on this port before it determines that the peer device is non-operational.
Stats: Rx	Total number of BFD control messages received from the remote peer.
Stats: Tx	Total number of BFD control messages sent to the remote peer.
Stats: SessionUpCount	The number of times the session has transitioned to the UP state.
Stats: SysUpTime	The amount of time that the system has been up.
Session Uptime	The amount of time the session has been in the UP state.
LastSessionDownTimestamp	The system time at which the session last transitioned from the UP state to some other state.
Physical Port	The physical port on which the peer is known.
Vlan Id	The VLAN ID of the VLAN on which the physical port is resident.

.Displaying summary neighbor information

Support for BFD for BGP neighbors is highlighted in the bold text in the following output for the **show ip bgp neighbors** command.

```
Neighbor AS4 Capability Negotiation:
    As-path attribute count: 2
    Outbound Policy Group:
```

```
   ID: 1, Use Count: 3
BFD:Enabled,BFDSessionState:UP,Multihop:Yes

    HoldOverTime(sec) Configured:22,Current:0,DownCount:0
TCP Connection state: ESTABLISHED, flags:00000044 (0,0)
 Maximum segment size: 1460
```

Configuring BFD for RSVP-TE LSPs

BFD can be configured for use with RSVP-LSPs to detect data plane failures for MPLS LSPs. Although the LSP ping facility can also be used for this purpose, BFD provides the following advantages:

- BFD provides faster failure detection because it does not required control plane verification, which is required by LSP ping.
- BFD can be used to detect faults on a large number of LSPs without requiring manual interaction, which is required by LSP ping.

BFD configuration for RSVP-TE LSPs is performed at the global and LSP levels, as described:

- **BFD for RSVP-TE LSPs global configuration** – allows you to enable and disable BFD on all of the RSVP-TE LSPs that have been configured for BFD at the LSP level. In addition, use the global command to set revised default values for the transmit interval, receive interval, and for the detection time multiplier for all BFD sessions on RSVP-TEs. This configuration command can also be used as a convenient method to turn BFD for MPLS on or off.
- **BFD for RSVP-TE LSPs configuration at the LSP level** – allows you to enable and disable BFD for individual RSVP-TE LSPs. You can also change the values for the transmit interval, receive interval, and for the detection time multiplier from the default values. If these values are not specified at this level, they are obtained from the values configured at the global level.

BFD, which is disabled by default, can be enabled or disabled at the global MPLS level, or for each individual LSP without affecting the LSP operational status. BFD parameters can also be changed without changing the state of the BFD session.

BFD for RSVP-TE LSPs operates with Fast ReRoute (FRR), Redundant, and Adaptive LSPs as described:

- **FRR LSPs –** Only one BFD session is created for an FRR LSP. A separate BFD session is not created for the detour path. When a switchover from a protected to a detour path occurs, the detour path resides on another interface module, and the BFD session is moved to that interface module. The BFD session can go down if the interface module has already reached the maximum number of BFD sessions. If the detour path is on the same interface module, the outgoing interface and label stack are updated on that interface module. A BFD session is not created for a detour path originated on a transit LSR.
- **Redundant LSPs –** One BFD session is created for the primary path of a redundant LSP. If the secondary path is in the hot-standby condition, a separate BFD session is created for it, but only if BFD is enabled on the secondary path. The two sessions operate independently.
- **Adaptive LSPs –** If a new instance of an adaptive LSP comes up on a different interface module, its BFD session is automatically created on that module. Otherwise, the local outgoing interface and label stack are updated on the existing interface module. When a BFD session is moved to a different interface module, the BFD session may be brought down if the interface module has already reached the maximum number of BFD sessions allowed on it.

BFD session support per-router and per-interface module

There is a limit to the number of BFD sessions available on a per-router and per-interface module basis as described:

- **per-router** – A maximum number of 250 BFD sessions are permitted per device
- **per-interface module** – A maximum number of 80 BFD sessions (Tx or Rx) are permitted per-interface module

These limitations are inclusive of any BFD sessions created for OSPFv2 or v3 and ISIS. If creating a BFD session will exceed these limits, the session will be denied. For a detailed description of how to calculate the number of BFD sessions supported, refer to "Number of BFD sessions supported" on page 2148.

BFD session creation

On ingress, one BFD session is created for each LSP after the LSP comes up. The BFD session status is then displayed in the output of the **show lsp** command. If the BFD session is not up, a failure reason is displayed in the output of the **show lsp** command. Possible reasons why a BFD session may fail to come up include exceeding the maximum supported number of BFD sessions, or if the global BFD configuration is disabled. If a BFD session does not come up because a BFD packet from the egress LSR is not received, an MPLS Echo Request with a BFD Discriminator TLV is resent until the session does come up. The retry timer is exponentially backed off.

On egress, a BFD session is created after the following sequence of events.

1. An MPLS Echo Request is received with a BFD Discriminator TLV
2. MPLS BFD is enabled globally
3. The maximum number of BFD sessions available on the device has not been reached.

NOTE
A BFD session created on an egress LSR is counted toward the maximum supported number of BFD sessions.

If the number of BFD sessions has reached the su pop rt ed maximum for the device, no MPLS Echo Reply or BFD control packet is sent. The ingress LSR will retry.

Because the source IP address cannot be changed for an MPLS BFD session after the session has come up, the LSR-ID is used as the source IP address for all MPLS BFD packets. This ensures that the session will not go down when an LSP path switch occurs.

BFD session down behavior

When a BFD session for an LSP goes down on an ingress LSR because the BFD detection time has expired, one of the following path switchovers will be triggered; from the protected path to the detour path, or from the primary path to the secondary path. In configurations with no alternative path, the LSP is brought down and the BFD session is deleted. The LSP then follows the normal retry procedures to come back up. On an egress LSR, a down BFD session does not have any impact on the RSVP session.

BFD session deletion

A BFD session is deleted when any of the following events occur:

- An LSP goes down
- BFD is disabled for the LSP
- BFD is disabled for all LSPs (using the global configuration)

These events are described in the following sections.

Enabling BFD for RSVP-TE LSPs at the global level

When using BFD for RSVP-TE LSPs, you must configure BFD globally at the **router mpls** level. You can also use this configuration to set new default values for the transmit interval, receive interval, and for the detection time multiplier, as shown.

```
NetIron(config)# router mpls
NetIron(config-mpls)# bfd
NetIron(config-mpls-bfd)# bfd min-tx 500 min-rx 500 multiplier 5
```

Syntax: [**no**] **bfd** [**min-tx** <*transmit-time*> **min-rx** <*receive-time*> **multiplier** <*number*>]

The <*transmit-time*> variable is the interval in milliseconds during which this device sends a BFD message to the peer informing it that it is still operational. Acceptable values are 50 - 30000. The default value is 1000 (unless changed at the global level).

The <*receive-time*> variable is the interval in milliseconds the device waits to receive a BFD message from the peer. The device waits for the number of times specified in the <*number*> variable before determining that the connection to the peer in not operational. Acceptable values are 50 - 30000. The default value is 1000 (unless changed at the global level).

The **multiplier** option allows you to specify a value for the number of times in a single sequence that this device will wait to receive a BFD message from the peer before determining that the connection to that peer is not operational. This value is set at the <*number*> variable. Acceptable values are 3 - 50. The default value is 3.

The **no** option globally removes the BFD for RSVP-TE LSPs configuration from the device.

NOTE
BFD parameters configured globally can be changed dynamically without affecting the operational status of the LSP and the BFD session. When you make changes to the global configuration, the changes are applied to all egress MPLS BFD sessions. and only to the ingress BFD sessions with parameters that are derived from the global configuration.

Enabling BFD for a specific RSVP-TE LSPs

When you configure BFD globally, you must also configure it locally for the individual LSPs on which you want it to operate. You can also set separate values for the transmit interval, receive interval, and for the detection time multiplier for the specified LSP. The following example enables BFD for the LSP named blue and sets new parameter values.

```
NetIron(config)# router mpls
NetIron(config-mpls)# lsp blue
NetIron(config-mpls-lsp-blue)# bfd
NetIron(config-mpls-lsp-blue-bfd)# bfd min-tx 500 min-rx 500 multiplier 5
```

Syntax: [**no**] **bfd min-tx** <*transmit-time*> **min-rx** <*receive-time*> **multiplier** <*number*>

The <*transmit-time*> variable is the interval in milliseconds during which this device sends a BFD message to the peer announcing that it is still operational. Acceptable values are 50 - 30000. The default value is 1000 (unless changed at the global level).

The <*receive-time*> variable is the interval in milliseconds this device waits to receive a BFD message from the peer. The device waits for the number of times specified in the <*number*> variable before determining that the connection to the peer is not operational. Acceptable values are 50 - 30000. The default value is 1000 (unless changed at the global level).

The **multiplier** option allows you to specify a value for the number of times in a single sequence that this device waits to receive a BFD message from the peer before determining that the connection to that peer is not operational. This value is set at the <*number*> variable. Acceptable values are 3 - 50. The default value is 3.

The **no** option globally removes the BFD for RSVP-TE LSPs configuration from the device.

NOTE
BFD parameters configured for a specific LSP can be changed dynamically without affecting the operational status of the LSP and the BFD session.

Using this command you can also configure BFD for the secondary path of an LSP as shown in the following example.

```
NetIron(config)# router mpls
NetIron(config-mpls)# lsp blue
NetIron(config-mpls-lsp-blue)# secondary-path alt_sf_to_sj
NetIron(config-mpls-lsp-blue-sec-path)# bfd
```

Displaying MPLS BFD information

You can display the following information about an LSP BFD configuration:

- BFD Application Information
- BFD MPLS Information
- Detailed BFD MPLS Information
- MPLS BFD Global Configuration Information

You can also obtain MPLS BFD information using the **show bfd** command, as described in "Displaying BFD information" on page 2149, and the **show mpls lsp** command, as described in "Displaying signalled LSP status information" on page 1366.

Displaying BFD application information

The following example illustrates the output from the **show bfd application** command.

```
NetIron# show bfd application
 Registered Protocols Count: 3
     Protocol  VRFID     Parameter
     ospf       0           1
     ospf6      0           0
     isis_task  0           0
     mpls       0           0
```

This display shows the following information.

TABLE 418 Display of BFD application information

This field...	Displays...
Protocol	Specifies protocols registered to use BFD on the device. Possible values are mpls/0, ospf/0, ospf6/0, or isis_task/0
VRFID	The VRFID of the protocol.
Parameter	The parameter value passed by the protocol during registration with BFD.

Displaying BFD MPLS information

The following example shows output from the **show bfd mpls** command.

```
NetIron# show bfd mpls
Total number of MPLS BFD sessions: 2
Session name                          State   Interface Holddown  Interval  RH
lsp1                                  UP      eth 1/2   3000000   1000000   Y
11.11.11.1/1/22.22.22.2               UP      eth 1/2   3000000   1000000   Y
```

Syntax: show bfd mpls

This display shows the following information.

TABLE 419 Display of BFD MPLS information

This field...	Displays...
Total number of MPLS BFD Sessions	The number of BFD sessions that have been established on this device.
Session name	The name of the session: **For LSP Sessions –** the LSP name. **For RSVP Sessions –** the session-id which is displayed as IPv4 tunnel endpoint, tunnel ID, or extended tunnel ID.
State	The current state of the BFD session: Up Down A.DOWN – The administrative down state INIT – The Init state UNKNOWN – The current state is unknown
Interface	The logical port (physical or virtual port) on which the BFD packet is sent out. The physical port can be either an Ethernet, POS, or VE-enabled interface. The VE interface ID is specified by the <*vid*> variable.
Holddown	The interval in microseconds after which the session will transition to the down state if no message is received.
Interval	The interval in microseconds at which the local device sends BFD messages to the remote peer.
RH	Heard from remote.

Displaying BFD MPLS detailed information

The following example shows a display of BFD MPLS detailed information as a result of the **show bfd mpls detail** command. To view BFD MPLS information for a single LSP or RSVP session, use the **show bfd mpls lsp** command.

NOTE
The **show bfd mpls lsp** command displays the same information as the **show bfd mpls rsvp-session** command.

```
NetIron# show bfd mpls lsp lsp2
Session name                          State   Interface Holddown  Interval  RH
lsp2                                  UP      eth 1/2   3000000   1000000   Y
  Local: Disc: 3, Diag: 0, Demand: 0 Poll: 0
         MinTxInterval: 500000, MinRxInterval: 500000, Multiplier: 3
  Remote: Disc: 3, Diag: 3, Demand: 1 Poll: 0
          MinTxInterval: 1000000, MinRxInterval: 1000000, Multiplier: 3
  Stats: RX: 305 TX: 305 SessionUpCount: 1 at SysUpTime: 0:0:4:46.200
  Session Uptime: 0:0:3:46.650, LastSessionDownTimestamp: 0:0:0:0.0
  Tx Port: eth 1/2, Rx Port: eth 1/2
```

Syntax: show bfd mpls [**detail** | **lsp** <*name*> | **rsvp-session** <*src-addr*> <*dest-addr*> <*tnnl-id*>]

This information shown in this display that is not defined in Table 419 is described in either Table 414 or Table 420.

TABLE 420 Display of BFD MPLS detail information

This field...	Displays...
Interface	The logical port (physical or virtual port) on which the BFD packet is sent out. The physical port can be either an Ethernet, POS, or VE-enabled interface. The VE interface ID is specified by the <*vid*> variable.
Tx Port:	The physical port on which the BFD packet is sent. When applicable, the Tx Port field displays a VE interface ID specified by the <*vid*> variable.
Rx Port:	The physical port on which the BFD packet is received.

Displaying MPLS BFD global configuration information

You can use the **show mpls bfd** command to display the global configuration information for a device, as shown in the following.

```
NetIron# show mpls bfd
MPLS BFD admin            = Enabled
Minimum TX interval       = 1000 msec
Minimum RX interval       = 1000 msec
Detection time multiplier = 3
```

Syntax: show mpls bfd

TABLE 421 Display of **BFD MPLS detail** command

This field...	Displays...
MPLS BFD admin	The global configuration state of MPLS BFD on the device: can be either Enabled or Disabled
Minimum TX interval	Desired Min Tx Interval - the minimum interval, in microseconds, the local system will use when transmitting BFD Control packets. The value zero is reserved.
Minimum RX interval	Required Min Rx Interval - the mimi num interval, in microseconds, between received BFD Control packets that this system is capable of supporting. If this value is zero, the transmitting system does not want the remote system to send any periodic BFD Control packets.
Detection time multiplier	The number of times in a single sequence this device waits to receive a BFD message from the peer before determining that the connection to that peer is not operational.

Chapter

Operations, Administration, and Maintenance (OAM) 60

The following OAM features are supported by PowerConnect B-MLXe Series.

- IEEE 802.1ag Connectivity Fault Management (CFM)
- IEEE 802.1ag Connectivity Fault Management (CFM) for C-VLANs and S-VLANs within an ESI
- IEEE 802.1ag Connectivity Fault Management (CFM) for B-VLANs
- Suport for Sub-second IEEE 802.1ag Timers
- IEEE 802.1ag on VPLS Endpoints
- IEEE 802.1ag over VLL
- MPLS OAM – LSP traceroute
- IEEE 802.3ah EFM-OAM
- Ping
- Ping within a VRF
- Trace Route
- Trace Route within a VRF
- Trace-l2 Protocol
- LSP Ping and Traceroute
- FRR bypass LSPs

Operations, Administration, and Maintenance (OAM) implementation refers to the tools and utilities for installing, monitoring, and troubleshooting the network.

IEEE 802.1ag Connectivity Fault Management (CFM)

Overview

IEEE 802.1ag Connectivity Fault Management (CFM) refers to the ability of a network to monitor the health of a service delivered to customers as opposed to just links or individual bridges.

The IEEE 802.1ag CFM standard specifies protocols, procedures, and managed objects to support transport fault management. This allows for the discovery and verification of the path, through bridges and LANs, taken by frames addressed to and from specified network users and the detection, and isolation of a connectivity fault to a specific bridge or LAN.

Ethernet CFM defines proactive and diagnostic fault localization procedures for point-to-point and multipoint Ethernet Virtual Connections that span one or more links. It operates end-to-end within an Ethernet network.

Ethernet OAM capabilities

Ethernet OAM is able to:

- Monitor the health of links (because providers and customers might not have access to the management layer)
- Check connectivity of ports
- Detect fabric failures
- Provide the building blocks for error localization tools
- Give appropriate scope to customers, providers and operators (hierarchical layering of OAM)
- Avoid security breaches

IEEE 802.1ag purpose

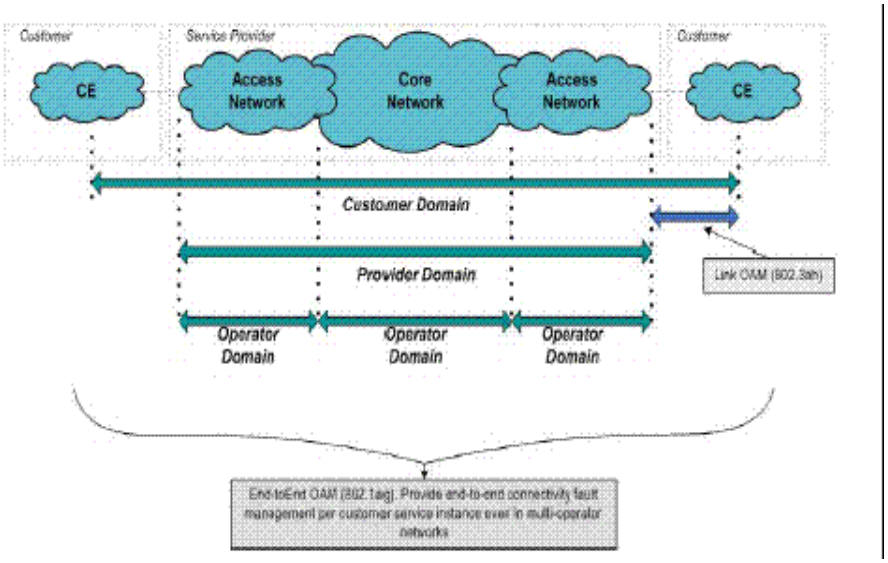
Bridges are increasingly used in networks operated by multiple independent organizations, each with restricted management access to each other's equipment. CFM provides capabilities for detecting, verifying and isolating connectivity failures in such networks.

There are multiple organizations involved in a Metro Ethernet Service: Customers, Service Providers and Operators.

Customers purchase Ethernet Service from Service Providers. Service Providers may utilize their own networks, or the networks of other Operators to provide connectivity for the requested service. Customers themselves may be Service Providers, for example a Customer may be an Internet Service Provider which sells Internet connectivity.

Operators will need minimal Ethernet OAM. Providers will need more comprehensive Ethernet OAM for themselves and to allow customers better monitoring functionality.

FIGURE 234 OAM Ethernet tools



IEEE 802.1ag provides hierarchical network management

Maintenance Domain (MD)

A Maintenance domain is part of a network controlled by a single operator. In Figure 234, we have customer domain, provider domain and operator domain.

Maintenance Domain level (MD level)

The MD levels are carried on all CFM frames to identify different domains.For example, in Figure 234, some bridges belong to multiple domains. Each domain associates a MD level.

- **Customer Level:** 5-7
- **Provider Level:** 3-4
- **Operator Level:** 0-2

Maintenance Association (MA)

Every MD can be further divided into smaller networks having multiple Maintenance End Points (MEP). Usually MA is associated with a service instances (for example a VLAN or a VPLS).

Maintenance End Point (MEP)

MEP is located on the edge of an MA. It defines the endpoint of the MA. Each MEP has unique ID (MEPID) within MA. The connectivity in a MA is defined as connectivity between MEPs. MEP generates Continuity Check Message and multicasts to all other MEPs in same MA to verify the connectivity.

Maintenance Intermediate Point (MIP)

MIP is located within a MA. It responds to Loopback and Linktrace messages for Fault isolation.

Mechanisms of Ethernet IEEE 802.1ag OAM

Mechanisms supported by IEEE 802.1ag include Connectivity Check (CC), Loopback, and Link trace. Connectivity Fault Management allows for end-to-end fault management that is generally reactive (through Loopback and Link trace messages) and connectivity verification that is proactive (through Connectivity Check messages).

Fault detection (continuity check message)

The Continuity Check Message (CCM) provides a means to detect hard and soft faults such as software failure, memory corruption, or misconfiguration. The failure detection is achieved by each Maintenance End Point (MEP) transmitting a CCM periodically within its associated Service Instance.

As a result, MEPs also receive CCMs periodically from other MEPs. If a MEP on local Bridge stops receiving the periodic CCMs from peer MEP on a remote Bridge, it can assume that either the remote Bridge has failed or failure in the continuity of the path has occurred. The Bridge can subsequently notify the network management application about the failure and initiate the fault verification and fault isolation steps either automatically or through operator command.

A CCM requires only N transmissions within its member group, where N is the number of members within the member group. In other words, if a Virtual Bridge LAN Service has N members, only N CCMs need to be transmitted periodically – one from each.

Continuity Check (CC) messages are periodic hello messages multicast by a MEP within the maintenance domain, at the rate of X; X can be 3.3 milliseconds (ms), 10ms, or 100ms, 1 second, 1 minute, or 10 minutes. All Maintenance association Intermediate Points (MIPs) and MEPs in that domain will receive it but will not respond to it. The receiving MEPs will build a MEP database that has entities of the format. MEPs receiving this CC message will catalog it and know that the various maintenance associations (MAs) are functional, including all intermediate MIPs.

CCMs are not directed towards any specific; rather they are multicast across the entire point-to-point or multipoint service on a regular basis. Accordingly, one or more service flows, including the determination of MAC address reachability across a multipoint network, are monitored for connectivity status with IEEE 802.1ag.

Fault verification (Loopback messages)

A unicast Loopback Message is used for fault verification. To verify the connectivity between MEP and its peer MEP or a MIP, the Loopback Message is initiated by a MEP with a destination MAC address set to the MAC address of either a Maintenance association Intermediate Point (MIP) or the peer MEP. The receiving MIP or MEP responds to the Loopback Message with a Loopback Reply.

A Loopback message helps a MEP identify the precise fault location along a given MA. A Loopback message is issued by a MEP to a given MIP along an MA. The appropriate MIP in front of the fault will respond with a Loopback reply. The MIP behind the fault will not respond. For Loopback to work, the MEP must know the MAC address of the MIP to ping.

Fault isolation (Linktrace messages)

Linktrace mechanism is used to isolate faults at Ethernet MAC layer. Linktrace can be used to isolate a fault associated with a given Virtual Bridge LAN Service. It should be noted that fault isolation in a connectionless (multi-point) environment is more challenging than a connection oriented (point-to-point) environment. In case of Ethernet, fault isolation can be even more challenging since a MAC address can age out when a fault isolates the MAC address. Consequently a network-isolating fault results in erasure of information needed for locating the fault.

A Linktrace Message uses a set of reserved multicast MAC address. The Linktrace Message gets initiated by a MEP and traverses hop-by-hop and each Maintenance Point (a MEP or MIP) along the path intercepts this Linktrace Message and forwards it onto the next hop after processing it until it reaches the destination MEP. The processing includes looking at the destination MAC address contained in the Linktrace Message.

Each MP along the path returns a unicast Linktrace Reply back to the originating MEP. The MEP sends a single LTM to the next hop along the trace path; however, it can receive many Linktrace Responses from different MPs along the trace path and the destination MEP as the result of the message traversing hop by hop. As mentioned previously, the age-out of MAC addresses can lead to erasure of information at MIPs, where this information is used for the Linktrace mechanism. Possible ways to address this behavior include:

- Carrying out Linktrace following fault detection or verification such that it gets exercised within the window of age-out.
- Maintaining information about the destination MEP at the MIPs along the path using CCMs.
- Maintaining visibility of path at the source MEPs through periodic LTMs

Linktrace may also be used when no faults are apparent in order to discover the routes normally taken by data through the network. In the rare instances during network malfunctions where Linktrace cannot provide the information needed to isolate a fault, issuing Loopback Messages to MPs along the normal data path may provide additional useful information.

The Linktrace message is used by one MEP to trace the path to another MEP or MIP in the same domain. It is needed for Loopback (Ping). All intermediate MIPs respond back with a Link trace reply to the originating MEP. After decreasing the TTL by one, intermediate MIPs forward the Link trace message until the destination MIP or MEP is reached. If the destination is a MEP, every MIP along a given MA responds to the originating MEP. The originating MEP can then determine the MAC address of all MIPs along the MA and their precise location with respect to the originating MEP.

Configuring IEEE 802.1ag CFM

Enabling or disabling CFM

To enable or disable the CFM protocol globally on the devices and enter into the CFM Protocol Configuration mode, enter a command such as the following.

```
NetIron#(config)cfm-enable
NetIron(config-cfm)#
```

Syntax: [no] cfm-enable

The **no** form of the command disables the CFM protocol.

Creating a Maintenance Domain

A Maintenance Domain is the network or the part of the network for which faults in connectivity are to be managed. A Maintenance Domain consists of a set of Domain Service Access Points.

A Maintenance Domain is, or is intended to be, fully connected internally. A Domain Service Access Point associated with a Maintenance Domain has connectivity to every other Domain Service Access Point in the Maintenance Domain, in the absence of faults.

Each Maintenance Domain can be separately administered.

The **domain-name** command in CFM protocol configuration mode creates a maintenance domain with a specified level and name and enters the Specific Maintenance Domain mode specified in the command argument.

```
NetIron(config-cfm)#domain-name VPLS-SP level 4
NetIron(config-cfm-md-VPLS-SP)#
```

Syntax: [no] domain-name NAME [id <*md-id*>] [level <*level*>]

The **NAME** parameter specifies the domain name. The NAME attribute is case-sensitive.

The **id** <*md-id*> is the Maintenance Domain Index. It is an optional parameter. The range is 1 - 4090.

The **level** parameter sets the domain level in the range 0 – 7. When the domain already exists, the **level** argument is optional. The levels are.

Customer's Domain Levels: 5 - 7

Provider Domain Levels: 3 - 4

Operator Domain Levels: 0 – 2

The **no** form of the command removes the specified domain from the CFM Protocol Configuration mode.

Setting Maintenance Domain parameters

Creating Maintenance Associations

The Maintenance Association Identifier is unique over the domain. If the Maintenance Association Identifier is globally unique, then that domain is global. CFM can detect connectivity errors only for a list of MEPs with unique MAIDs.

The **ma-name** command, in Maintenance Domain mode, creates a maintenance association within a specified domain. The **ma-name** command changes the Maintenance Domain mode to a Specific Maintenance Association mode.

```
NetIron(config-cfm-md-VPLS-SP)# ma-name ma_1 vlan-id 30 priority 4
NetIron(config-cfm-md-VPLS-SP-ma-ma_1)#
```

Syntax: [no] ma-name NAME [id <*ma-id*>] [esi <*esi-id*>] [vlan-id <*vlan-id*>][vpls-id <*vpls-id*>][priority <*priority*>]

The **NAME** parameter specifies the maintenance association name. The NAME attribute is case-sensitive.

The **id** <*ma-id*> is the Maintenence Association Index. It is an optional parameter. The range is 1 - 4090.

The **esi-id** specifies a unique ESI identifier of the maintenance association. In case of creating a MA a ESI ID should be set. This option is available only on platforms that support the Ethernet Service Instance (ESI) framework.

The **vlan-id** specifies a unique VLAN identifier of the maintenance association in the range <*1-4090*>. In case of creating a MA a VLAN ID should be set.

The **vpls-id** specifies a unique VPLS identifier of the maintenance association. In case of creating a MA, a VPLS ID should be set.

The **priority** parameter specifies the priority of the CCM messages, sent by MEPs, in the range <*0-7*>. When the maintenance association is already created, the **priority** argument is optional.

The **no** form of the command removes the created MA.

Configuring a CCM interval for a Maintenance Association (MA)

The **ccm-interval** command sets the time interval between two successive Continuity Check messages (CCMs) that are sent by MEPs in the specified Maintenance Domain. The default value is 10 seconds.

```
NetIron(config-cfm)#domain name VPLS-SP level 4
NetIron(config-cfm-md-VPLS-SP)#ma-name ma_1 vlan-id 30 priority 3
NetIron(config-cfm-md-VPLS-SP-ma-ma_1)#ccm-interval 10-second
NetIron(config-cfm-md-VPLS-SP-ma-ma_1)#
```

Syntax: [no] ccm-interval [1-second | 1-minute | 10-second | 10-minute|3.3-ms | 10-ms | 100-ms]

The **1 second** parameter sets the time interval between two successive CCM packets to 1 second.

The**1 minute** parameter sets the time interval between two successive CCM packets to 1 minute.

The **10 second** parameter sets the time interval between two successive CCM packets to 10 seconds.

The **10 minute** parameter sets the time interval between two successive CCM packets to 10 minutes.

The **3.3 milliseconds** parameter sets the time interval between two successive CCM packets to 3.3 milliseconds.

The **10 milliseconds** parameter sets the time interval between two successive CCM packets to 10 milliseconds.

The **100 milliseconds** parameter sets the time interval between two successive CCM packets to 100 milliseconds.

Configuring local ports

The **mep** command, in Maintenance Association mode, adds local ports as MEP to a specific maintenance association. If configuring a CFM packet to a “down” MEP, it will need to be sent out on the port on which it was configured. If configuring a CFM packet to an “up” MEP, it will need to be sent to the entire VLAN for multicast traffic, and unicast traffic will need to be sent to a particular port according to the MAC table.

Configuring a MED for each of the Domain Service Access Points of a service instance creates a MA to monitor the connectivity:

- The list of MEPs configured with identical values for MA ID defines an MA.
- Each Bridge has its own Maintenance Association managed object for an MA.
- Each individual MEP is configured with a ID that is unique within that MA.
- Each MEP is associated with a Service Access Point that provides access to a single service instance.

NOTE
When configuring 802.1ag over VPLS, if the VPLS endpoint is deleted from the configuration, the MEP configuration is deleted under CFM without warning.

To add local ports to an upstream MEP, enter commands such as the following.

```
NetIron(config-cfm)# domain name VPLS-SP level 4
NetIron(config-cfm-md-VPLS-SP)# ma-name ma_1 vlan-id 30 priority 3
NetIron(config-cfm-md-VPLS-SP-ma_1)# mep 1 up port eth 2/1
NetIron(config-cfm-md-VPLS-SP-ma_1)#
```

Syntax: [no] **mep** <*mep-id*> [**up** I **down**] [**vlan** <*vlan-id*> **port ethernet** <*slot/port*> | **port ethernet** <*slot/port*>]

The **mep-id** parameter specifies the maintenance end point ID (mandatory) in the range <*1-8192*>.

The **up** parameter sets the MEP direction away from the monitored VLAN.

The **down** parameter sets the MEP direction towards the monitored VLAN.

The **vlan-id** parameter specifies the VLAN end-points. It is configured only for MAs associated with VPLS and not configured for MAs with a VLAN.

The **port-id** parameter specifies the target interface on which it is used.

The **no** form of the command removes the specified MEPs.

Configuring Remote MEPs

The **remote-mep** command is used to configure the remote MEP's you are expecting. If a remote MEP is not specified, the remote MEP database is built based on the CCM. If one remote MEP never sends CCM, the failure can not be detected.

```
NetIron(config-cfm-md-VPLS-SP)# ma-name ma_1 vlan-id 30
NetIron(config-cfm-md-VPLS-SP-ma_1)# remote-mep 1 to 120
NetIron(config-cfm-md-VPLS-SP-ma_1)#
```

Syntax: [no] **remote-mep** <*mep-id*> [**to** <*mep-id*>]

The **mep-id** parameter specifies the maintenance end point ID (mandatory) in the range <*1-8192*>.

The **no** form of the command removes the specified remote MEPs.

Setting the Remote Check Start-Delay

When configuring the remote MEPs range, you can set a wait time before the MEPs come up and the CCM check operation is started. The default is set to 30 seconds.

```
NetIron#(config)cfm-enable
NetIron(config-cfm)#rmep-check start-delay 120
NetIron(config-cfm)#
```

Syntax: [no] **rmep-check start-delay** < *seconds*>

The **seconds** parameter is the wait time interval before the CCM check is started. The range is 10 – 600 seconds.

Specifying MIP creation policy

The **mip-policy** command, in Maintenance Association mode, specifies the conditions in which MIPs are automatically created on ports.

NOTE
MIP functionality of 802.1ag over VPLS with sub-second timer will have all the configuration restrictions of the VPLS CPU-protection.

A MIP can be created on a port and VLAN, only when explicit or default policy has been defined for them. For a specific port and VLAN a MIP will be created at the lowest of the levels. Additionally, the level created should be the next higher than the MEP level defined for these port and VLAN.

```
NetIron(config-cfm)#domain name VPLS-SP level 4
NetIron(config-cfm-md-VPLS-SP)#ma-name ma_1 vlan-id 30
NetIron(config-cfm-md-VPLS-SP-ma_1)#mip-policy explicit
NetIron(config-cfm-md-VPLS-SP-ma_1)#
```

Syntax: [no] mip-policy [explicit |default]

Use the **explicit** parameter to specify that explicit MIPs are configured only if a MEP exists on a lower MD Level.

Use the **default** parameter to specify that MIPs will always be created.

The **no** form of the command restores the default Policy.

Y.1731 performance management

The Y.1731 feature provides the following performance monitoring capability for point-to-point links as defined in ITU-T Rec Y.1731:

- Frame Delay Measurement (ETH-DM)
- Frame Delay Measurement Variation

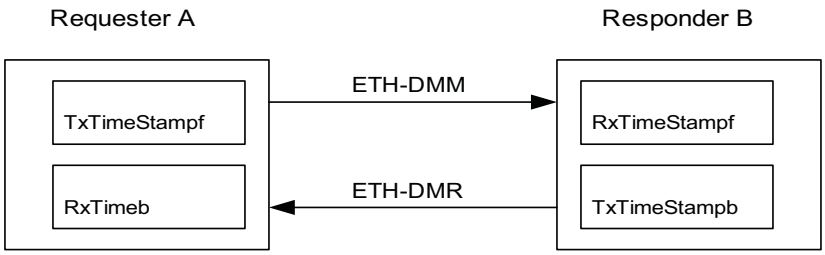
When using Y.1731, ETH-DM can be performed using one-way ETH-DM and two-way ETH-DM.

NOTE
This release of the Multi-Service IronWare only supports two-way ETH-DM.

About Y.1731

Table 422 shows an ETH-DM requester and responder.

TABLE 422 ETH-DM requester and responder.



ETH-DM packets are transmitted, received and processed by LP CPU and are timestamped by the hardware on transmit and receive path.

An ETH-DM packet contains 4 timestamps for measuring the round-trip delay.

Requester A, transmits ETH-DMM packets with TxTimeStampf (timestamp at the transmission time of the packet).

Responder B, responds with an ETH-DMR packet using two timestamps to account for its processing time: RxTimeStampf (Timestamp at the time of receiving the DMM packet) and TxTimeStampb (timestamp at the time of transmitting the DMR packet).

Upon receiving an ETH-DMR packet, requester A stamps the packet with RxTimeb (timestamp at the time the DMR packet is received).

Frame Delay = (RxTimeb – TxTimeStampf) – (TxTimeStampb – RxTimeStampf)

This release provides Y.1731 support for the following:

- VLANs
- VPLS
  - Both VC-mode tagged and raw
- VLL
  - Both tagged and raw modes
- Up and Down MEPs for VLANs, VPLS, and VLL

- Over LAG ports
  - The active primary port of the trunk would be used to transmit ETH-DM frames in case of down MEP
- Through 802.1ag MIPs
  - MIP would behave as a transient node for ETH-DM frames

Configuration considerations:

When using Y.1731, consider the following:

- ETH-DM is reliable only if the transmitted DM frame (DMM) and received DM reply (DMR) are on the same line processor (LP). In the event that they are different, results will not be accurate.
- Maximum frame-delay that can be measured is 4 seconds. If a DMR packet is received with a delay greater than 4 seconds, the packet is discarded and ignored.
- ETH-DM does not gather path data. To determine which path the DM applies to, use the **cfm linktrace domain** command because ETH-DM frames follow the same path.
- One-way ETH-DM is not supported in this release of the Multi-Service IronWare.

