PowerConnect B-MLXe

Configuration Guide

Regulatory Model Codes: Brocade MLXe-4, Brocade MLXe-8, Brocade MLXe-16

Contents

Chapter 24 Configuring OSPF Version 2

Chapter 36 Configuring BGP or MPLS VPNs

Chapter 52 Protecting against Denial of Service Attacks

Chapter 53 Reverse Path Forwarding

Chapter 54 Securing SNMP Access

Chapter 59 BiDirectional Forwarding Detection (BFD)

Chapter 60 Operations, Administration, and Maintenance (OAM)

About This Document

Audience

This document is designed for system administrators with a working knowledge of Layer 2 and Layer 3 switching and routing.

If you are using a Dell device, you should be familiar with the following protocols if applicable to your network – IP, RIP, OSPF, BGP, ISIS, IGMP, PIM, MPLS, and VRRP.

Supported features

Table 1 describes all of the features supported on PowerConnect B-MLXe device. Features or options not listed in Table 1 or documented in this guide are not supported.

TABLE 1 Supported features

Category	Feature description
System Level Features	
Cisco Discovery Protocol (CDP)	Allows you to configure a device to intercept and display the contents of CDP packets. This feature is useful for learning device and interface information for Cisco devices in the network.
Foundry Discovery Protocol (FDP)	Enables the devices to advertise themselves to other devices on the network.
Denial of Service (DoS) Protection	Protection from SYN attacks Protection from Smurf attacks
CLI Logging	
Management Options	Serial, Telnet and SSH access to industry-standard Command Line Interface (CLI) SSHv2 TFTP and SCP SNMP versions 1, 2, and 3
Management Options	Web GUI
High Availability	Hitless Software Upgrade Hitless Layer 2 Failover Hitless Layer 3 Failover (BGP and OSPF) IPv4 Multicast (IGMP, PIM-DM, PIM-SM, PIM-SSM)
IP Security	Dynamic ARP Inspection (DAI) DHCP Snooping DHCP with Option 82 Insertion
	IP Source Guard

TABLE 1 Supported features

Category	Feature description
Security	AAA Login Authentication using RADIUS, TACACS, TACACS+, local account, enable and line passwords AAA Enable Authentication using RADIUS, TACACS, TACACS+, local account, enable and line passwords AAA Command Authorization using RADIUS, TACACS+ AAA Command Accounting using RADIUS, TACACS+ AAA EXEC Accounting using RADIUS, TACACS+ Local passwords Secure Shell (SSH) version 2 Secure Copy (SCP) User accounts AES for SNMPv3 AES for SSHv2 Note: Telnet, SSH and SNMP servers are disabled by default, and can be enabled selectively.
Logging	Multiple SysLogD server logging
sFlow	sFlow version 5 ACL-based sFlow
Jumbo Packets	Jumbo Packet Support
Uni-Directional Link Detection (UDLD)	Monitors a link between two devices and brings the ports on both ends of the link down if the link goes down at any point between the two devices.
UDLD on tagged ports	Allows ports to send out UDLD control packets that are tagged with a specific VLAN ID as tagged UDLD control packets.
Enhanced User Password Combination	
ACL Accounting	Global statistics for inbound and outbound packets denied by ACLs
Layer 2 Features	
IEEE 802.1d	Spanning Tree Protocol (STP) Single Spanning Tree Protocol (SSTP)
IEEE 802.1p	Class of service for traffic prioritization
IEEE 802.1q	Refer to VLANs, below
IEEE 802.1w	Rapid Spanning Tree Protocol (RSTP) Single Spanning Tree Protocol (SSTP)
IEEE 802.1s	Multiple Spanning Tree Protocol
IEEE 802.1x	Port Security
IEEE 802.3ad	Link Aggregation Control Protocol
L2 ACL	Filtering based on MAC layer-2 parameters.
CPU Protection	Enhances the efficiency of the CPU on an Interface module and protects it from an excessive amount of network traffic.
MAC Port Security	
Multicast	IGMP v1, v2, v3 snooping PIM-SM snooping (IPv4 only)
	Concurrent multicast routing and snooping for IPv4

TABLE 1 Supported features

Category	Feature description
Foundry MRP	Foundry Metro Ring Protocol (MRP) Phase 1 and Phase 2
PVST or PVST+	Per-VLAN Spanning Tree (PVST)
SuperSpan	An STP enhancement that allows Service Providers (SPs) to use STP in both SP networks and customer networks.
Topology Groups	A named set of VLANs that share a Layer 2 topology. You can use topology groups with the following Layer 2 protocols: • STP • MRP • VSRP • IEEE 802.1W
Link Aggregate Groups (LAGs)	Allows you to manually configure multiple high-speed load-sharing links between two switches or routers.
Uplink-Switch	Isolated Private VLANs
VLANs	IEEE 802.1q tagging Port-based VLANs Dual-Mode VLAN Ports VLAN Transparent Hardware Flooding
VLANs	Super Aggregated VLANs (SAV) VLAN Translation Protocol-Based VLANs
VSRP	Virtual Switch Redundancy Protocol (VSRP) VSRP-fast start
VSRP - MRP Signaling	
Advanced Layer 2 Features	
IEEE 802.1ag	Connectivity Fault Management (CFM) for C-VLANs only Yes
Layer 3 Features	
IPv4 ACLs	Standard and Extended Inbound and Outbound ACL logging

TABLE 1 Supported features

Category	Feature description
BGP	BGP routes BGP peers BGP dampening BGP Confederations BGP Route Reflectors Multi-hop E-BGP Community filters Restart helper mode Multipath load sharing MD5 authentication BGP4 MIB and notifications as per RFC 4273 Multi-protocol BGP Extended Communities Route Refresh Co-operative BGP Route Filtering Graceful Restart Helper Change BGP default of BGP MED for route cost to IGP cost
	Graceful Restart
FDR	Foundry Direct Routing
IP Forwarding	IPv4 Routing IPv6 Routing Secondary Addresses
IP Static Entries	Routes ARP
IS-IS	Routes Adjacencies LSPs MD5 Authentication 3-Way Handshake for Pt-to-Pt Adjacencies BFD for IS-IS IS-IS Black Hole Avoidance PSPF Optimizations
	Traffic Engineering Extensions
IPv4 Multicast Routing	IGMP v1, v2, v3 PIM-DM PIM-SM PIM-SSM MSDP Anycast RP
Multicast	Prune Wait Timer for PIM DM