Configuring Y.1731 performance monitoring

Use the **cfm delay_measurement domain** command to issue the delay measurement. If the number of delay measurement frame is greater than 16, then the last 16 delay measurement replies are printed.

You can issue the **cfm delay measurement** command from different sessions if they are for different **src-meps**. However, if it is for same **src-mep**, it only completes one session at a time.

```
NetIron# cfm delay_measurement domain md2 ma ma2 src-mep 3 target-mep 2

sent = 10 number = 10 A total of 10 delay measurement replies received.
Success rate is 100 percent (10/10)

================================================================================
Round Trip Frame Delay Time      : min =  31.501 us  avg =  32.586 us  max =  34.052 us

Round Trip Frame Delay Variation : min =      45 ns  avg =     839 ns  max =   1.875 us
================================================================================
```

Syntax: **cfm delay_measurement domain** <domain-name> **ma** <ma-name> **src-mep** <mep-id> **dst-mep** <mep-id> [**timeout** <timeout>] [**number** <number>]

The **domain** <domain-name> parameter specifies the maintenance domain to be used for a delay measurement message. The <domain-name> attribute is case-sensitive.

The **ma** <ma-name> parameter specifies the maintenance association to be used for a delay measurement message. The <ma-name> attribute is case-sensitive.

The **src-mep** <mep-id> parameter specifies the source mep-id in the range <1-8192>.

The **dst-mep** <mep-id> parameter specifies the destination mep-id in the range <1-8192>.

The **number** <number> parameter specifies the number of delay_measurement messages to be sent. The range is 1-1000. The default value is 10. This is an optional parameter.

The **timeout** <timeout> parameter specifies the timeout used to wait for previous delay_measurement reply before sending the next delay_measurement message. The range is 1-4 seconds. The default value is 1second. This is an optional parameter.

If a **delay_measurement** reply is received before the timeout, then the next delay measurement frame is sent immediately after processing the delay measurement reply. However, if the **delay measurement** reply is not received within the specified timeout, then the next **delay measurement** frame will be sent.

Y. 1731 show commands

Use the **show cfm statistic delay_measurement domain** command to display delay measurement statistics. If the command is issued gain, the output is replaced with the new values.

```
NetIron#show cfm statistics delay_measurement domain md2 ma ma2 rmep-id 2
Domain: md2 Level: 7
Maintenance association: ma2 VLAN ID: 2 Priority: 7

================================================================================================
Round Trip Frame Delay Time : min =  31.501 us  avg =  32.586 us  max =  34.052 us

Round Trip Frame Delay Variation : min = 45 ns     avg =     839 ns     max =   1.875 us
================================================================================================

Port Used to transmit delay_measurement: 2/2
Number of delay_measurement frames Used to calculate Statistics: 10
```

Syntax: show cfm statistics delay_measurement domain <domain- name> **ma** <ma-name> **rmep** <rmep-id>

The **domain** <domain-name> parameter specifies the maintenance domain to be used for a delay measurement message. The <domain-name> attribute is case-sensitive.

The **ma** <ma-name> parameter specifies the maintenance association to be used for a delay measurement message. The <ma-name> attribute is case-sensitive.

The **rmep** <rmep-id> parameter specifies the remote mep id to be used for a delay measurement message.

Sample configuration

1. MEP configuration (prerequisite for ETH-DM to work).

Requester-A :

```
NetIron(config)#cfm-enable
NetIron(config-cfm)# domain-name md2 level 7
NetIron(config-cfm-md-md2)#  ma-name ma2 vlan-id 2 priority 7
NetIron(config-cfm-md-md2-ma-ma2)# mep 3 down port ethe 2/2
NetIron(config-cfm-md-md2-ma-ma2)#

Responder-B:
NetIron(config)#cfm-enable
NetIron(config-cfm)# domain-name md2 level 7
NetIron(config-cfm-md-md2)#  ma-name ma2 vlan-id 2 priority 7
NetIron(config-cfm-md-md2-ma-ma2)# mep 2 down port ethe 2/2
NetIron(config-cfm-md-md2-ma-ma2)#
```

2. Issue the **cfm delay_measurement** command.

```
NetIron# cfm delay_measurement domain md2 ma ma2 src-mep 3 target-mep 2

CFM monitoring and show commands

Sending linktrace messages

The **cfm linktrace domain** command sends a linktrace message to a specified MEP in the domain. Enter a command such as the following to send a linktrace mesage to a specified MEP in the domain.

```
NetIron# cfm linktrace domain VPLS-SP ma ma_1 src-mep 21 target-mep 1 timeout 10 t
Linktrace to 000c.dbfb.5378 on Domain VPLS-SP, level 4: timeout 10ms, 4 hops
----------------------------------------------------------------
Hops           MAC             Ingress     Ingress Action   Relay Action
            Forwarded          Egress      Egress Action    Nexthop
----------------------------------------------------------------
   1    000c.dbe2.6ea0                                        RLY_FDB
           Forwarded               5/4           EgrOK
   2    000c.dbfb.5378              7/2           IgrOK      RLY_HIT
        Not Forwarded
Destination 000c.dbfb.5378 reached
```

Syntax: **[no] cfm linktrace domain NAME ma MA-NAME src- mep** <*mep-id*> **dst-mip HH:HH:HH:HH:HH:HH | target-mep** <*mep-id*>} **[timeout** <*timeout*>**] [ttl** <*TTL*>**]**

The **domain** NAME parameter specifies the maintenance domain to be used for a linktrace message. The NAME attribute is case-sensitive.

The **ma** MA NAME parameter specifies the maintenance association to be used for a linktrace message. The NAME attribute is case-sensitive.

The **src-mep** <*mep-id*> parameter specifies the Source ID in the range 1 – 8192.

The **dst-mip** HH:HH:HH:HH:HH:HH parameter specifies the MAC-address of the MIP linktrace destination.

The **dst-mep** <*mepid*> parameter specifies the Destination ID of the linktrace destination.

The **timeout** <*timeout*> parameter specifies the time to wait for a linktrace reply. The range is 1 – 30 seconds.

The **ttl** <*TTL*> parameter specifies the initial TTL field value in the range 1 – 64.The default is 8 seconds.

Sending loopback messages

The **cfm loopback domain** command, sends a loopback message to a specific MIP in a specified domain.

```
NetIron#cfm loopback domain VPLS-SP ma ma_1 src-mep 2 target-mep 1 timeout 10
number 10
cfm: Sending 10  Loopback to 000c.dbfb.5378, timeout 10 msec

Reply from 000c.dbfb.5378: time<1ms
Reply from 000c.dbfb.5378: time<1ms
A total of 10 loopback replies received.
Success rate is 100 percent (10/10), round-trip min/avg/max=0/0/1 ms.
```

Syntax: [no] cfm loopback domain NAME ma MA-NAME scr-mep <*mep-id*> {dst-mip HH:HH:HH:HH:HH:HH | target-mep <*mep-id*>} [number <*number*>] [timeout <*timeout*>]

The **domain** NAME parameter specifies the maintenance domain to be used for a linktrace message. The NAME attribute is case-sensitive.

The **ma** MA-NAME parameter specifies the maintenance association to be used for a linktrace message. The MA-NAME attribute is case-sensitive.

The **src-mep** <*mep-id*> parameter specifies the Source ID in the range <*1-8192*>.

The **dst- mip** HH:HH:HH:HH:HH:HH parameter specifies the MAC address of the MIP linktrace destination.

The **dst-mep** <*mep-id*> parameter specifies the Destination ID in the range <*1-8192*>.

The **number** <*number*> parameter specifies the number of loopback messages to be sent.

The **timeout** <*timeout*> parameter specifies the timeout used to wait for linktrace reply.

Displaying CFM configurations

The **show cfm** command, displays the current configuration and status of CFM. For the **show cfm** command to take effect, CFM should first be enabled in Protocol Configuration mode.

```
NetIron#show cfm
Domain: md2
Index: 1
Level: 6
  Maintenance association: ma2
  Ma Index: 1
  CCM interval: 10000 ms
  VLAN ID: 2
  Priority: 6
  MEP   Direction  MAC             PORT
  ====  =========  =========       ====
     3  DOWN       0012.f2f7.3831  ethe 2/2
```

Syntax: show cfm [domain NAME] [ma NAME]

The [**domain NAME**] parameter specifies a domain for display. By default, all defined domains are shown.

The [**ma NAME**] parameter specifies the maintenance association name. By default, all defined domains are shown.

TABLE 423 Show CFM output descriptions

This field...	Displays...
Domain	The Domain is the network or the part of the network for which faults in connectivity are displayed.
Index	The Domain Index.
Level	The level is the domain level in the range <*0-7*>. The levels can be: • Customer's MD levels: 5 - 7 • Provider's MD levels: 3 - 4 • Operator's MD levels: 0 – 2
Maintenance Association	The maintenance association name.
Ma Index	The Maintenance Association Index.
CCM interval	The time interval between two successive Continuity Check messages (CCMs) that are sent by MEPs in the specified Maintenance Domain.
VLAN ID	The VLAN identifier of the maintenance association.
VPLS ID	The VPLS identifier of the maintenance association.
Priority	The priority of the CCM messages, sent by 'MEPs, in the range <*0-7*>.
MEP	The maintenance end point ID
Direction	DIsplays the direction the MEP was sent: Up - The MEP direction away from the monitored VLAN. Down - The MEP direction is towards the monitored VLAN.
MAC	DIsplays the associated MAC Address.
PORT	DIsplays the associated port.

TABLE 423 Show CFM output descriptions

This field...	Displays...
MIP	DIsplays the associated MIP
VLAN	DIsplays the associated VLAN.

The show cfm brief show a summary of the configured MEPs and RMEPs.

```
NetIron MLXe-4000 Router#show cfm brief
Domain: md2
Index: 1
Level: 6  Num of MA: 1
  Maintenance association: ma2
  MA Index: 1
  CCM interval: 10000 ms

  Priority: 6
  Num of MEP: 1               Num of RMEP: 1
  rmepstart: 0 rmepfail: 0 rmepok 1
```

Syntax: show cfm [domain NAME] [ma NAME] brief

TABLE 424 Show cfm brief output description

This field...	Displays...
Domain	The Domain is the network or the part of the network for which faults in connectivity are displayed.
Index	The Domain Index.
Level	The level is the domain level in the range <*0-7*>. The levels can be: • Customer's MD levels: 5 - 7 • Provider's MD levels: 3 - 4 • Operator's MD levels: 0 – 2
Maintenance Association	The maintenance association name.
Ma Index	The Maintenance Association Index.
CCM interval	The time interval between two successive Continuity Check messages (CCMs) that are sent by MEPs in the specified Maintenance Domain.
VLAN ID	The VLAN identifier of the maintenance association.
VPLS ID	The VPLS identifier of the maintenance association.
Priority	The priority of the CCM messages, sent by 'MEPs, in the range <*0-7*>.
Numof MEP	The number of MEPs configured.
Num of RMEP	The number of remote MEPs configured
remepstart	The number of RMEPs in the start state.
rmepfail	The number of RMEPs that have failed.
rmepok	The number of RMEPs in an OK state.

Displaying connectivity statistics

The **show cfm connectivity** command, displays connectivity statistics for the remote database. For the **show cfm connectivity** command to take effect, CFM should first be enabled in the Protocol Configuration mode.

```
NetIron#show cfm connectivity
Domain: md2 Index: 1
Level: 6
  Maintenance association: ma2
  MA Index: 1
  CCM interval: 10000 ms
  VLAN ID: 2
  Priority: 6
  RMEP  MAC             VLAN/PEER         AGE     PORT     SLOTS
  ====  =====           ===============  =======  ======== =========
     2  0012.f2f7.3931        2               20       2/2 2
```

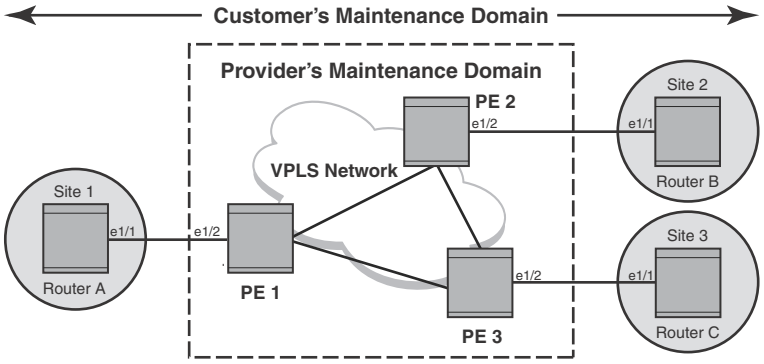
Syntax: show cfm connectivity

TABLE 425 Show CFM connectivity output descriptions

This field...	Displays...
Domain	The Domain is the network or the part of the network for which faults in connectivity are displayed.
Index	The Domain Index.
Level	The level is the domain level in the range <*0-7*>. The levels can be: • Customer's MD levels: 5 - 7 • Provider's MD levels: 3 - 4 • Operator's MD levels: 0 - 2
Maintenance association	The maintenance association name.
Ma Index	The Maintenance Association Index.
CCM interval	The time interval between two successive Continuity Check messages (CCMs) that are sent by MEPs in the specified Maintenance Domain.
VPLS ID	The VPLS identifier of the maintenance association.
Priority	The priority of the CCM messages, sent by MEPs, in the range <*0-7*>.
RMEP	The remote maintenance end point ID
MAC	DIsplays the associated MAC Address.
VLAN or VC	VLAN ID or VC label learned from the CCM packet. VC label is in hexadecimal format.
Age	Uptime since RMEP discovery or from last age out
PORT	Displays the associated port.
SLOTMASK	Mask of slots that are receiving CCM packets which are used for multi-slot trunks. For example a value of 0005 indicates Slots 1 and 3.

Sample configuration for a customer's domain

FIGURE 235 Sample configuration



Configuring Router A

CFM configuration steps for Router A are listed below.

1. To enable CFM, enter the following command.

   ```
   RouterA(config)#cfm-enable
   ```

2. Create a maintenance domain with a specified name CUST_1 and level 7.

   ```
   RouterA(config-cfm)#domain-name CUST_1 level 7
   ```

3. Create a maintenance association within a specified domain of **vlan-id 30** with a priority 3 .

   ```
   RouterA(config-cfm-md-CUST_1)#ma-name ma_5 vlan-id 30 priority 3
   ```

4. Set the time interval between successive Continuity Check Messages to **10-seconds**.

   ```
   RouterA(config-cfm-md-CUST_1-ma-ma_5)#ccm-interval 10-second
   ```

5. Configuring a MED for each of the Domain Service Access Points of a service instance creates a MA to monitor the connectivity. Add ethernet port 1/2 to a specified maintenance association.

   ```
   RouterA(config-cfm-md-CUST_1-ma-ma_5)#mep 2 down vlan 30 port ethe 1/2
   ```

Configuring Router B

CFM configuration steps for Router B are listed below.

1. To enable CFM for VPLS, enter the following command.

   ```
   RouterB(config)#cfm-enable
   ```

2. Create a maintenance domain with a specified name **CUST_1** and level **7**.

   ```
   RouterB(config-cfm)#domain-name CUST_1 level 7
   ```

3. Create a maintenance association within a specified domain of **vlan-id 30** with a priority **5** .

   ```
   RouterB(config-cfm-CUST_1)#ma-name ma_5 vlan-id 30 priority 5
   ```

4. Set the time interval between successive Continuity Check Messages to **10-seconds**.

   ```
   RouterB(config-cfm-md-CUST_1-ma-ma_5)#ccm-interval 10-second
   ```

5. Configuring a MED for each of the Domain Service Access Points of a service instance creates a MA to monitor the connectivity. Add ethernet port **1/2** as MEP to a specified maintenance association.

```
RouterB(config-cfm-md-CUST_1-ma-ma_5)#mep 2 down vlan 30 port ethe 1/2
```

Configuring Router C

CFM configuration steps for Router C are listed below.

1. To enable CFM for VPLS, enter the following command.

```
RouterC(config)#cfm-enable
```

2. Create a maintenance domain with a specified name **CUST_1** and level **7**.

```
RouterC(config-cfm)#domain-name CUST_1 level 7
```

3. Create a maintenance association within a specified domain of **vlan-id 30** with a priority **4** .

```
RouterC(config-cfm-CUST_1)#ma-name ma_5 vlan-id 30 priority 4
```

4. Set the time interval between successive Continuity Check Messages to **10-seconds**.

```
RouterC(config-cfm-md-CUST_1-ma-ma_5)#ccm-interval 10-second
```

5. Configuring a MED for each of the Domain Service Access Points of a service instance creates a MA to monitor the connectivity. Add ethernet port **1/2** as MEP to a specified maintenance association.

```
Routerc(config-cfm-md-CUST_1-ma-ma_5)#mep 1 down vlan 30 port ethe 1/2
```

Configuring CFM using Provider Bridges

Below is an example for configuring CFM when using Provider Bridges configurations as in the figure on "Sample configuration" on page 2189.

Configuring Router A

CFM configuration steps for Router A are listed below.

1. Create the port-based VLAN that contains the tagged interface that you want to use by entering the following commands.

```
RouterA(config)# vlan30
RouterA(config-vlan-30)# tagged ethe 1/1
```

2. To enable CFM, enter the following command.

```
RouterA(config)#cfm-enable
```

3. Create a maintenance domain with a specified name CUST_1 and level 7.

```
RouterA(config-cfm)#domain-name CUST_1 level 7
```

4. Create a maintenance association within a specified ESI **Site1vlan30**, and a **vlan-id 30** with a priority **3**.

```
RouterA(config-cfm-md-CUST_1)#ma-name ma_5 esi Site1vlan30 vlan-id 30 priority
3
```

5. Set the time interval between successive Continuity Check Messages to **10-seconds**.

```
RouterA(config-cfm-md-CUST_1-ma-ma_5)#ccm-interval 10-second
```

6. Configuring a MED for each of the Domain Service Access Points of a service instance creates a MA to monitor the connectivity. Add ethernet port 1/2 to a specified maintenance association.

```
RouterA(config-cfm-md-CUST_1-ma-ma_5)#mep 2 down port ethe 1/2
```

7. To configure the hostnameas **RouterA**, enter a command such as the following.

```
RouterA(config)#hostname RouterA
```

8. Configure interface ethernet 1/1 as the custome-edge by entering the following commands.

```
RouterA(config)#interface ethernet 1/1
RouterA(config-if-e10000-1/1)#port-type customer-edge
RouterA(config-if-e10000-1/1)enable
RouterA(config-if-e10000-1/1)end
```

Configuring Router B

CFM configuration steps for Router B are listed below.

1. Create the port-based VLAN that contains the tagged interface that you want to use by entering the following commands.

```
RouterB(config)# vlan30
RouterB(config-vlan-30)# tagged ethe 1/1
```

2. To enable CFM, enter the following command.

```
RouterB(config)#cfm-enable
```

3. Create a maintenance domain with a specified name CUST_1 and level 7.

```
RouterB(config-cfm)#domain-name CUST_1 level 7
```

4. Create a maintenance association within a specified ESI **Site2vlan30**, and a **vlan-id 30** with a priority **3** .

```
RouterB(config-cfm-md-CUST_1)#ma-name ma_5 esi Site2vlan30 vlan-id 30 priority
3
```

5. Set the time interval between successive Continuity Check Messages to **10-seconds**.

```
RouterB(config-cfm-md-CUST_1-ma-ma_5)#ccm-interval 10-second
```

6. Configuring a MED for each of the Domain Service Access Points of a service instance creates a MA to monitor the connectivity. Add ethernet port 1/2 to a specified maintenance association.

```
RouterB(config-cfm-md-CUST_1-ma-ma_5)#mep 2 down port ethe 1/2
```

7. To configure the hostnameas **RouterB**, enter a command such as the following.

```
RouterB(config)#hostname RouterB
```

8. Configure interface ethernet 1/1 as the custome-edge by entering the following commands.

```
RouterB(config)#interface ethernet 1/1
RouterB(config-if-e10000-1/1)#port-type customer-edge
RouterB(config-if-e10000-1/1)enable
RouterB(config-if-e10000-1/1)end
```

Configuring Router C

CFM configuration steps for Router C are listed below.

1. Create the port-based VLAN that contains the tagged interface that you want to use by entering the following commands.

```
RouterC(config)# vlan30
RouterC(config-vlan-30)# tagged ethe 1/1
```

2. To enable CFM, enter the following command.

```
RouterC(config)#cfm-enable
```

3. Create a maintenance domain with a specified name CUST_1 and level 7.

```
RouterC(config-cfm)#domain-name CUST_1 level 7
```

4. Create a maintenance association within a specified ESI **Site3vlan30**, and a vlan-id 30 with a priority **3** .

```
RouterC(config-cfm-md-CUST_1)#ma-name ma_5 esi Site3vlan30 vlan-id 30 priority
3
```

5. Set the time interval between successive Continuity Check Messages to **10-seconds**.

```
RouterC(config-cfm-md-CUST_1-ma-ma_5)#ccm-interval 10-second
```

6. Configuring a MED for each of the Domain Service Access Points of a service instance creates a MA to monitor the connectivity. Add ethernet port 1/2 to a specified maintenance association.

```
RouterC(config-cfm-md-CUST_1-ma-ma_5)#mep 2 down port ethe 1/2
```

7. To configure the hostnameas **RouterC**, enter a command such as the following.

```
RouterC(config)#hostname RouterC
```

8. Configure interface ethernet 1/1 as the **custome-edge** by entering the following commands.

```
RouterC(config)#interface ethernet 1/1
RouterC(config-if-e10000-1/1)#port-type customer-edge
RouterC(config-if-e10000-1/1)enable
RouterC(config-if-e10000-1/1)end
```

Provider Bridge NetIron1

1. Create the port-based VLAN that contains the tagged interface that you want to use by entering the following commands.

```
NetIron1(config)# vlan30
NetIron1(config-vlan-30)# tagged ethe 1/1
```

2. Create the ESI NetIron**1vlan300** as an encapsulated SVLAN with the ESI client **Site1vlan30** by entering the following commands.

```
NetIron1(config)#esi NetIron1vlan300 encapsulation svlan
NetIron1(config)#esi-client Site1vlan30
```

3. Add the port-based **VLAN300** that contains the tagged interfaces that you want to use by entering the following commands.

```
NetIron1(config)# vlan300
NetIron1(config-vlan-300)# tagged ethe 1/1 ethe 1/3
```

4. To enable CFM, enter the following command.

```
NetIron1(config)#cfm-enable
```

5. Create a maintenance domain with a specified name **CUST_1** and level **5**.

```
NetIron1(config-cfm)#domain-name CUST_1 level 5
```

6. Create a maintenance association within a specified ESI **Site1vlan30**, and a **vlan-id 30** with a priority **3** .

```
NetIron1(config-cfm-md-CUST_1)#ma-name ma_5 esi Site1vlan30 vlan-id 30
priority 3
```

7. Set the time interval between successive Continuity Check Messages to **10-seconds**.

```
NetIron1(config-cfm-md-CUST_1-ma-ma_5)#ccm-interval 10-second
```

8. Configuring a MED for each of the Domain Service Access Points of a service instance creates a MA to monitor the connectivity. Add ethernet port **1/2** as MEP to a specified maintenance association.

```
NetIron1(config-cfm-md-CUST_1-ma-ma_5)#mep 4 up port ethe 1/2
```

9. To configure the hostname as NetIron**1**, enter a command such as the following.

```
NetIron1(config)#hostname NetIron1
```

10. Configure interface ethernet **1/1** as the **provider network** by entering the following commands.

```
NetIron1(config)#interface ethernet 1/1
NetIron1(config-if-e10000-1/1)#port-type provider-network
NetIron1(config-if-e10000-1/1)enable
NetIron1(config-if-e10000-1/1)end
```

11. Configure interface ethernet **1/2** as the **customer-edge** by entering the following commands.

```
NetIron1(config)#interface ethernet 1/2
NetIron1(config-if-e10000-1/2)#port-type custonmer-edge
NetIron1(config-if-e10000-1/2)enable
NetIron1(config-if-e10000-1/2)end
```

12. Configure interface ethernet **1/3** as the **provider network** by entering the following commands.

```
NetIron1(config)#interface ethernet 1/3
NetIron1(config-if-e10000-1/3)#port-type provider-network
NetIron1(config-if-e10000-1/3)enable
NetIron1(config-if-e10000-1/3)end
```

Provider Bridge NetIron2

1. Create the port-based **VLAN300** that contains the tagged interfaces that you want to use by entering the following commands.

```
NetIron2(config)# vlan300
NetIron2(config-vlan-300)# tagged ethe 1/1 ethe 1/3
```

2. To enable CFM, enter the following command.

```
NetIron2(config)#cfm-enable
```

3. Create a maintenance domain with a specified name **CUST_1** and level **5**.

```
NetIron2(config-cfm)#domain-name CUST_1 level 5
```

4. Create a maintenance association within a specified ESI **Site2vlan30**, and a **vlan-id 30** with a priority **3**.

```
NetIron2(config-cfm-md-CUST_1)#ma-name ma_5 esi Site2vlan30 vlan-id 30
priority 3
```

5. Set the time interval between successive Continuity Check Messages to **10-seconds**.

```
NetIron2(config-cfm-md-CUST_1-ma-ma_5)#ccm-interval 10-second
```

6. Configuring a MED for each of the Domain Service Access Points of a service instance creates a MA to monitor the connectivity. Add ethernet port **1/2** as MEP to a specified maintenance association.

```
NetIron2(config-cfm-md-CUST_1-ma-ma_5)#mep 5 up port ethe 1/2
```

7. To configure the hostname as NetIron**1**, enter a command such as the following.

```
NetIron2(config)#hostname NetIron1
```

8. Configure interface ethernet **1/1** as the **provider network** by entering the following commands.

```
NetIron2(config)#interface ethernet 1/1
NetIron2(config-if-e10000-1/1)#port-type provider-network
NetIron2(config-if-e10000-1/1)enable
NetIron2(config-if-e10000-1/1)end
```

9. Configure interface ethernet **1/2** as the **customer-edge** by entering the following commands.

```
NetIron2(config)#interface ethernet 1/2
NetIron2(config-if-e10000-1/2)#port-type custonmer-edge
NetIron2(config-if-e10000-1/2)enable
NetIron2(config-if-e10000-1/2)end
```

10. Configure interface ethernet **1/3** as the **provider network** by entering the following commands.

```
NetIron2(config)#interface ethernet 1/3
NetIron2(config-if-e10000-1/3)#port-type provider-network
NetIron2(config-if-e10000-1/3)enable
NetIron2(config-if-e10000-1/3)end
```

Provider Bridge NetIron3

1. Create the port-based VLAN that contains the tagged interface that you want to use by entering the following commands.

```
NetIron3(config)# vlan30
NetIron3(config-vlan-30)# tagged ethe 1/2
```

2. Create the ESI NetIron**3vlan300** as an encapsulated SVLAN with the ESI client **Site3vlan30** by entering the following commands.

```
NetIron3(config)#esi NetIron3vlan300 encapsulation svlan
NetIron3(config)#esi-client Site3vlan30
```

3. Add the port-based **VLAN300** that contains the tagged interfaces that you want to use by entering the following commands.

```
NetIron3(config)# vlan300
NetIron3(config-vlan-300)# tagged ethe 1/1 ethe 1/3
```

4. To enable CFM, enter the following command.

```
NetIron3(config)#cfm-enable
```

5. Create a maintenance domain with a specified name **CUST_1** and level **5**.

```
NetIron3(config-cfm)#domain-name CUST_1 level 5
```

6. Create a maintenance association within a specified ESI **Site3vlan30**, and a **vlan-id 30** with a priority **3**.

```
NetIron3(config-cfm-md-CUST_1)#ma-name ma_5 esi Site3vlan30 vlan-id 30
priority 3
```

7. Set the time interval between successive Continuity Check Messages to **10-seconds**.

```
NetIron3(config-cfm-md-CUST_1-ma-ma_5)#ccm-interval 10-second
```

8. Configuring a MED for each of the Domain Service Access Points of a service instance creates a MA to monitor the connectivity. Add ethernet port **1/2** as MEP to a specified maintenance association.

```
NetIron3(config-cfm-md-CUST_1-ma-ma_5)#mep 6 up port ethe 1/2
```

9. To configure the hostname as NetIron**3**, enter a command such as the following.

```
NetIron3(config)#hostname NetIron3
Configure interface ethernet 1/1 as the provider network by entering the
following commands:
NetIron3(config)#interface ethernet 1/1
NetIron3(config-if-e10000-1/1)#port-type provider-network
NetIron3(config-if-e10000-1/1)enable
NetIron3(config-if-e10000-1/1)end
```

10. Configure interface ethernet **1/2** as the **customer-edge** by entering the following commands.

```
NetIron3(config)#interface ethernet 1/2
NetIron3(config-if-e10000-1/2)#port-type custonmer-edge
NetIron3(config-if-e10000-1/2)enable
NetIron3(config-if-e10000-1/2)end
```

11. Configure interface ethernet **1/3** as the **provider network** by entering the following commands.

```
NetIron3(config)#interface ethernet 1/3
NetIron3(config-if-e10000-1/3)#port-type provider-network
NetIron3(config-if-e10000-1/3)enable
NetIron3(config-if-e10000-1/3)end
```

Displaying the connectivity status in a customer's domain

The following output are for 3 VPLS CEs. The 3 CEs are monitoring Ethernet LAN service in VLAN 30. The Ethernet SP is providing transport service for the customer's VLAN 30 through VPLS which is transparent to customer. The customer is only concerned about RMEPs from remote sites.

```

Sample configuration for a customer domain using MPLS VLL

The topology inside an MPLS networks can be managed by using LSP ping and LSP trace route to detect and diagnose LSP failures. CFM packets are Ethernet packets with well know CFM etype and are not shown in the MPLS cloud. Therfore, the topology inside MPLS cannot be managed by the CFM protocol. However, you can use CFM to monitor the health of a VPLS or VLL instances.

FIGURE 236 Sample configuration

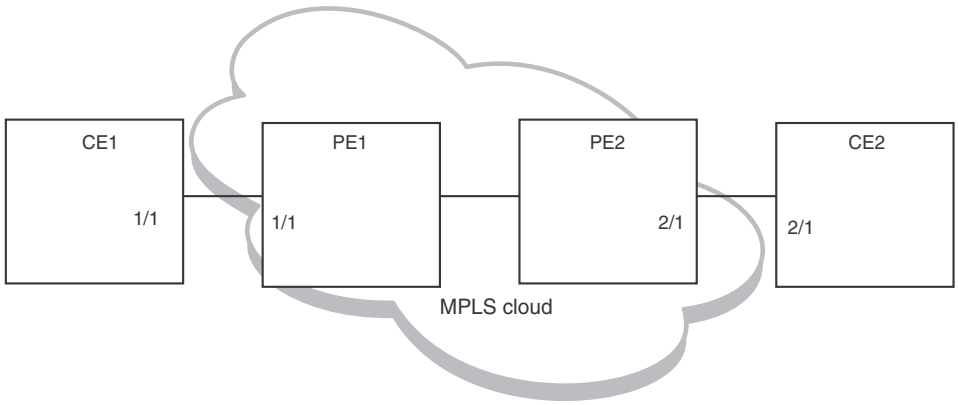

Figure 236 shows a deployment scenario where CE1 and CE2 are customer devices and PE1 and PE2 are provider routers. Port 1/1 on PE1 and port 2/1 on PE2 are VLL-end points. Port 1/1 on PE1 is connected to port 1/1 on CE1 and port 2/1 on PE2 is connected to port 2/1 on CE2.

Achieving end-to-end connectivity between CE1 and CE2

To achieve end-to-end connectivity between CE1 and CE2, configure DOWN MEP on 1/1 and 2/1.PE1 and PE2 acts as MIP. The configuration for this is as follows.

Configuring CE1

1. To enable CFM, enter the following command.

   ```
   CE1(config)#cfm-enable
   ```

2. Create a maintenance domain with a specified name CUST_1 and level 7.

   ```
   CE1(config-cfm)#domain-name CUST_1 level 7
   ```

3. Create a maintenance association within a specified domain of vlan-id 30 with a priority 3.

   ```
   CE1(config-cfm-md-CUST_1)#ma-name ma_5 vlan-id 30 priority 3
   ```

4. Set the time interval between successive Continuity Check Messages.The default is 10-seconds.

   ```
   CE1(config-cfm-md-CUST_1-ma-ma_5)#ccm-interval 10-second
   ```

5. Configure a MEP on port 1/1 and vlan 30.

   ```
   CE1(config-cfm-md-CUST_1-ma-ma_5)#mep 1 down vlan 30 port ethe 1/1
   ```

6. 6. Configure a remote-mep.

   ```
   CE1(config-cfm-md-CUST_1-ma-ma_5)#remote-mep 2 to 2
   ```

Configuring CE2

1. To enable CFM, enter the following command.

   ```
   CE2(config)#cfm-enable
   ```

2. Create a maintenance domain with a specified name CUST_1 and level 7.

   ```
   CE2(config-cfm)#domain-name CUST_1 level 7
   ```

3. Create a maintenance association within a specified domain of vlan-id 30 with a priority 3.

   ```
   CE2(config-cfm-md-CUST_1)#ma-name ma_5 vlan-id 30 priority 3
   ```

4. Set the time interval between successive Continuity Check Messages.The default is 10-seconds.

   ```
   CE2(config-cfm-md-CUST_1-ma-ma_5)#ccm-interval 10-second
   ```

5. Configure a MEP on port 2/1 and vlan 30.

   ```
   CE1(config-cfm-md-CUST_1-ma-ma_5)#mep 2 down vlan 30 port ethe 2/1
   ```

6. Configure a remote-mep.

   ```
   CE1(config-cfm-md-CUST_1-ma-ma_5)#remote-mep 1 to 1
   ```

MPLS Configurations on PE1

Before configuring CFM on PE1, the MPLS Configuration on PE1 must be done.

Enter the following commands to configure VLL peers from PE1 to PE 2.

1. To create a VLL instance, enter commands such as the following.

```
PE1(config)#router mpls
PE1(config-mpls)vll pe1-to-pe2 30
```

2. To specify a VLL peer, enter a command such as the following.

```
PE1(config-mpls-vll)vll-peer 1.1.1.2
```

3. To specify an un-tagged endpoint for a VLL instance, enter the following commands.

```
PE1(config-mpls-vll)untagged ethe 1/1
```
Tagged ports are configured under a VLAN ID.

4. To specify a tagged endpoint for a VLL instance, enter the following commands.

```
PE1(config-mpls-vll)vlan 30
PE1(config-mpls-vll-vlan)tagged ethe 1/1
```

IEEE 802.1ag Configuration on PE1

If the VLL configuration is not done prior to configuring the maintenance association, then the maintenance association is not allowed.

1. To enable CFM, enter the following command.

```
PE1(config)#cfm-enable
```

2. Create a maintenance domain with a specified name CUST_1 and level 7.

```
PE1(config-cfm)#domain-name CUST_1 level 7
```

3. Create a maintenance association within a specified domain of vll-id 30 with a priority 3.

```
PE1(config-cfm-md-CUST_1)#ma-name ma_5 vll-id 30 priority 3
```

4. Set the time interval between successive Continuity Check Messages.The default is 10-seconds.

```
PE1(config-cfm-md-CUST_1-ma-ma_5)#ccm-interval 10-second
```
In the above configuration, a MIP (Maintenance Intermediate Point) is created by default on the VLL port. You can also configure an explicit MIP on PE1. In that case, MIP is created on the VLL-port if there is a MEP (Maintenance End Point) created on the port at some lower Maintenance Domain Level.

5. To configure an explicit MIP on PE1, enter the following command.

```
PE1(config-cfm-md-CUST_1-ma-ma_5)# mip-creation explicit
```

6. To change back to default use the following command .

```
PE1(config-cfm-md-CUST_1-ma-ma_5)# mip-creation default
```

MPLS Configurations on PE2

Before configuring CFM on PE2, MPLS is configured on PE2.

Use the following steps to configure VLL peers from PE2 to PE 1.

1. To create a VLL instance, enter commands such as the following.

```
PE2(config)#router mpls
PE2(config-mpls)vll pe2-to-pe1 30
```

2. To specify a VPLS peer enter a command such as the following.

```
PE2(config-mpls-vll)vpls-peer 1.1.1.1
```

3. To specify an un-tagged endpoint for a VLL instance, enter the following commands.

```
PE2(config-mpls-vll)untagged ethe 2/1
```
Tagged ports are configured under a VLAN ID.

4. To specify a tagged endpoint for a VLL instance, enter the following commands.

```
PE2(config-mpls-vll)vlan 30
PE2(config-mpls-vll-vlan)tagged ethe 2/1
```

IEEE 802.1ag Configurations on PE2

If the VLL configuration is not done prior to configuring the maintenance association, then the maintenance association is not allowed.

1. To enable CFM, enter the following command.

```
PE2(config)#cfm-enable
```

2. Create a maintenance domain with a specified name CUST_1 and level 7.

```
PE2(config-cfm)#domain-name CUST_1 level 7
```

3. Create a maintenance association within a specified domain of vll-id 30 with a priority 3 .

```
PE2(config-cfm-md-CUST_1)#ma-name ma_5 vll-id 30 priority 3
```

4. Set the time interval between successive Continuity Check Messages.The default is 10-seconds.

```
PE2(config-cfm-md-CUST_1-ma-ma_5)#ccm-interval 10-second
```
In the above configuration, MIP is created by default on the VLL-endpoint. You can also configure an explicit-mip on PE2. In that case, MIP is created on the VLL-port if there is a MEP is created on the endpoint at some lower MD Level.

5. To configure an explicit-mip on PE2, enter the following command.

```
PE2(config-cfm-md-CUST_1-ma-ma_5)# mip-creation explicit
```

6. To change back to default use the following command.

```
PE2(config-cfm-md-CUST_1-ma-ma_5)# mip-creation default
```

Verifying connectivity using IEEE 802.1ag

Once CE1,CE2,PE1 and PE2 are configured, you can determine the end-to-end connectivity by looking at the remote-mep status by using the following show commands.

```
CE1#show cfm connectivity
Domain: CUST_1 Level: 7
Maintenance association: ma_5
CCM interval: 10000 ms
VLAN ID: 30
Priority: 3
RMEP MAC          VLAN/PEER AGE PORT SLOTS
==== ================== ==== ==== ====
2   000c.dbe2.8a00 30 879 1/2 1,
CE1#show cfm connectivity domain CUST_1 ma ma_5 rmep-id 2
Domain: CUST_1 Level: 7
```

```
Maintenance association: ma_5 VLAN ID: 30 Priority: 3
CCM interval: 10
RMEP  MAC      PORT Oper Age CCM  RDI   Port   Intf  Intvl  Seq
State Val Cnt Status Status  Error  Error
==== =============== === === ===== ===  ===  ====  ====== ====== ====
2      000c.dbe2.8a00 1/1 OK  26000 2600 N     0      0      N      N=
```

Syntax: show cfm connectivity [domain <*name*>**] [ma MA** <*name*>**]**

The [**domain** <*name*>] parameter displays the specific domain information. By default, all defined domains are shown.

The [**ma** <*name*>] parameter specifies the maintenance association name. By default, all defined domains are shown.

TABLE 426 Show CFM connectivity output descriptions

This field...	Displays...
Domain	The Domain is the network or the part of the network for which faults in connectivity are displayed.
Level	The level is the domain level in the range <*0-7*>. The levels can be: • Customer's MD levels: 5 - 7 • Provider's MD levels: 3 - 4 • Operator's MD levels: 0 - 2
Maintenance association	The maintenance association name.
CCM interval	The time interval between two successive Continuity Check messages (CCMs) that are sent by MEPs in the specified Maintenance Domain.
VPLS ID	The VPLS identifier of the maintenance association.
Priority	The priority of the CCM messages, sent by MEPs, in the range <*0-7*>.
RMEP	The remote maintenance end point ID
MAC	DIsplays the associated MAC Address.
VLAN/VC	VLAN ID or VC label learned from the CCM packet. VC label is in hexadecimal format.
Age	Uptime since RMEP discovery or from last age out
PORT	DIsplays the associated port.
SLOTMASK	Mask of slots that are receiving CCM packets which are used for multi-slot trunks. For example a value of 0005 indicates Slots 1 and 3.

Verifying connectivity in a VLL network using IEEE 802.1ag Loopback

You can manually monitor the status of a VLL peer using IEEE 802.1ag CFM Loopback (MAC ping) as shown below.

```
CE1#cfm loopback domain CUST_1 ma ma_5 src-mep 1 target-mep 2
DOT1AG: Sending 10 Loopback to 000c.dbe2.8a00, timeout 10000 msec
Type Control-c to abort
Reply from 000c.dbe2.8a00: time=3ms
Reply from 000c.dbe2.8a00: time<1ms
Reply from 000c.dbe2.8a00: time<1ms
Reply from 000c.dbe2.8a00: time<1ms
Reply from 000c.dbe2.8a00: time=38ms
Reply from 000c.dbe2.8a00: time<1ms
Reply from 000c.dbe2.8a00: time<1ms
Reply from 000c.dbe2.8a00: time<1ms
Reply from 000c.dbe2.8a00: time<1ms
Reply from 000c.dbe2.8a00: time<1ms
A total of 10 loopback replies received.
Success rate is 100 percent (10/10), round-trip min/avg/max=0/4/38 ms.
```

Syntax: [no] cfm linktrace domain NAME ma MA-NAME src- mep <*mep-id*> dst-mip HH:HH:HH:HH:HH:HH | target-mep <*mep-id*>} [timeout <*timeout*>] [ttl <*TTL*>]

The **domain** NAME parameter specifies the maintenance domain to be used for a linktrace message. The NAME attribute is case-sensitive.

The **ma** MA NAME parameter specifies the maintenance association to be used for a linktrace message. The NAME attribute is case-sensitive.

The **src-mep** <*mep-id*> parameter specifies the Source ID in the range 1 – 8192.

The **dst-mip** HH:HH:HH:HH:HH:HH parameter specifies the MAC-address of the MIP linktrace destination.

The **dst-mep** <*mepid*> parameter specifies the ID of the linktrace destination.

The **timeout** <*timeout*> parameter specifies the time to wait for a linktrace reply. The range is 1 – 30 seconds.

The **ttl** <*TTL*> parameter specifies the initial TTL field value in the range 1 – 64.The default is 8 seconds

Verifying Connectivity in a VLL Network Using IEEE 802.1ag Linktrace

You can manually monitor the status of a VLL peer using IEEE 802.1ag CFM Loopback (MAC Ping) as shown below.

```
NetIron1#cfm linktrace domain CUST_1 ma ma_5 src-mep 1 target-mep 2
Linktrace to 000c.dbe2.8a00 on Domain CUST_1, level 4: timeout 10ms, 8 hops
-------------------------------------------------------------
Hops   MAC     Ingress  Ingress Action  Relay Action
Forwarded  Egress   Egress Action    Nexthop
-------------------------------------------------------------
Type Control-c to abort
1   000c.dbe2.8a00 1.1.1.1   IgrOK          RLY_HIT
Not Forwarded
Destination 000c.dbe2.8a00 reached
```

Syntax: [no] cfm loopback domain NAME ma MA-NAME scr-mep <*mep-id*> {dst-mip HH:HH:HH:HH:HH:HH | target-mep <*mep-id*>} [number <*number*>] [timeout <*timeout*>]

The **domain** NAME parameter specifies the maintenance domain to be used for a linktrace message. The NAME attribute is case-sensitive.

The **ma** MA-NAME parameter specifies the maintenance association to be used for a linktrace message. The MA-NAME attribute is case-sensitive.

The **src-mep** <*mep-id*> parameter specifies the Source ID in the range <*1-8192*>.

The **dst- mip** HH:HH:HH:HH:HH:HH parameter specifies the MAC address of the MIP linktrace destination.

The **dst-mep** <*mep-id*> parameter specifies the Destination ID in the range <*1-8192*>.

The **number** <*number*> parameter specifies the number of loopback messages to be sent.

The **timeout** <*timeout*> parameter specifies the timeout used to wait for linktrace reply.

If the linktrace and loopback to target-mep 2 fails, then the linktrace can be done on the MIPs on PE1 and PE2 to know the exact failure.

Deployment scenario with PEs functioning as DOWN MEP

It is also possible to configure DOWN MEP on VLL end-points. For example, in Figure 236 , the DOWN MEP can be configured to monitor the connectivity between CE1 and PE1 or to monitor the connectivity between CE2 and PE2.

Configuring CE1

1. To enable CFM, enter the following command.

   ```
   CE1(config)#cfm-enable
   ```

2. Create a maintenance domain with a specified name CUST_2 and level 6.

   ```
   CE1(config-cfm)#domain-name CUST_2 level 6
   ```

3. Create a maintenance association within a specified domain of vlan-id 30 with a priority 3 .

   ```
   CE1(config-cfm-md-CUST_2)#ma-name ma_6 vlan-id 30 priority 3
   ```

4. Set the time interval between successive Continuity Check Messages.The default is 10-seconds.

   ```
   CE1(config-cfm-md-CUST_2-ma-ma_6)#ccm-interval 10-second
   ```

5. Configure a MEP on port 1/1 and vlan 30.

   ```
   CE1 (config-cfm-md-CUST_2-ma-ma_6)#mep 3 down vlan 30 port ethe 1/1
   ```

6. Configure a remote-mep.

   ```
   CE1(config-cfm-md-CUST_1-ma-ma_5)#remote-mep 4 to 4
   ```

Configuring PE1

The MPLS-VLL configuration is the same as shown in the previous deployment scenario. If the VLL configuration is not done prior to configuring maintenance association, the MA configuration will not be allowed. Also the port and vlan in the MEP configuration should exist in the VLL configuration prior to MEP configuration , otherwise it is not allowed. The port in the MEP configuration can be either a tagged or untagged port already present in the VLL configuration.

1. To enable CFM, enter the following command.

   ```
   PE1(config)#cfm-enable
   ```

2. Create a maintenance domain with a specified name CUST_2 and level 6.

   ```
   PE1(config-cfm)#domain-name CUST_2 level 6
   ```

3. Create a maintenance association within a specified domain of vll-id 30 with a priority 3 .

```
PE1(config-cfm-md-CUST_2)#ma-name ma_6 vll-id 30 priority 3
```

4. Set the time interval between successive Continuity Check Messages.The default is 10-seconds.

```
PE1(config-cfm-md-CUST_2-ma-ma_6)#ccm-interval 10-second
```

5. Configure a MEP on port 1/1 and vlan 30

```
CE-1 (config-cfm-md-CUST_2-ma-ma_6)#mep 4 down vlan 30 port ethe 1/1
```

To monitor the connectivity between CE-1 and PE-1, you can use the **show cfm connectivity** commands as mentioned in the previous scenario. You can also use the **loopback** or **linktrace** commands on CE-1 or PE-1.

Deployment scenario with PEs functioning as UP MEP

UP MEPs can also be configured on PEs. This monitors connectivity of VLL end points.

Configuring PE1

The MPLS-VLL configuration is the same as shown in the previous deployment scenario. If the VLL configuration is not done prior to configuring maintenance association,the MA configuration would not be allowed. Also the port and vlan in the MEP configuration should exist in VLL configuration prior to MEP configuration , otherwise it will not be allowed. The port in the MEP configuration can be either a tagged or untagged port already present in VLL configuration.

1. To enable CFM, enter the following command.

```
PE1(config)#cfm-enable
```

2. Create a maintenance domain with a specified name PROVIDER_1 and level 4.

```
PE1(config-cfm)#domain-name PROVIDER_1 level 4
```

3. Create a maintenance association within a specified domain of vll-id 30 with a priority 3 .

```
PE1(config-cfm-md-PROVIDER_1)#ma-name ma_8 vll-id 30 priority 3
```

4. Set the time interval between successive Continuity Check Messages.The default is 10-seconds.

```
PE1(config-cfm-md-PROVIDER_1-ma-ma_8)#ccm-interval 10-second
CE1 (config-cfm-md-PROVIDER_1-ma-ma_8)#mep 6 up vlan 30 port ethe 1/1
```

Configuring PE2

The configuration on PE1 is similar to the PE1 configuration.

1. To enable CFM, enter the following command.

```
PE2(config)#cfm-enable
```

2. Create a maintenance domain with a specified name PROVIDER_1 and level 4.

```
PE2(config-cfm)#domain-name PROVIDER_1 level 4
```

3. Create a maintenance association within a specified domain of vll-id 30 with a priority 3 .

```
PE1(config-cfm-md-PROVIDER_1)#ma-name ma_8 vll-id 30 priority 3
```

4. Set the time interval between successive Continuity Check Messages.The default is 10-seconds.

```
PE1(config-cfm-md-PROVIDER_1-ma-ma_8)#ccm-interval 10-second
CE1 (config-cfm-md-PROVIDER_1-ma-ma_8)#mep 7 up vlan 30 port ethe 2/1
```

To monitor the connectivity between PE1 and PE2, you could use the "`show cfm connectivity`" commands as mentioned in the previous scenario. Also you could use either loopback or linktrace on PE1 or PE2.

Configuring PE2

1. To enable CFM, enter the following command.

```
PE2(config)#cfm-enable
```

2. Create a maintenance domain with a specified name PROVIDER_1 and level 4.

```
PE2config-cfm)#domain-name PROVIDER_1 level 4
```

3. Create a maintenance association within a specified domain of vll-id 30 with a priority 3 .

```
PE1(config-cfm-md-PROVIDER_1)#ma-name ma_8 vll-id 30 priority 3
```

4. Set the time interval between successive Continuity Check Messages.The default is 10-seconds.

```
PE1(config-cfm-md-PROVIDER_1-ma-ma_8)#ccm-interval 10-second
```

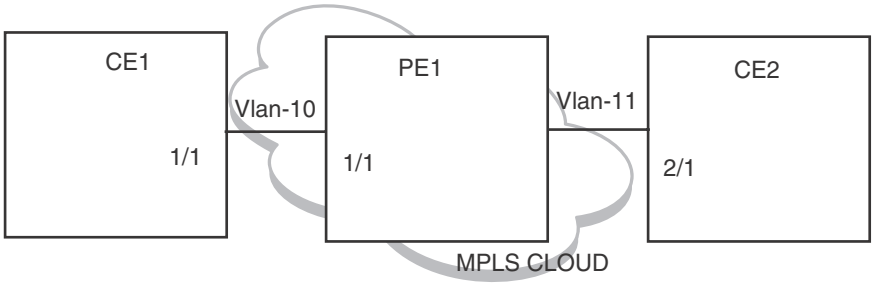
5. Configure MEP 4 down on port 1/1 and vlan 30

```
CE-1 (config-cfm-md-CUST_2-ma-ma_6)#mep 4 down vlan 30 port ethe 1/1
```

To monitor the connectivity between PE-1 and PE-2, we could use "**show cfm connectivity**" commands as mentioned in the previous scenario. Also we could use either loopback or linktrace on PE-1 or PE-2.

IEEE 802.1ag with VLL-LOCAL

FIGURE 237 IEEE 802.1ag over VLL-LOCAL



In the case of IEEE 802.1ag over VLL-LOCAL, the PE acts as a MIP and VLL does VLAN translation. As shown in Figure 237. MEP is configured on vlan-10 on CE1 and vlan-11 on CE2. On PE1 , MIP is configured on VLL-LOCAL and which has vlan-10, port 1/1 and vlan-11,port 2/1 configured as end points.

UP MEP would not be allowed for VLL-Local.

MPLS configurations on PE1

Before configuring CFM on PE1 we need to do MPLS Configuration on PE1.

Enter the following commands to configure VLL peers from PE1 to PE 2.

1. To create a VLL instance, enter commands such as the following.

```
PE1(config)#router mpls
PE1(config-mpls)vll-local test1
```

2. To specify an un-tagged endpoint for a VLL instance, enter the following commands.

```
PE1(config-mpls-vll-test1)untagged ethe 1/1
```

Tagged ports are configured under a VLAN ID.

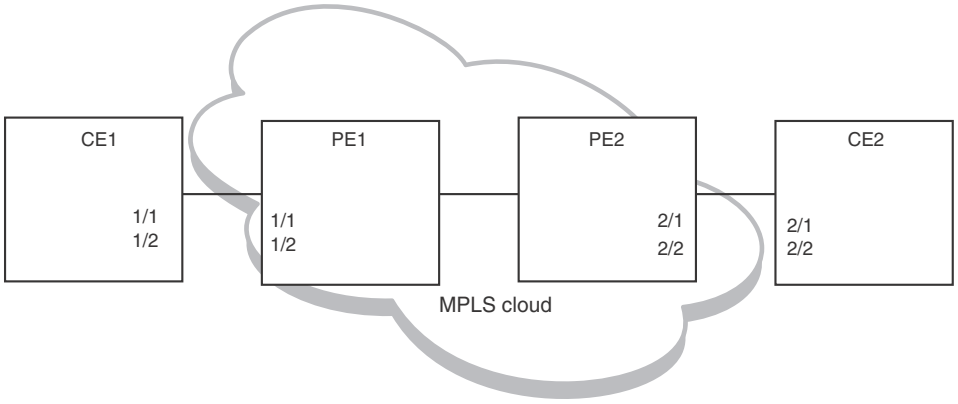
3. To specify a tagged endpoint for a VLL instance, enter the following commands.

```
PE1(config-mpls-vll-test1)vlan 30
PE1(config-mpls-vll-vlan)tagged ethe 1/1
```

As in the previous case, to monitor the connectivity between CE1 and CE2, you can use "**show cfm connectivity**" commands as mentioned in the previous scenario. Also we could use either loopback or linktrace on CE1 or CE2.

LAG-support for IEEE 802.1ag-over-vll

FIGURE 238 - IEEE 802.1ag over VLL scenerio



As shown in Figure 238, you can have MEP configuration over a LAG port. On CE1 and CE2 DOWN MEP is configured on VLAN and on PE1 and PE2 DOWN or UP MEP would be configured, depending on what to monitor.

The configuration and monitoring of MEPs is similar as mentioned in the previous examples.

Deletion of VLL

NOTE
Deletion of VLL would cause the deletion of Maintenance Association and corresponding MEPs on that MA.

Sub-second timer support

The ccm-interval command sets the time interval between two successive Continuity Check messages (CCMs) that are sent by MEPs in the specified Maintenance Domain. The default value is 10 seconds. There is support for sub-second timers 3.3 ms, 10 ms and 100 ms. As in the case of VLAN and VPLS, for sub-second timers pbif hardware assist is used to transmit and process the CCM packets.

NOTE
The sub-second timer functionality is not supported on VLL-Local.

Hitless upgrade support

Hitless upgrade support for IEEE 802.1ag over VLL is similar to IEEE 802.1ag hitless upgrade support for VLAN/VPLS.

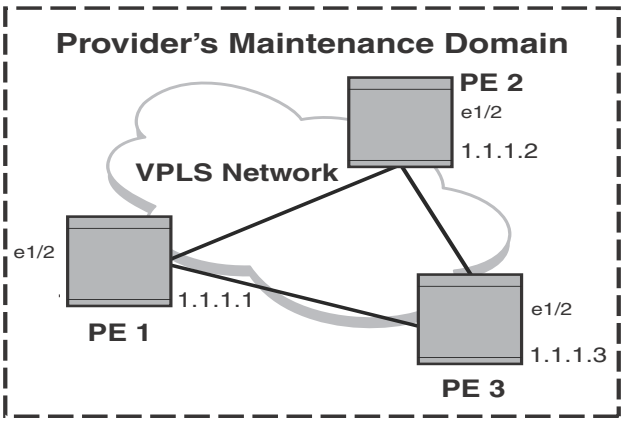
Monitoring the status of devices in a VPLS network in a Provider's Maintenance Domain

CFM provides capabilities to detect, verify, and isolate connectivity failures.

NOTE
When configuring 802.1ag over VPLS, if the VPLS endpoint is deleted from the configuration, the MEP configuration is deleted under CFM without warning.

In the Figure 239, CFM is applied over a VPLS network; ports 1/2 and 1/3 are customer facing networks; and port 1/1 is an uplink to a VPLS cloud.

FIGURE 239 VPLS cloud with CFM enabled



Configuring PE 1

1. To enable CFM for VPLS, enter the following command.

```
PE1(config)#cfm-enable
```

2. Create a maintenance domain with a specified name **VPLS-SP** and level **4**.

```
PE1(config-cfm)#domain-name VPLS-SP level 4
```

3. Create a maintenance association within a specified domain of **vpls-id 1** with a priority **3** .

```
PE1(config-cfm-md-VPLS-SP)#ma-name ma_1 vpls-id 1 priority 3
```

4. Configuring a MED for each of the Domain Service Access Points of a service instance creates a MA to monitor the connectivity. Add ethernet port **1/2** as MEP to a specified maintenance association.

```
PE1(config-cfm-md-VPLS-SP-ma-ma_1)#mep 1 up vlan 30 port ethe 1/2
```

MPLS configurations

Enter the following commands to configure VPLS peers from PE 2 to PE3.

1. To create a VPLS instance, enter commands such as the following.

```
PE1(config)#router mpls
PE1(config-mpls)#vpls 1 1
```

2. To specify two remote VPLS peers within a VPLS instance, enter a commands such as the following.

```
PE1(config-mpls-vpls-1)#vpls-peer 1.1.1.2
PE1(config-mpls-vpls-1)#vpls-peer 1.1.1.3
```

3. Tagged ports are configured under a VLAN ID. To specify a tagged endpoint for a VPLS instance, enter the following commands.

```
PE1(config-mpls-vpls-1)#vlan 30
PE1(config-mpls-vpls-1-vlan-30)#tagged ethe 1/2 to 1/3
```

Configuring PE 2

CFM configuration steps for Router 2 are listed below.

1. To enable CFM, enter the following command.

```
PE2(config)#cfm-enable
```

2. Create a maintenance domain with a specified name **VPLS-SP** and level **4**.

```
PE2(config-cfm)#domain-name VPLS-SP level 4
```

3. Create a maintenance association within a specified domain of **vpls-id 1** with a priority **3** .

```
PE2(config-cfm-VPLS-SP)#ma-name ma_1 vpls-id 1 priority 3
```

4. Configuring a MED for each of the Domain Service Access Points of a service instance creates a MA to monitor the connectivity. Add ethernet port **1/2** as MEP to a specified maintenance association.

```
PE2(config-cfm-md-VPLS-SP-ma-ma_1)#mep 2 up vlan 30 port ethe 1/2
```

MPLS configurations

Enter the following commands to configure VPLS peers from PE1 toPE 3.

1. To create a VPLS instance, enter commands such as the following.

```
PE2(config)#router mpls
PE2(config-mpls)vpls 1 1
```

2. To specify two remote VPLS peers within a VPLS instance, enter a command such as the following.

```
PE2(config-mpls-vpls-1)vpls-peer 1.1.1.1
PE2(config-mpls-vpls-1)vpls-peer 1.1.1.3
```

Tagged ports are configured under a VLAN ID. To specify a tagged endpoint for a VPLS instance, enter the following commands.

```
PE2(config-mpls-vpls-1)vlan 30
PE2(config-mpls-vpls-1-vlan-30)tagged ethe 1/2
```

Configuring PE 3

CFM configuration steps for PE 3 are listed below.

1. To enable CFM for VPLS, enter the following command.

```
PE3(config)#cfm-enable
```

2. Create a maintenance domain with a specified name **VPLS-SP** and level **4**.

```
PE3(config-cfm)#domain-name VPLS-SP level 4
```

3. Create a maintenance association within a specified domain of **vpls-id 1** with a priority **3** .

```
PE3(config-cfm-md-VPLS-SP)#ma-name ma_1 vpls-id 1 priority 3
```

4. Configuring a MED for each of the Domain Service Access Points of a service instance creates a MA to monitor the connectivity. Add ethernet port 1/2 as MEP to a specified maintenance association.

```
PE3(config-cfm-md-VPLS-SP-ma-ma_1)#mep 3 up vlan 30 port ethe 1/2
```

MPLS configurations

Enter the following commands to configure VPLS peers from Router 1 to Router 2.

1. To create a VPLS instance, enter commands such as the following.

```
PE3(config)router mpls
PE3(cconfig-mpls)vpls 1 1
```

2. To specify two remote VPLS peers within a VPLS instance, enter a command such as the following.

```
PE3(config-mpls-vpls-1)vpls-peer 1.1.1.1
PE3(config-mpls-vpls-1)vpls-peer 1.1.1.2
```

3. Tagged ports are configured under a VLAN ID. To specify a tagged endpoint for a VPLS instance, enter the following commands.

```
PE3(config-mpls-vpls-1)vlan 30
PE3(config-mpls-vpls-1-vlan-30)tagged ethe 1/2
```

Verifying connectivity in a VPLS network using IEEE 802.1ag

To display VPLS IEEE 802.1ag connectivity, enter the following commands.

```
NetIron#sh cfm domain VPLS-SP
Domain: VPLS-SP
Level: 4
  Maintenance association: ma_1
  CCM interval: 10
  VPLS ID: 1
  Priority: 3
  MEP   Direction  MAC             PORT
  ====  =========  =========       ====
     1    UP       000c.dbe3.8210  ethe 1/3
```

Syntax: show cfm [domain NAME] [ma NAME]

The **domain NAME** parameter displays the specific domain information. By default, all defined domains are shown.

The [**ma NAME**] parameter specifies the maintenance association name. By default, all defined domains are shown.

TABLE 427 Output for show CFM domain command

This field...	Displays...
Domain	The Domain is the network or the part of the network for which faults in connectivity are displayed.
Level (Maintenance Domain)	The level is the domain level in the range <*0-7*>. The levels can be: • Operator's MD levels: 0 - 2 • Provider's MD levels: 3 - 4 • Customer's MD levels: 5 – 7
Maintenance association	The maintenance association name.
CCM interval	The time interval between two successive Continuity Check messages (CCMs) that are sent by MEPs in the specified Maintenance Domain.
VLAN ID	The VLAN identifier of the maintenance association.
VPLS ID	The VPLS identifier of the maintenance association.
Priority	The priority of the CCM messages, sent by 'MEPs, in the range <*0-7*>.
MEP	The maintenance end point ID
Direction	Displays the direction the MEP was sent: Up - The MEP direction away from the monitored VLAN. Down - The MEP direction is towards the monitored VLAN.
MAC	Displays the associated MAC Address.
PORT	Displays the associated port.

The **show cfm connectivity** command, displays connectivity statistics for the remote database. For the **show cfm connectivity** command to take effect, CFM should first be enabled in the Protocol Configuration mode.

```
NetIron#show cfm connectivity
  Domain: VPLS-SP Level: 4
  Maintenance association: ma_1
  CCM interval: 10
  VPLS ID: 1
  Priority: 3
  RMEP     MAC          VLAN/VC AGE   PORT SLOTMASK
  ====    =====         ======= ====  ==== ====
     4  000c.dbe2.d80a  00f00a1 2157       0008
     2  000c.dbe2.b560  00f00a0 2597       0008

NetIron#show cfm connectivity domain VPLS-SP ma ma_1 rmep-id 2

Maintenance association: ma_1 VPLS ID: 1 Priority: 3
CCM interval: 10
  RMEP   MAC            PORT    Oper  Age  CCM  RDI Port   Intf   Intvl Seq
                                 State Val  Cnt      Status Status Error Error
  ====  ============== ======= ===== ===  === ==== ====== ====== ===== =====
     2  000c.dbe2.b560  00f00a0   OK  26000 2600   N     0      0     N     N
```

Syntax: show cfm connectivity[domain NAME] [ma MA NAME]

The [**domain NAME**] parameter displays information for a specific domain. By default, all defined domains are shown.

The [**ma NAME**] parameter specifies the maintenance association name. By default, all defined domains are shown.

TABLE 428 Output for show CFM connectivity command

This field...	Displays...
Domain	The Domain is the network or the part of the network for which faults in connectivity are displayed.
Level	The level is the domain level in the range <*0-7*>. The levels can be: • Customer's MD levels: 0 - 2 • Provider's MD levels: 3 - 4 • Operator's MD levels: 5 – 7
Maintenance association	The maintenance association name.
CCM interval	The time interval between two successive Continuity Check messages (CCMs) that are sent by MEPs in the specified Maintenance Domain.
VLAN ID	The VLAN identifier of the maintenance association.
VPLS ID	The VPLS identifier of the maintenance association.
Priority	The priority of the CCM messages, sent by 'MEPs, in the range <*0-7*>.
RMEP	The remote maintenance end point ID
MAC	DIsplays the associated MAC Address.
PORT	DIsplays the associated port.
Oper State	Defines the state of the port attached to the MEP. Possible values OK and Fail
Age Val	Age of the operational state of the port.

TABLE 428 Output for show CFM connectivity command

This field...	Displays...
CCM Count	Displays the total number of Continuity Check messages (CCMs) that are sent.
RDI	Remote Defect Indicator
Port Status	The status of a port
Intf Status	The status of the interface
Intvl Error	Displays Y if there has been an interval error and N if no interval errors have been detected.
Seq Error	Displays Y if there has been a sequence error and N if no sequence errors have been detected.

Verifying connectivity in a VPLS network using IEEE 802.1ag Loopback

You can manually monitor the status of VPLS peers using IEEE 802.1ag CFM Linktrace (MAC traceroute) and CFM Loopback (MAC Ping) as shown below.

```
PowerConnect#cfm linktrace domain VPLS-SP ma ma_1 src-mep 1 target-mep 4
Linktrace to 000c.dbe2.d80a on Domain VPLS-SP, level 4: timeout 10ms, 8 hops
----------------------------------------------------------------
Hops           MAC             Ingress     Ingress Action   Relay Action
            Forwarded          Egress      Egress Action    Nexthop
----------------------------------------------------------------

Type Control-c to abort
   1    000c.dbe2.d80a               1.1.1.1      IgrOK      RLY_HIT
        Not Forwarded
Destination 000c.dbe2.d80a reached
```

Syntax: [no] cfm linktrace domain NAME ma MA-NAME src- mep <*mep-id*> dst-mip HH:HH:HH:HH:HH:HH | target-mep <*mep-id*>} [timeout <*timeout*>] [ttl <*TTL*>]

The **domain NAME** parameter specifies the maintenance domain to be used for a linktrace message. The NAME attribute is case-sensitive.

The **ma MA NAME** parameter specifies the maintenance association to be used for a linktrace message. The NAME attribute is case-sensitive.

The **src-mep** <*mep-id*> parameter specifies the Source ID in the range <*1-8192*>.

The **dst-mip** HH:HH:HH:HH:HH:HH parameter specifies the MAC-address of the MIP linktrace destination.

The **dst-mep** <*mepid*> parameter specifies the ID of the linktrace destination.

The **timeout** <*timeout*> parameter specifies the timeout used to wait for linktrace reply. The default value is < *1-30* > seconds.

The **ttl** <*TTL*> parameter specifies the initial TTL field value in the range < *1-64*>.The default is 8 seconds.

```
PowerConnect#cfm loopback domain VPLS-SP ma ma_1 src-mep 1 target-mep 4
DOT1AG: Sending 10  Loopback to 000c.dbe2.d80a, timeout 10000 msec
Type Control-c to abort
Reply from 000c.dbe2.d80a: time=3ms
Reply from 000c.dbe2.d80a: time<1ms
Reply from 000c.dbe2.d80a: time<1ms
Reply from 000c.dbe2.d80a: time<1ms
Reply from 000c.dbe2.d80a: time=38ms
Reply from 000c.dbe2.d80a: time<1ms
Reply from 000c.dbe2.d80a: time<1ms
Reply from 000c.dbe2.d80a: time<1ms
Reply from 000c.dbe2.d80a: time<1ms
Reply from 000c.dbe2.d80a: time<1ms
A total of 10 loopback replies received.
Success rate is 100 percent (10/10), round-trip min/avg/max=0/4/38 ms.
#
```

Syntax: [no] cfm loopback domain NAME ma MA-NAME scr-mep <*mep-id*> {dst-mip HH:HH:HH:HH:HH:HH | target-mep <*mep-id*>} [number <*number*>] [timeout <*timeout*>]

The **domain** NAME parameter specifies the maintenance domain to be used for a linktrace message. The NAME attribute is case-sensitive.

The **ma** MA-NAME parameter specifies the maintenance association to be used for a linktrace message. The MA-NAME attribute is case-sensitive.

The **src-mep** <*mep-id*> parameter specifies the Source ID in the range <*1-8192*>.

The **dst- mip** HH:HH:HH:HH:HH:HH parameter specifies the MAC address of the MIP linktrace destination.

The **dst-mep** <*mep-id*> parameter specifies the Destination ID in the range <*1-8192*>.

The **number** <*number*> parameter specifies the number of loopback messages to be sent.

The **timeout** <*timeout*> parameter specifies the timeout used to wait for linktrace reply.

You have to configure MAs with different MD levels to monitor the different endpoints with different

NOTE
You have to configure MAs with different MD levels to monitor the different endpoints with different VLAN IDs in the same VPLS instance.

Syslog message

If CFM is configured, a syslog message will be generated when remote MEPs change their states or if there are service cross connections.

Sample Syslog Messages

```
NetIron#
SYSLOG: Jan  7 11:22:55:<9>Router2, DOT1AG: Remote MEP 4 in Domain VPLS-SP, MA
ma_1 aged out
SYSLOG: Jan  7 11:23:13:<9>Router2, DOT1AG: Remote MEP 4 in Domain VPLS-SP, MA
ma_1 become UP state
```

When a failure is detected within a VPLS cloud, use LSP Ping and Traceroute. Refer to "LSP ping and traceroute" on page 2229 for additional information.

Support for IEEE 802.1ag CFM for Provider Bridges (PB) and Provider Backbone Bridges (PBB)

The PowerConnect support the following single tagging and double tagging cases:

- MEP (up/down) and MIP on C-VLANs
- MEP (up/down) and MIP on S-VLANs - The ability to change tag-type 88a8 to S-VLANs

IEEE 802.3ah EFM-OAM

The IEEE 802.3ah Ethernet in the First Mile (EFM) is supported on the PowerConnect devices.

The IEEE 802.3ah Ethernet in the First Mile (EFM) standard specifies the protocols and Ethernet interfaces for using Ethernet over access links as a first-mile technology and transforming it into a highly reliable technology.

Using the Ethernet in the First Mile solution, the user will gain broadcast Internet access, in addition to services, such as Layer 2 transparent LAN services, Voice services over Ethernet Access networks, and Video and multicast applications, reinforced by security and Quality of Service control in order to build a scalable network.

The in-band management specified by this standard defines the operations, administration and maintenance (OAM) mechanism needed for the advanced monitoring and maintenance of Ethernet links in the first mile. The OAM capabilities facilitate network operation and troubleshooting. Basic 802.3 frames convey OAM data between two ends of the physical link. EFM OAM is optional and can be disabled on each physical port.