TABLE 1 Supported features

Category	Feature description
OSPF	OSPF routes OSPF adjacencies - Dynamic OFPF LSAs OSPF filtering of advertised routes MD5 authentication Restart helper mode BFD for OSPF OSPF Administrative Distance Control Using Route Maps OSPF Dynamic Metric Calculation for Trunks/VE Interfaces OSPF VRF-Lite for CE routers
	Graceful Restart Traffic Engineering (TE) Extensions
	Graceful Restart Helper
Policy-Based Routing (PBR)	
Multi-VRF	Multi-VRF for IPv4 Unicast (OSPF and Static)
	Multi-VRF for IPv4 Unicast (BGP)
RIP Versions 1 and 2	RIP routes
VRRP and VRRPE	Virtual Router Redundancy Protocol (VRRP) and VRRP Extended (VRRPE)
QoS Features	
Traffic Policing	The following rate limiting types are available on inbound and outbound ports: • Port-based • Port-and-ACL-based (Both L2 and L3 ACLs) • Hardware-based rate limiting of CPU-copied traffic
	• Port-and-priority-based • VLAN-based • VLAN-group-based (outbound only) • VLAN and priority based • VLAN-group and priority based (outbound only)
Traffic Scheduling	The following scheduling schemes are supported: • Strict Priority (SP) Scheduling
	• Weighted Fair Queuing (WFQ) scheduling • Mixed SP and WFQ scheduling
VPN Features	
Topology Groups	A named set of VLANs and VPLS endpoints that share a Layer 2 topology. You can use topology groups with the following Layer 2 protocols: • STP • MRP • VSRP • IEEE 802.1w

TABLE 1 Supported features

Category	Feature description
Layer 2 VPN	VPLS • Local VPLS (without MPLS) • VLL • Local VLL • Single Tag
	VPLS • Multicast Snooping for VPLS • IGMP and PIM Proxy for VPLS • Disabling of VPLS Local Switching • BGP Auto-Discovery • Double Tag • VPLS cpu protection
Layer 3 VPN (Requires ME_PREM plus L3_PREM licenses)	BGP/MPLS VPNs (RFC 2547bis) • OSPF Sham Link Support • Support for RFC 4382: MPLS-L3VPN Standard MIB • Multi-VRF • Per-VRID virtual MAC address assignment • Per-VRF VRRP-E • Static Routes Across VRFs
IPv6 Features	
IPv6 ACLs	Extended ACLs
IPv6 Routing Protocols	• RIPng • IS-IS for IPv6 • OSPFv3 • IPsec Authentication
	• BGP4+
IPv6 Multicast Routing	• MLD v1, v2 • PIM-SSM • PIM-SM • Anycast RP
MPLS Features	

TABLE 1 Supported features

Category	Feature description
MPLS	LDP RSVP-TE OSPF-TE ISIS-TE LSR Support OAM - LSP ping and LSR Traceroute (only on Ingress and Egress routers) VPLS and VLL Hot-standby LSPs VPLS and VLL support LAG endpoints from VPLS and VLL MPLS over LAG Fast Reroute Detour Support CSPF Adaptive LSPs
	BFD for RSVP-TE Fast Reroute Bypass Support LSP Accounting OAM - LSP ping and Traceroute

Document conventions

This section describes text formatting conventions and important notice formats used in this document.

Text formatting

The narrative-text formatting conventions that are used are as follows

bold text	Identifies command names
	Identifies the names of user-manipulated GUI elements
	Identifies keywords
	Identifies text to enter at the GUI or CLI
italic text	Provides emphasis
	Identifies variables
	Identifies document titles
`code` text	Identifies CLI output

For readability, command names in the narrative portions of this guide are presented in bold: for example, **show version**.

Command syntax conventions

Command syntax in this manual follows these conventions:

command and parameters	Commands and parameters are printed in bold.
[ ]	Optional parameter.
variable	Variables are printed in italics enclosed in angled brackets < >.
...	Repeat the previous element, for example “member[;member...]”
|	Choose from one of the parameters.

Notes, cautions, and danger notices

The following notices and statements are used in this manual. They are listed below in order of increasing severity of potential hazards.

NOTE
A note provides a tip, guidance or advice, emphasizes important information, or provides a reference to related information.

CAUTION
A Caution statement alerts you to situations that can be potentially hazardous to you or cause damage to hardware, firmware, software, or data.

DANGER
A Danger statement indicates conditions or situations that can be potentially lethal or extremely hazardous to you. Safety labels are also attached directly to products to warn of these conditions or situations.

Related publications

The following Dell documents supplement the information in this guide:

- *Brocade MLXe and NetIron Family Configuration Guide*
- *PowerConnect B-MLXe Hardware Installation Guide*
- *PowerConnect B-MLXe Diagnostic Reference*

NOTE
For the latest edition of these documents, which contain the most up-to-date information, Refer to product manuals at manuals at support.dell.com.

Getting technical help or reporting errors

Dell is committed to ensuring that your investment in our products remains cost-effective. If you need assistance or find errors in the manuals, contact Dell Technical Support. When contacting Dell Technical Support have the device configuration file and an output capture of **show tech-support** command available.

Contacting Dell

For customers in the United States, call 800-WWW.DELL (800.999.3355).

NOTE
If you do not have an active Internet connection, you can find contact information on your purchase invoice, packing slip, bill, or Dell product catalog.

Dell provides several online and telephone-based support and service options. Availability varies by country and product, and some services may not be available in your area. To contact Dell for sales, technical support, or customer service issues.

1. Visit *http://www.support.dell.com*.
2. Click your country or region at the bottom of the page. For a full listing of countries and regions, click **All**.
3. In the Support menu, click **All Support**.
4. Choose the method of contacting Dell that is convenient for you.

Getting Started with the Command Line Interface 1

Overview

The following command line features are supported by NetIron MLX Series devices:

- On-Line Help
- Command Completion
- Scroll Control
- Line Editing Commands
- Accessing the CLI
- Single User in CONFIG Mode
- Multi-User Conflict During Deletion Of Group Configuration (Or Stanza)
- Searching and Filtering Output
- CLI Parsing
- Syntax Shortcuts
- Web Management Interface

This chapter presents information to help you become familiar with the PowerConnect command line interface (CLI).

As with other devices, you can manage a PowerConnect using any of the following applications:

- **Command Line Interface (CLI)** – a text-based interface accessible directly from a PC or terminal attached to the management module's serial (Console) port or 10BaseT/100BaseTX Ethernet (management) port, or from a Telnet connection to the PC or terminal.
- **Web Management Interface** – a GUI-based management interface accessible through an HTTP (web browser) connection.
- **SNMP Network Manager** – an optional SNMP-based standalone GUI application.

This user guide describes how to configure the features using the CLI. This chapter how to use the CLI.

NOTE
This user guide assumes that an IP address and default gateway have been assigned to the PowerConnect when it was installed. If you need to assign an IP address or default gateway to the device, refer to the PowerConnect Installation guides.

Logging on through the CLI

After an IP address is assigned to the device's management port, you can access the CLI through a PC or terminal attached to the management module's serial (Console) port or 10BaseT/100BaseTX Ethernet (management) port, or from a Telnet or SSH connection to the PC or terminal.

You can initiate a local Telnet, SSH or SNMP connection by specifying the management port's IP address.

The commands in the CLI are organized into the following levels:

- **User EXEC** – Lets you display information and perform basic tasks such as pings and traceroutes.
- **Privileged EXEC** – Lets you use the same commands as those at the User EXEC level plus configuration commands that do not require saving the changes to the system-config file.
- **CONFIG** – Lets you make configuration changes to the device. To save the changes across software reloads and system resets, you need to save them to the system-config file. The CONFIG level contains sub-levels for individual ports, for VLANs, for routing protocols, and other configuration areas.

NOTE
By default, the PowerConnect devices have all management access disabled, except for console port management. To create access, you must configure Enable passwords or local user accounts, or you can configure the device to use a RADIUS or TACACS or TACACS+ server for authentication.

On-line help

To display a list of available commands or command options, enter "?" or press Tab. If you have not entered part of a command at the command prompt, all the commands supported at the current CLI level are listed. If you enter part of a command, then enter "?" or press Tab, the CLI lists the options you can enter at this point in the command string.

If you enter an invalid command, a message appears indicating the command was unrecognized.

Example

```
NetIron(config)# rooter ip
Unrecognized command
```

Command completion

The CLI supports command completion, so you do not need to enter the entire name of a command or option. As long as you enter enough characters of the command or option name to avoid ambiguity with other commands or options, the CLI understands what you are typing.

Scroll control

By default, the CLI uses a page mode to paginate displays that are longer than the number of rows in your terminal emulation window. For example, if you display a list of all the commands at the global CONFIG level but your terminal emulation window does not have enough rows to display them all at once, the page mode stops the display and lists your choices for continuing the display.

Example

```
aaa
access-list
all-client
arp
banner
base-mac-addr
boot
some lines omitted for brevity...

 default-vlan-id
 enable
 enable-acl-counter
 end
 exit
--More--, next page: Space, next line: Return key, quit: Control-c
```

The software provides the following scrolling options:

- Press the Space bar to display the next page (one screen at time).
- Press the Return or Enter key to display the next line (one line at a time).
- Press Ctrl-C cancel the display.

Line editing commands

The CLI supports the following line editing commands. To enter a line-editing command, use the CTRL-key combination for the command by pressing and holding the CTRL key, then pressing the letter associated with the command.

TABLE 2 CLI line-editing commands

Ctrl-key combination	Description
Ctrl-A	Moves to the first character on the command line.
Ctrl-B	Moves the cursor back one character.
Ctrl-C	Escapes and terminates command prompts and ongoing tasks (such as lengthy displays), and displays a fresh command prompt.
Ctrl-D	Deletes the character at the cursor.
Ctrl-E	Moves to the end of the current command line.
Ctrl-F	Moves the cursor forward one character.
Ctrl-K	Deletes all characters from the cursor to the end of the command line.
Ctrl-L; Ctrl-R	Repeats the current command line on a new line.
Ctrl-N	Enters the next command line in the history buffer.
Ctrl-P	Enters the previous command line in the history buffer.
Ctrl-U; Ctrl-X	Deletes all characters from the cursor to the beginning of the command line.

TABLE 2 CLI line-editing commands (Continued)

Ctrl-key combination	Description
Ctrl-W	Deletes the last word you typed.
Ctrl-Z	Moves from any CONFIG level of the CLI to the Privileged EXEC level; at the Privileged EXEC level, moves to the User EXEC level.

EXEC commands

There are two different levels of EXEC commands, the ***User Level*** and the ***Privileged Level***.

User level

The User level commands are at the top of the CLI hierarchy. These are the first commands that you have access to when connected to the device through the CLI. For example, when you first connect to the PowerConnect, you may see one of the following prompts.

```
NetIron MLXe>
```

The "PowerConnect" part of the prompt is configurable. Your system may display a different string.

At this level, you can view basic system information and verify connectivity but cannot make any changes to the device configuration. To make changes to the configuration, you must move to other levels of the CLI hierarchy. such as the Privileged EXEC level.

Privileged EXEC level

Commands at the Privileged EXEC level enable you to transfer and store software images and configuration files between the network and the system, and review the configuration.

You reach this level by entering the **enable** [<*password*>] or **enable** <*username*> <*password*> at the User EXEC level.