OAM initiatives are classified into three layers: transport, connectivity and service. The transport layer is the collection of forwarding entities and interconnected segments that form a multi-hop Ethernet network, and provide connectivity between devices. The transport layer OAM is specified by the IEEE 802.3ah (Clause 57) and provides single-link OAM capabilities. When OAM is present, two connected OAM sub-layers exchange protocol data units (OAMPDUs). OAM PDUs are standard-size frames that can be sent at a maximum rate of 10 frames per second. This limitation is necessary for reducing the impact on the usable bandwidth. It is possible to send each frame several times in order to increase the probability of reception. A combination of the destination MAC address, the Ethernet type/length field and Subtype allow distinguishing OAM PDU frames from other frames.

OAM functionality is designed to provide reliable service assurance mechanisms for both provider and customer networks.

The IEEE 802.3ah EFM standard offers an opportunity to create the operations, OAM sub-layer within the data-link layer of the OSI protocol stack. The data-link layer provides utilities for monitoring and troubleshooting Ethernet links.

Possible applications

The data-link layer OAM is targeted at last-mile applications and service providers can use it for demarcation point OAM services.

Ethernet Last Mile applications require robust infrastructure that is both passive and active. 802.3ah OAM aims to solve validation and testing problems in such an infrastructure.

Using the Ethernet demarcation service providers can additionally manage the remote device without utilizing an IP layer. This can be done by using link-layer SNMP counters, request and reply, loopback testing and other techniques.

EFM- OAM protocol

The functionality of the OAM-EFM can be summarized under the following categories:

Discovery: Discovery is the mechanism to detect the presence of an OAM sublayer on the remote device. During the discovery process, information about OAM entities, capabilities and configuration are exchanged

Link monitoring: This process is used to detect link faults and to provide information about the number of frame errors and coding symbol errors.

Remote fault detection: Provides a mechanism for an OAM entity to convey error conditions to its peer via a flag in the OAMPDUs.

Remote loopback: This mechanism is used to troubleshoot networks and to isolate problem segments in a large network by sending test segments.

Discovery

This is the first phase of the EFM-OAM. At this phase, EFM-OAM identifies network devices along with their OAM capabilities. The Discovery process relies on the Information OAMPDUs (discussed below). During discovery, the following information is advertised through the TLVs within periodic Information OAMPDUs:

- OAM configuration (capabilities): Advertises the capabilities of the local OAM entity. Using this information, a peer can determine what functions are supported and accessible (e.g. loopback capability)
- OAM mode: This is conveyed to the remote OAM entity. The mode can be either active or passive, and can also be used to determine device's functionality
- OAMPDU configuration: This includes maximum OAMPDU size to delivery. In combination with the limited rate of ten frames/sec this information can be used to limit the bandwidth allocated to OAM traffic.

Timers

- Two configurable timers control the protocol, one determining the rate at which OAMPDUs are to be sent, and the second controlling the rate at which OAMPDUs are to be received to maintain the adjacency between devices.
- An additional 1-second non-configurable timer is used for error aggregation, which is necessary for the Link Monitoring Process to generate link quality events.
- The timer should generate PDUs in the range of 1s - 10sec. The default value is 1sec.
- The Hold timer should assume the peer is dead if no packet is received for a period of 1s to 10s. The default value is 5 seconds.

Flags

- Included in every OAMPDU is a flags field, which contains, besides other information, the status of the discovery process. There are three possible values for the status:
- Discovering: Discovery is in progress.

- Stable: Discovery is completed. Once aware of this, the remote OAM entity can start sending any type of OAMPDU.
- Unsatisfied: When there are mismatches in the OAM configuration that prevent OAM from completing the discovery, the discovery process is considered unsatisfactory and cannot continue.

Process overview

The discovery process allows a local Data Terminating Entity (DTE) to detect OAM on a remote DTE. Once OAM support is detected, both ends of the link exchange state and configuration information (such as mode, PDU size, loopback support, etc.). If both DTEs are satisfied with the settings, OAM is enabled on the link. However, the loss of a link or a failure to receive OAMPDUs for five seconds may cause the discovery process the start over again.

DTEs may either be in active or passive mode. Active mode DTEs instigate OAM communications and can issue queries and commands to a remote device. Passive mode DTEs generally wait for the peer device to instigate OAM communications and respond to, but do not instigate, commands and queries. Rules of what DTEs in active or passive mode can do are discussed in the following sections.

Rules for active mode

A DTE in Active mode:

- Initiates the OAM Discovery process
- Sends Information PDUs
- May send Event Notification PDUs
- May send Variable Request/Response PDUs
- May send Loopback Control PDUs.

Exceptions:

- Does not respond to Variable Request PDUs from DTEs in Passive mode
- Does not react to Loopback Control PDUs from DTEs in Passive mode.

Rules for passive mode

A DTE in Passive mode:

- Waits for the remote device to initiate the Discovery process
- Sends Information PDUs
- May send Event Notification PDUs
- May respond to Variable Request PDUs
- May react to received Loopback Control PDUs
- Is not permitted to send Variable Request or Loopback Control OAMPDUs

Link monitoring process

The Link Monitoring Process is used for detecting and indicating link faults under a variety of circumstances. Link monitoring uses the Event Notification OAMPDU, and sends events to the remote OAM entity when there are problems detected on the link. The error events defined in the standard are:

- Errored Symbol Period (errored symbols per second): the number of symbol errors that occurred during a specified period exceeded a threshold. These are coding symbol errors (for example, a violation of 4B/5B coding)
- Errored Frame (errored frames per second): the number of frame errors detected during a specified period exceeded a threshold
- Errored Frame Period (errored frames per N frames): the number of frame errors within the last N frames has exceeded a threshold
- Errored Frame Seconds Summary (errored secs per M seconds): the number of errored seconds (one second intervals with at least one frame error) among the last M seconds has exceeded a threshold.

Since 802.3ah OAM does not guarantee the delivery of OAMPDUs, the Event Notification OAMPDU (discussed in the OAMPDU section below) can be sent multiple times to reduce the probability of losing notifications. A sequence number is used to recognize duplicate events. The Link Monitoring Process operates for all the links on which EFM OAM is enabled

Remote failure indication

Faults in Ethernet that are caused by slowly deteriorating quality are more difficult to detect than completely disconnected links. A flag in the OAMPDU allows an OAM entity to send failure conditions to its peer. The failure conditions are defined as follows:

- Link Fault: The Link Fault condition is detected when the receiver loses the signal. This condition is sent once per second in the Information OAMPDU.
- Dying Gasp: This condition is detected when the receiver goes down. The Dying Gasp condition is considered as unrecoverable. Conditions for dying gasp:
  - Reload or reset from MP
  - Interface disable (admin shutdown)
  - Link-OAM disable on interface (deconfiguration)
  - Crash on the box
- Device power down (incidental or deliberate).
- Critical Event: When a critical event occurs, the device is unavailable as a result of malfunction, and it is to be restarted by the user. The critical events can be sent immediately and continually.

When the dying gasp or critical event occurs, the device driver will call a special API in the EFMOAM implementation.

The link fault applies only when the physical sublayer is capable of independent transmission and reception.

When a link receives no signal from its peer at the physical layer (for example, if the peer's laser is malfunctioning), the local entity sets this flag to let the peer know that its transmit path is inoperable. The link-down API will be called by the device driver in order to notify the remote device of the link fault.

Since the above conditions are severe, when they are set in the flag, the OAMPDU is not subject to normal rate limiting policy.

Remote loopback

An OAM entity can put its remote entity into loopback mode using a loopback control OAMPDU. This helps users ensure quality of links during installation or when troubleshooting. In loopback mode, each frame received is transmitted back on that same port except for OAMPDUs and pause frames. The periodic exchange of OAMPDUs must continue while in the loopback state to maintain the OAM session. The loopback command is acknowledged by responding with an Information OAMPDU with the loopback state indicated in the state field. This allows to estimate if a network segment can satisfy an SLA.

Enabling and disabling EFM-OAM

The link-oam command, in Protocol Configuration mode, enables and disables the EFM-OAM protocol and enters into the EFM-OAM Protocol Configuration mode. The link-oam disable and enable command resets all link-oam parameters to default values.

By default, EFM-OAM is disabled.

To enable EFM-OAM, enter a command such as the following:

```
PowerConnect(config)link-oam
PowerConnect(config-link-oam)#enable
```

Syntax: [no]link-oam

Syntax: enable

The **no** form of the command sets the 802.3ah EFM-OAM to the disabled state.

Specifying the timeout value

The timeout command is a hold down timer that specifies the number of seconds before it declares that the other side has stopped sending OAMPDUs.

```
PowerConnect(config-link-oam) #timeout 10
```

Syntax: [no] timeout <value>

The **no** form of the command restores the default value of 5 OAMPDUs.

The <**value**> parameter specifies the number of seconds before declaring the remote as down. in the range of <1-10>.

Specifying the PDU rate

To set the number of PDUs to be transmitted per second, use the pdu-rate command. The default value is 1.

```
PowerConnect(config-link-oam) #pdu-rate 10
```

Syntax: [no] pdu-rate <value>

The <**value**> parameter specifies the number of PDUs in the range of <1-10>.

The **no** form of the command restores the default value of 1.

Enabling and disabling the EFM-OAM state on the specified interface

The ethernet <slot/port> link-oam command, in Interface Configuration mode, enables and disables EFM-OAM on the specified interface and sets its mode to active or passive.

When both peers are in passive mode (abnormal configuration), the information from “Remote Status” is not updated anymore and it may be inaccurate. By default port state is disabled.

For the link-oam command to take effect, EFM-OAM should first be enabled in the Protocol Configuration mode.

```
PowerConnect(config-link-oam)# ethernet 2/1 link-oam active
```

Syntax: [no]ethernet <slot/port> **link-oam** {active | passive}

When active mode is specified, the device can send OAMPDU packets over this port in order to initiate an EFM-OAM discovery process. For the discovery process to be initiated the EFM-OAM protocol must have been enabled.

When passive mode is specified, the device cannot use this port to send OAMPDU packets, but can respond if it receives OAMPDUs from remote.

The **no** form of the command sets the 802.3ah EFM-OAM to the disabled state.

Display information

The following show commands will display OAM information.

DIsplaying OAM information

To show OAM information on all OAM enabled ports, enter a command such as the following:

```
PowerConnect#show link-oam info
Ethernet Link Status     OAM Status      Mode       Local Stable    Remote Stable
1/1      up              up              active     satisfied       satisfied
1/2      up              up              passive    satisfied       satisfied
1/3      up              up              active     satisfied       satisfied
1/4      up              init            passive    unsatisfied     unsatisfied
1/5      down            down            passive    unsatisfied     unsatisfied
1/6      down            down            passive    unsatisfied     unsatisfied
1/7      down            down            passive    unsatisfied     unsatisfied
```

Displaying detailed information from a specific port

To show detailed OAM information, enter a command such as the following:

```
PowerConnect#show link-oam info detail
OAM information for Ethernet port: 1/1
        +link-oam mode:        active
        +link status:          up
        +oam status:           up
        Local information
                multiplexer action:  forward
                parse action:        forward
                stable:              satisfied
                state:               up
                loopback state:      disabled
                dying-gasp:          false
                critical-event:      false
                link-fault:          false
        Remote information
                multiplexer action:  forward
                parse action:        forward
                stable:              satisfied
                loopback support:    disabled
                dying-gasp:          false
                critical-event:      false
                link-fault:          false
OAM information for Ethernet port: 1/2
        +link-oam mode:        passive
        +link status:          up
        +oam status:           up
        Local information
                multiplexer action:  forward
                parse action:        forward
                stable:              satisfied
                state:               up
                loopback state:      disabled
                dying-gasp:          false
                critical-event:      false
                link-fault:          false
        Remote information
                multiplexer action:  forward
                parse action:        forward
                stable:              satisfied
                loopback support:    disabled
                dying-gasp:          false
                critical-event:      false
                link-fault:          false
```

Syntax: show link-oam info detail ethernet < all I slot/port>

To show detailed OAM information on a specific ethernet port, enter a command such as the following:

```
PowerConnect#show link-oam info detail ethernet 1/1
OAM information for Ethernet port: 1/1
        +link-oam mode:        active
        +link status:          up
        +oam status:           up
        Local information
                multiplexer action:  forward
                parse action:        forward
                stable:              satisfied
                state:               up
                loopback state:      disabled
                dying-gasp:          false
                critical-event:      false
                link-fault:          false
        Remote information
                multiplexer action:  forward
                parse action:        forward
                stable:              satisfied
                loopback support:    disabled
                dying-gasp:          false
                critical-event:      false
                link-fault:          false
```

Syntax: show link-oam info detail [all | ethernet <slot/port>]

DIsplaying OAM statistics

To show OAM statistics, enter a command such as the following:

```
PowerConnect#show link-oam statistics
Ethernet Tx Pdus         Rx Pdus
1/1      507             362
1/2      358             359
1/3      480             355
1/4      0               0
1/5      0               0
1/6      0               0
1/7      0               0
1/8      0               0
1/9      0               0
1/10     0               0
```

Syntax: show link-oam statistics

DIsplaying detailed OAM statistics

To show detailed OAM statistics, enter a command such as the following:

```
PowerConnect#show link-oam statistics detail
OAM statistics for Ethernet port: 1/1
        Tx statistics
                information OAMPDUs:                   587
                loopback control OAMPDUs:              0
                variable request OAMPDUs:              0

                critical-event records:               0
                dying-gasp records:                   0
                discarded TLVs:                       0
                unrecognized TLVs:                    0
```

To show detailed OAM statistics, enter a command such as the following:

```
PowerConnect#show link-oam statistics detail ports ethernet 1/1
OAM statistics for Ethernet port: 1/1
        Tx statistics
                information OAMPDUs:                    827
                loopback control OAMPDUs:               0
                variable request OAMPDUs:               0
                variable response OAMPDUs:              0
                unique event notification OAMPDUs:      0
                duplicate event notification OAMPDUs:   0
                oranization specific OAMPDUs:           0
                link-fault records:                     0
                critical-event records:                 0
                dying-gasp records:                     0
        Rx statistics
                information OAMPDUs:                    682
                loopback control OAMPDUs:               0
                variable request OAMPDUs:               0
                variable response OAMPDUs:              0
                unique event notification OAMPDUs:      0
                duplicate event notification OAMPDUs:   0
                oranization specific OAMPDUs:           0
                unsupported OAMPDUs:                    0
                link-fault records:                     0
                critical-event records:                 0
                dying-gasp records:                     0
                discarded TLVs:                         0
                unrecognized TLVs:                      0
```

Syntax: show link-oam statistics detail ports [all | ethernet <slot/port>]

This field...	Displays...
Ethernet Port	Indicates if the ethernet port that EFM-OAM is enabled on.
Link Status	Indicates if the physical link is operational or any fault is detected on the link.
OAM Status	Indicates the status of OAM on the link between the local and remote DTEs. The status is enabled if OAM client is satisfied with local and remote settings.
Mode	Indicates if the DTE is in active or passive modes. Active DTEs can start the discovery process and passive ones can only respond.
Local Stable	Indicates the reception of the remote DTE state information and is satisfied with the remote OAM settings.
Remote Stable	Indicates the reception of the local DTE state information at the remote DTE and is satisfied with the local OAM settings.

Ping

Ping is a tool that helps you to verify the Internet connectivity at the IP level. The **ping** command sends an Internet Control Message Protocol (ICMP) echo request to the IP address or selected hostname.

Executing ping

The **ping** command, in the (Enable) mode, pings another device from the PowerConnect. The PowerConnect supports IP ping, which you can use to test connectivity to remote hosts. Ping sends an echo request packet to an address and waits for a reply.

The device can execute multiple ping commands at the same time. If you can connect to the device via the console, or through an inbound telnet or SSH session, it should be possible to initiate a ping. This applies to all versions of the ping command described below. The device can also resolve multiple DNS queries simultaneously, which allows multiple ping commands with the **hostname** option to be executed at the same time.

To initiate the PowerConnect to ping to a target device with the IP address of 192.22.2.33, enter a command such as the following.

```
NetIron# ping 192.22.2.33
```

Syntax: **ping** <*ip addr*> | <*hostname*> | **vrf** <*instance-name*> [**source** <*ip addr*>] [**count** <*num*>] [**timeout** <*msec*>] [**ttl** <*num*>] [**size** <*byte*>] [**quiet**] [**numeric**] [**no-fragment**] [**verify**] [**data** <1-to-4 byte hex>] [**brief**]

The required parameter is the IP address or the host name of the device.

The **vrf** <*instance-name*> parameter specifies a VPN routing/forwarding instance as the origin of the ping packets.

The **source** <*ip addr*> parameter specifies an IP address to be used as the origin of the ping packets.

The **count** <*num*> parameter specifies how many ping packets the device sends. You can specify from 1 – 4294967296. The default is 1.

The **timeout** <*msec*> parameter specifies how many milliseconds the device waits for a reply from the pinged device. You can specify a timeout from 1 – 4294967296 milliseconds. The default is 5000 (5 seconds).

The **ttl** <*num*> parameter specifies the maximum number of hops. You can specify a TTL from 1 – 255. The default is 64.

The **size** <*byte*> parameter specifies the size of the ICMP data portion of the packet. This is the payload and does not include the header. You can specify from 0 – 9170. The default is 16.

The **no-fragment** parameter turns on the “do not fragment” bit in the IP header of the ping packet. This option is disabled by default.

The **quiet** parameter hides informational messages such as a summary of the ping parameters sent to the device and instead displays only messages indicating the success or failure of the ping. This option is disabled by default.

The **verify** parameter verifies that the data in the echo packet (the reply packet) is the same as the data in the echo request (the ping). By default the device does not verify the data.

The **data** <*1 – 4 byte hex*> parameter lets you specify a specific data pattern for the payload instead of the default data pattern, “abcd”, in the packet’s data payload. The pattern repeats itself throughout the ICMP message (payload) portion of the packet.

NOTE
For numeric parameter values, the CLI does not check that the value you enter is within the allowed range. If you exceed the range for a numeric value, the software rounds the value to the nearest valid value.

The **brief** keyword causes ping test characters to be displayed. The following ping test characters are supported:

! Indicates that a reply was received.

. Indicates that the network server timed out while waiting for a reply.

U Indicates that a destination unreachable error PDU was received.

I Indicates that the user interrupted ping.

Executing ping VRF

NOTE
The Ping utilities have been enhanced by adding the **ping vrf** command in release 02.1.00 to help with management of Layer-3 VPNs.

The **ping vrf** command lets you test a specific VPN connection. To use this option, enter the following command.

Syntax: ping vrf <*vrf-name*> <*ip-address*>

The **vrf-name** parameter is the name of the VRF that you want to conduct a ping to.

The **ip-address** parameter is the IP address containing the VRF that you want to conduct a ping to.

Executing ping IPv6

The **ping ipv6** command allows you to verify the connectivity from a device to an IPv6 device by performing an ICMP for IPv6 echo test. As with IPv4, multiple IPv6 ping commands can be executed simultaneously by the device.

For example, to ping a device with the IPv6 address of 2001:3424:847f:a385:34dd::45 from the device, enter the following command.

```
NetIron# ping ipv6 2001:3424:847f:a385:34dd::45
```

Syntax: ping ipv6 <*ipv6-address*> | <*host-name*> | **vrf** <*instance-name*>**[outgoing-interface [eth** <*slot/port*> | **pos** <*slot/port*> | **ve** <*number*>**]] [source** <*ipv6-address*>**] [count** <*number*>**] [timeout** <*milliseconds*>**] [ttl** <*number*>**] [size** <*bytes*>**] [quiet] [numeric] [no-fragment] [verify] [data <1-to-4 byte hex>] [brief]**

The required parameter is the IPv6 address or the host name of the device. The <*ipv6-address*> parameter specifies the address of the target device. You must specify this address in hexadecimal using 16-bit values between colons, or specify a host name using an ASCII string.

The **vrf** <*instance-name*> parameter specifies a VPN routing/forwarding instance as the origin of the ping packets.

The **outgoing-interface** keyword specifies a physical interface over which you can verify connectivity. If you specify a physical interface, such as an Ethernet interface, you must also specify the port number of the interface. If you specify a virtual interface, such as a VE, you must specify the number associated with the VE.

Specify either **eth** <*slot/port*> or **pos** <*slot/port*>.

The **source** <*ipv6-address*> parameter specifies an IPv6 address to be used as the origin of the ping packets.

The **count** <*number*> parameter specifies how many ping packets the sends. You can specify from 1 - 4294967296. The default is 1.

The **timeout** <*milliseconds*> parameter specifies how many milliseconds the waits for a reply from the pinged device. You can specify a timeout from 1 - 4294967296 milliseconds. The default is 5000 (5 seconds).

The **ttl** <*number*> parameter specifies the maximum number of hops. You can specify a TTL from 1 - 255. The default is 64.

The **size** <*bytes*> parameter specifies the size of the ICMP data portion of the packet. This is the payload and does not include the header. You can specify from 0 - 9150. The default is 16.

The **no-fragment** keyword turns on the "don't fragment" bit in the IPv6 header of the ping packet. This option is disabled by default.

The **quiet** keyword hides informational messages such as a summary of the ping parameters sent to the device and instead only displays messages indicating the success or failure of the ping. This option is disabled by default.

The **verify** keyword verifies that the data in the echo packet (the reply packet) is the same as the data in the echo request (the ping). By default the device does not verify the data.

The **data** <*1 - 4 byte hex*> parameter lets you specify a specific data pattern for the payload instead of the default data pattern, "abcd", in the packet's data payload. The pattern repeats itself throughout the ICMP message (payload) portion of the packet.

NOTE
For parameters that require a numeric value, the CLI does not check that the value you enter is within the allowed range. Instead, if you do exceed the range for a numeric value, the software rounds the value to the nearest valid value.

The **brief** keyword causes ping test characters to be displayed. The following ping test characters are supported:

! Indicates that a reply was received.

. Indicates that the network server timed out while waiting for a reply.

U Indicates that a destination unreachable error PDU was received.

I Indicates that the user interrupted ping.

Trace route

The trace route tool works by sending ICMP echo packets with varying IP Time-to-Live (TTL) values to the destination.

You can use IP traceroute to identify the path that packets take through the network on a hop-by-hop basis. The command output displays all network layer devices, such as routers, through which the traffic passes on its way to the destination.

The device can execute simultaneous **traceroute** commands from multiple inbound telnet or SSH sessions. Multiple simultaneous traceroutes from Web and SNMP, however are not allowed. The device can also resolve multiple DNS queries simultaneously, which allows multiple **traceroute** commands with the **hostname** option to be executed at the same time.

NOTE
Traceroute commands in outbound telnet sessions run on the remote telnet server and not on the local device.

Executing traceroute

The **traceroute** command, in the (Enable) mode, displays the routing path from the routing switch to the destination IP address as soon as the information is received. Traceroute requests display all responses to a given TTL. In addition, if there are multiple equal-cost routes to the destination, the device displays up to three responses by default.

Example

```
NetIron> traceroute 192.33.4.7 minttl 5 maxttl 5 timeout 5
```

Example

```
NetIron1# traceroute vrf blue 10.10.10.10
```

Syntax: **traceroute** <host-ip-addr> [maxttl <value>] [minttl <value>] [numeric] [timeout <value>] [source-ip <ip addr>]

The **maxttl** parameter is the maximum TTL (hops) value: Possible value is 1 – 255. The default is 30 seconds.

The **minttl** parameter is the minimum TTL (hops) value: Possible value is 1 – 255. The default is 1 second.

The **numeric** parameter lets you change the display to list devices by IP address instead of by name.

The **timeout** parameter specifies the possible values. Possible value range is 1 – 120. Default value is 2 seconds.

The **source-ip** <*ip addr*> parameter specifies an IP address to be used as the origin for the traceroute.

The **vrf** <*vrf-name*> parameter is the name of the VRF whose route you want to trace.

The **vrf** <*ip-address*> parameter is the IP address containing the VRFwhose route you want to trace.

Executing traceroute VRF

In the (Enable) mode, the **traceroute vrf** command functions like the standard **traceroute** command but requires you to specify a VRF table name. The **traceroute vrf** command must be used when the route to the destination is associated with a VRF table.

Example

```
NetIron# traceroute vrf blue 10.10.10.10
```

Syntax: traceroute vrf <*vrf-name*> <*ip-address*>

The **vrf** <*vrf-name*> parameter is the name of the VRF for you want are running the traceroute.

The **vrf** <*ip-address*> parameter is the IP address containing the VRF that you want to conduct a traceroute to.

Executing traceroute IPv6

The **traceroute ipv6** command traces a path from a device that supports IPv6 to an IPv6 host.

The CLI displays trace route information for each hop as soon as the information is received. Traceroute requests display all responses to a minimum TTL of 1 second and a maximum TTL of 30 seconds. In addition, if there are multiple equal-cost routes to the destination, the device displays up to three responses.

Example

To trace the path from the device to a host with an IPv6 address of 3301:23dd:349e:a384::34, enter the following command.

```
NetIron> traceroute ipv6 3301:23dd:349e:a384::34
```

Syntax: traceroute ipv6 <*ipv6-address*>

The <*ipv6-address*> parameter specifies the address of an IPv6 host. You must specify this address in hexadecimal using 16-bit values between colons.

Trace-l2 protocol

Trace-l2 traces introduces a new proprietary protocol that traces the traffic path to a specified device in a VLAN. Also, it can be used to probe all reachable paths to all devices in a VLAN. It does the following:

- Traces a particular IP, MAC or hostname in a VLAN.
- Probes the entire Layer 2 topology.
- Displays the input or output ports of each hop in the path.
- Displays the round trip travel time of each hop.
- Displays hops in a VLAN that form a loop.
- Displays each hop's Layer 2 protocol such as STP, RSTP, 802.1w, SSTP, metro ring, or route-only.

The resulting trace displays a report that provides information about a packet's path to a device, such as hop and port information and travel time. It also can locate any Layer 2 loop in a VLAN. The probed Layer 2 information is discarded after 10 minutes or when a new **trace-l2** command is issued again.

For each hop in the path, trace-l2 displays its input/output port, L2 protocols of the input port, and the microsecond travel time between hop and hop. It also prints out the hops which form a loop, if any. Displaying L2 topology lets a user easily obtain information of all hops.

Configuration considerations

The configuration considerations are as follows:

- Trace-l2 is enabled on the PowerConnect devices. It can be used to trace traffic only to devices.
- The devices that will participate in the trace-l2 protocol must be assigned to a VLAN and all devices on that VLAN must be Dell devices that support the trace-l2 protocol.
- Dell devices, as well as other vendor devices, that do not support the trace-l2 protocol, simply forward trace-l2 packets without a reply. Hence, these devices are transparent to the trace-l2 protocol.
- The destination for the packet with the trace-l2 protocol must be a device that supports the trace-l2 protocol and the destination cannot be a client, such as a personal computer, or devices from other vendors.

Tracing a traffic path

The trace-l2 protocol is enabled on a VLAN. You can trace the traffic path of a packet by entering a command such as the following.

```
NetIron(config)#trace-l2 vlan 10 2.2.2.2
```

Syntax: [no] trace-l2 vlan <*vlan-id*> <*destination-address*>

The <*destination address*> can be a MAC address, an IP address, or a host. You can enter the destination-address in one of the following formats:

- HHHH.HHHH.HHHH – Destination MAC address
- A.B.C.D – Destination IP address
- ASCII string – destination host name

If a destination address is not specified or the destination does not exists, trace-l2 collects L2 topology information which can be displayed by issuing a **trace-l2 show** command. The command displays the following information.

```
trace-l2 reply vlan 2 from e26, 1.1.1.2, total round trip = 814 microsec
hop input  output   IP and/or MAC address       microsec   comment
  1   e28    e25    1.1.1.4 00e0.803f.c400         316     e28: ring 11
  2   e15    e13    1.1.1.1 0004.8057.0d00         235     e15: ring 11
  3   e27           1.1.1.2 00e0.8057.2500         263     e27: ring 11
```

In the output above, the last hop is the destination. Because 1.1.1.2 and 2.2.2.2 are addresses of the same device, the device can use 1.1.1.2 in the reply.

In general, **trace-l2** first tries to use the IP address of the virtual routing interface that is associated with a VLAN. If the virtual routing interface is not available, it then uses the loopback address. If both addresses are not available, it displays MAC address only.

The **input** and **output** ports show the path of the hops. Hop 3 has no output port because it is the destination.

The **microsec** column is the round trip time (sum of the time) to and from the previous hop. For example, 316 microsec for hop 1 is the time from the source to hop 1 and from hop 1 to the source. One way time is not available because the tracel2 protocol does not synchronize the clocks between hops.

The **comment** column shows the Layer 2 protocol used on the input port. It could be the following:

- STP – spanning tree protocol
- RSTP – Rapid STP, 802.1w draft 3
- 802.1w – Rapid STP

- ring – Metro ring ID of input port.
- Single STP – Includes Single STP, Single RSTP and Single 802.1w
- STP port disabled – The **spanning-tree ethernet disabled** command is configured.
- route-only – This device has route-only configuration
- port route-only – The input port has route-only configuration

Displaying Layer 2 topology information

To display information about the Layer 2 topology, first issue a **trace-l2 vlan** command, then enter the **trace-l2 show** command as in the following example.

```
NetIron(config)#trace-l2 vlan 10
Vlan 10 L2 topology probed, use "trace-l2 show" to display
FES Switch(config)#trace-l2 show
Vlan 10 L2 topology was probed 6 sec ago, # of paths: 2
path 1 from e27, 1 hops:
hop input  output IP and/or MAC address       microsec comment
1   e13           1.1.1.1 0004.8057.0d00           383 802-1w
path 2 from e25, 2 hops:
hop input  output IP and/or MAC address       microsec comment
1   e27    e26    1.1.1.3 00e0.8052.ea00           657 802-1w
2   e28           1.1.1.4 00e0.803f.c400           296 route-only
```

The **trace-l2 show** command does not display a path if the path is a subset of another path; therefore, the number of paths displayed could be fewer than the number of devices.

If the topology contains Layer 2 loops, a message such as the following is displayed.

```
*** Warning! The following 3 hops form a loop in vlan 2
  hop input  output IP and/or MAC address       microsec comment
  1   e25           1.1.2.2 00e0.8057.2500
  2   e28           4.4.100.1 00e0.803f.c400
  3   e29           1.1.1.1 0004.8057.0d00
```

Syntax: trace-l2 show

LSP ping and traceroute

Overview

The LSP Ping and Traceroute feature provides Operation, Administration, and Maintenance (OAM) functionality for MPLS networks based up RFC 4379 (Detecting Multi-Protocol Label Switched (MPLS) Data Plane Failures).

The LSP ping and traceroute functions provide a mechanism to detect MPLS data plane failure. LSP ping is used to detect data plane failure and to check the consistency between the data plane and the control plane. LSP traceroute is used to isolate the data plane failure to a particular router and to provide LSP path tracing. They are implemented using MPLS echo request and reply messages which are sent as UDP packets to a well-known UDP port 3503. This section provides the details of LSP Ping and Traceroute operation

LSP ping operation

An MPLS echo request (described in "MPLS echo request" on page 2230) is sent from the ingress to the egress LSR. At the transit LSRs, the ping packet is label switched (the same as a regular MPLS data packet) without any control plane intervention. Upon arriving at the egress LSR, the echo request is sent to the control plane for processing based on the IP Router Alert option and the well-known destination UDP port 3503. An echo reply (described in "MPLS echo reply" on page 2231) is sent back as a UDP packet with an appropriate return code that depends on the result of the FEC stack validation.

LSP traceroute operation

An MPLS echo request (described in "MPLS echo request" on page 2230) is sent from the ingress LSR with the TTL of the outermost label set to an incremental value that starts with a TTL value of 1. This request causes the MPLS echo request to be forwarded to the control plane for processing at each transit LSR, based on the MPLS TTL expiration value. An echo reply (described in "MPLS echo reply" on page 2231) is sent back with a return code indicating that it is the transit LSR for the FEC specified in the echo request. This process repeats until the echo request arrives at the egress LSP. The echo request is then forwarded to the control plane for processing, based on the IP Router Alert option. An echo reply is sent back as a UDP packet with an appropriate return code that depends on the result of the FEC stack validation.

MPLS echo request

The MPLS echo request is sent from the ingress LSR as a labeled UDP packet (except for single-hop LSP). The echo request has the following characteristics.

IP/UDP header information:

- Source address = user-input or LSR ID.
- Destination address = user-input or 127.0.0.1.
- UDP source port = 3503.
- UDP destination port = 3503.
- IP TTL = 1
- Router Alert option is set.

By default, the reply mode is set to 2 (reply by way of an IPv4 UDP packet), and you can set it to 1 (no reply) or 3 (reply by way of an IPv4 UDP packet with Router Alert option).

The sender handle is set to an internally-generated, 32-bit number that is assigned to each ping or traceroute session when the ping or traceroute operation begins. This sender handle is sent back in the echo reply, which is used to locate the appropriate ping or traceroute session.

The sequence number is a running number associated with each ping or traceroute session. It is starts with a value of 1.

The TTL for the outermost label is set to 255 for a ping. For traceroute, it is 1, 2, 3, and so on.

You can configure a timeout when starting the ping or traceroute command. The default value is 5 seconds.

MPLS echo reply

The MPLS echo reply is sent by the transit (for traceroute) or egress (for ping and traceroute) LSR as a regular IPv4 UDP packet or an IPv4 UDP packet with Router Alert option depending on the reply-mode field of the echo request. If reply with Router Alert option is chosen, the user should make sure that all intermediate routers are capable of handling MPLS echo reply. If a reply is sent with Router Alert option and the reply is sent over a tunnel interface, the MPLS Router Alert label (label value 1) will be the topmost label for the packet. A reply with a Router Alert option should be used if and only if the normal IP return path is deemed unreliable.

The echo reply has the following characteristics.

IP/UDP header information:

- Source address = LSR ID
- Destination address = source IP address from the echo request
- UDP source port = 3503
- UDP destination port = UDP source port from the echo request
- IP TTL = 255
- Router Alert option set if and only if reply-mode field of the echo request set to 3.

The sender handle is copied from echo request message

The sequence number is copied from echo request message

LSP ping TLVs

Table 429 lists the TLVs defined in RFC 3479 that are included in an echo request and reply.

TABLE 429 Show Cfm output descriptions

TLV type	TLV name	TX in echo request	TX in echo reply
1	Target FEC stack	Yes	No
2	Downstream mapping	Yes if the **dsmap** option is set	Yes for transit LSRs only if downstream mapping TLV is included in the MPLS Echo request.
3	Pad	Depend on the size option	Yes (if value = 2)
7	Interface and Label Stack	N/A	Yes if the I flag in DS mapping is set
9	Errored TLV	N/A	Yes (if error is detected)
10	Reply TOS bytes	Yes if reply-tos option is set	TLV is not sent back. Just copy TOS byte into IP header.

The PowerConnect devices support sending and receiving downstream mapping TLVs without multipath information (where the multipath type is always set to 0). Note that the detailed multipath information can be used by the ingress LSR to ping or traceroute through all ECMP paths at the transit LSR. Currently, the PowerConnect devices do not support LDP LSPs with ECMP. Consequently, the multipath type of non-zero is not relevant in these operations.

LSP FEC types

For LDP LSPs, the LDP IPv4 prefix sub-TLV (sub-type = 1) is encoded in the target FEC stack of the echo request. For RSVP LSPs, the RSVP IPv4 LSP sub-TLV (sub-type = 3) is encoded in the target FEC stack.

NOTE
Static RSVP LSPs are no longer supported, so a ping or traceroute for a static LSP is not supported.

Redundant RSVP LSPs

For RSVP LSPs with redundant paths, ping or traceroute on a LSP is performed on the currently active path. For example, if the secondary path is the active path for an LSP, the MPLS echo request packets are sent out on the secondary path's interface.