Example

```
NetIron>enable
```

or

```
NetIron>enable user1 mypassword
```

After entering the enable command, you see the following prompt.

```
NetIron>#
```

The prompt indicates that you are at the Privilege EXEC level.

When you are at the Privilege EXEC level, you can enter commands that are available at that level. It is also at this level where you enter the **configure terminal** command to Global Configuration level.

Global level

The global CONFIG level allows you to globally apply or modify parameters for ports on the device. You reach this level by entering **configure terminal** at the privileged EXEC level.

```
NetIron> enable
NetIron># configure terminal
```

The prompt changes to the Global Configuration level.

```
NetIron(config)#
```

CONFIG commands

CONFIG commands modify the configuration of a PowerConnect. When you are at the Global Configuration level, you can enter commands to configure the features in a PowerConnect. This section describes the CONFIG CLI levels.

Redundancy level

This redundancy level allows you to configure redundancy parameters for redundant management modules. You reach this level by entering the **redundancy** command at the global CONFIG level.

Interface level

The interface level allows you to assign or modify specific port parameters on a specific port. You reach this level by entering the following at the global CONFIG level:

- **interface ethernet** <*slot/port*>
- **interface loopback** <*num*>
- **interface management** <*portnum*>
- or **interface ve** <*num*>
- **interface tunnel** <*tunnel_id*>
- **interface group-ve** <*vlan_group_id*>

LAG level

The LAG level allows you to change parameters for statically-configured LAG groups. You reach this level by entering a **LAG** command with the appropriate port parameters.

Router RIP level

The RIP level allows you to configure parameters for the RIP routing protocol. You reach this level by entering the **router rip** command at the global CONFIG level.

Router OSPF level

The OSPF level allows you to configure parameters for the OSPF routing protocol. You reach this level by entering the **router ospf** command at the global CONFIG level.

BGP level

The BGP level allows you to configure Border Gateway Protocol version 4 (BGP4) features. You reach this level by entering the **router bgp** command at the global CONFIG level.

Global BGP and BGP4 unicast address family level

The global BGP and BGP4 unicast address family levels are present only on devices that support IPv6. The global BGP level allows you to configure the BGP routing protocol. The BGP4 unicast address family level allows you to configure a BGP4 unicast route. For backward compatibility, you can currently access BGP4 unicast address family commands at both global BGP configuration and BGP4 unicast address family configuration levels. Therefore, the global BGP and BGP4 unicast address family commands are documented together.

You reach the global BGP level by entering the **router bgp** command at the global CONFIG level. You reach the BGP4 unicast address family level by entering the **address-family ipv4 unicast** command at the global BGP level.

BGP4 multicast address family level

The BGP4 multicast address family level allows you to configure BGP4 multicast routes. You reach this level by entering the **address-family ipv4 multicast** command at the global BGP, BGP4 unicast address family, or IPv6 BGP unicast address family levels.

Router DVMRP level

The DVMRP level allows you to configure details for the DVMRP multicast protocol. You reach this level by entering the **router dvmrp** command at the global CONFIG level.

Router PIM level

The PIM level allows you to configure parameters for the Protocol Independent Multicast (PIM) routing protocol. You reach this level by entering the **router pim** command at the global CONFIG level.

Route Map level

The Route Map level allows you to configure parameters for a BGP4 route map. You reach this level by entering the **route-map** <*name*> command at the global CONFIG level.

Router VRRP level

The VRRP level allows you to configure parameters for the Virtual Router Redundancy Protocol (VRRP). You reach this level by entering the **router vrrp** command at the global CONFIG level, then entering the **ip vrrp vrid** <*num*> command at the interface configuration level.

Router VRRPE level

The VRRPE level allows you to configure parameters for VRRP Extended. You reach this level by entering the **router vrrp-extended** command at the global CONFIG level, then entering the **ip vrrp-extended vrid** <*num*> command at the interface configuration level.

VLAN level

Policy-based VLANs allow you to assign VLANs to a protocol, port, or 802.1q tags.

You reach this level by entering the **vlan** <*vlan-id*> command at the Global CONFIG Level.

Ethernet Service Instance (ESI) level

Ethernet Service Instance (ESI) allow you to assign an ESI to a protocol, or port.

Metro ring level

Metro rings provide Layer 2 connectivity and fast failover in ring topologies.

You reach this level by entering the metro-ring <*ring-id*> command at the VLAN CONFIG Level.

VSRP level

The VSRP level allows you to configure parameters for the Virtual Switch Redundancy Protocol (VSRP). You reach this level by entering the **vsrp vrid** <*num*> command at the VLAN configuration level, then entering the **vsrp vrid** <*num*> command at the VLAN configuration level.

Topology group level

A topology group enables you to control the Layer 2 protocol configuration and Layer 2 state of a set of ports in multiple VLANs based on the configuration and states of those ports in a single master VLAN. One instance of the Layer 2 protocol controls all the VLANs.

You reach this level by entering the **topology-group** <*group-id*> command at the Global CONFIG Level.

802.1X port security level

The 802.1X port security level allows you to configure the 802.1X port security. You reach this level by entering the **dot1x-enable** command at the Global level.

MAC port security level

The MAC port security level allows you to configure the port security feature. You reach this level by entering the **port security** command at the at the Global or Interface levels.

Accessing the CLI

The CLI can be accessed through both serial and Telnet connections. For initial log on, you must use a serial connection. Once an IP address is assigned, you can access the CLI through Telnet.

Once connectivity to the device is established, you will see the a prompt.

```
NetIron>
```

When accessing the CLI through Telnet, you maybe prompted for a password. By default, the password required is the password you enter for general access at initial setup. You also have the option of assigning a separate password for Telnet access with the **enable telnet password** <*password*> command, found at the Global Level.

At initial log on, all you need to do is type **enable** at the prompt, then press Return. You only need to enter a password after a permanent password is entered at the Global CONFIG Level of the CLI.