If the active path changes while a ping or traceroute is in progress, the echo request continues to be sent out on the old active path. This implies that the echo request that was sent after path switchover times out. The user subsequently needs to restart the ping or traceroute.

One-to-one Fast ReRoute (FRR) LSPs

Similar to the redundant LSPs, a ping or traceroute on a one-to-one FRR LSP is performed on the active path. If a path switchover occurs while a ping or traceroute is in-progress, the echo request continues to be sent out on the old active path. This implies that the echo request sent after path switchover will time out.

A user can ping or trace the route of the ingress-originated detour of a one-to-one FRR LSP by specifying the detour parameter. The operation is started only if the detour is operationally up.

FRR bypass LSPs

The LSP ping and traceroute facilities support FRR bypass LSPs. You can ping or trace the protected LSP and bypass tunnel separately.

You can ping or trace the ingress-originated or transit-originated bypass tunnel by specifying either the name of bypass LSP (as you would any regular LSP name) or the entire RSVP session ID (including the tunnel endpoint, the tunnel ID, and the extended tunnel ID).

NOTE
In the current facility backup implementation, the bypass LSP name must be unique in the system (for example, the name cannot be the same as the regular LSP name).

The traceroute output of a backup tunnel depends on the setting of the **propagate-ttl** and **label-propagate-ttl** options. If both **propagate-ttl** and **label-propagate-ttl** options are turned on, the traceroute output shows the detail of the bypass path. If both options are turned off, the bypass path is shown as a single hop. The options should be either both ON or both OFF.

To trace the route of a backup path, the TTL of the bypass and protected labels (if they are not implicit NULL labels) are set as in the following example:

- Both **propagate-ttl** and **label-propagate-ttl** are ON: TTL = 1, 2, 3, and so on, are set for both labels.
- Otherwise: bypass label TTL is set to 255. Protected label TTL is set to 1, 2, 3, and so on.

IP TTL is set to topmost label TTL. Otherwise, it is set to 255.

Transit-originated detour

The user can initiate a ping or traceroute operation on a transit-originated, detour LSP. Because the session name does not uniquely identify a session on a transit LSR, the user needs to specify the entire session ID (including the tunnel endpoint, tunnel ID, and extended tunnel ID) for the detour LSP to which the LSP ping or traceroute command is applied.

LSP reoptimization

If LSP reoptimization happens while the ping or traceroute is operating, the echo request is still sent out on the current LSP instance until the new instance is created. This avoids displaying partial information from the old and new paths if they are different; particularly for a traceroute. Similarly, if the ping or traceroute operation is started while LSP reoptimization is occurring, the LSP label, out interface, and other parameters from the currently up instance will be used.

PHP behavior

Ping is transparent to the penultimate LSR. MPLS and IP TTL operations performed on a ping packet are the same as tor a regular data packet. In the default case where the MPLS TTL is copied into the IP TTL, the echo request packet can arrive at the egress LSR with an IP TTL value greater than 1. Consequently, in this situation, the IP Router Alert option is used to direct the echo request packet to the control plane for ping processing.

For a traceroute operation; if the echo request is received with a downstream mapping TLV, the Implicit Null label is encoded in the Downstream label in the echo reply just like any other label.

Since a PowerConnect router advertises an implicit Null label to its upstream LSR for both LDP and RSVP LSPs, packets that arrive at the egress LSR do not have the tunnel label. For a single-hop LSP, the echo request is sent out from ingress LSR as an unlabeled UDP packet.

Using the LSP ping and Traceroute commands

The following sections described operation of the LSP Ping and Traceroute command:

- “Executing LDP LSP ping”
- “Executing RSVP LSP ping”
- “Executing LDP LSP traceroute”
- “Executing RSVP LSP traceroute”

Executing LDP LSP ping

The LDP LSP ping command, sends an MPLS echo request from the ingress to the egress LSR.

To perform the LDP LSP ping operation, use the following command.

```
NetIron)# ping mpls ldp 22.22.22.22
Send 5 80-byte MPLS Echo Requests for LDP FEC 22.22.22.22/32, timeout 5000 msec
Type Control-c to abort
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max=0/1/1 ms.
NetIron)#
```

Syntax: **ping mpls ldp** <*ip-address*> **|** <*ip-address/mask-length*> **[count** <*num*>**] [destination** <*ip-address*>**] [detail] [reply-mode no-reply | reply-mode router-alert] [reply-tos** <*num*>**] [size <bytes] [source** <*ip-address*>**] [timeout** <*msec*>**]**

The **ldp** <*ip-address*> and <*ip-address/mask-length*> variables specify the LDP IPv4 destination prefix and mask length. If the **mask-length** is not specified, the default value is 32.

The **count** option with the <*num*> variable specifies the number of echo requests to send. The default value is 5.

The **destination** option specifies an IP address within the 127/8 subnet. The default address is 127.0.0.1

The **detail** option displays the details of the echo request and reply messages. By default, the display is in the brief mode.

The **reply-mode** option species the reply mode field in the echo request if and only if the user does not want the reply to be sent as an IPv4 UDP packet.

The **no-reply** option can be used to test one-way connectivity.

The **router-alert** option is used when the normal IP return path is unreliable. This option indicates that the reply should be sent as an IPv4 UDP packet with the Router Alert option. This option requires extra overhead processing at each LSR along the return path.

The **reply-tos** option specifies a TOS value between 0 and 254 to be included in the Reply-TOS-byte TLV. This value will be copied to the IP header TOS byte of the echo reply. By default, the reply-tos TLV is not included in the echo request.

NOTE
The last bit of the TOS byte is always 0.

The **size** option specifies that the size of the echo request including the label stack to be sent will be the value of the variable <*bytes*>. The pad TLV is used to fill the echo request message to the specified size. The minimum size is 80 byte for an LDP echo request. The maximum size is the size of the LSP MTU.

The **source** option specifies the IP address of any interface. This address is used as the destination address for the echo reply address. The default address is the LSR ID.

The **timeout** option specifies an interval in milliseconds for the echo request message. The default timeout is 5 seconds. The maximum timeout value is 5 minutes.

Executing RSVP LSP ping

The RSVP ping command in the (enable) mode, sends an MPLS echo request from the ingress to the egress LSR.

To perform the RSVP LSP ping operation, use the following command.

```
NetIron# ping mpls rsvp lsp tomlxe2frr-18
Send 5 92-byte MPLS Echo Requests over RSVP LSP tomlxe2frr-18, timeout 5000 msec
Type Control-c to abort
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max=0/1/5 ms.
NetIron)#
```

Syntax: **ping mpls rsvp lsp** <*lsp-name*> **| session** <*tunnel-source-address*> <*tunnel-destination-address*> <*tunnel-id*> **[count** <*num*>**] [destination** <*ip-address*>**] [detail] [detour] [reply-mode no-reply | reply-mode router-alert] [reply-tos** <*num*>**] [size <bytes] [source** <*ip-address*>**] [standby] [timeout** <*msec*>**]**

The **rsvp lsp** option specifies the name of the RSVP IPv4 LSP in the <*lsp-name*> variable.

The **rsvp session** option specifies the session ID. The <*tunnel-source-address*>, <*tunnel-destination-address*> and <*tunnel-id*> variables must all be specified to form a valid session ID.

The **count** option with the <*num*> variable specifies the number of echo requests to send. The default value is 5.

The **destination** option specifies an IP address within the 127/8 subnet. The default address is 127.0.0.1

The **detail** option displays the details of the echo request and reply messages. By default, the display is in the brief mode.

The **detour** option specifies a ping detour path. For a detour originated on the ingress LSR, you can ping the detour path using either the LSP name or session ID with the **detour** option specified.

The **reply-mode** option species the reply mode field in the echo request if and only if the user does not want the reply to be sent as an IPv4 UDP packet.

The **no-reply** option can be used to test one-way connectivity.

The **router-alert** option is used when the normal IP return path is unreliable. This option indicates that the reply should be sent as an IPv4 UDP packet with the Router Alert option. This option requires extra overhead processing at each LSR along the return path.

The **reply-tos** option specifies a TOS value between 0 and 254 to be included in the Reply-TOS-byte TLV. This value will be copied to the IP header TOS byte of the echo reply. By default, the reply-tos TLV is not included in the echo request.

NOTE
The last bit of the TOS byte is always 0.

The **size** option specifies that the size of the echo request including the label stack to be sent will be the value of the variable <*bytes*>. The pad TLV is used to fill the echo request message to the specified size. The minimum size is 92 bytes for an MPLS Echo request. The maximum size is the size of the LSP MTU.

The **source** option specifies the IP address of any interface. This address is used as the destination address for the echo reply address. The default address is the LSR ID.

The **standby** option directs the ping operation to the secondary path of a redundant LSP that is operationally up.

The **timeout** option specifies an interval in milliseconds for the echo request message. The default timeout is 5 seconds. The maximum timeout value is 5 minutes.

Executing LDP LSP traceroute

The LDP LSP traceroute command in the (enable) mode, sends and MPLS echo request from the ingress to the egress LSR.

To perform the LDP LSP traceroute operation, use the following command.

```
NetIron# traceroute mpls ldp 22.22.22.22
Trace LDP LSP to 22.22.22.22/32, timeout 5000 msec, TTL 1 to 30
Type Control-c to abort
 1 10ms 22.22.22.22 return code 3(Egress)
NetIron)#
```

Syntax: **traceroute mpls ldp** <*ip-address/mask-length*> **[destination** <*ip-address*>**] [dsmap] [min-ttl** <*min-num*>**] [max-ttl** <*max-num*>**] [reply-mode router-alert] [reply-tos** <*num*>**] [size <bytes] [source** <*ip-address*>**] [timeout** <*msec*>**]**

The **ldp** <*ip-address/mask-length*> variable specifies the LDP IPv4 destination prefix and mask length. If the **mask-length** is not specified, the default value is 32.

The **destination** option specifies an IP address within the 127/8 subnet. The default address is 127.0.0.1

The **dsmap** option enables the Downstream (DS) mapping TLV in the echo request for traceroute operation. The DS mapping TLV is used to instruct the transit LSR to include the next-hop interface and label information in the echo reply. By default, the DS TLV is not included in the echo request.

The **min-ttl** option specifies a minimum value in the <*min-num*> variable for the outermost label in traceroute operation. The default minimum TTL value is 1. Acceptable values that can be configured are: 1 - 255.

The **max-ttl** option specifies a maximum value in the <*max-num*> variable for the outermost label in traceroute operation. The default maximum TTL value is 30. Acceptable values that can be configured are: 1 - 255.

The **reply-mode router-alert** option is used when the normal IP return path is unreliable. This option indicates that the reply should be sent as an IPv4 UDP packet with the Router Alert option. This option requires extra overhead processing at each LSR along the return path.

The **reply-tos** option specifies a TOS value between 0 and 254 to be included in the Reply-TOS-byte TLV. This value will be copied to the IP header TOS byte of the echo reply. By default, the reply-tos TLV is not included in the echo request.

NOTE
The last bit of the TOS byte is always 0.

The **size** option specifies that the size of the echo request including the label stack to be sent will be the value of the variable <*bytes*>. The pad TLV is used to fill the echo request message to the specified size. The minimum size is 92 bytes for an MPLS Echo request. The maximum size is the size of the LSP MTU.

The **source** option specifies the IP address of any interface. This address is used as the destination address for the echo reply address. The default address is the LSR ID.

The **timeout** option specifies an interval in milliseconds for the echo request message. The default timeout is 5 seconds. The maximum timeout value is 5 minutes.

Executing RSVP LSP traceroute

The RSVP LSP traceroute command in the (enable) mode, sends and MPLS echo request from the ingress to the egress LSR.

To perform the RSVP LSP traceroute operation, use the following command.

```
NetIron # traceroute mpls rsvp lsp tomlxe2frr-18
Trace RSVP LSP tomlxe2frr-18, timeout 5000 msec, TTL 1 to 30
Type Control-c to abort
 1 1ms 22.22.22.22 return code 3(Egress)
NetIron#
```

Syntax: **traceroute mpls rsvp lsp** <*lsp-name*> | **session** <*tunnel-source-address*> <*tunnel-destination-address*> <*tunnel-id*> **[destination** <*ip-address*>**] [dsmap] [detour] [min-ttl** <*min-num*>**] [max-ttl** <*max-num*>**] [reply-mode router-alert] [reply-tos** <*num*>**] [size <bytes] [source** <*ip-address*>**] [standby] [timeout** <*msec*>**]**

The **rsvp lsp** option specifies the name of the RSVP IPv4 LSP in the <*lsp-name*> variable.

The **rsvp session** option specifies the session ID. The <*tunnel-source-address*>, <*tunnel-destination-address*> and <*tunnel-id*> variables must all be specified to form a valid session ID.

The **destination** option specifies an IP address within the 127/8 subnet. The default address is 127.0.0.1

The **dsmap** option enables the Downstream (DS) mapping TLV in the echo request for traceroute operation. The DS mapping TLV is used to instruct the transit LSR to include the next-hop interface and label information in the echo reply. By default, the DS TLV is not included in the echo request.

The **detour** option specifies a traceroute detour path. For a detour originated on the ingress LSR, you can ping the detour path using either the LSP name or session ID with the **detour** option specified.

The **reply-mode router-alert** option is used when the normal IP return path is unreliable. This option indicates that the reply should be sent as an IPv4 UDP packet with the Router Alert option. This option requires extra overhead processing at each LSR along the return path.

The **reply-tos** option specifies a TOS value between 0 and 254 to be included in the Reply-TOS-byte TLV. This value will be copied to the IP header TOS byte of the echo reply. By default, the reply-tos TLV is not included in the echo request.

NOTE
The last bit of the TOS byte is always 0.

The **size** option specifies that the size of the echo request including the label stack to be sent will be the value of the variable <*bytes*>. The pad TLV is used to fill the echo request message to the specified size. The minimum size is 92 bytes for an MPLS Echo request. The maximum size is the size of the LSP MTU.

The **source** option specifies the IP address of any interface. This address is used as the destination address for the echo reply address. The default address is the LSR ID.

The **standby** option directs the traceroute operation to the secondary path of a redundant LSP that is operationally up.

The **timeout** option specifies an interval in milliseconds for the echo request message. The default timeout is 5 seconds. The maximum timeout value is 5 minutes.

Displaying LSP ping and traceroute statistics

You can use the **show mpls statistics oam** command to display the following LSP ping and traceroute counters:

- Ping and traceroute requests that are issued by the user
- Echo requests sent
- Echo requests received
- Echo request time-outs
- Echo replies sent
- Echo replies received
- Echo replies with error return codes

To display the LSP ping and traceroute counters use the **show mpls statistics oam** command, as shown in the following.

```
PowerConnect # show mpls statistics oam
User ping request processed: 8
User traceroute request processed: 3
Echo requests: sent(102658), received(2865), timeout(0)
Echo replies: sent(2865), received(102628)
Echo reply return code distribution:        TX         RX
  Egress(3)                        :        0          102628
  Transit(8)                       :        0          0
  No return code(0)                :        0          0
  Malformed request(1)             :        0          0
  Unsupported TLV(2)               :        2865       0
  No FEC mapping(4)                :        0          0
  DS map mismatch(5)               :        0          0
  Unknown upstream intf(6)         :        0          0
  Reserved return code(7)          :        0          0
  Unlabeled output intf(9)         :        0          0
  FEC mapping mismatch(10)         :        0          0
  No label entry(11)               :        0          0
  Rx intf protocol mismatch(12)    :        0          0
  Premature LSP termination(13)    :
```

Syntax: show mpls statistics oam

When the detail option is specified, the echo reply is shown with a error return code based on the error codes listed in RFC 4379.

Clearing the LSP ping and traceroute counters

You can use the **clear mpls statistics oam** command to clear the LSP ping and traceroute counters as shown in the following.

```
NetIron # clear mpls statistics oam
```

Syntax: clear mpls statistics oam

Chapter

61 Foundry Direct Routing and CAM Partition Profiles for the PowerConnect B-MLXe

PowerConnect B-MLXe supports the following Foundry Direct Routing (FDR) and CAM Partition features:

- Foundry Direct Routing
- CAM Partition Profiles
- Supernet CAM Partition Sharing
- CAM Overflow Logging

Configuring FDR globally

The default CAM modecurrently supported is static CAM mode which is also known as Foundry Direct Routing (FDR). You can set the CAM mode to dynamic IP CAM mode using the following command:

```
NetIron(config)# cam-mode ip dynamic
```

You must reload the device for this command to take effect.

Syntax: [no] **cam-mode ip dynamic** [**dynamic** | **static**]

The **dynamic** parameter sets the IP CAM mode to dynamic.

The **static** parameter sets the IP CAM mode to static. This is the default state.

Configuring FDR for IPv6 routes

FDR, also known as IP static CAM mode, can be configured for IPv6 routes. The default for IPv6 routes is static CAM mode. You can set the CAM mode to dynamic using the following command:

```
NetIron(config)# cam-mode ipv6 dynamic
```

You must reload the device for this command to take effect.

Syntax: [no] **cam-mode ipv6** [**dynamic** | **static** | **host**]

The **dynamic** parameter sets the IPv6 CAM mode to dynamic, and programs only the IPv6 prefix into the CAM.

The **static** parameter sets the IPv6 CAM mode to static, and programs only the IPv6 prefix into the CAM. This is the default state.

The **host** parameter programs the complete 128 bit IPv6 address into the CAM.

Configuring FDR for IPv4 and IPv6 VPN routes

FDR can be configured for IPv4 or IPv6 VPN routes. The default CAM mode for IPv4 or IPv6 VPN routes is static. You can set the CAM mode to dynamic using the following command:

```
NetIron(config)# cam-mode ipvpn dynamic
```

You must reload the device for this command to take effect.

Syntax: [no] cam-mode ipvpn [dynamic | static]

The dynamic parameter sets the IPv4 or IPv6 VPN CAM mode to dynamic.

The static parameter sets the IPv4 or IPv6 VPN CAM mode to static. This is the default state.

CAM partition profiles

CAM is partitioned on the device by a variety of profiles that you can select depending on your application.

To implement a CAM partition profile, enter the following command.

```
NetIron(config) cam-partition profile ipv4
```

Syntax: cam-partition profile [ipv4 | ipv4-ipv6| ipv4-ipv6-2 | ipv4-vpls | ipv4-vpn | ipv6 | l2-metro | l2-metro-2 | mpls-l3vpn | mpls-l3vpn-2 | mpls-vpls | mpls-vpls-2 | mpls-vpn-vpls | multi-service | multi-service-2 |multi-service-3 | multi-service-4]

The ipv4 parameter adjusts the CAM partitions, optimize the device for IPv4 applications.

The ipv4-ipv6 parameter adjusts the CAM partitions, to optimize the device for IPv4 and IPv6 dual stack applications

The ipv4-ipv6-2 parameter adjusts the CAM partitions, to optimize the device for increased IPv4 routes with room or IPv6.

The ipv4-vpls parameter adjusts the CAM partitions, to optimize the device for IPv4 and MPLS VPLS applications

The ipv4-vpn parameter adjusts the CAM partitions, to optimize the device for IPv4 and MPLS Layer-3 VPN applications

The ipv6 parameter adjusts the CAM partitions, to optimize the device for IPv6 applications.

The l2-metro parameter adjusts the CAM partitions, to optimize the device for Layer 2 Metro applications.

The l2-metro-2 parameter provides another alternative to l2-metro to optimize the device for Layer 2 Metro applications. It adjusts the CAM partitions.

The mpls-l3vpn parameter adjusts the CAM partitions, to optimize the device for Layer 3, BGP or MPLS VPN applications.

The mpls-l3vpn-2 parameter provides another alternative to mpls-l3vpn to optimize the device for Layer 3, BGP or MPLS VPN applications. It adjusts the CAM partitions.

The mpls-vpls parameter adjusts the CAM partitions, to optimize the device for MPLS VPLS applications.

The mpls-vpls-2 parameter provides another alternative to mpls-vpls to optimize the device for MPLS VPLS applications. It adjusts the CAM partitions.

The mpls-vpn-vpls parameter adjusts the CAM partitions, to optimize the device for MPLS Layer-3 and Layer-2 VPN applications.

The **multi-service** parameter adjusts the CAM partitions, to optimize the device for Multi-Service applications.

The **multi-service-2** parameter provides another alternative to **multi-service** to optimize the device for Multi-Service applications. It adjusts the CAM partitions.

NOTE
You must reload your device for this command to take effect.

The **multi-service-3** parameter provides another alternative to multi-service to optimize the device for Multi-Service applications to support IPv6 VRF. It adjusts the CAM partitions.

The **multi-service-4** parameter provides another alternative to multi-service to optimize the device for Multi-Service applications to support IPv6 VRF. It adjusts the CAM partitions.

Supernet CAM partition sharing

TCAM allocation is optimized to allow dynamic allocation of resources to each level. If one level runs out of TCAM resources, it can use resources that have been allocated to another level and remain unused. This feature is applicable to IPv4, IPv6, and L-3 VPN routes.

Displaying CAM partition

The **show cam-partition** command provides information about available CAM in three formats: raw size, user size, and reserved size.

```
NetIron#show cam-partition
CAM partitioning profile: default
Slot 1 XPP20SP 0:
# of CAM device               = 4
Total CAM Size                 = 917504 entries (63Mbits)

...
```

The formats are:

- **Raw Size:** This is double the value of the CAM partition standard entry count. A standard entry contains 64 bits of data and 64 bits for a mask. The raw size may cover invalid entries.
- **User Size:** The actual number of entries that the application can use. For a 128bit application, such as L4 ACL and IPV6, two standard entries equal one user entry. This format also covers invalid entries.
- **Reserved:** The number of entries not usable in this partition. You can subtract this value from user size to obtain the actual available CAM size.

Syntax: show cam-partition

Displaying CAM Partition for IPv6 VPN

The IPv6 VPN CAM partition is created when multi-service-3 or multi-service-4 CAM profile is configured. The IPv6 VPN CAM partition contains 10 sub partitions.The sub-partition is allocated with a fixed size, but can be dynamically changed. If the size of sub-partition is dynamically changed, the output from the **show cam-partition** command is affected. The following example displays information about IPv6 VPN CAM partition when the current CAM profile is multi-service-3:

```
NetIron# show cam-partition
CAM partitioning profile: multi-service-3
Slot 1 XPP20SP 0:
# of CAM device                = 4
Total CAM Size                 = 917504 entries (63Mbits)
……
IPv6 VPN: Raw Size 131072, User Size 65536(0 reserved)
  Subpartition  0: Raw Size 2048, User Size 1024, (0 reserved)
  Subpartition  1: Raw Size 117734, User Size 58867, (0 reserved)
  Subpartition  2: Raw Size 9333, User Size 4666, (0 reserved)
  Subpartition  3: Raw Size 1285, User Size 642, (0 reserved)
  Subpartition  4: Raw Size 384, User Size 192, (0 reserved)
……
Slot 1 XPP20SP 0:
……

```

The type of CAM partitioning profile configured is displayed in the “CAM partitioning profile line. The “multi-service-3” or “multi-service-4” provife indicates that the system will allocate a partition for IPV6 VPN.

The output displays the size of the available CAM, amount of CAM currently free, and what percentage of the available CAM is used currently.

(**size**): The effective user size obtained by subtracting the reserved size from the user size.

(**free**): The amount of CAM currently available.

(**used**): The percentage of CAM currently being used.

Syntax: show cam-partition usage slot <*slot-number*>

Displaying CAM information

The following commands display CAM information.

Show cam l2vpn

To display all VLL or VPLS MAC entries, including local entries (Port or VLAN or MAC from end points) and remote entries (VC or MAC from VLL or VPLS peers) enter the following command.

```
NetIronr# show cam l2vpn 2/1
Slot Index    MAC            Age  Port  IFL/  VC Label  Out Port Remote DA/ PRAM
     (Hex)                          VLAN                          SA  (Hex)
2    9fff6   abcd.1234.5678  Dis  2/4   4096   74565     2/2      0     DA   8f
2    9fff7   deed.1234.5678  Dis  2/2   500    N/A       Filter   0     DA   8e
```

Syntax: show cam l2vpn <*slot/port*> [<*MAC address*>]

Show cam ipvpn

To display IPv4 VPN CAM entries, including local (Port+VLAN+IP) and remote (VC+IP) entries, enter the following command.

```
NetIron# show cam ipvpn 2/1
Slot Index   IP_Address     Port  Vlan  VC Lbl MAC            Age Out Vlan Out Port
2    0x60000 160.2.3.4/32   2/6   18    N/A    N/A            Dis 10       3/5
2    0x60001 224.7.8.9/32   N/A   N/A   4660   6336.9db8.0600 Dis 20       3/5
```

Syntax: show cam ipvpn <*slot/port*> [**IP prefix**]

Show cam label-out

To display Outbound Label ACL CAMs, enter the following command.

```
NetIron# show cam label-out 2/1
Slot Index   Port  Outer Lbl  Inner Lbl  MAC             Action
2    0xc0000 2/1   1024       1025       abcd.1234.5678  Drop
2    0xc0002 2/1   1027       1028       bade.1234.5678  Drop
```

Syntax: show cam label-out <*slot/port*>

Show IFL CAM partition

To display information about the IFL CAM partition, enter the following command.

```
NetIron#show cam ifl 2/1
Slot  Index    Port  Outer VLAN  Inner VLAN   PRAM   IFL ID
      (Hex)                                  (Hex)
2     00c5fff  2/1   100         200          185fff  4096
```

Syntax: show cam ifl <*slot/port*>

Show CAM IP

To display IP CAM information, enter the following command.

```
NetIron# show cam ip 10/1
Slot Index      IP_Address                  MAC            Age VLAN Out Port
10   0x02ff9(L) 10.10.10.10/32              N/A            Dis N/A  CPU
10   0x02ffa(L) 224.0.0.2/32                N/A            Dis N/A  CPU
10   0x02ffb(L) 224.0.0.18/32               N/A            Dis N/A  CPU
10   0x02ffc(L) 224.0.0.6/32                N/A            Dis N/A  CPU
10   0x02ffd(L) 224.0.0.5/32                N/A            Dis N/A  CPU
10   0x02ffe(L) 224.0.0.9/32                N/A            Dis N/A  CPU
10   0x02fff(L) 255.255.255.255/32          N/A            Dis N/A  CPU
10   0x3548a(R) 10.10.10.10/32              N/A            Dis N/A  Drop
10   0x3ffff(R) 0.0.0.0/0                   N/A            Dis N/A  Drop
```

Syntax: show cam ip <*slot/port*>

Show CAM IPv6

To display IPv6 CAM information, enter the following command

```
NetIron# show cam ipv6 10/3
Slot Index   IPV6_Address                    MAC            Age VLAN Out Port
10   0x5fffc fe80::0/10                      N/A            Dis N/A  CPU
10   0x5fffe ::/0                            N/A            Dis N/A  Drop
```

Syntax: show cam ipv6 <*slot/port*>

Displaying IPv6 VPN CAM information

The **show cam ipv6-vpn** command displays CAM information for an IPv6 VPN CAM entry on a single port, or for all ports on a device. IPv6 VPN CAM contains the destination IPv6 VPN address and layer 3 VPN ID. To display information for an IPv6 VPN CAM entry, enter the following command:

```
NetIron# show cam ipv6-vpn 1/1
LP Index IPV6 VPN Address                    MAC                Age
   (Hex)                                    IFL ID    Out IF   PRAM
1  407f0 10:2037::/128                        N/A                Dis
                                           (21847     Filter  1d615)
1  407f2 10:2036::/128                        N/A                Dis
                                           (21846      Drop    5af6d)
```

Syntax: show cam ipv6-vpn <*slot/port*>

Show cam v6acl

The **show cam v6acl** command displays IPv6 ACL CAM sessions configured on the device. The VLAN column is expanded to display either VLAN or IFL ID as shown in the example below:

```
NetIron# show cam v6acl 1/1
LP Index Src IP Addr                                    SPort IFL/VLAN ID
         Dst IP Addr                                    DPort Pro Age Out IF PRAM
1  74000 6000:1::/64                                    0     536977
         7000:1::/64                                    0     6   Dis Pass   000a4
1  74008 6000:2::/64                                    0     536977
         7000:2::/64                                    0     6   Dis Pass   000a5
1  74010 6000:3::/64                                    0     536977
         7000:3::/64                                    0     6   Dis Pass   000a6
1  74018 6000:4::/64                                    0     536977
         7000:4::/64                                    0     6   Dis Pass   000a7
1  74020 6000:5::/64                                    0     536977
         7000:5::/64                                    0     6   Dis Pass   000a8
1  74028 6000:6::/64                                    0     536977
```

Syntax: show cam ipv6-vpn <*slot/port*>

Show IFL CAM ISID partition

To display information about 802.1AH for ISID, enter the following command:

```
NetIron#show cam ifl-isid 1/1
Slot Index   Port   Outer VLAN Itag ISID  PRAM   IFL ID      IPV4/V6
       (Hex)                             (Hex)              Routing
1    0085fe8 1/14     27        37        185fe8  1             0/0
1    0085fe9 1/13     26        36        185fe9  1             0/1
1    0085fea 1/16     25        35        185fea  1             1/0
1    0085feb 1/15     24        34        185feb  1             1/1
```

Syntax: show cam ifl-isid <*slot/port*>

This output includes an IPv4/ IPv6 Routing column. The IPv4/IPv6 Routing column indicates whether IPv4 or IPv6 is enabled or disabled on the interface. The number 1 represents enabled, and the number 0 represents disabled. For example, if 0/0 is displayed, then IPv4/IPv6 is disabled. If 0/1 is displayed, then IPv4 is disabled/ IPv6 is enabled. The IPv4/IPv6 Routing column is also displayed in the output of the **show cam ifl** command and **show cam ifl-mpls** command.

Configuring CAM partition size

When you configure a tftp file size into the device, the device can only perform a parameter check based on the default CAM profile configured. In this situation, it is possible that you have configured a CAM partition size that conflicts with the physical CAM size. The following **system-max** commands may cause a conflict with the physical CAM size:

- system-max
  - ifl-cam
  - ip-source-guard-cam
  - ipv4-mcast-cam
  - ipv6-mcast-cam
  - lsp-out-acl-cam
  - receive cam

When you have configured a CAM size that conflicts with the physical CAM size, a partition is created with the maximum possible CAM indices assigned to it. The following Syslog message is generated:

```
NetIron# show log
Syslog logging: enabled (0 messages dropped, 0 flushes, 0 overruns)
    Buffer logging: level ACDMEINW, 27 messages logged
    level code: A=alert C=critical D=debugging M=emergency E=error
                I=informational N=notification W=warning

Dynamic Log Buffer (50 lines):
Sep  9 18:48:23:A:CAM IPv6 VPN SNet 9 partition warning: request 32, actual 0,
sl
ot 1, ppcr 0
```

CAM overflow logging

At system initialization, a threshold value is calculated for each sub-partition. If a partition does not have any sub-partitions, the value is based on the entire partition size. If a partition has movable sub-partition boundaries, the threshold value is also based on the entire partition size. By default, the threshold value is 5% of the total entry count. A repeat timer (default to 5 minutes) is also set for each partition to check usage. When the timer expires, if the number of unused CAM entries drops below the threshold percentage value, a log message is generated.

`CAM partition <partition name including sub-partition ID if applicable> warning: total <total count>, free <current free count>, slot <1 based slot number>, ppcr <0 based ppcr id>`

After the log message is generated, the sub-partition time stamp is updated to the current time.

Configuring minimum logging interval and threshold value

You can configure a minimum logging interval and threshold value for CAM partition logging using the following command.

```
NetIron(config)# cam-partition logging 10% 5
```

Syntax: [**no**] **cam-partition logging** <*threshold percentage*> <*interval in minutes*>

You can configure the <*threshold percentage*> variable to change the threshold value from the default 5%.

The <*interval in minutes*> variable allows you to set the minimum logging interval.

NOTE
Because IP and IPv6 sub-partitions can dynamically grow and shrink, for these partitions, logging is implemented at the entire partition level. An SNMP trap is generated with the logging message.

Appendix

Using Syslog

A

The following Syslog features are support.

- Syslog Messages
- Real-Time Display of Syslog Messages
- BFD Syslog
- Increased Syslog buffer
- Time Stamps
- Option for Show Log Command
- Disabling Logging of a Message Level
- Interface Name in Syslog Messages
- TCP or UDP Port Numbers in Syslog Messages
- Logging all CLI Commands
- BFD Logging
- Number of Entries the Local Buffer Can Hold: 1-5000

This appendix describes how to display Syslog messages and how to configure the Syslog facility, and lists the Syslog messages that a PowerConnect can display during standard operation.

NOTE
This appendix does not list Syslog messages that can be displayed when a debug option is enabled.

A PowerConnect's software can write syslog messages to provide information at the following severity levels:

- Emergencies
- Alerts
- Critical
- Errors
- Warnings
- Notifications
- Informational
- Debugging

The device writes the messages to a local buffer, which can hold up to 5000 entries.

You also can specify the IP address or host name of up to six Syslog servers. When you specify a Syslog server, the PowerConnect writes the messages both to the system log and to the Syslog server.

Using a Syslog server ensures that the messages remain available even after a system reload. The PowerConnect's local Syslog buffer is cleared during a system reload or reboot, but the Syslog messages sent to the Syslog server remain on the server.

The Syslog service on a Syslog server receives logging messages from applications on the local host or from devices such as a PowerConnect. Syslog adds a time stamp to each received message and directs messages to a log file. Most Unix workstations come with Syslog configured. Some third party vendor products also provide Syslog running on NT.

Syslog uses UDP port 514 and each Syslog message thus is sent with destination port 514. Each Syslog message is one line with Syslog message format. The message is embedded in the text portion of the Syslog format. There are several subfields in the format. Keywords are used to identify each subfield, and commas are delimiters. The subfield order is insensitive except that the text subfield should be the last field in the message. All the subfields are optional.

Displaying Syslog messages

To display the Syslog messages in the device's local buffer, enter the following command at any level of the CLI.

```
NetIron# show logging

Syslog logging: enabled (0 messages dropped, 0 flushes, 0 overruns)
    Buffer logging: level ACDMEINW, 3 messages logged
    level code: A=alert C=critical D=debugging M=emergency E=error
                I=informational N=notification W=warning

Static Log Buffer:
Dec 15 19:04:14:A:Fan 1, fan on right connector, failed

Dynamic Log Buffer (50 entries):
Dec 15 18:46:17:I:Interface ethernet 1/4, state up
Dec 15 18:45:21:I:Bridge topology change, vlan 4095, interface 4, changed
state to forwarding
Dec 15 18:45:15:I:Warm start
```

For information about the Syslog configuration information, time stamps, and dynamic and static buffers, refer to "Displaying the Syslog configuration" on page 2255.

Enabling real-time display of Syslog messages

By default, to view Syslog messages generated by a PowerConnect, you need to display the Syslog buffer or the log on a Syslog server used by the PowerConnect.

You can enable real-time display of Syslog messages on the management console. When you enable this feature, the software displays a Syslog message on the management console when the message is generated.

When you enable the feature, the software displays Syslog messages on the serial console when they occur. However, to enable display of real-time Syslog messages in Telnet or SSH sessions, you also must enable display within the individual sessions.

To enable real-time display of Syslog messages, enter the following command at the global CONFIG level of the CLI.

```
NetIron(config)# logging console
```

Syntax: [no] logging console

This command enables the real-time display of Syslog messages on the serial console. You can enter this command from the serial console or a Telnet or SSH session.