To reach the Global CONFIG Level, the uppermost level of the CONFIG commands, enter the following commands

NetIron> enable	User Level commands
NetIron# configure terminal	Privileged Level-EXEC commands
NetIron(config)#	Global Level-CONFIG commands

You can then reach all other levels of the CONFIG command structure from this point.

The CLI prompt will change at each level of the CONFIG command structure, to easily identify the current level.

```
NetIron>    User Level EXEC Command
NetIron#    Privileged Level EXEC Command
NetIron(config)#Global Level CONFIG Command
NetIron(config-if-e10000-5/1)#Interface Level CONFIG Command
NetIron(config-lbif-1)#Loopback Interface CONFIG Command
NetIron(config-ve-1)#Virtual Interface CONFIG Command
NetIron(config-trunk-4/1-4/8)# trunk group CONFIG Command
NetIron(config-if-e10000-tunnel)#IP Tunnel Level CONFIG Command
NetIron(config-bgp-router)#BGP Level CONFIG Command
NetIron(config-dvmrp-router)#DVMRP Level CONFIG Command
NetIron(config-ospf-router)#OSPF Level CONFIG Command
NetIron(config-isis-router)#IS-IS Level CONFIG Command
NetIron(config-pim-router)#PIM Level CONFIG Command
NetIron(config-redundancy)#Redundant Management Module CONFIG Command
NetIron(config-rip-router)#RIP Level CONFIG Command
NetIron(config-port-80)#Application Port CONFIG Command
NetIron(config-bgp-routemap Map_Name)#Route Map Level CONFIG Command
NetIron(config-vlan-1)#VLAN Port-based Level CONFIG Command
NetIron(config-vlan-atalk-proto)#VLAN Protocol Level CONFIG Command
```

NOTE

The CLI prompt at the interface level includes the port speed. The speed is one of the following:
NetIron(config-if–e100-5/1)# – The interface is a 10/100 port.
NetIron(config-if–e1000-5/1)# – The interface is a Gigabit port.
For simplicity, the port speeds sometimes are not shown in example Interface level prompts in this manual.

Single user in CONFIG mode

By default, more than one user can enter the CONFIG mode of a device CLI, which is accessed through the **configure terminal** command. While in CONFIG mode, users can override another user's configuration changes.

You can configure a device to allow only one user to be in CONFIG mode at any one time. Other users who try to enter that mode in will be denied. To allow only one user to enter CONFIG mode, enter the following command.

```
NetIron#configure terminal
NetIron(config)# single-config-user
NetIron(config)# write memory
```

Syntax: [no] single-config-user

After the **single-config-user** command is issued, the device will not allow more than one user to enter CONFIG mode. However, if you run the command while more than one user is in CONFIG mode, the other users continue to be in CONFIG mode and can potentially override each other's configuration changes. Only users who try to enter the CONFIG mode after the command is issued are prevented from entering CONFIG mode. If a user is already in that mode and another user tries to enter CONFIG mode after the **single-config-user** command is issued, the following error is displayed.

```
NetIron#configure terminal
Single user config mode is being enforced. Config mode is being used by
<session-type> session.
```

where <*session-type*> can be one of the following:

- console
- telnet <*number*>
- SSH <*number*>

Multi-user conflict during deletion of group configuration (or stanza)

By default, a user may delete a group configuration, even if another user is simultaneously in that mode. You can disable this feature by issuing the **enable multi-user-mode-deletion** command.

To allow only one user to delete group configurations, enter the following command.

```
NetIron#configure terminal
NetIron(config)# enable multi-user-mode-deletion
NetIron(config)# write memory
```

When a user attempts to delete a group configuration from the CLI, and another user is already within that group configuration, the user who tries to delete a group configuration in that mode will be denied and will receive the following error message.

```
Session 1:
NetIron(config)# vlan 10
NetIron(config-vlan-10)#
Session 2:
NetIron(config)# no vlan 10
"Error: Cannot undo the configuration as {console|telnet|SSH} session is
using this mode."
```

Syntax: [no] enable multi-user-mode-deletion

Use the **no** form of this command will allow multiple users the ability to delete group configurations.

NOTE
This feature will not work on commands that are issued from the WEB management and the SNMP management.

Navigating among command levels

To reach other CLI command levels, you need to enter certain commands. At each level there is a launch command that allows you to move either up or down to the next level.

CLI command structure

Many CLI commands may require textual or numeral input as part of the command.

Required or optional fields

These fields are either required or optional depending on how the information is bracketed. For clarity, a few CLI command examples are explained below.

Example

Syntax: **[no] deny redistribute** <*value*> **all | bgp | rip | static address** <*ip-addr*> <*ip-mask*> **[match-metric** <*value*> **| set-metric** <*value*>**]**

When an item is bracketed with *"< >"* symbols, the information requested is a variable and required.

When an item is not enclosed by *"< >"* or "[ ]" symbols, the item is a required keyword.

When an item is bracketed with "[ ]" symbols, the information requested is optional.

Optional fields

When two or more options are separated by a vertical bar, " | ", you must enter one of the options as part of the command.

Example

Syntax: **priority normal | high**

For example, the "normal | high" entry in the Syntax above means that priority can be either priority normal or priority high. The command in the syntax above requires that you enter either normal or high as part of the command.

List of available options

To get a quick display of available options at a CLI level or for the next option in a command string, enter a question mark (?) at the prompt or press TAB.

Example

To view all available commands at the user EXEC level, enter the following or press TAB at the User EXEC CLI level.

```
NetIron> ? <return>
enable
exit
fastboot
ping
show
stop-trace-route
traceroute
```

You also can use the question mark (?) with an individual command, to see all available options or to check context.

Example

Enter the following to view possible **copy** command options.

```
NetIron# copy ?
  flash
  running-config
  startup-config
  tftp
NetIron# copy flash ?
  tftp
```

Searching and filtering output

You can filter CLI output from **show** commands and at the --More-- prompt. You can search for individual characters, strings, or construct complex regular expressions to filter the output.

Searching and filtering output from show commands

You can filter output from **show** commands to display lines containing a specified string, lines that do not contain a specified string, or output starting with a line containing a specified string. The search string is a regular expression consisting of a single character or string of characters. You can use special characters to construct complex regular expressions. refer to "Using special characters in regular expressions" on page 13 for information on special characters used with regular expressions.

Displaying lines containing a specified string

The following command filters the output of the **show interface** command for port 3/11 so it displays only lines containing the word "Internet". This command can be used to display the IP address of the interface.

```
NetIron# show interface e 3/11 | include Internet
  Internet address is 192.168.1.11/24, MTU 1518 bytes, encapsulation ethernet
```

Syntax: <*show-command*> **| include** <*regular-expression*>

NOTE
The vertical bar (|) is part of the command.

Note that the regular expression specified as the search string is case sensitive. In the example above, a search string of "Internet" would match the line containing the IP address, but a search string of "internet" would not.

Displaying lines that do not contain a specified string

The following command filters the output of the **show who** command so it displays only lines that do not contain the word "closed". This command can be used to display open connections to the device.

```
NetIron# show who | exclude closed
Console connections:
        established
        you are connecting to this session
        2 seconds in idle
Telnet connections (inbound):
```

```
 1      established, client ip address 192.168.9.37
        27 seconds in idle
Telnet connection (outbound):
SSH connections:
```

Syntax: <*show-command*> **| exclude** <*regular-expression*>

Displaying lines starting with a specified string

The following command filters the output of the **show who** command so it displays output starting with the first line that contains the word "SSH". This command can be used to display information about SSH connections to the PowerConnect.

```
NetIron# show who | begin SSH
SSH connections:
 1      established, client ip address 192.168.9.210
        7 seconds in idle
 2      closed
 3      closed
 4      closed
 5      closed
```

Syntax: <*show-command*> **| begin** <*regular-expression*>

Searching and filtering output at the --More-- prompt

The --More-- prompt is displayed when output extends beyond a single page. From this prompt, you can press the Space bar to display the next page, the Return or Enter key to display the next line, or Ctrl-C or Q to cancel the display. You can also search and filter output from this prompt.

Example

```
NetIron# ?
  append               Append one file to another
  attrib               Change file attribute
  boot                 Boot system from bootp/tftp server/flash image
  cd                   Change current working directory
  chdir                Change current working directory
  clear                Clear table/statistics/keys
  clock                Set clock
  configure            Enter configuration mode
  copy                 Copy between flash, tftp, config/code
  cp                   Copy file commands
  debug                Enable debugging functions (see also 'undebug')
  delete               Delete file on flash
  dir                  List files
  dm                   test commands
  dot1x                802.1X
  erase                Erase image/configuration files from flash
  exit                 Exit Privileged mode
  fastboot             Select fast-reload option
  force-sync-standby   Sync active flash (pri/sec/mon/startup config/lp images)
                       to standby
  format               Format PCMCIA card
  hd                   Hex dump
  ipc                  IPC commands
--More--, next page: Space, next line: Return key, quit: Control-c
```

At the --More-- prompt, you can press the forward slash key (/) and then enter a search string. The device displays output starting from the first line that contains the search string, similar to the **begin** option for **show** commands.

Example

```
--More--, next page: Space, next line: Return key, quit: Control-c
/telnet
```

The results of the search are displayed.

```
searching...
telnet               Telnet by name or IP address
terminal             Change terminal settings
traceroute           TraceRoute to IP node
undelete             Recover deleted file
whois                WHOIS lookup
write                Write running configuration to flash or terminal
```

To display lines containing only a specified search string (similar to the **include** option for **show** commands) press the plus sign key (+) at the --More-- prompt and then enter the search string.

```
--More--, next page: Space, next line: Return key, quit: Control-c
+telnet
```

The filtered results are displayed.

```
filtering...
  telnet              Telnet by name or IP address
```

To display lines that do not contain a specified search string (similar to the **exclude** option for **show** commands) press the minus sign key (-) at the --More-- prompt and then enter the search string.

```
--More--, next page: Space, next line: Return key, quit: Control-c
-telnet
```

The filtered results are displayed.

```
filtering...
sync-standby         Sync active flash (pri/sec/mon/startup config/lp images)
                     to standby if different
terminal             Change terminal settings
traceroute           TraceRoute to IP node
undelete             Recover deleted file
whois                WHOIS lookup
write                  Write running configuration to flash or terminal
```

As with the commands for filtering output from **show** commands, the search string is a regular expression consisting of a single character or string of characters. You can use special characters to construct complex regular expressions. Refer to the next section for information on special characters used with regular expressions.

Using special characters in regular expressions

You use a regular expression to specify a single character or multiple characters as a search string. In addition, you can include special characters that influence the way the software matches the output against the search string. These special characters are listed in the following table.

TABLE 3 Special characters for regular expressions

Character	Operation
.	The period matches on any single character, including a blank space. For example, the following regular expression matches “aaz”, “abz”, “acz”, and so on, but not just “az”: a.z
*	The asterisk matches on zero or more sequential instances of a pattern. For example, the following regular expression matches output that contains the string “abc”, followed by zero or more Xs: abcX*
+	The plus sign matches on one or more sequential instances of a pattern. For example, the following regular expression matches output that contains "de", followed by a sequence of “g”s, such as “deg”, “degg”, “deggg”, and so on: deg+
?	The question mark matches on zero occurrences or one occurrence of a pattern. For example, the following regular expression matches output that contains "dg" or "deg": de?g **NOTE:** Normally when you type a question mark, the CLI lists the commands or options at that CLI level that begin with the character or string you entered. However, if you enter Ctrl-V and then type a question mark, the question mark is inserted into the command line, allowing you to use it as part of a regular expression.
^	A caret (when not used within brackets) matches on the beginning of an input string. For example, the following regular expression matches output that begins with “deg”: ^deg
$	A dollar sign matches on the end of an input string. For example, the following regular expression matches output that ends with “deg”: deg$
_	An underscore matches on one or more of the following: • , (comma) • { (left curly brace) • } (right curly brace) • ((left parenthesis) •) (right parenthesis) • The beginning of the input string • The end of the input string • A blank space For example, the following regular expression matches on “100” but not on “1002”, “2100”, and so on. _100_
[ ]	Square brackets enclose a range of single-character patterns. For example, the following regular expression matches output that contains “1”, “2”, “3”, “4”, or “5”: [1-5] You can use the following expression symbols within the brackets. These symbols are allowed only inside the brackets. • ^ – The caret matches on any characters except the ones in the brackets. For example, the following regular expression matches output that does not contain “1”, “2”, “3”, “4”, or “5”: [^1-5] • - The hyphen separates the beginning and ending of a range of characters. A match occurs if any of the characters within the range is present. Refer to the example above.