To also enable the real-time display for a Telnet or SSH session, enter the following command from the Privileged EXEC level of the session.

```
telnet@NetIron# terminal monitor
Syslog trace was turned ON
```

Syntax: [no] terminal monitor

Notice that the CLI displays a message to indicate the status change for the feature. To disable the feature in the management session, enter the **terminal monitor** command again. The command toggles the feature on and off.

```
telnet@NetIron# terminal monitor
Syslog trace was turned OFF
```

Here is an example of how the Syslog messages are displayed.

```
telnet@NetIron# terminal monitor
Syslog trace was turned ON
SYSLOG: <9>NetIron, Power supply 2, power supply on left connector, failed

SYSLOG: <14>NetIron, Interface ethernet 1/6, state down

SYSLOG: <14>NetIron, Interface ethernet 1/2, state up
```

Configuring the Syslog service

The procedures in this section describe how to perform the following Syslog configuration tasks:

- Specify a Syslog server. You can configure the PowerConnect to use up to six Syslog servers. (Use of a Syslog server is optional. The system can hold up to 100 Syslog messages in an internal buffer.)
- Change the level of messages the system logs.
- Change the number of messages the local Syslog buffer can hold.
- Display the Syslog configuration.
- Clear the local Syslog buffer.

Logging is enabled by default, with the following settings:

- Messages of all severity levels (Emergencies – Debugging) are logged.
- By default, up to 50 messages are retained in the local Syslog buffer. This can be changed.
- No Syslog server is specified.

Displaying the Syslog configuration

To display the Syslog parameters currently in effect on a PowerConnect, enter the following command from any level of the CLI.

```
NetIron> show logging

Syslog logging: enabled (0 messages dropped, 0 flushes, 0 overruns)
    Buffer logging: level ACDMEINW, 3 messages logged
    level code: A=alert C=critical D=debugging M=emergency E=error
                I=informational N=notification W=warning

Static Log Buffer:
Dec 15 19:04:14:A:Fan 1, fan on right connector, failed

Dynamic Log Buffer (50 entries):
Dec 15 18:46:17:I:Interface ethernet 1/4, state up
Dec 15 18:45:21:I:Bridge topology change, vlan 4095, interface 4, changed
state to forwarding
Dec 15 18:45:15:I:Warm start
```

Syntax: show logging

The Syslog display shows the following configuration information, in the rows above the log entries themselves.

TABLE 430 CLI Display of Syslog buffer configuration

This field...	Displays...
Syslog logging	The state (enabled or disabled) of the Syslog buffer.
messages dropped	The number of Syslog messages dropped due to user-configured filters. By default, the software logs messages for all Syslog levels. You can disable individual Syslog levels, in which case the software filters out messages at those levels. refer to "Disabling logging of a message level" on page 2260. Each time the software filters out a Syslog message, this counter is incremented.
flushes	The number of times the Syslog buffer has been cleared by the **clear logging** command. refer to "Clearing the Syslog messages from the local buffer" on page 2262.
overruns	The number of times the dynamic log buffer has filled up and been cleared to hold new entries. For example, if the buffer is set for 100 entries, the 101st entry causes an overrun. After that, the 201st entry causes a second overrun.
level	The message levels that are enabled. Each letter represents a message type and is identified by the key (level code) below the value. If you disable logging of a message level, the code for that level is not listed.
messages logged	The total number of messages that have been logged since the software was loaded.
level code	The message levels represented by the one-letter codes.

Static and dynamic buffers

The software provides two separate buffers:

- **Static** – logs power supply failures, fan failures, and temperature warning or shutdown messages
- **Dynamic** – logs all other message types. In previous releases, power supply messages were displayed in static logs only, with only the last event logged in. The power supply messages are now displayed in both static and dynamic logs.

In the static log, new messages replace older ones, so only the most recent message is displayed. For example, only the most recent temperature warning message will be present in the log. If multiple temperature warning messages are sent to the log, the latest one replaces the previous one. The static buffer is not configurable.

The message types that appear in the static buffer do not appear in the dynamic buffer. The dynamic buffer contains up to the maximum number of messages configured for the buffer (50 by default), then begins removing the oldest messages (at the bottom of the log) to make room for new ones.

The static and dynamic buffers are both displayed when you display the log.

```
NetIron(config)# show logging
Syslog logging: enabled (0 messages dropped, 0 flushes, 0 overruns)
    Buffer logging: level ACDMEINW, 3 messages logged
    level code: A=alert C=critical D=debugging M=emergency E=error
          I=informational N=notification W=warning

Static Log Buffer:
Dec 15 19:04:14:A:Fan 1, fan on right connector, failed
Dec 15 19:00:14:A:Fan 2, fan on left connector, failed

Dynamic Log Buffer (50 entries):
Dec 15 18:46:17:I:Interface ethernet 1/4, state up
Dec 15 18:45:21:I:Bridge topology change, vlan 4095, interface 4, changed
state to forwarding
Dec 15 18:45:15:I:Warm start
```

Notice that the static buffer contains two separate messages for fan failures. Each message of each type has its own buffer. Thus, if you replace fan 1 but for some reason that fan also fails, the software replaces the first message about the failure of fan 1 with the newer message. The software does not overwrite the message for fan 2, unless the software sends a newer message for fan 2.

When you clear log entries, you can selectively clear the static or dynamic buffer, or you can clear both. For example, to clear only the dynamic buffer, enter the following command at the Privileged EXEC level.

```
NetIron# clear logging dynamic-buffer
```

Syntax: clear logging [dynamic-buffer | static-buffer]

You can specify **dynamic-buffer** to clear the dynamic buffer or **static-buffer** to clear the static buffer. If you do not specify a buffer, both buffers are cleared.

Time stamps

The contents of the time stamp differ depending on whether you have set the time and date on the onboard system clock:

- If you have set the time and date on the onboard system clock, the date and time are shown in the following format:

  mm dd hh:mm:ss

  where:

  - *mm* – abbreviation for the name of the month
  - *dd* – day

- *hh* – hours
- *mm* – minutes
- *ss* – seconds

For example, “Oct 15 17:38:03” means October 15 at 5:38 PM and 3 seconds.

- If you have not set the time and date on the onboard system clock, the time stamp shows the amount of time that has passed since the device was booted, in the following format:

  <num>d<num>h<num>m<num>s

  where:

  - <*num*>d – day
  - <*num*>h – hours
  - <*num*>m – minutes
  - <*num*>s – seconds

  For example, “188d1h01m00s” means the device had been running for 188 days, 11 hours, one minute, and zero seconds when the Syslog entry with this time stamp was generated.

Example of Syslog messages on a device whose onboard clock is set

The example shows the format of messages on a device whose onboard system clock has been set. Each time stamp shows the month, the day, and the time of the system clock when the message was generated. For example, the system time when the most recent message (the one at the top) was generated was October 15 at 5:38 PM and 3 seconds.

```
NetIron(config)# show log
Syslog logging: enabled (0 messages dropped, 0 flushes, 0 overruns)
    Buffer logging: level ACDMEINW, 38 messages logged
    level code: A=alert C=critical D=debugging M=emergency E=error
                I=informational N=notification W=warning

Static Log Buffer:
Dec 15 19:04:14:A:Fan 1, fan on right connector, failed
Dec 15 19:00:14:A:Fan 2, fan on left connector, failed

Dynamic Log Buffer (50 entries):
Oct 15 17:38:03:warning:list 101 denied tcp 209.157.22.191(0)(Ethernet 4/18
0010.5a1f.77ed) -> 198.99.4.69(http), 1 event(s)
Oct 15 07:03:30:warning:list 101 denied tcp 209.157.22.26(0)(Ethernet 4/18
0010.5a1f.77ed) -> 198.99.4.69(http), 1 event(s)
Oct 15 06:58:30:warning:list 101 denied tcp 209.157.22.198(0)(Ethernet 4/18
0010.5a1f.77ed) -> 198.99.4.69(http), 1 event(s)
```

Example of Syslog messages on a device whose onboard clock is not set

The example shows the format of messages on a device whose onboard system clock is not set. Each time stamp shows the amount of time the device had been running when the message was generated. For example, the most recent message, at the top of the list of messages, was generated when the device had been running for 21 days, seven hours, two minutes, and 40 seconds.

```
NetIron(config)# show log
Syslog logging: enabled (0 messages dropped, 0 flushes, 0 overruns)
    Buffer logging: level ACDMEINW, 38 messages logged
    level code: A=alert C=critical D=debugging M=emergency E=error
                I=informational N=notification W=warning

Static Log Buffer:

Dynamic Log Buffer (50 entries):
21d07h02m40s:warning:list 101 denied tcp 209.157.22.191(0)(Ethernet 4/18
0010.5a1f.77ed) -> 198.99.4.69(http), 1 event(s)
19d07h03m30s:warning:list 101 denied tcp 209.157.22.26(0)(Ethernet 4/18
0010.5a1f.77ed) -> 198.99.4.69(http), 1 event(s)
17d06h58m30s:warning:list 101 denied tcp 209.157.22.198(0)(Ethernet 4/18
0010.5a1f.77ed) -> 198.99.4.69(http), 1 event(s)
```

Ascending or descending option for show log command

A new option was added to the show log command that allows you to display the log in either ascending or descending order based on time. The command will still work without the option selected and will display the log in default descending chronological order. The command is executed as shown

```
NetIron# show log ascending
```

Syntax: show log [ascending | descending]

The **ascending** option displays the oldest log entry first.

The **descending** option displays the most recent log entry first. This is the default condition.

Disabling or re-enabling Syslog

Syslog is enabled by default. To disable it, enter the following command at the global CONFIG level.

```
NetIron(config)# no logging on
```

Syntax: [no] logging on [<*udp-port*>**]**

The <*udp-port*> parameter specifies the application port used for the Syslog facility. The default is 514.

To re-enable logging, enter the following command.

```
NetIron(config)# logging on
```

This command enables local Syslog logging with the following defaults:

- Messages of all severity levels (Emergencies – Debugging) are logged.
- Up to 50 messages are retained in the local Syslog buffer.
- No Syslog server is specified.

Specifying a Syslog server

To specify a Syslog server, enter a command such as the following

```
NetIron(config)# logging host 10.0.0.99
```

For backward compatibility, the software reads the old command syntax from the startup configuration, and converts it to the new command syntax in the running configuration.

Syntax: [no] logging host <*ip-addr*> | <*server-name*>

Specifying an additional Syslog server

To specify an additional Syslog server, enter the **logging host** <*ip-addr*> command again, as in the following example. You can specify up to six Syslog servers.

Enter a command such as the following

```
NetIron(config)# logging host 10.0.0.99
```

For backward compatibility, the software reads the old command syntax from the startup configuration, and converts it to the new command syntax in the running configuration.

Syntax: [no] logging host <*ip-addr*> | <*server-name*>

Disabling logging of a message level

If you want to disable the logging of a message level, you must disable each message level individually.

For example, to disable logging of debugging and informational messages, enter the following commands

```
NetIron(config)# no logging buffered debugging
NetIron(config)# no logging buffered informational
```

Syntax: [no] logging buffered <*level*> | <*num-entries*>

The <*level*> parameter can have one of the following values:

- alerts
- critical
- debugging
- emergencies
- errors
- informational
- notifications
- warnings

The commands in the example above change the log level to notification messages or higher. The software will not log informational or debugging messages. The changed message level also applies to the Syslog servers.

Changing the number of entries for the local buffer

You also can use the **logging buffered** command to change the number of entries the local Syslog buffer can store.

Example

```
NetIron(config)# logging buffered 100
```

Syntax: [no] logging buffered <*level*> | <*num-entries*>

The default number of messages is 50. The change takes effect immediately and does not require you to reload the software.

Changing the log facility

The Syslog daemon on the Syslog server uses a facility to determine where to log the messages from the PowerConnect. The default facility for messages the PowerConnect sends to the Syslog server is "user". You can change the facility using the following command.

NOTE
You can specify only one facility. If you configure the PowerConnect to use two Syslog servers, the device uses the same facility on both servers.

```
NetIron(config)# logging facility local0
```

Syntax: [no] logging facility <*facility-name*>

The <*facility-name*> can be one of the following:

- kern – kernel messages
- user – random user-level messages
- mail – mail system
- daemon – system daemons
- auth – security or authorization messages
- syslog – messages generated internally by Syslog
- lpr – line printer subsystem
- news – netnews subsystem
- uucp – uucp subsystem

Displaying the interface name in Syslog messages

By default, an interface's slot number (if applicable) and port number are displayed when you display Syslog messages. If you want to display the name of the interface instead of its number, enter the following command.

```
NetIron(config)# ip show-portname
```

This command is applied globally to all interfaces on the PowerConnect.

Syntax: [no] Ip show-portname

When you display the messages in the Syslog, you refer to the interface name under the Dynamic Log Buffer section. The actual interface number is appended to the interface name. For example, if the interface name is "lab" and its port number is "2", you refer to "lab2" displayed as in the example below.

```
NetIron# show logging
Syslog logging: enabled (0 messages dropped, 0 flushes, 0 overruns)
    Buffer logging: level ACDMEINW, 3 messages logged
    level code: A=alert C=critical D=debugging M=emergency E=error
         I=informational N=notification W=warning
Static Log Buffer:
Dec 15 19:04:14:A:Fan 1, fan on right connector, failed
Dynamic Log Buffer (50 entries):
Dec 15 18:46:17:I:Interface ethernet Lab2, state up
Dec 15 18:45:15:I:Warm start
```

Clearing the Syslog messages from the local buffer

To clear the Syslog messages stored in the PowerConnect's local buffer, use the following command.

```
NetIron# clear logging
```

Syntax: clear logging

Displaying TCP or UDP port numbers in Syslog messages

The command **ip show-acl-service-number** allows you to change the display of TCP or UDP application information from the TCP or UDP well-known port name to the TCP or UDP port number. For example, entering the following command causes the PowerConnect to display http (the well-known port name) instead of 80 (the port number) in the output of show commands, and other commands that contain application port information. By default, the PowerConnect displays TCP or UDP application information in named notation.

In this release, you can display TCP or UDP port number instead of their names in syslog messages by entering the following command.

```
NetIron(config)# ip show-service-number-in-log
```

Syntax: [no] ip show-service-number-in-log

Logging all CLI commands to Syslog

This feature allows you to log all valid CLI command from each user session into the system log.

To enable CLI command logging, enter the following command.

```
NetIron(config)# logging cli-command
```

Syntax: [no] logging cli-command

Example of CLI command logging

In the following example, two CLI sessions are run. In the first example, a telnet session enables CLI command logging and configures **router bgp** and the BGP **no neighbor** command as shown.

```
telnet@ NetIron-2(config)# logging cli-command
telnet@ NetIron-2(config)# router bgp
telnet@ NetIron-2(config-bgp)# no nei 10.1.1.8 remote 10
```

In the next example, a console session configures **router bgp** and the BGP **neighbor** command as shown.

```
NetIron-2(config)# router bgp
NetIron-2(config-bgp)# nei 10.1.1.8 remote 10
```

Using the **show log** command, you would refer to a series of log records as shown in the following.

```
NetIron(config-bgp)# show log
Syslog logging: enabled (0 messages dropped, 0 flushes, 0 overruns)
    Buffer logging: level ACDMEINW, 24 messages logged
    level code: A=alert C=critical D=debugging M=emergency E=error
                I=informational N=notification W=warning
Dynamic Log Buffer (50 lines):
Sep 9 18:38:23:I:CLI CMD: "nei 10.1.1.8 remote 10" from console
Sep 9 18:38:21:I:CLI CMD: "router bgp" from console
Sep 9 18:38:07:I:CLI CMD: "no nei 10.1.1.8 remote 10" from telnet client 10.1.1.1
Sep 9 18:38:05:I:CLI CMD: "router bgp" from telnet client 10.1.1.1
```

Syslog messages

The tables that follow list all of the Syslog messages. The messages are listed by message level, in the following order:

- Emergencies (none)
- Alerts
- Critical
- Errors
- Warnings
- Notifications
- Informational
- Debugging

TABLE 431 Syslog messages system

Message level	Message	Explanation
Alert	ISIS Memory Limit Exceeded	IS-IS is requesting more memory than is available.
Alert	System Power supply <*num*>, <*location*>, failed	A power supply has failed. The <*num*> is the power supply number. The <*location*> describes where the failed power supply is in the chassis.
Alert	System <*power type*> Power Supply <*num*>, <*location*>,< *state*>	The <*power type*> refers to AC or DC power supply. The <*num*> is the power supply number as positioned in the chassis. The <*location*> describes where the power supply is in the chassis in relation to its state. The <*state*> refers to how the power supply is functioning in the chassis. The <*state*> can be one of the following: • Installed (OK) - The power supply is installed and ok. • Installed (Failed or Disconnected)- The power supply has failed, or the power cord is disconnected. • Not Installed (FAILED) - The power supply is physically removed from the chassis.
Alert	System Fan <*num*>, <*location*>, failed	A fan has failed. The <*num*> is the power supply number. The <*location*> describes where the failed power supply is in the chassis. The location can be one of the following
Alert	System Management module at slot <*slot-num*> state changed from <*module-state*> to <*module-state*> due to <*reason*>.	Indicates a state change in a management module. The <*slot-num*> indicates the chassis slot containing the module. The <*module-state*> can be one of the following: • active • standby • crashed • coming-up • unknown A **due to** clause has been added to this message. The <*reason*> variable can be either or the following: • MP upgrade to ver <*version number*> where <*version number*> is the version number of the Multi-Service IronWare software that the management module was upgraded to. • Active Reboot
Alert	System Temperature <*degrees*> C degrees, warning level <*warn-degrees*> C degrees, shutdown level <*shutdown-degrees*> C degrees	Indicates an overtemperature condition on the active module. The <*degrees*> value indicates the temperature of the module. The <*warn-degrees*> value is the warning threshold temperature configured for the module. The <*shutdown-degrees*> value is the shutdown temperature configured for the module.

TABLE 431 Syslog messages system (Continued)

Message level	Message	Explanation
Alert	System <*num-modules*> modules and 1 power supply, need more power supply!!	Indicates that the chassis needs more power supplies to run the modules in the chassis. The <*num-modules*> parameter indicates the number of modules in the chassis.
Alert	System: Health Monitoring: TM Egress data errors detected on LP <*num*>/TM <*num*>	The system has detected egress data errors on the specified line processor and traffic manager. The LP and TM <*num*> parameters indicate the number of the line processor and traffic manager on which the errors were detected.
Error	Error Module down in slot 3, reason CARD_DOWN_REASON_BOOT_FAILED.Err or Code (1).	• The error message displayed on the Management Module console when the Interface Module fails to boot up. The message will display the error code reason. • When the Interface Module is in DOWN state, the error code is included in the dynamic buffer. The error code is 0 when there is no error code reported from the Interface Module.
Warning	CAM partition <*partition name*> warning total <*total-count*>, free <current free-count>, slot <*slot-number*>, ppcr <*ppcr-id*>	Indicates that the CAM partition specified by the <*partition name*> has exceeded a threshold (configurable with a default value of within 5% of the capacity of the partition) and may soon overflow the threshold. The <*free-count*> specifies the amount of free space still available in the partition. The <*slot-number*> and ppcr <*ppcr-id*> indicate where the overflow is occurring. The <*partition-name*> includes the sub-partition ID if applicable.
Warning	System Not enough power to power on module in slot <*num*>	There is not enough power available in the chassis to power on the module in the specific slot number. The slot <*num*> refers to the slot number in the chassis.
Notification	System Module up in slot <*n*>	
Notification	System Module down in slot <*n*> reason <*reason*>	Indicates that the module in the slot specified by the <*n*> variable is down for one of the following reasons as specified by the <*reason*> variable: • CARD_DOWN_REASON_NONE • CARD_DOWN_REASON_ADMIN_DOWN • CARD_DOWN_REASON_CONFIG_MISMATCH • CARD_DOWN_REASON_LOSS_HEARTBEAT • CARD_DOWN_REASON_BOOT_FAILED • CARD_DOWN_REASON_TIMEOUT • CARD_DOWN_REASON_STRIPE_SYNC_FAILED • CARD_DOWN_REASON_REBOOTED • CARD_DOWN_REASON_OVER_HEAT • CARD_DOWN_REASON_POWERED_OFF_BY_USER • CARD_DOWN_REASON_LINK_DOWN

TABLE 431 Syslog messages system (Continued)

Message level	Message	Explanation
Notification	System Module <*n*> powered on	
Notification	System Module <*n*> powered off	
Notification	System Switch fabric <*n*> powered on	
Notification	System Switch fabric <*n*> powered off	
Notification	System Enough power available to power on module in slot <*num*>.	There is enough power available in the chassis to power on the module in the specific slot number. The slot <*num*> refers to the slot number in the chassis.
Notification	System Module was inserted to slot <*slot-num*>	Indicates that a module was inserted into a chassis slot. The <*slot-num*> is the number of the chassis slot into which the module was inserted.
Notification	System Module was removed from slot <*slot-num*>	Indicates that a module was removed from a chassis slot. The <*slot-num*> is the number of the chassis slot from which the module was removed.
Notification	System Set fan speed to <*speed*> <*percentage*>	Indicates that the fan speed has been changed to the value described in the <*speed*> variable and that the fan is now operating at the <*percentage*> of capacity described. The possible <*speed*> <*percentage*> values are: • LOW (50%) • MEDIUM (75%) • MEDIUM-HIGH (90%) • HIGH (100%)
Informational	System Cold start	The device has been powered on.
Informational	System Warm start	The system software (flash code) has been reloaded.
Informational	System Interface <*portnum*>, state up	A port has come up. The <*portnum*> is the port number.
Informational	System Interface <*portnum*>, state down	A port has gone down. The <*portnum*> is the port number.
Informational	System Interface <*portnum*>, line protocol up	The line protocol on a port has come up. The <*portnum*> is the port number.
Informational	System Interface <*portnum*>, line protocol down	The line protocol on a port has gone down. The <*portnum*> is the port number.
Informational	System Interface <*portnum*> is down (remote fault)	The interface is down due to Remote Fault. This is indicated as “(remote fault)”. The <*portnum*> is the port number of the interface.
Informational	System <*portnum*> is down (local fault)	The port is down due to Local Fault. This is indicated as “(local fault)”. The <*portnum*> is the port number of the interface.

TABLE 431 Syslog messages system (Continued)

Message level	Message	Explanation
Informational	System Syslog server <*IP-address*> deleted | added | modified from console | telnet | ssh | web | snmp OR Syslog operation enabled | disabled from console | telnet | ssh | web | snmp	A user made Syslog configuration changes to the specified Syslog server address, or enabled or disabled a Syslog operation through the Web, SNMP, console, SSH, or Telnet session.
Informational	System SSH | telnet server enabled | disabled from console | telnet | ssh | web | snmp session [by user <*username*>]	A user enabled or disabled an SSH or Telnet session, or changed the SSH enable or disable configuration through the Web, SNMP, console, SSH, or Telnet session.
Informational	System Module <*n*> CPU <*m*> crashed	
Informational	System IfIndex assignment was changed .)	The maximum number of ifIndex per module has been changed.

TABLE 432 Syslog messages security

Message level	Message	Explanation
Warning	Security Port security violation at interface e<*portnum*>, address <*mac*>, vlan <*id*>	
Warning	Security Interface e<*portnum*> was shut down due to port security violation	
Informational	Security console login {by <*user*>I<*null*>} to USER EXEC mode Security {telnet I ssh} login {by <*user*>I<*null*>} from src {IP <*ip*> I IPv6 <*ipv6-addr*>} to USER EXEC mode	A user has logged into the USER EXEC mode of the CLI. The <*user*> is the user name.
Informational	Security console logout {by <*user*>I<*null*>} from USER EXEC mode Security {telnet I ssh} logout {by <*user*>I<*null*>} from src {IP <*ip*> I IPv6 <*ipv6-addr*>} from USER EXEC mode	A user has logged out of the USER EXEC mode of the CLI. The <*user*> is the user name.
Informational	Security console login {by <*user*>I<*null*>} to Privileged EXEC mode Security {telnet I ssh} login {by <*user*>I<*null*>} from src {IP <*ip*> I IPv6 <*ipv6-addr*>} to Privileged EXEC mode	A user has logged into the Privileged EXEC mode of the CLI. The <*user*> is the user name.
Informational	Security console logout {by <*user*>I<*null*>} from Privileged EXEC mode Security {telnet I ssh} logout {by <*user*>I<*null*>} from src {IP <*ip*> I IPv6 <*ipv6-addr*>} from Privileged EXEC mode	A user has logged out of Privileged EXEC mode of the CLI. The <*user*> is the user name.
Informational	Security outbound telnet <*session number*> login to server IP <*ip*> from SSH session <*session number*>	A user has initiated an outbound Telnet session from an inbound SSH session. The first <*session number*> is the number of the outbound Telnet session. The <*ip*> is the IP address to which the Telnet session is connected. The second <*sessions number*> is the number of the inbound SSH session.

TABLE 432 Syslog messages security (Continued)

Message level	Message	Explanation
Informational	Security outbound telnet <*session number*> logout from server IP <*ip*> from SSH session <*session number*>	A user has terminated an outbound Telnet session initiated from an inbound SSH session. The first <*session number*> is the number of the outbound Telnet session. The <*ip*> is the IP address from which the Telnet session has disconnected. The second <*sessions number*> is the number of the inbound SSH session.
Informational	Security startup-config was changed {by <*user*>} from {web management I snmp management I ssh client <*ip*> I telnet client <*ip*>}	A configuration change was saved to the startup configuration file. The <*user*> is the user's ID, if they entered a user ID to log in.
Informational	Security running-config was changed {by <*user*>} from {web management I snmp management I ssh client <*ip*> I telnet client <*ip*>}	A configuration change was saved to the running configuration file. The <*user*> is the user's ID, if they entered a user ID to log in.
Informational	Security telnet | SSH | web access [by <*username*>] from src IP <*source ip address*>, src MAC <*source MAC address*> rejected, <*n*> attempts	There were failed web, SSH, or Telnet login access attempts from the specified source IP and MAC address. • [by <*user*> <*username*>] does not appear if telnet or SSH clients are specified. • <*n*> is the number of times this SNMP trap occurred in the last five minutes, or other configured number of minutes.
Informational	Security user <*username*> added | deleted | modified from console | telnet | ssh | web | snmp	A user created, modified, or deleted a local user account through the Web, SNMP, console, SSH, or Telnet session.
Informational	Security Enable super | port-config | read-only password deleted | added | modified from console | telnet | ssh | web | snmp OR Line password deleted | added | modified from console | telnet | ssh | web | snmp	A user created, re-configured, or deleted an Enable or Line password through the Web, SNMP, console, SSH, or Telnet session.

TABLE 433 Syslog messages VLAN

Message level	Message	Explanation
Informational	VLAN Id <*vlan-id*> added | deleted | modified from console | telnet | ssh | web | snmp session	A user created, modified, or deleted a VLAN through the Web, SNMP, console, SSH, or Telnet session.

TABLE 434 Syslog messages STP

Message level	Message	Explanation
Informational	STP VLAN <*id*> - New RootBridge <*string*> RootPort <*portnum*> (<*reason*>)	A Spanning Tree Protocol (STP) topology change has occurred. The <*id*> is the ID of the VLAN in which the STP topology change occurred. The <*portnum*> is the number of the port connected to the new root bridge.
Informational	STP VLAN <*id*> - Bridge is RootBridge <*string*> (<*reason*>)	A Spanning Tree Protocol (STP) topology change has occurred, resulting in the PowerConnect becoming the root bridge. The <*id*> is the ID of the VLAN in which the STP topology change occurred.
Informational	STP VLAN <*id*> Port <*portnum*> - Bridge TC Event (<*reason*>)	A Spanning Tree Protocol (STP) topology change has occurred on a port. The <*id*> is the ID of the VLAN in which the STP topology change occurred. The <*portnum*> is the port number.
Informational	STP VLAN <*vlanid*> Port <*portnum*> - State <*state*> (<*reason*>)	
Informational	STP Root Guard Port <*portnum*>, VLAN <*vlan-id*> inconsistent (Received superior BPDU)	The specified port was blocked because i t has Root Guard enabled and received a superior BPDU .
Informational	STP Root Guard Port <*portnum*>, VLAN <*vlan-id*> consistent (Timeout)	The specified block Root Guard-protected port was unblocked.
Informational	STP BPDU Guard port <*portnum*> disable System Interface ethernet <*portnum*>, state down - disabled	The **spanning-tree protect do-disable** command is configured on the specified port and the port became disabled due to a receipt of a BPDU packet.
Informational	STP BPDU Guard re-enabled on ports ethe <*portnum*> System Interface ethernet <*portnum*>, state up	The **spanning-tree protect re-enable** was issued to re-enable the specified port

TABLE 435 Syslog messages RSTP

Message level	Message	Explanation
Informational	RSTP VLAN <*id*> Port <*portnum*> - Bridge TC Event (reason)	802.1W recognized a topology change event in the bridge. The topology change event is the forwarding action that started on a non-edge Designated port or Root port.
Informational	RSTP VLAN <*id*> Port <*portnum*> - STP State <*state*> (reason)	802.1W changed the state of a port to a new state forwarding, learning, blocking. If the port changes to blocking, the bridge port is in discarding state.
Informational	RSTP VLAN <*id*> - New RootPort <*portnum*> (reason)	802.1W changed the port's role to Root port, using the root selection computation.
Informational	RSTP VLAN <*id*> - New RootBridge <*string*> RootPort <*portnum*> (reason)	802.1W selected a new root bridge as a result of the BPDUs received on a bridge port.

TABLE 435 Syslog messages RSTP (Continued)

Message level	Message	Explanation
Informational	RSTP VLAN <*id*> - Bridge is RootBridge <*string*> (reason)	802.1W changed the current bridge to be the root bridge of the given topology due to administrative change in bridge priority.
Informational	vlan <*vlan-id*> Bridge is RootBridge <*mac-address*> (MsgAgeExpiry)	The message age expired on the Root port so 802.1W changed the current bridge to be the root bridge of the topology.

TABLE 436 Syslog messages LAG

Message level	Message	Explanation
Informational	LAG group (<*ports*>) created by 802.3ad link-aggregation module.	802.3ad link aggregation is configured on the device, and the feature has dynamically created a LAG group (aggregate link). The <*ports*> is a list of the ports that were aggregated to make the LAG group.

TABLE 437 Syslog messages MRP

Message level	Message	Explanation
Informational	MRP interface ethernet <*portnum*> vlan <*vlan-master*>, changing to <*state-string*>	
Informational	MRP metro ring <*ring-id*> cannot be enabled. No free CAM entries	

TABLE 438 Syslog messages UDLD

Message level	Message	Explanation
Informational	UDLD Logical link on interface ethernet <*portnum*> is up	
Informational	UDLD Logical link on interface ethernet <*portnum*> is down	

TABLE 439 Syslog messages VSRP

Message level	Message	Explanation
Informational	VSRP VLAN <*vlanid*> VRID <*id*> - transition to <*state-string*>	
Informational	VSRP VLAN <*vlanid*> VRID <*id*> - aware change <*old-portnum*> -> <*new-portnum*>\n	
Informational	VSRP VLAN <*vlanid*> VRID <*id*> - aware learn <*portnum*>	

TABLE 440 Syslog messages VRRP

Message level	Message	Explanation
Notification	VRRP intf state changed, intf <*portnum*>, vrid <*virtual-router-id*>, state <*vrrp-state*>	A state change has occurred in a Virtual Router Redundancy Protocol (VRRP) interface. The <*portnum*> is the port. The <*virtual-router-id*> is the virtual router ID (VRID) configured on the interface. The <*vrrp-state*> can be one of the following: • init • master • backup • unknown

TABLE 441 Syslog messages IP

Message level	Message	Explanation
Warning	IP Dup IP <*ip-addr*> detected, sent from MAC <*mac-addr*> interface <*portnum*>	Indicates that the PowerConnect received a packet from another device on the network with an IP address that is also configured on the PowerConnect. The <*ip-addr*> is the duplicate IP address. The <*mac-addr*> is the MAC address of the device with the duplicate IP address. The <*portnum*> is the port that received the packet with the duplicate IP address. The address is the packet's source IP address.

TABLE 442 Syslog messages ICMP

Message level	Message	Explanation
Notification	ICMP Local ICMP exceeds <*burst-max*> burst packets, stopping for <*lockup*> seconds!!	The number of ICMP packets exceeds the <*burst-max*> threshold set by the **ip icmp burst** command. The PowerConnect may be the victim of a Denial of Service (DoS) attack. All ICMP packets will be dropped for the number of seconds specified by the <*lockup*> value. When the lockup period expires, the packet counter is reset and measurement is restarted.
Notification	ICMP Transit ICMP in interface <*portnum*> exceeds <*num*> burst packets, stopping for <*num*> seconds!!	Threshold parameters for ICMP transit (through) traffic have been configured on an interface, and the maximum burst size for ICMP packets on the interface has been exceeded. The <*portnum*> is the port number. The first <*num*> is the maximum burst size (maximum number of packets allowed). The second <*num*> is the number of seconds during which additional ICMP packets will be blocked on the interface. **NOTE:** This message can occur in response to an attempted Smurf attack.

TABLE 443 Syslog messages ACL

Message level	Message	Explanation
Warning	ACL list <*acl-num*> denied <*ip-proto*> <*src-ip-addr*> (<*src-tcp/udp-port*>) (Ethernet <*portnum*> <*mac-addr*>) -> <*dst-ip-addr*> (<*dst-tcp/udp-port*>), 1 events	Indicates that an Access Control List (ACL) denied (dropped) packets. The <*acl-num*> indicates the ACL number. Numbers 1 – 99 indicate standard ACLs. Numbers 100 – 199 indicate extended ACLs. The <*ip-proto*> indicates the IP protocol of the denied packets. The <*src-ip-addr*> is the source IP address of the denied packets. The <*src-tcp/udp-port*> is the source TCP or UDP port, if applicable, of the denied packets. The <*portnum*> indicates the port number on which the packet was denied. The <*mac-addr*> indicates the source MAC address of the denied packets. The <*dst-ip-addr*> indicates the destination IP address of the denied packets. The <*dst-tcp/udp-port*> indicates the destination TCP or UDP port number, if applicable, of the denied packets.
Warning	ACL:rip filter list <*list-num*> <*direction*> V1 | V2 denied <*ip-addr*>, <*num*> packets	Indicates that a RIP route filter denied (dropped) packets. The <*list-num*> is the ID of the filter list. The <*direction*> indicates whether the filter was applied to incoming packets or outgoing packets. The value can be one of the following: • in • out The V1 or V2 value specifies the RIP version (RIPv1 or RIPv2). The <*ip-addr*> indicates the network number in the denied updates. The <*num*> indicates how many packets matching the values above were dropped during the five-minute interval represented by the log entry.
Notification	ACL insufficient L4 session resource, using flow based ACL instead	The device does not have enough Layer 4 session entries. To correct this condition, allocate more memory for sessions. To allocate more memory, enter the following command at the global CONFIG level of the CLI interface **system-max session-limit** <*num*>
Notification	ACL system fragment packet inspect rate <*rate*> exceeded	The fragment rate allowed on the device has been exceeded. The <*rate*> indicates the maximum rate allowed. This message can occur if fragment thottling is enabled.