TABLE 3 Special characters for regular expressions (Continued)

Character	Operation
|	A vertical bar separates two alternative values or sets of values. The output can match one or the other value. For example, the following regular expression matches output that contains either “abc” or “defg”: abc|defg
( )	Parentheses allow you to create complex expressions. For example, the following complex expression matches on “abc”, “abcabc”, or “defg”, but not on “abcdefgdefg”: ((abc)+)|((defg)?)

If you want to filter for a special character instead of using the special character as described in the table above, enter “\” (backslash) in front of the character. For example, to filter on output containing an asterisk, enter the asterisk portion of the regular expression as “*”.

```
NetIron# show ip route bgp | include \*
```

Allowable characters for LAG names

When creating a LAG name, you can use spaces in a file or subdirectory name if you enclose the name in double quotes. For example, to specify a subdirectory name that contains spaces, enter a string such as the following: “a long subdirectory name”. The maximum length for a string is 64 characters.

The following characters are valid in file names:

- All upper and lowercase letters
- All digits

Any of the following special characters are valid:

- $
- %
- '
- -
- _
- @
- ~
- `
- !
- (
-)
- {
- }
- ^
- #
- &

CLI parsing enhancement

The response to an invalid keyword, the command returns to the cursor will include all valid content up to where the error was made. The prompt will only delete the invalid keyword "proc" and return to a prompt with the command "PowerConnect# show". This will allow the user to continue typing from the point of failure, rather than having to type out the entire command again.

```
NetIron# show proc
Unrecognized command
NetIron# show
```

Syntax shortcuts

A command or parameter can be abbreviated as long as enough text is entered to distinguish it from other commands at that level. For example, given the possible commands **copy tftp**... and **config tftp**..., possible shortcuts are **cop tftp** and **con tftp** respectively. In this case, **co** does not properly distinguish the two commands.

Saving configuration changes

You can make configuration changes while the device is running. The type of configuration change determines whether or not it becomes effective immediately or requires a save to flash (**write memory**) and reset of the system (**reload**), before it becomes active.

This approach in adopting configuration changes:

- Allows you to make configuration changes to the operating or running configuration of the device to address a short-term requirement or validate a configuration without overwriting the permanent configuration file, the startup configuration, that is saved in the system flash, and;
- Ensures that dependent or related configuration changes are all cut in at the same time.

In all cases, if you want to make the changes permanent, you need to save the changes to flash using the **write memory** command. When you save the configuration changes to flash, this will become the configuration that is initiated and run at system boot.

NOTE
Most configuration changes are dynamic and thus do not require a software reload. If a command requires a software reload to take effect, the documentation states this.

Modifying startup and running configuration file manually

When you manually modify a **startup-config** or **running-config** file, ensure that you do not delete the (**!**) from any of the lines in the configuration file.

Securing Access to Management Functions 2

Overview

The following Security features are supported by NetIron MLX Series devices:

- Restricting Remote Access to Management Functions
- Setting Up Local User Accounts
- Web Management Interface
- SSL Security for the Web Management Interface
- TACACS or TACACS+ Security
- New encryption code for passwords, authentication keys, and community strings
- RADIUS Security
- Interactive multi-factor RADIUS security support (e.g., for RSA SecurID)
- AAA on the Console
- AAA Authentication-Method Lists
- AES Encryption for SNMPv3
- AES Encryption for SSHv2

By default, the PowerConnect devices have all management access disabled. This chapter explains how to secure access to management functions on the PowerConnect devices. It contains the following sections:

- "Securing access methods" on page 18 lists the management access methods available on the PowerConnect devices and the ways you can secure each one
- "Restricting remote access to management functions" on page 20 explains how to restrict access to management functions from remote sources, including Telnet, the Web Management Interface, and SNMP
- "Setting passwords" on page 26 explains how to set passwords for Telnet access and management privilege levels
- "Setting up local user accounts" on page 31 explains how to define user accounts to regulate who can access management functions.
- "Configuring TACACS or TACACS+ security" on page 39 explains how to configure TACACS or TACACS+ authentication, authorization, and accounting.
- "Configuring RADIUS security" on page 55 explains how to configure RADIUS authentication, authorization, and accounting.
- "Configuring AAA on the console" on page 72
- "Configuring authentication-method lists" on page 73 explains how to set the order that authentication methods are consulted when more than one is used with an access method.

NOTE
For the PowerConnect devices, RADIUS Challenge is supported for 802.1x authentication but not for login authentication. Also, multiple challenges are supported for TACACS+ login authentication.

Securing access methods

The following table lists the management access methods available on the PowerConnect devices, how they are secured by default, and the ways in which they can be secured.