TABLE 443 Syslog messages ACL (Continued)

Message level	Message	Explanation
Notification	AC port fragment packet inspect rate <*rate*> exceeded on port <*portnum*>	The fragment rate allowed on an individual interface has been exceeded. The <*rate*> indicates the maximum rate allowed. The <*portnum*> indicates the port. This message can occur if fragment thottling is enabled.
Notification	ACL Port <*portnum*>, exceed configured L4 rule-based CAM size, larger L4 partition size required	
Notification	ACL Port <*portnum*>, exceed configured L2 ACL rule-based CAM size, larger partition size is required	
Notification	ACL Port <*portnum*>, exceed configured outbound L4 rule-based CAM size, larger outbound L4 partition size required	
Notification	ACL Port <*portnum*>, exceed configured IPv6 L4 rule-based CAM size, larger IPv6 L4 partition size required	
Notification	ACL Port <*portnum*>, exceed configured IPv6 outbound L4 rule-based CAM size, larger IPv6 outbound L4 partition size required	
Notification	ACL Port <*portnum*>, error in allocating inbound L4 rule-based ACL CAM entry	
Notification	ACL Port <*portnum*>, error in allocating outbound L4 rule-based ACL CAM entry	
Notification	ACL Port <*portnum*>, inbound ACL CAM programming incomplete	
Notification	ACL Port <*portnum*>, outbound ACL CAM programming incomplete	
Informational	ACL <*aclid*> added | deleted | modified from console | telnet | ssh | web | snmp session	A user created, modified, deleted, or applied an ACL through the Web, SNMP, console, SSH, or Telnet session.

TABLE 444 Syslog messages RACL

Message level	Message	Explanation
Notification	RACL Port <*portnum*>, IP Receive ACL exceed configured CAM size, larger partition size required	
Notification	RACL Port <*portnum*>, IP Receive ACL exceed configured RL class limit	
Notification	RACL Port <*portnum*>, IP Receive ACL CAM malloc error	

TABLE 445 Syslog messages OSPF

Message level	Message	Explanation
Alert	OSPF Memory Overflow	OSPF has run out of memory.
Alert	OSPF LSA Overflow, LSA Type = <*lsa-type*>	Indicates an LSA database overflow. The <*lsa-type*> parameter indicates the type of LSA that experienced the overflow condition. The LSA type is one of the following: • 1 – Router • 2 – Network • 3 – Summary • 4 – Summary • 5 – External
Notification	OSPF interface state changed, rid <*router-id*>, intf addr <*ip-addr*>, state <*ospf-state*>	Indicates that the state of an OSPF interface has changed. The <*router-id*> is the router ID of the PowerConnect. The <*ip-addr*> is the interface's IP address. The <*ospf-state*> indicates the state to which the interface has changed and can be one of the following: • down • loopback • waiting • point-to-point • designated router • backup designated router • other designated router • unknown
Notification	OSPF virtual intf state changed, rid <*router-id*>, area <*area-id*>, nbr <*ip-addr*>, state <*ospf-state*>	Indicates that the state of an OSPF virtual routing interface has changed. The <*router-id*> is the router ID of the router the interface is on. The <*area-id*> is the area the interface is in. The <*ip-addr*> is the IP address of the OSPF neighbor. The <*ospf-state*> indicates the state to which the interface has changed and can be one of the following: • down • loopback • waiting • point-to-point • designated router • backup designated router • other designated router • unknown

TABLE 445 Syslog messages OSPF (Continued)

Message level	Message	Explanation
Notification	OSPF nbr state changed, rid <*router-id*>, nbr addr <*ip-addr*>, nbr rid <*nbr-router-ld*>, state <*ospf-state*>	Indicates that the state of an OSPF neighbor has changed. The <*router-id*> is the router ID of the PowerConnect. The <*ip-addr*> is the IP address of the neighbor. The <*nbr-router-id*> is the router ID of the neighbor. The <*ospf-state*> indicates the state to which the interface has changed and can be one of the following: • down • attempt • initializing • 2-way • exchange start • exchange • loading • full • unknown
Notification	OSPF virtual nbr state changed, rid <*router-id*>, nbr addr <*ip-addr*>, nbr rid <*nbr-router-id*>, state <*ospf-state*>	Indicates that the state of an OSPF virtual neighbor has changed. The <*router-id*> is the router ID of the PowerConnect. The <*ip-addr*> is the IP address of the neighbor. The <*nbr-router-id*> is the router ID of the neighbor. The <*ospf-state*> indicates the state to which the interface has changed and can be one of the following: • down • attempt • initializing • 2-way • exchange start • exchange • loading • full • unknown

TABLE 445 Syslog messages OSPF (Continued)

Message level	Message	Explanation
Notification	OSPF intf config error, rid <*router-id*>, intf addr <*ip-addr*>, pkt src addr <*src-ip-addr*>, error type <*error-type*>, pkt type <*pkt-type*>	Indicates that an OSPF interface configuration error has occurred. The <*router-id*> is the router ID of the PowerConnect. The <*ip-addr*> is the IP address of the interface on the PowerConnect. The <*src-ip-addr*> is the IP address of the interface from which the PowerConnect received the error packet. The <*error-type*> can be one of the following: • bad version • area mismatch • unknown NBMA neighbor • unknown virtual neighbor • authentication type mismatch • authentication failure • network mask mismatch • hello interval mismatch • dead interval mismatch • option mismatch • unknown The <*packet-type*> can be one of the following: • hello • database description • link state request • link state update • link state ack • unknown

TABLE 445 Syslog messages OSPF (Continued)

Message level	Message	Explanation
Notification	OSPF virtual intf config error, rid <*router-id*>, intf addr <*ip-addr*>, pkt src addr <*src-ip-addr*>, error type <*error-type*>, pkt type <*pkt-type*>	Indicates that an OSPF virtual routing interface configuration error has occurred. The <*router-id*> is the router ID of the PowerConnect. The <*ip-addr*> is the IP address of the interface on the PowerConnect. The <*src-ip-addr*> is the IP address of the interface from which the PowerConnect received the error packet. The <*error-type*> can be one of the following: • bad version • area mismatch • unknown NBMA neighbor • unknown virtual neighbor • authentication type mismatch • authentication failure • network mask mismatch • hello interval mismatch • dead interval mismatch • option mismatch • unknown The <*packet-type*> can be one of the following: • hello • database description • link state request • link state update • link state ack • unknown

TABLE 445 Syslog messages OSPF (Continued)

Message level	Message	Explanation
Notification	OSPF intf authen failure, rid <*router-id*>, intf addr <*ip-addr*>, pkt src addr <*src-ip-addr*>, error type <*error-type*>, pkt type <*pkt-type*>	Indicates that an OSPF interface authentication failure has occurred. The <*router-id*> is the router ID of the PowerConnect. The <*ip-addr*> is the IP address of the interface on the PowerConnect. The <*src-ip-addr*> is the IP address of the interface from which the PowerConnect received the authentication failure. The <*error-type*> can be one of the following: • bad version • area mismatch • unknown NBMA neighbor • unknown virtual neighbor • authentication type mismatch • authentication failure • network mask mismatch • hello interval mismatch • dead interval mismatch • option mismatch • unknown The <*packet-type*> can be one of the following: • hello • database description • link state request • link state update • link state ack • unknown

TABLE 445 Syslog messages OSPF (Continued)

Message level	Message	Explanation
Notification	OSPF virtual intf authen failure, rid <*router-id*>, intf addr <*ip-addr*>, pkt src addr <*src-ip-addr*>, error type <*error-type*>, pkt type <*pkt-type*>	Indicates that an OSPF virtual routing interface authentication failure has occurred. The <*router-id*> is the router ID of the PowerConnect. The <*ip-addr*> is the IP address of the interface on the PowerConnect. The <*src-ip-addr*> is the IP address of the interface from which the PowerConnect received the authentication failure. The <*error-type*> can be one of the following: • bad version • area mismatch • unknown NBMA neighbor • unknown virtual neighbor • authentication type mismatch • authentication failure • network mask mismatch • hello interval mismatch • dead interval mismatch • option mismatch • unknown The <*packet-type*> can be one of the following: • hello • database description • link state request • link state update • link state ack • unknown

TABLE 445 Syslog messages OSPF (Continued)

Message level	Message	Explanation
Notification	OSPF intf rcvd bad pkt, rid <*router-id*>, intf addr <*ip-addr*>, pkt src addr <*src-ip-addr*>, pkt type <*pkt-type*>	Indicates that an OSPF interface received a bad packet. The <*router-id*> is the router ID of the PowerConnect. The <*ip-addr*> is the IP address of the interface on the PowerConnect. The <*src-ip-addr*> is the IP address of the interface from which the PowerConnect received the authentication failure. The <*packet-type*> can be one of the following: • hello • database description • link state request • link state update • link state ack • unknown **NOTE:** This message is typically generated during BFD or OSPF reconverge within the following scenarios: • The router is undergoing hitless upgrade • Management module switchover, • Interface module CPU utilization is at 95% or more, • The **clear ip ospf neighbor all** command is issued. During these processes, OSPF adj is deleted due to BFD time out while the router can still receive OSPF packets destined to a previous session from its neighbor because the neighbor has an inconsistent OSPF state due to timing. This message will go away shortly when BFD or OSPF re-establishes neighbor.
Notification	OSPF virtual intf rcvd bad pkt, rid <*router-id*>, intf addr <*ip-addr*>, pkt src addr <*src-ip-addr*>, pkt type <*pkt-type*>	Indicates that an OSPF interface received a bad packet. The <*router-id*> is the router ID of the PowerConnect. The <*ip-addr*> is the IP address of the interface on the PowerConnect. The <*src-ip-addr*> is the IP address of the interface from which the PowerConnect received the authentication failure. The <*packet-type*> can be one of the following: • hello • database description • link state request • link state update • link state ack • unknown

TABLE 445 Syslog messages OSPF (Continued)

Message level	Message	Explanation
Notification	OSPF intf retransmit, rid <*router-id*>, intf addr <*ip-addr*>, nbr rid <*nbr-router-id*>, pkt type is <*pkt-type*>, LSA type <*lsa-type*>, LSA id <*lsa-id*>, LSA rid <*lsa-router-id*>	An OSPF interface on the PowerConnect has retransmitted a Link State Advertisement (LSA). The <*router-id*> is the router ID of the PowerConnect. The <*ip-addr*> is the IP address of the interface on the PowerConnect. The <*nbr-router-id*> is the router ID of the neighbor router. The <*packet-type*> can be one of the following: • hello • database description • link state request • link state update • link state ack • unknown The <*lsa-type*> is the type of LSA. The <*lsa-id*> is the LSA ID. The <*lsa-router-id*> is the LSA router ID.
Notification	OSPF virtual intf retransmit, rid <*router-id*>, intf addr <*ip-addr*>, nbr rid <*nbr-router-id*>, pkt type is <*pkt-type*>, LSA type <*lsa-type*>, LSA id <*lsa-id*>, LSA rid <*lsa-router-id*>	An OSPF interface on the PowerConnect has retransmitted a Link State Advertisement (LSA). The <*router-id*> is the router ID of the PowerConnect. The <*ip-addr*> is the IP address of the interface on the PowerConnect. The <*nbr-router-id*> is the router ID of the neighbor router. The <*packet-type*> can be one of the following: • hello • database description • link state request • link state update • link state ack • unknown The <*lsa-type*> is the type of LSA. The <*lsa-id*> is the LSA ID. The <*lsa-router-id*> is the LSA router ID.
Notification	OSPF originate LSA, rid <*router-id*>, area <*area-id*>, LSA type <*lsa-type*>, LSA id <*lsa-id*>, LSA router id <*lsa-router-id*>	An OSPF interface has originated an LSA. The <*router-id*> is the router ID of the PowerConnect. The <*area-id*> is the OSPF area. The <*lsa-type*> is the type of LSA. The <*lsa-id*> is the LSA ID. The <*lsa-router-id*> is the LSA router ID.

TABLE 445 Syslog messages OSPF (Continued)

Message level	Message	Explanation
Notification	OSPF max age LSA, rid <*router-id*>, area <*area-id*>, LSA type <*lsa-type*>, LSA id <*lsa-id*>, LSA rid <*lsa-router-id*>	An LSA has reached its maximum age. The <*router-id*> is the router ID of the PowerConnect. The <*area-id*> is the OSPF area. The <*lsa-type*> is the type of LSA. The <*lsa-id*> is the LSA ID. The <*lsa-router-id*> is the LSA router ID.
Notification	OSPF LSDB overflow, rid <*router-id*>, limit <*num*>	A Link State Database Overflow (LSDB) condition has occurred. The <*router-id*> is the router ID of the PowerConnect. The <*num*> is the number of LSAs.
Notification	OSPF LSDB approaching overflow, rid <*router-id*>, limit <*num*>	The software is close to an LSDB condition. The <*router-id*> is the router ID of the PowerConnect. The <*num*> is the number of LSAs.
Notification	OSPF intf rcvd bad pkt Bad Checksum, rid <*ip-addr*>, intf addr <*ip-addr*>, pkt size <*num*>, checksum <*num*>, pkt src addr <*ip-addr*>, pkt type <*type*>	The device received an OSPF packet that had an invalid checksum. The rid <*ip-addr*> is PowerConnect's router ID. The intf addr <*ip-addr*> is the IP address of the interface that received the packet. The pkt size <*num*> is the number of bytes in the packet. The checksum <*num*> is the checksum value for the packet. The pkt src addr <*ip-addr*> is the IP address of the neighbor that sent the packet. The pkt type <*type*> is the OSPF packet type and can be one of the following: • hello • database description • link state request • link state update • link state acknowledgement • unknown (indicates an invalid packet type)
Notification	OSPF intf rcvd bad pkt Bad Packet type, rid <*ip-addr*>, intf addr <*ip-addr*>, pkt size <*num*>, checksum <*num*>, pkt src addr <*ip-addr*>, pkt type <*type*>	The device received an OSPF packet with an invalid type. The parameters are the same as for the Bad Checksum message. The pkt type <*type*> value is "unknown", indicating that the packet type is invalid.

TABLE 445 Syslog messages OSPF (Continued)

Message level	Message	Explanation
Notification	OSPF intf rcvd bad pkt Unable to find associated neighbor, rid <*ip-addr*>, intf addr <*ip-addr*>, pkt size <*num*>, checksum <*num*>, pkt src addr <*ip-addr*>, pkt type <*type*>	The neighbor IP address in the packet is not on the PowerConnect's list of OSPF neighbors. The parameters are the same as for the Bad Checksum message.
Notification	OSPF intf rcvd bad pkt Invalid packet size, rid <*ip-addr*>, intf addr <*ip-addr*>, pkt size <*num*>, checksum <*num*>, pkt src addr <*ip-addr*>, pkt type <*type*>	The device received an OSPF packet with an invalid packet size. The parameters are the same as for the Bad Checksum message.

TABLE 446 Syslog messages OSPFv3

Message level	Message	Explanation
Alert	OSPFv3 Memory Overflow	OSPF has run out of memory.
Alert	OSPFv3 LSA Overflow, LSA Type = <*lsa-type*>	Indicates an LSA database overflow. The <*lsa-type*> parameter indicates the type of LSA that experienced the overflow condition. The LSA type is one of the following: • 1 – Router • 2 – Network • 3 – Summary • 4 – Summary • 5 – External
Notification	OSPFv3 interface state changed, rid <*router-id*>, intf addr <*ip-addr*>, state <*ospf-state*>	Indicates that the state of an OSPF interface has changed. The <*router-id*> is the router ID of the PowerConnect. The <*ip-addr*> is the interface's IP address. The <*ospf-state*> indicates the state to which the interface has changed and can be one of the following: • down • loopback • waiting • point-to-point • designated router • backup designated router • other designated router • unknown

TABLE 446 Syslog messages OSPFv3 (Continued)

Message level	Message	Explanation
Notification	OSPFv3 virtual intf state changed, rid <*router-id*>, area <*area-id*>, nbr <*ip-addr*>, state <*ospf-state*>	Indicates that the state of an OSPF virtual routing interface has changed. The <*router-id*> is the router ID of the router the interface is on. The <*area-id*> is the area the interface is in. The <*ip-addr*> is the IP address of the OSPF neighbor. The <*ospf-state*> indicates the state to which the interface has changed and can be one of the following: • down • loopback • waiting • point-to-point • designated router • backup designated router • other designated router • unknown
Notification	OSPFv3 nbr state changed, rid <*router-id*>, nbr addr <*ip-addr*>, nbr rid <*nbr-router-ld*>, state <*ospf-state*>	Indicates that the state of an OSPF neighbor has changed. The <*router-id*> is the router ID of the PowerConnect. The <*ip-addr*> is the IP address of the neighbor. The <*nbr-router-id*> is the router ID of the neighbor. The <*ospf-state*> indicates the state to which the interface has changed and can be one of the following: • down • attempt • initializing • 2-way • exchange start • exchange • loading • full • unknown
Notification	OSPFv3 virtual nbr state changed, rid <*router-id*>, nbr addr <*ip-addr*>, nbr rid <*nbr-router-id*>, state <*ospf-state*>	Indicates that the state of an OSPF virtual neighbor has changed. The <*router-id*> is the router ID of the PowerConnect. The <*ip-addr*> is the IP address of the neighbor. The <*nbr-router-id*> is the router ID of the neighbor. The <*ospf-state*> indicates the state to which the interface has changed and can be one of the following: • down • attempt • initializing • 2-way • exchange start • exchange • loading • full • unknown

TABLE 446 Syslog messages OSPFv3 (Continued)

Message level	Message	Explanation
Notification	OSPFv3 intf config error, rid <*router-id*>, intf addr <*ip-addr*>, pkt src addr <*src-ip-addr*>, error type <*error-type*>, pkt type <*pkt-type*>	Indicates that an OSPF interface configuration error has occurred. The <*router-id*> is the router ID of the PowerConnect. The <*ip-addr*> is the IP address of the interface on the PowerConnect. The <*src-ip-addr*> is the IP address of the interface from which the PowerConnect received the error packet. The <*error-type*> can be one of the following: • bad version • area mismatch • unknown NBMA neighbor • unknown virtual neighbor • authentication type mismatch • authentication failure • network mask mismatch • hello interval mismatch • dead interval mismatch • option mismatch • unknown The <*packet-type*> can be one of the following: • hello • database description • link state request • link state update • link state ack • unknown

The parameters are the same as for the Bad Checksum message. The pkt type <*type*> value is "unknown", indicating that the packet type is invalid.

TABLE 446 Syslog messages OSPFv3 (Continued)

Message level	Message	Explanation
Notification	OSPFv3 intf rcvd bad pkt Unable to find associated neighbor, rid <*ip-addr*>, intf addr <*ip-addr*>, pkt size <*num*>, checksum <*num*>, pkt src addr <*ip-addr*>, pkt type <*type*>	The neighbor IP address in the packet is not on the PowerConnect's list of OSPF neighbors. The parameters are the same as for the Bad Checksum message.
Notification	OSPFv3 intf rcvd bad pkt Invalid packet size, rid <*ip-addr*>, intf addr <*ip-addr*>, pkt size <*num*>, checksum <*num*>, pkt src addr <*ip-addr*>, pkt type <*type*>	The device received an OSPF packet with an invalid packet size. The parameters are the same as for the Bad Checksum message.

TABLE 447 Syslog messages IS-IS

Message level	Message	Explanation
Alert	ISIS Memory Limit Exceeded	IS-IS is requesting more memory than is available.
Notification	ISIS ENTERED INTO OVERLOAD STATE	The PowerConnect has set the overload bit to on (1), indicating that the PowerConnect's IS-IS resources are overloaded.
Notification	ISIS Entered Overload State Due to <*overload-reason*>	The PowerConnect has set the overload bit to on (1), indicating that the PowerConnect's IS-IS resources are Overloaded. Reasons for the overload as expressed in the <*overload-reason*> variable are: • Configuration • Startup Configuration • LSP Buffer Allocation Failure • LSP Header Allocation Failure • Maximum Number of LSPs Exceeded • LSP Fragmentation Count Exceeded • LSP Sequence Number Wrap Around • LSP Option Allocation Failure • Path Entry Allocation Failure • Route Entry Allocation Failure Definitions of the <*overload-reason*> values are described in Table 448.
Notification	ISIS Exited Overload State	The PowerConnect has set the overload bit to off (0), indicating that the PowerConnect's IS-IS resources are no longer overloaded.
Notification	ISIS L1 ADJACENCY DOWN <*system-id*> on circuit <*circuit-id*>	The PowerConnect's adjacency with this Level-1 IS has gone down. The <*system-id*> is the system ID of the IS. The <*circuit-id*> is the ID of the circuit over which the adjacency was established.

TABLE 447 Syslog messages IS-IS (Continued)

Message level	Message	Explanation
Notification	ISIS L1 ADJACENCY UP <*system-id*> on circuit <*circuit-id*>	The PowerConnect's adjacency with this Level-1 IS has come up. The <*system-id*> is the system ID of the IS. The <*circuit-id*> is the ID of the circuit over which the adjacency was established.
Notification	ISIS L2 ADJACENCY DOWN <*system-id*> on circuit <*circuit-id*>	The PowerConnect's adjacency with this Level-2 IS has gone down. The <*system-id*> is the system ID of the IS. The <*circuit-id*> is the ID of the circuit over which the adjacency was established.
Notification	ISIS L2 ADJACENCY UP <*system-id*> on circuit <*circuit-id*>	The PowerConnect's adjacency with this Level-2 IS has come up. The <*system-id*> is the system ID of the IS. The <*circuit-id*> is the ID of the circuit over which the adjacency was established.
Notification	ISIS <*LSP-type*> LSP <*LSP-ID*> Seq <*sequence-number*> Len <*length*> LifeTime <*lifetime*> on <*interface-name*> dropped due to <*LSP-drop-reason*>	The PowerConnect has dropped the received LSP. The <*LSP-Type*> can be one of the following: • L1 • L2 The <*LSP-ID*> variable is in the 8 byte LSP ID value. The <*sequence-number*> is a 4 byte value that is associated with each LSP ID. The <*length*> is the length of the LSP PDU. The <*lifetime*> is the life period of the LSP. The <*interface-name*> is the name of the interface and is displayed in the following form "Ethernet 1/1". The <*LSP-drop-reason*> variable describes the following reasons that the LSP was dropped: • Adjacency not found • Adjacency Level Mismatch • IS Level Mismatch • Length Too Short • Length Too Large • Authentication Failure • Max Area Check Failure • Zero Checksum • Checksum Mismatch • Invalid Length Definitions of the <*LSP-drop-reason*> values are described in Table 448.

TABLE 447 Syslog messages IS-IS (Continued)

Message level	Message	Explanation
Notification	ISIS <*NbrType*> Neighbor <*Hostname/systemID*> DOWN on <*interface-name*> due to <*neighbor-down-reason*>	The PowerConnect's Neighbor has gone down. The <*NbrType*> can be one of the following: • L1 • L2 • PTPT The <*interface-name*> is the name of the interface and is displayed in the following form "Ethernet 1/1". The <*neighbor-down-reason*> variable can be any one of the following reasons that the Neighbor is Down: • BFD Trigger • Maximum Adjacencies • User Trigger • Hold Timer Expiry • Adjacency ID Mismatch • Adjacency Type Mismatch • Interface Down • Interface State Change Definitions of the <*neighbor-down-reason*> values are described in Table 448.
Notification	ISIS <*NbrType*> neighbor <*Hostname/systemID*> UP on <*interface-name*>	The PowerConnect's Neighbor has come up. The <*NbrType*> can be one of the following: • L1 • L2 • PTPT The <*interface-name*> is the name of the interface and is displayed in the following form "Ethernet 1/1".
Notification	ISIS PTP ADJACENCY DOWN <*mac*> on interface <*portnum*>	
Notification	ISIS PTP ADJACENCY UP <*mac*> on interface <*portnum*>	

TABLE 448 Definition of IS-IS variables

Variable	Value	Definition
<*neighbor-down-reason*>	BFD Trigger	BFD identified link failures and triggered IS-IS to clean the neighbors on that link.
	Maximum Adjacencies	IS-IS has reached the maximum number of adjacencies. Therefor, it has deleted the adjacency with the lowest SNPA address to accommodate the new adjacency.
	User Trigger	The user triggered to delete the adjacency using the clear **isis neighbor** <*systemID*> command or the **clear isis all** command.
	Hold Timer Expiry	The adjacency was deleted because there were no "hellos" received within the hold time period.

TABLE 448 Definition of IS-IS variables (Continued)

Variable	Value	Definition
	Adjacency ID Mismatch	The adjacency was deleted because the new “hello” received from this adjacency has a different System ID.
	Adjacency Type Mismatch	The adjacency was deleted because the new “hello” received from this adjacency has a different adjacency Type.
	Interface Down	The adjacency was deleted because the interface went down.
	Interface State Change	The adjacency was deleted because the interface state has changed due to user configuration.
<overload-reason>	Configuration	The Overload condition was entered because of a user configuration.
	Startup Configuration	The Overload condition was entered because of the startup configuration.
	LSP Buffer Allocation Failure	The Overload condition was entered because of an LSP buffer allocation error.
	LSP Header Allocation Failure	The Overload condition was entered because of an LSP header allocation error.
	Maximum Number of LSPs Exceeded	The Overload condition was entered because the LSP count reached the maximum value.
	LSP Fragmentation Count Exceeded	The Overload condition was entered because of IS-IS trying to generate the 256th LSP fragment.
	LSP Sequence Number Wrap Around	The Overload condition was entered because the LSP numbers reached the maximum value.
	LSP Option Allocation Failure	Self LSP building failed due to an internal buffer allocation failure.
	Path Entry Allocation Failure	The SPF computation failed due to a Path Entry allocation failure.
	Route Entry Allocation Failure	The SPF computation failed due to a Route Entry allocation failure.
<LSP-drop-reason>	Adjacency not found	The LSP was dropped because the is no adjacency found on the interface.
	Adjacency Level Mismatch	The LSP was dropped because the adjacency is at a different level from the LSP level.
	IS Level Mismatch	The LSP was dropped because IS-IS is configured at a different level than the LSP level.
	Length Too Short	The LSP length is shorter than the LSP header length.
	Length Too Large	The LSP length is larger than the Maximum LSP buffer length.
	Authentication Failure	The LSP was dropped because of an authentication failure.
	Max Area Check Failure	The LSP has a Max Area Count different than the configured Max Area Count of the device.
	Zero Checksum	The LSP has a zero checksum.

TABLE 448 Definition of IS-IS variables (Continued)

Variable	Value	Definition
	Checksum Mismatch	The LSP checksum is different than the computed checksum.
	Invalid Length	The LSP length is different than the sum of the option lengths in the LSP.

TABLE 449 Syslog messages BGP

Message level	Message	Explanation
Debug	BGP4 Not enough memory available to run BGP4	The device could not start the BGP4 routing protocol because there is not enough memory available.
Error	BGP No of prefixes received from BGP peer <*ip-addr*> exceeds maximum prefix-limit...shutdown	The PowerConnect has received more than the specified maximum number of prefixes from the neighbor, and the PowerConnect is therefore shutting down its BGP4 session with the neighbor.
Error	BGP received invalid AS4_PATH attribute length (3) - entire AS4_PATH ignored	Possible attribute length can be only even number and cannot be odd. If an attribute with odd length is received, this error is displayed.
Error	BGP received invalid AS4_PATH attribute flag (0x40) - entire AS4_PATH ignored	If the flag that describes the attribute has unacceptable values then this error is displayed.
Error	BGP received invalid Confed info in AS4_PATH (@byte 43) - entire AS4_PATH ignored	Confedration segments(AS_CONFED_SEQ/SET) must precede the (AS_SEQ/SET), if not, this error is displayed.
Error	BGP received incorrect Seq type/len in AS4_PATH (@byte 41) - entire AS4_PATH ignored	Valid segment types are (AS_SEQ/SET, AS_CONFED_SEQ/SET), any other values results in an error being displayed.
Error	BGP received multiple AS4_PATH attributes - used first AS4_PATH attribute only	When AS4_PATH is received more than one time in the update message, this error is displayed.
Warning	BGP No of prefixes received from BGP peer <*ip-addr*> exceeds warning limit <*num*>	The PowerConnect has received more than the allowed percentage of prefixes from the neighbor. The <*ip-addr*> is the IP address of the neighbor. The <*num*> is the number of prefixes that matches the percentage you specified. For example, if you specified a threshold of 100 prefixes and 75 percent as the warning threshold, this message is generated if the PowerConnect receives a 76th prefix from the neighbor.
Notification	BGP Peer <*ip-addr*> UP (ESTABLISHED)	Indicates that a BGP4 neighbor has come up. The <*ip-addr*> is the IP address of the neighbor's BGP4 interface with the PowerConnect.

TABLE 449 Syslog messages BGP (Continued)

Message level	Message	Explanation
Notification	BGP Peer <*ip-addr*> DOWN (IDLE)	Indicates that a BGP4 neighbor has gone down. The <*ip-addr*> is the IP address of the neighbor's BGP4 interface with the PowerConnect.
Notification	BGP Peer <*ip*> DOWN (<*reason*><*recv notif*>)	
Notification	Configuration (Wait for BGP)	IS-IS is waiting for BGP convergence to complete. (See "Setting the overload bit" on page 941.)

TABLE 450 Syslog messages NTP

Message level	Message	Explanation
Warning	NTP server <*ip-addr*> failed to respond	Indicates that a Simple Network Time Protocol (SNTP) server did not respond to the device's query for the current time. The <*ip-addr*> indicates the IP address of the SNTP server.

TABLE 451 Syslog messages TCP

Message level	Message	Explanation
Notification	TCP Local TCP exceeds <*burst-max*> burst packets, stopping for <*lockup*> seconds!!	The number of TCP SYN packets exceeds the <*burst-max*> threshold set by the **ip tcp burst** command. The PowerConnect may be the victim of a TCP SYN DoS attack. All TCP SYN packets will be dropped for the number of seconds specified by the <*lockup*> value. When the lockup period expires, the packet counter is reset and measurement is restarted.
Notification	TCP Transit TCP in interface <*portnum*> exceeds <*num*> burst packets, stopping for <*num*> seconds!!	Threshold parameters for TCP transit (through) traffic have been configured on an interface, and the maximum burst size for TCP packets on the interface has been exceeded. The <*portnum*> is the port number. The first <*num*> is the maximum burst size (maximum number of packets allowed). The second <*num*> is the number of seconds during which additional TCP packets will be blocked on the interface. **NOTE:** This message can occur in response to an attempted TCP SYN attack.

TABLE 452 Syslog messages DOT1X

Message level	Message	Explanation
Warning	DOT1X security violation at port <*portnum*>, malicious mac address detected <*mac-address*>	A security violation was encountered at the specified port number.
Warning	DOT1X Port <*portnum*>, AuthControlledPortStatus change restricted	
Notification	DOT1X Port <*portnum*> port default vlan-id changes to <*vlan-id*>	
Notification	DOT1X Port <*portnum*> currently used vlan-id changes to <*vlan-id*> due to move to restricted vlan	
Notification	DOT1X issues software port up indication of Port <*portnum*> to other software applications	The device has indicated that the specified port has been authenticated, but the actual port may not be active.
Notification	DOT1X issues software port down indication of Port <*portnum*> to other software applications	The device has indicated that the specified is no longer authorized, but the actual port may still be active.
Informational	DOT1X Port <*portnum*>, AuthControlledPortStatus change authorized	The status of the interface's controlled port has changed from unauthorized to authorized.
Informational	DOT1X Port <*portnum*>, AuthControlledPortStatus change unauthorized	The status of the interface's controlled port has changed from authorized to unauthorized.
Informational	DOT1X Port <*portnum*> currently used vlan-id changes to <*vlan-id*> due to dot1x-RADIUS vlan assignment	A user has completed 802.1X authentication. The profile received from the RADIUS server specifies a VLAN ID for the user. The port to which the user is connected has been moved to the VLAN indicated by <*vlan-id*>.
Informational	DOT1X Port <*portnum*> currently used vlan-id is set back to port default vlan-id <*vlan-id*>	The user connected to <*portnum*> has disconnected, causing the port to be moved back into its default VLAN, <*vlan-id*>.
Informational	DOT1X Port <*portnum*> is unauthorized because system resource is not enough or the invalid information to set the dynamic assigned IP ACLs or MAC address filters	802.1X authentication could not take place on the port. This happened because strict security mode was enabled and one of the following occurred: • Insufficient system resources were available on the device to apply an IP ACL or MAC address filter to the port • Invalid information was received from the RADIUS server (for example, the Filter-ID attribute did not refer to an existing IP ACL or MAC address filter)
Debug	DOT1X Not enough memory	There is not enough system memory for 802.1X authentication to take place. Contact Dell Technical Support.

TABLE 453 Syslog messages SNMP

Message level	Message	Explanation
Informational	SNMP Auth. failure, intruder IP <*ip-addr*>	A user has tried to open a management session with the device using an invalid SNMP community string. The <*ip-addr*> is the IP address of the host that sent the invalid community string.
Informational	SNMP read-only community | read-write community | contact | location | user | group | view | engineId | trap [host] [<*value -str*>] deleted | added | modified from console | telnet | ssh | web | snmp session	A user made SNMP configuration changes through the Web, SNMP, console, SSH, or Telnet session. [<*value-str*>] does not appear in the message if SNMP community or engineId is specified.

TABLE 454 Syslog messages MPLS

Message level	Message	Explanation
Informational	Deleting VLL <*name*> (ID <*number*>)at <*string*> port <*slot/port*> with peer IPv4 address <*ip-address*>	Sent when PW traps are generated if the PW has been deleted, i.e. when the pwRowStatus in the MIB has been set to destroy(6), the PW has been deleted by a non-MIB application, or due to auto discovery process.
Informational	MPLS Deleting VLL <*vll-name*> (ID <*vll-id*>)	Sent when the specified VLL is being deleted.
Informational	MPLS Deleting VLL <*vll-name*> (ID <*vll-id*>) at {tagged | untagged} port <*slot*>/<*port*>	Sent when the specified VLL with the at the specified tagged or untagged port is being deleted.
Informational	MPLS Deleting VLL <*vll-name*> (ID <*vll-id*>) with peer IPv4 address <*ip*>	Sent when the specified VLL with the specified IPv4 peer is being deleted.
Informational	VLL is down for table index <*number*>	Sent when PW traps are generated if the VLL is down for one index
Informational	VLL is up for table index <*number*>	Sent when PW traps are generated if VLL is up for one index
Informational	VLLs are down for table indexes <*number*> through <*number*>	Sent when PW traps are generated if the VLLs represented by sequential entries in the database are down
Informational	VLLs are up for table indexes <*number*> through <*number*>	Sent when PW traps are generate dif VLLs represented by sequential entries in the database are up
Informational	VRF Port <*slot-port*> added to VRF <*name*> with updated port count <*number*>	Sent when an MPLS L3 VPN trap is generated if the state of an interface within the VRF changed from down to up.
Informational	VRF Port <*slot-port*> deleted from VRF <*name*> with updated port count <*number*>	Sent when an MPLS L3 VPN trap is generated if the state of an interface within the VRF changed from down to up.
Notification	MPLS Deleting VLL <*name*> (ID <*vc-id*>) at {tagged I untagged} port <*portnum*> with peer IPv4 address <*ip*>	

TABLE 454 Syslog messages MPLS (Continued)

Message level	Message	Explanation
Notification	MPLS LSP <*lspname*> switches to new active path <*pathame*>	
Notification	MPLS LSP <*lspname*> using path <*pathname*> is down	
Notification	MPLS LSP <*lspname*> using path <*pathname*> is up	
Notification	MPLS VLL is down for table index <*n*>	
Notification	MPLS VLL is up for table index <*n*>	
Notification	MPLS VLLs are down for table indexes <*n*> through <*m*>	
Notification	MPLS VLLs are up for table indexes <*n*> through <*m*>	
Notification	MPLS VPLS [ID <*id*>] peer <*ip*> is down	Sent when a single VPLS peer is transitioning to a down state
Notification	MPLS VPLS [ID <*id*>] peer <*ip*> is up	Sent when a single VPLS peer is transitioning to an up state
Notification	MPLS VPLS <*name*> (ID <*id*>) endpoint <*ip-address*> is down	Sent when a single VPLS endpoint is transitioning to a down state.
Notification	MPLS VPLS <*name*> (ID <*id*>) endpoint <*ip-address*> is up	Sent when a single VPLS endpoint is transitioning to an up state.
Notification	MPLS VPLS for instance indices <*list*> <*n*> through <*m*> are up	Sent when multiple VPLS instances are transitioning to an up state.
Notification	MPLS VPLS for instance indices <*list*> <*n*> through <*m*> are down	Sent when multiple VPLS instances are transitioning to a down state.
Notification	MPLS VPLS peer <*ip*> associated with VC ID <*n*> is up	Sent when a single VPLS peer is transitioning to an up state.
Notification	MPLS VPLS peer <*ip*> associated with VC ID <*n*> is down	Sent when a single VPLS peer is transitioning to a down state.
Notification	MPLS VPLS peer <*ip*> associated with instances <*n*>-<*m*> <*list*> is down	Sent when multiple VPLS instances associated with a peer are transitioning to a down state.
Notification	MPLS VPLS peer <*ip*> associated with instances <*list*> <*n*>-<*m*> <*list*> is up	Sent when multiple VPLS instances associated with a peer are transitioning to an up state.
Notification	MPLS VPL endpoint <*slot*>/<*port*> associated with instance indices <*list*> is dowm	Sent when multiple VPLS instances associated with an endpoint is transitioning to a down state.
Notification	MPLS VPL endpoint <*slot*>/<*port*> associated with instance indices <*list*> is up	Sent when multiple VPLS instances associated with an endpoint is transitioning to an up state.
Notification	MPLS VLL-Local <*name*> is down	Sent when a single VLL-Local instance is transitioning to a down state.
Notification	MPLS VLL-Local <*name*> is up	Sent when a single VLL-Local instance is transitioning to an up state.

TABLE 454 Syslog messages MPLS (Continued)

Message level	Message	Explanation
Notification	MPLS VLL-Local for instance indices <*list*> <*n*> through <*m*> are up	Sent when multiple VLL-Local instances are transitioning to an up state.
Notification	MPLS VLL-Local for instance indices <*list*> <*n*> through <*m*> are down	Sent when multiple VLL-Local instances are transitioning to a down state.
Notification	MPLS VLL <*name*> (ID <*id*> is down	Sent when a single VLL peer is transitioning to a down state.
Notification	MPLS VLL <*name*> (ID <*id*> is up	Sent when a single VLL peer is transitioning to an up state.
Notification	MPLS VLL for instance indices <*list*> <*n*> through <*m*> are up	Sent when multiple VLL instances are transitioning to an up state.
Notification	MPLS VLL for instance indices <*list*> <*n*> through <*m*> are down	Sent when multiple VLL instances are transitioning to a down state.

TABLE 455 Syslog messages VRF

Message level	Message	Explanation
Notification	VRF Port <*portnum*> added to VRF <*name*> with updated port count <*n*>	
Notification	VRF Port <*portnum*> deleted from VRF <*name*> with updated port count <*n*>	
Informational	VRF <vrf_name> has been configured as management VRF.	Indicates that the specified VRF has been configured as a management VRF.
Informational	VRF <vrf_name> has been un-configured as management VRF.	Indicates that the specified VRF has been removed as a management VRF.

TABLE 456 Syslog messages

Message level	Message	Explanation
Notification	Authentication Enabled on <*portnum*>	The multi-device port authentication feature was enabled on the on the specified <*portnum*>.
Notification	Authentication Disabled on <*portnum*>	The multi-device port authentication feature was disabled on the on the specified <*portnum*>.

TABLE 457 Syslog messages BFD

Message level	Message	Explanation
Notification	BFD Session UP for NBR <*neighbor-ID*> on <*port*>	The BFD session is UP with the neighbor specified by the <*neighbor-ID*> on the port specified by the <*port*> variable.

TABLE 457 Syslog messages BFD (Continued)

Message level	Message	Explanation
Notification	BFD Session DOWN for NBR <*neighbor-ID*> on <*port*> Reason Neighbor Signaled Session Down	The BFD session with the neighbor specified by the <*neighbor-ID*> on the port specified by the <*port*> variable is Down because the BFD neighbor has signaled the session to be down.
Notification	BFD Session DOWN for NBR <*neighbor-ID*> on <*port*> Reason Administratively Down	The BFD session with the neighbor specified by the <*neighbor-ID*> on the port specified by the <*port*> variable is Down for Administrative reasons.

TABLE 458 Syslog messages Optics

Message level	Message	Explanation
Notification	Transceiver type checking has been disabled!	The transceiver type checking feature has been disabled. The device will continue to report incompatible transceivers through syslog messages and but will not shutdown a port that contains one.
Notification	Session DOWN for LSP <*lsp-name*> Reason Adminstratively Down	The BFD session for the LSP specified by the <*lsp-name*> is Down for Administrative reasons.
Notification	Session Up for LSP <*lsp-name*>	The BFD session for the LSP specified by the <*lsp-name*> is Up.
Notification	Session DOWN for RSVP session <*session-id*> Reason Adminstratively Down	The BFD session for the RSVP session specified by the <*session-id*> is Down for Administrative reasons. The form of the <*session-id*> displayed is IPv4 tunnel endpoint or tunnel ID or extended tunnel ID. For example 22.22.22.2/3/11/11/11/1
Notification	Session UP for RSVP session <*session-id*>	The BFD session for the RSVP session specified by the <*session-id*> is Up. The form of the <*session-id*> displayed is IPv4 tunnel endpoint or tunnel ID or extended tunnel ID. For example 22.22.22.2/3/11/11/11/1
Notification	Transceiver type checking has been enabled!	The transceiver type checking feature has been re-enabled. The feature is enabled by default and does not send the message under normal circumstances. However, if it is disabled and then re-enabled the device will send this message..
Warning	Optic is not Dell qualified (<*port*>) Type <*type-description*> Vendor <*vendor-name*> , Version <*version-num*> Part# <*part-no*>, Serial# <*serial-no*>	The optic module installed in the Interface module at the port specified by the <*port*> variable is not Dell qualified although the port is still operational. The Type, Vendor, Version, Part#, and Serial # of the optic module is provided.

TABLE 458 Syslog messages Optics (Continued)

Message level	Message	Explanation
Alert	Optic is not Dell qualified, optical monitoring is not supported (<*port*>) Type <*type-description*> Vendor <*vendor-name*> , Version <*version-num*> Part# <*part-no*>, Serial# <*serial-no*>	The optic module installed in the Interface module at the port specified by the <*port*> variable is not Dell qualified and will not be able to be monitored using the Optical Monitoring function. The Type, Vendor, Version, Part#, and Serial # of the optic module is provided.
Alert	Optic is not capable of optical monitoring (<*port*>) Type <*type-description*> Vendor <*vendor-name*> , Version <*version-num*> Part# <*part-no*>, Serial# <*serial-no*>	The optic module installed in the Interface module at the port specified by the <*port*> variable is not able to be monitored using the Optical Monitoring function. The Type, Vendor, Version, Part#, and Serial # of the optic module is provided.
Alert	Incompatible optical trans-receiver detected on port <*n*>	Indicates that in incompatible XFP or SFP has been installed in the port specified. A port with an incompatible optical module installed are shut down.

TABLE 459 Syslog messages LDP

Message level	Message	Explanation
Notification	MPLS LDP path vector limit mismatch for session <*lsrId*><*labelSpaceId*> (value <*local vector limit*>) with peer <*lsrId*><*labelSpaceId*> (value <*peer vector limit*>)	This notification is generated when the value of the LDP path vector limit value from the peer does not match that of the entity.
Notification	MPLS LDP entity session <*lsrId*><*labelSpaceId*> with peer <*lsrId*><*labelSpaceId*> is up	This notification is sent when the value of 'mplsLdpSessionState' enters the 'operational(5)' state.
Notification	MPL LDP entity session <*lsrId*><*labelSpaceId*> with peer <*lsrId*><*labelSpaceId*> is down	This notification is sent when the value of 'mplsLdpSessionState' leaves the 'operational(5)' state.

A Syslog messages

Appendix

Global and Address Family Configuration Levels

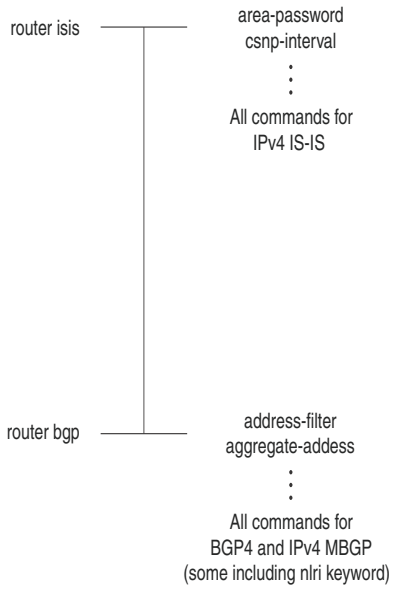
B

The following Global and Address Family Configuration Level features are supported by the NetIron MLX Series devices.

- Accessing the Address Family Configuration Level Under BGP
- Backward Compatibility for Existing BGP4 and IPv4 IS-IS
- Global BGP4 Commands and BGP4 Unicast Route Commands

This appendix describes the restructured CLI for BGP and IS-IS on devices that support IPv6. In earlier versions of software, the CLI for BGP4 and IPv4 IS-IS is structured as shown in Figure 240.

FIGURE 240 Earlier structure of BGP4 and IPv4 IS-IS CLI



To configure BGP4 and IPv4 MBGP, enter the **router bgp** command, which takes you to the BGP router configuration level. At this level, you can access commands to configure all aspects of BGP4 and IPv4 MBGP, including commands that configure the protocol, and commands that configure unicast routes and multicast routes. (To configure aspects of multicast routes, specify the nlri keyword with a command.)

To configure IPv4 IS-IS, enter the **router isis** command, which takes you to the IS-IS device configuration level. At this level, you can access commands that allow you to configure all aspects of IPv4 IS-IS, including commands that configure the protocol, and commands that configure unicast routes.

In both cases, the device determines, for example, whether commands entered at the BGP device configuration level apply to BGP4, to BGP4 unicast routes, or to IPv4 MBGP routes.

The introduction of IPv6 required the restructuring of existing BGP4 and IPv4 IS-IS CLI for the following reasons:

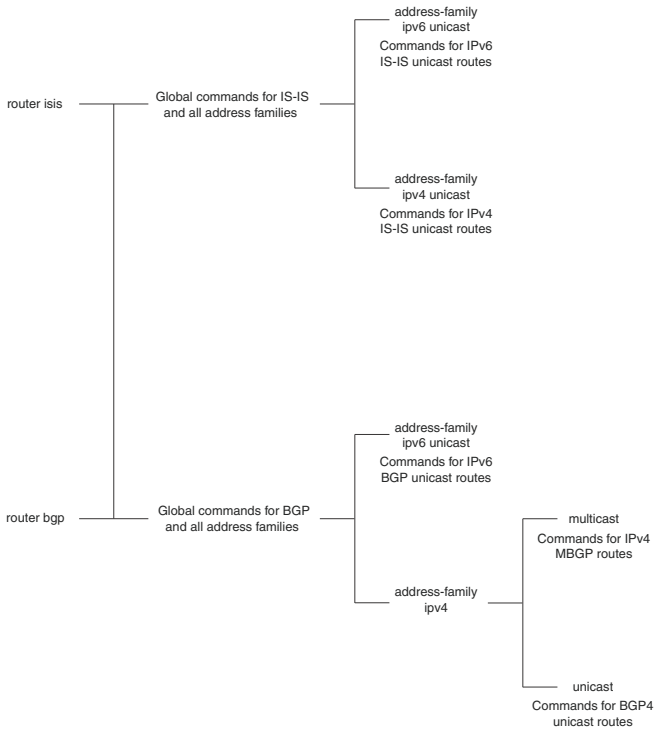
- To accommodate the IPv6-related CLI.
- To simplify the configuration of BGP4 unicast and IPv4 MBGP routes.

The CLI includes two layers of CLI for BGP and IS-IS (refer to Figure 241):

- A global layer to configure BGP and IS-IS protocols.
- Address families that separate the configuration of:
  - IPv6 and IPv4
  - Routing protocol

  Sub-address families separate the configuration of:
  - Unicast routes
  - Multicast routes

FIGURE 241 IPv4, BGP4+ and IS-IS CLI structures



Accessing the address family configuration level

For example, to access the BGP4 multicast address family configuration level, enter the following command while at the global BGP configuration level.

```
NetIron(config-bgp)# address-family ipv4 multicast
NetIron(config-bgp-ipv4m)#
```

Syntax: address-family ipv4 unicast | ipv4 multicast | ipv6 unicast

The (config-bgp-ipv4m)# prompt indicates that you are at the IPv4 multicast address family configuration level. At this level, you can access commands that allow you to configure BGP4 multicast routes. The commands that you enter at this level apply to BGP4 multicast routes only. You can generate a configuration for BGP4 multicast routes that is separate and distinct from configurations for BGP4 unicast routes and BGP4+ unicast routes.

NOTE
Each address family configuration level gives you access to commands that apply to that address family only. To enable a feature in a particular address family, you must specify any associated commands for that feature in that address family.

To exit the BGP4 multicast address family configuration level, enter this command.

```
NetIron(config-bgp-ipv4m)# exit-address-family
NetIron(config-bgp)#
```

Syntax: exit-address-family

When you enter the **exit-address-family** command at an address family configuration level you return to the global IS-IS configuration level, or the BGP4 unicast address family configuration level, (the default BGP4 level). For backward compatibility, you can currently access commands related to BGP4 unicast routes at both global BGP4 configuration and BGP4 unicast address family configuration levels. Both levels are indicated by the (config-bgp)# prompt.

Backward compatibility for existing BGP4 and IPv4 IS-IS configurations

When a device is upgraded to the current software version, the software automatically converts the existing BGP4 unicast and all IPv4 IS-IS configurations into the new address families. The software also automatically converts some of the IPv4 MBGP configuration into the new address family. Software conversion actions include:

- Leaves the global BGP4 and IPv4 IS-IS configurations as is.
- Converts the configuration for BGP4 unicast neighbors and routes into the BGP4 unicast address family.
- Converts the configuration for IPv4 IS-IS unicast routes into the IPv4 IS-IS unicast address family.
- Converts the configuration for IPv4 MBGP neighbors into IPv4 MBGP address family.

NOTE
The software does not convert all aspects of the IPv4 MBGP configuration. You must reconfigure the network routes, aggregate routes, redistribution of routes into IPv4 MBGP, and route map filters. Use the **show run** and **show ip bgp config** commands to check your IPv4 MBGP configuration.

Previously, IPv4 MBGP routes were configured using commands that included the **nlri** keyword The current software version does not support the **nlri** keyword with IPv4 and IPv6 MBGP commands. You must now use the address families to configure all versions of BGP, IS-IS, and MBGP.

Global BGP4 commands and BGP4 unicast route commands

A global BGP command configures the BGP routing protocol and applies to all IPv4 and IPv6 address families. You can access the global commands while at the global BGP configuration level.

A BGP4 unicast route command configures a BGP4 unicast route. For backward compatibility, you can access BGP4 unicast route commands at both global BGP4 configuration and BGP4 unicast address family configuration levels. To help you distinguish the global BGP4 commands from the BGP4 unicast route commands at the global BGP4 configuration level, this section lists global BGP commands:

- **address-filter**
- **always-compare-med**
- **as-path-filter**
- **as-path-ignore**
- **bgp-redistribute-internal**
- **cluster-id**
- **community-filter**
- **compare-routerid**
- **confederation identifier**
- **confederation peers**
- **default-local-preference**
- **distance**
- **enforce-first-as**
- **fast-external-fallover**
- **ignore-invalid-confed-as-path**
- **local-as**
- **med-missing-as-worst**
- **timers**

The following global BGP commands are used to configure peer groups and neighbors:

- **neighbor** <*ipv4-address*> | <*ipv6-address*> | <*peer-group-name*> **description**
- **neighbor** <*ipv4-address*> | <*ipv6-address*> | <*peer-group-name*> **distribute-list acl_name in**
- **neighbor** <*ipv4-address*> | <*ipv6-address*> | <*peer-group-name*> **distribute-list acl_name out**
- **neighbor** <*ipv4-address*> | <*ipv6-address*> | <*peer-group-name*> **distribute-list in**
- **neighbor** <*ipv4-address*> | <*ipv6-address*> | <*peer-group-name*> **distribute-list out**
- **neighbor** <*ipv4-address*> | <*ipv6-address*> | <*peer-group-name*> **ebgp-multihop**
- **neighbor** <*ipv4-address*> | <*ipv6-address*> | <*peer-group-name*> **filter-list in**
- **neighbor** <*ipv4-address*> | <*ipv6-address*> | <*peer-group-name*> **filter-list out**
- **neighbor** <*ipv4-address*> | <*ipv6-address*> | <*peer-group-name*> **next-hop-self**
- **neighbor** <*ipv4-address*> | <*ipv6-address*> | <*peer-group-name*> **password**
- **neighbor** <*ipv4-address*> | <*ipv6-address*> | <*peer-group-name*> **peer-group**

- **neighbor** <*ipv4-address*> | <*ipv6-address*> | <*peer-group-name*> **remote-as**
- **neighbor** <*ipv4-address*> | <*ipv6-address*> | <*peer-group-name*> **remove-private-as**
- **neighbor** <*ipv4-address*> | <*ipv6-address*> | <*peer-group-name*> **shut_down**
- **neighbor** <*ipv4-address*> | <*ipv6-address*> | <*peer-group-name*> **soft-reconfiguration inbound**
- **neighbor** <*ipv4-address*> | <*ipv6-address*> | <*peer-group-name*> **timers**
- **neighbor** <*ipv4-address*> | <*ipv6-address*> | <*peer-group-name*> **update-source**

The following address family commands modify the behavior of BGP for a specific address family:

- **aggregate-address**
- **client-to-client-reflection**
- **dampening**
- **default-information-originate**
- **default-metric**
- **maximum-paths**
- **multipath**
- **neighbor** <*ipv4-address*> | <*ipv6-address*> | <*peer-group-name*> **filter-list in** (applies to the IPv4 unicast address family only)
- **network**
- **next-hop-enable-default**
- **next-hop-recursion** (applies to the IPv4 unicast address family only)
- **readvertise** (applies to the IPv4 unicast address family only)
- **redistribute**
- **table-map**
- **update-time**

The following commands configure policies for neighbors or peer groups for a specific address family:

- **neighbor** <*ipv4-address*> | <*ipv6-address*> | <*peer-group-name*> **activate**
- **neighbor** <*ipv4-address*> | <*ipv6-address*> | <*peer-group-name*> **capability orf prefixlist**
- **neighbor** <*ipv4-address*> | <*ipv6-address*> | <*peer-group-name*> **default-originate**
- **neighbor** <*ipv4-address*> | <*ipv6-address*> | <*peer-group-name*> **filter-list as-path-access-list in**
- **neighbor** <*ipv4-address*> | <*ipv6-address*> | <*peer-group-name*> **filter-list as-path-access-lis out**
- **neighbor** <*ipv4-address*> | <*ipv6-address*> | <*peer-group-name*> **maximum-prefix**
- **neighbor** <*ipv4-address*> | <*ipv6-address*> | <*peer-group-name*> **prefix-list prefix_list_name in**
- **neighbor** <*ipv4-address*> | <*ipv6-address*> | <*peer-group-name*> **prefix-list prefix_list_name out**
- **neighbor** <*ipv4-address*> | <*ipv6-address*> | <*peer-group-name*> **route-map in**
- **neighbor** <*ipv4-address*> | <*ipv6-address*> | <*peer-group-name*> **route-map out**
- **neighbor** <*ipv4-address*> | <*ipv6-address*> | <*peer-group-name*> **route-reflector-client**

- **neighbor** <*ipv4-address*> | <*ipv6-address*> | <*peer-group-name*> **send-community**
- **neighbor** <*ipv4-address*> | <*ipv6-address*> | <*peer-group-name*> **unsuppress-map**
- **neighbor** <*ipv4-address*> | <*ipv6-address*> | <*peer-group-name*> **weight**

Currently, you can create a neighbor with an IPv4 or IPv6 address at the global BGP configuration or IPv4 unicast address family configuration level. For example, if you create a neighbor with an IPv4 address at this level, by default, the neighbor is enabled to exchange IPv4 unicast prefixes. However, this neighbor cannot exchange IPv4 multicast prefixes until you explicitly enable it to do so by entering the **neighbor** <*ipv4-address*> | <*peer-group-name*> **activate** command at the IPv4 multicast address family configuration level. Likewise, if you create a neighbor with an IPv6 address at this level, the neighbor will not exchange IPv6 unicast prefixes until you explicitly enable it to do so by entering the **neighbor** <*ipv6-address*> | <*peer-group-name*> **activate** command at the IPv6 unicast address family configuration level.

If you create a neighbor at the IPv4 multicast address family configuration or IPv6 unicast address family configuration levels, by default, the neighbor is enabled to exchange IPv4 multicast prefixes or IPv6 unicast prefixes, respectively. You do not need to explicitly enable the neighbor at either level.

Appendix

Commands That Require a Reload

C

The following commands that require a reload features are supported by the NetIron MLX Series devices.

- cam-mode ip
- cam-mode ipvpn
- default-max-frame-size
- multicast-flooding
- port-priority
- system-max
- virtual-interface-mac
- vll-mtu-enforcement

Most CLI commands take effect as soon as you enter them. However, a small number of commands require a software reload to take effect. Table 460 lists these commands.

To place a configuration change made by one of these commands into effect, you must save the change to the startup-config file, then reload the software. If you reload the software without saving the change to the startup-config file, the device does not make the change.

To reload the software, you must perform a warm start. To perform a warm start, do one of the following:

- Enter the **reload** command at the Privileged EXEC level of the CLI.
- Enter the **boot system** command at the Privileged EXEC level of the CLI.

TABLE 460 Commands that require a software reload

Command	See ...
cam-mode ip	"Configuring FDR globally" on page 2239
cam-mode ipvpn	"Configuring FDR globally" on page 2239
default-max-frame-size	"Setting the maximum frame size globally" on page 681
multicast-flooding	"Hardware flooding for layer 2 multicast and broadcast packets" on page 261
system-max	"Displaying and modifying default settings for system parameters" on page 100
virtual-interface-mac	"Assigning a MAC address to a virtual interface" on page 677
vll-mtu-enforcement	"Enabling VLL MTU enforcement (optional)" on page 1466

Appendix

Software Specifications

D

This appendix lists the following information for the PowerConnect Series devices:

- IPv6 Phase II
- IEEE compliance
- RFC support
- Internet draft support

IPv6 Phase II

	The PowerConnect Series devices are compliant to IPv6 Phase II specifications.

IEEE COMPLIANCE

- 802.1ag — Connectivity Fault Management
- 802.1D — MAC Bridges
- 802.1Q — Virtual Bridged LANs
- 802.1s — Multiple Spanning Trees
- 802.1w — Rapid STP
- 802.1X — User authentication
- 802.3 — Ethernet Like MIB
- 802.3ad — Link Aggregation
- 802.3ae —10-Gigabit Ethernet
- 802.3x — Flow Control
- Ethernet Interface MIB
- Repeater MIB
- SNMP MIB II
- SNMP v1, v2c and V3

RFC COMPLIANCE

RFC compliance - BGPv4

- 1745 — OSPF Interactions
- 1772 — Application of BGP in the Internet
- 1997 — Communities & Attributes
- 2385 — BGP Session Protection viaTCP MD5
- 2439 — Route Flap Dampening
- 4456 — Route Reflection
- 2918 — Route Refresh Capability
- 3065 — BGP4 Confederations
- 3392 — Capabilities Advertisement with BGP-4
- 3682 — Generalized TTL Security Mechanism, for eBGP Session Protection
- 4271 — BGPv4
- 4273 — BGP MIB
- 4486 — Subcodes for BGP Cease Notification Message
- 4893 — BGP Support for Four-octet AS Number Space

RFC compliance - OSPF

- 1745 — OSPF Interactions
- 1765 — OSPF Database Overflow
- 1850 — OSPF Traps
- 2154 — OSPF w/Digital Signatures (Password, MD-5)
- 2328 — OSPF v2
- 2370 — OSPF Opaque LSA Option (partially supported)
- 3101 — OSPF NSSA
- 3137 — OSPF Stub Router Advertisement
- 3623 — Graceful OSPF Restart
- 3630 — TE Extensions to OSPF v2
- 4303 — IP Encapsulating Security Payload (ESP)
- 4552 — Authentication/Confidentiality for OSPFv3
- 4835 — Cryptographic Message Syntax (CMS) Multiple Signer Clarification

RFC compliance - IS-IS

- 1142 — OSI IS-IS Intra-domain Routing Protocol
- 1195 — Routing in TCP or IP and Dual Environments
- 2763 — Dynamic Host Name Exchange

- 2966 — Domain-wide Prefix Distribution
- 2973 — IS-IS Mesh Groups
- 3567 — IS-IS Cryptographic Authentication (MD-5) (partially supported)
- 3373 — Three-Way Handshake for IS-IS Point-to-Point Adjacencies

RFC compliance - RIP

- 1058 — RIP v1
- 1723 — RIP v2
- 1812 — RIP Requirements

RFC compliance - IP multicast

- 1075 — DVMRP v2
- 1112 — Host Extensions
- 2362 — PIM-SM
- 2858 — BGP-MP
- 3376 — IGMP v3
- 3446 — Anycast RP
- 4610— Anycast-RP Using Protocol Independent Multicast (PIM)
- 3569 — Overview of SSM
- 3618 — MSDP
- 3973 — PIM-DM
- 4611— MSDP Deployment Scenarios
- PIM-DM v1

RFC compliance - general protocols

- 1027 — Proxy ARP
- 1042—Standard for the Transmission of IP Datagrams over IEEE 802 Networks
- 1122 — Host Requirements
- 1166 — Internet Numbers
- 1256 — IRDP
- 1332— PPP IPCP
- 1340 — Assigned Numbers
- 1354 — IP Forwarding Table MIB
- 1377— PPP OSI NLCP
- 1519 — CIDR
- 1542 — BootP Extensions
- 1591 — DNS (client)
- 1661 — PPP

- 1662 — PPP in HDLC Framing
- 1812 — Requirements for IPv4 Routers
- 1858 — Security Considerations for IP Fragment Filtering
- 2131 — BootP or DHCP Helper
- 2474 — DiffServ Definition
- 2475 — DiffServ Architecture
- 2578 — Structure of Management Information Version 2 (SMIv2)
- 2597— Assured Forwarding PHB Group
- 2615 — PPP over Sonet or SDH
- 2784 — Generic Routing Encapsulation (GRE) (partially supported)
- 3246 — An Expedited Forwarding PHB
- 3768 — VRRP
- 4447 — Pseudowire Setup and Maintenance Using the Label Distribution Protocol (LDP)
- 4459 — MTU and Fragmentation - Support fragment of inner packet (partially supported)
- 768 — UDP
- 783 — TFTP
- 791 — IP
- 792 — ICMP
- 793 — TCP
- 826 — ARP
- 894 — IP over Ethernet
- 903 — RARP
- 906 — TFTP Bootstrap
- 950 — Subnets
- 951 — BootP

RFC compliance - management

- 854 — TELNET
- 1213 — MIB II

  Refer to the *IronWare MIB Reference* for details.
- 1445 — Administrative Model for SNMPv2 - Support for View Subtree (partially supported)
- 1492 —TACACS+
- 1724 — RIPv2 MIB
- 1757 — RMON Groups 1, 2, 3, 9

  Refer to the *IronWare MIB Reference* for details.
- 2030 — SNTP
- 2068 — HTTP
- 2284 — PPP EAP -Support EAP extension
- 2578 — SNMPV2

- 2579 —Textual Conventions for SMIv2
- 2665 — Ethernet-Like MIB
- 2674— 802.1Q and 802.1p Bridge MIB
- 2787— VRRP-MIB
- 2863 — Interfaces Group MIB
- 2865 — RADIUS
- 2866 — RADIUS Accounting
- 2868 — RADIUS Attributes for Tunnel Protocol (partially supported)
- 2869 — RADIUS Extensions - EAP Message (type 79) and Message-Authenticator (type 80)
- 2933 — IGMP MIB
- 2934 — PIM MIB
- 3164 — BSD Syslog Protocol
- 3176 — InMon Corporation's sFlow: A Method for Monitoring Traffic in Switched And Routed Networks.
- 3410 — SNMPV3
- 3411— Architecture for SNMP
- 3412 — Message Processing and Dispatching for SNMP
- 3413 — Simple Network Management Protocol (SNMP) Applications (partially supported)
- 3414 — USM for SNMPV3
- 3415 — VACM for SNMPV3
- 3416 — Version 2 of the Protocol Operations for the SNMP
- 3418 — Management Information Base (MIB) for the SNMP
- 3579 — RADIUS Support for Extensible Authentication Protocol (EAP) (partially supported)
- 3584 — Coexistence between Version 1, Version 2, and Version 3 of the Internet-standard Network Management Framework
- 3592 — SDH or SONET MIB (partially supported)
- 3812 — MPLS TE Standard MIB
- 3815 — Managed Objects for the Multiprotocol Label Switching (MPLS) and Label Distribution Protocol (LDP)

  Refer to the *IronWare MIB Reference* for details.
- 3826 — The Advanced Encryption Standard (AES) Cipher Algorithm in the SNMP User-based Security Model
- 4188 — Definitions of Managed Objects for Bridges
- 4251 — The Secure Shell (SSH) Protocol Architecture
- 4252 — The Secure Shell (SSH) Authentication Protocol
- 4253 — The Secure Shell (SSH) Transport Protocol
- 4254 — The Secure Shell (SSH) Connection Protocol
- 4273 — Definitions of Managed Objects for BGP-4
- 4382 — MPLS or BGP Layer 3 Virtual Private Network (VPN) Management Information Base
- 4444 — Management Information Base for Intermediate System to Intermediate System (IS-IS)

- draft-grant-tacacs-02.txt — The TACACS+ Protocol
- draft-ietf-bfd-mib — Bidirectional Forwarding Detection Management Information Base
- draft-ietf-pwe3-enet-mib-11.txt — Ethernet Pseudo Wire (PW) Management Information Base
- draft-ietf-pwe3-pw-mib-11.txt — PW-STD-MIB Definitions (read-only)

RFC compliance - IPv6 management

- 2466 — IPv6 MIB for ICMPv6 Group

RFC compliance - IPv6 core

- 1191— Path MTU Discovery (partially supported)
- 1887 — IPv6 Unicast Address Allocation Architecture
- 1981 — Path maximum transmission unit (MTU) discovery for IPv6
- 2374 — IPv6 aggregatable global unicast address format
- 2375 — IPv6 Multicast Address Assignments
- 2450 — Proposed TLA and NLA Assignment Rules
- 2460 — IPv6 Specification
- 2461 — IPv6 Neighbor Discovery
- 2462 — IPv6 Stateless Address Auto-configuration
- 2463 — ICMPv6 (superseded by RFC 4443)
- 2464 — Transmission of IPv6 over Ethernet Networks
- 2471 — IPv6 Testing Address Allocation
- 2526 — Reserved IPv6 Subnet Anycast Address
- 2711 — IPv6 Router Alert Option
- 2928 — Initial IPv6 subTLA ID Assignments
- 3513 — IPv6 addressing architecture
- 3587 — IPv6 Global Unicast Address Format
- 3596 — DNS support
- 4007 — IPv6 scoped address architecture
- 4193 — Unique Local IPv6 Unicast Addresses
- 4291 — IPv6 Addressing architecture
- 4443 — ICMPv6 (supersedes RFC 2463)

RFC compliance - IPv6 routing

- 2080 — RIPng for IPv6
- 2472 — IPv6 over PPP
- 2545 — Use of MP-BGP-4 for IPv6
- 2740 — OSPFv3 for IPv6
- 5095 — Deprecation of Type 0 Routing Headers in IPv6

- draft-ietf-isis-igp-p2p-over-lan

RFC compliance - IPv6 multicast

- 2710 — Multicast Listener Discovery (MLD) for IPv6
- 3810 — Multicast Listener Discovery Version 2 for IPv6
- 4604 — IGMPv3 & MLDv2 for SSM

RFC compliance - IPv6 transitioning

- 2893 — Transition Mechanisms for IPv6 Hosts and Routers
- 3056 — Connection of IPv6 Domains through IPv4 Clouds

RFC compliance - MPLS

- 2205 — RSVP v1 Functional Specification
- 2209 — RSVP v1 Message Processing Rules
- 2702 — TE over MPLS
- 2747 — RSVP Cryptographic Authentication
- 3031 — MPLS Architecture
- 3032 — MPLS Label Stack Encoding
- 3036 — LDP Specification
- 3037— LDP Applicability
- 3209 — RSVP-TE (partially supported)
- 3270 — MPLS Support of Differentiated Services (partially supported)
- 3784 — ISIS-TE
- 4090 — Fast Re-Route for RSVP-TE Extensions (partially supported)
- 4448 — Encapsulation Methods for Transport of Ethernet over MPLS Networks

RFC compliance - L3VPN

- 2858 — Multiprotocol Extensions for BGP-4
- 3107 — Carrying Label Information in BGP-4
- 4364 — BGP or MPLS IP VPNs
- 4365 — Applicability Statement for BGP or MPLS IP VPNs
- 4382 — MPLS or BGP Layer 3 VPN MIB
- 4576 — Using LSA Options Bit to Prevent Looping in BGP or MPLS IP VPNs (DN Bit)
- 4577 — OSPF as the PE or CE Protocol in BGP or MPLS IP VPNs
- 4762 — Virtual Private LAN Service (VPLS) Using LDP Signaling (partially supported)
- draft-ietf-l2vpn-l2-framework — Framework for Layer 2 Virtual Private Networks

Internet drafts

In addition to the RFCs listed in "RFC COMPLIANCE", the PowerConnect supports the following Internet drafts:

- Draft-ietf-tcpm-tcpsecure-TCP Security
- Draft-ietf-isis-IPv6 for IPv6 with IS-IS
- Draft-ietf-idr-restart - Graceful Restart Mechanism for BGP
- Draft-ietf-idr-route-filter- Cooperative Route Filtering Capability for BGP-4
- Draft-ietf-ssm-arch SSM for IP
- Draft-ietf-pim-sm-v2-new - PIM-SM Protocol Specification, SSM Mode of Operation (partially supported)
- Draft-ietf-isis-igp-p2p-over-lan - Point-to-point operation over LAN in link state routing protocols (partially supported)
- Draft-ietf-bfd-base.txt - BFD
- Draft-ietf-bfd-v4v6-1hop.txt - BFD for IPv4 and IPv6 (Single Hop)
- Draft-ietf-bfd-generic.txt - Generic Application of BFD
- Draft-ietf-idr-bgp-ext-communities - BGP Extended Communities Attribute
- Draft-ietf-l3vpn-mpls-vpn-mib - MPLS or BGP Layer 3 VPN MIB
- Draft-ietf-l2vpn-requirements - Service Requirements for Layer 2 Provider Provisioned Virtual Private Networks
- draft-ietf-l2vpn-vpls-mib-01, VPLS-Generic-Draft-01-Mib module. No other module of this draft is supported.
- Draft-ietf-pwe3-arch - PWE3 Architecture
- Draft-ietf-pwe3-ethernet-encap - Encapsulation Methods for Transport of Ethernet Frames Over IP or MPLS Networks
- Draft-ietf-pwe3-pw-tc-mib - Definitions for Textual Conventions and OBJECT-IDENTITIES for Pseudo-Wires Management
- Draft-ietf-pwe3-pw-mib - Pseudo Wire (PW) Management Information Base

NOTE
For standards that are partially supported, contact Dell for more details.

Appendix

Acknowledgements

E

This appendix presents the acknowledgements for portions of code from various vendors that are included in the PowerConnect devices covered in this manual.