TABLE 4 Ways to secure management access to the PowerConnect devices

Access method	How the access method is secured by default	Ways to secure the access method	Refer to page
Serial access to the CLI	Not secured	Establish passwords for management privilege levels Establish username and password to log in to the console.	page 27 page 72
Access to the Privileged EXEC and CONFIG levels of the CLI	Not secured	Establish a password for Telnet access to the CLI	page 27
		Establish passwords for management privilege levels	page 27
		Set up local user accounts	page 31
		Configure TACACS or TACACS+ security	page 39
		Configure RADIUS security	page 55
Telnet access Telnet server is turned off by default.		Regulate Telnet access using ACLs	page 20
		Allow Telnet access only from specific IP addresses	page 23
		Allow Telnet access only to clients connected to a specific VLAN	page 25
		Disable Telnet access	page 26
		Establish a password for Telnet access	page 27
		Establish passwords for privilege levels of the CLI	page 27
		Set up local user accounts	page 31
		Configure TACACS or TACACS+ security	page 39
		Configure RADIUS security	page 55

TABLE 4 Ways to secure management access to the PowerConnect devices (Continued)

Access method	How the access method is secured by default	Ways to secure the access method	Refer to page
Secure Shell (SSH) access For more information on SSH, refer to Chapter 48, "Configuring Secure Shell and Secure Copy"	Not configured	Configure SSH	page 2015
		Disable SSH server.	
		Set up access using DSA Challenge-Response Authentication (excludes use of username and password credentials)	page 2018
		Regulate SSH access using ACLs	page 21
		Allow SSH access only from specific IP addresses	page 23
		Establish passwords for privilege levels of the CLI	page 27
		Set up local user accounts	page 31
		Configure TACACS or TACACS+ security	page 39
		Configure RADIUS security	page 55
Web management access	SNMP read or read-write community strings Web server is turned off by default.		
		Configure SSL security for the Web Management Interface	page 37
		Set up local user accounts	page 31
		Establish SNMP read or read-write community strings for SNMP versions 1 and 2	page 23
		Configure AAA command for Web access	
		Configure TACACS or TACACS+ security	page 39
		Configure RADIUS security	page 55
SNMP access	SNMP read or read-write community strings and the password to the Super User privilege level **NOTE:** SNMP read or read-write community strings are always required for SNMP access to the device. SNMP access is disabled by default.	Regulate SNMP access using ACLs	page 22
		Allow SNMP access only from specific IP addresses	page 23
		Disable SNMP access	page 26
		Allow SNMP access only to clients connected to a specific VLAN	page 25
		Establish passwords to management levels of the CLI	page 27
		Set up local user accounts	page 31
		Configure AAA command for SNMP access	
		Establish SNMP read or read-write community strings	page 39
TFTP access	Not secured	Allow TFTP access only to clients connected to a specific VLAN	page 25

Restricting remote access to management functions

You can restrict access to management functions from remote sources, including Telnet, and SNMP. The following methods for restricting remote access are supported:

- Using ACLs to restrict Telnet, SSH or SNMP access
- Allowing remote access only from specific IP addresses
- Allowing remote access only to clients connected to a specific VLAN
- Specifically disabling Telnet, SSH, Web Management Interface, or SNMP access to the device

Using ACLs to restrict remote access

You can use ACLs to control the following access methods to management functions on the PowerConnect router:

- Telnet access
- SSH access
- SNMP access

NOTE
IP ACLs are IP version specific. When both IPv4 and IPv6 ACLs are configured, the IPv4 ACL will be applied to sessions from IPv4 clients and the IPv6 ACL will be applied to sessions from IPv6 clients.

Follow the steps listed below to configure access control for these management access methods.

1. Configure an ACL with the IP addresses you want to allow to access the device. You can specify an IPv6 ACL, a numbered standard IPv4 ACL, or a named standard IPv4 ACL.
2. Configure a Telnet access group, SSH access group, web access group, and SNMP community strings for SNMPv1, SNMPv2c or SNMPv3 user. Each of these configuration items accepts an ACL as a parameter. The ACL contains entries that identify the IP addresses that can use the access method.

The following sections present examples of how to secure management access using ACLs. Refer to "Access Control List" on page 785 and "Configuring an IPv6 Access Control List" on page 1769 for more information on configuring ACLs.

NOTE
ACL filtering for remote management access is done in hardware.

Using an ACL to restrict Telnet access

To configure an ACL that restricts Telnet access to the device, enter commands such as the following:

```
NetIron(config)# access-list 10 deny host 209.157.22.32
NetIron(config)# access-list 10 deny 209.157.23.0 0.0.0.255
NetIron(config)# access-list 10 deny 209.157.24.0 0.0.0.255
NetIron(config)# access-list 10 deny 209.157.25.0/24
NetIron(config)# access-list 10 permit any
NetIron(config)# telnet access-group 10
NetIron(config)# write memory
```

The commands configure ACL 10, then apply it as the access list for Telnet access. The device allows Telnet access to all IP addresses except those listed in ACL 10.

Syntax: [no] telnet access-group {<*num*> | <*name*> **| ipv6** <*ipv6-acl-name*>}

Use the **ipv6** parameter if you are applying an IPv6 access list.

The <*num*> variable specifies the number of a standard IPv4 ACL, 1 – 99.

The <*name*> variable specifies the standard IPv4 access list name.

The <*ipv6-acl-name*> variable specifies the IPv6 access list name.

NOTE
ACLs for Telnet sessions will be applied only to inbound sessions.

To configure a more restrictive ACL, create permit entries and omit the **permit any** entry at the end of the ACL.

Example

```
NetIron(config)# access-list 10 permit host 209.157.22.32
NetIron(config)# access-list 10 permit 209.157.23.0 0.0.0.255
NetIron(config)# access-list 10 permit 209.157.24.0 0.0.0.255
NetIron(config)# access-list 10 permit 209.157.25.0/24
NetIron(config)# telnet access-group 10
NetIron(config)# write memory
```

The ACL in the example permits Telnet access only from the IPv4 addresses in the **permit** entries and denies Telnet access from all other IP addresses.

Using an ACL to restrict SSH access

To configure an ACL that restricts SSH access to the device, enter commands such as the following:

```
NetIron(config)# access-list 12 deny host 209.157.22.98
NetIron(config)# access-list 12 deny 209.157.23.0 0.0.0.255
NetIron(config)# access-list 12 deny 209.157.24.0/24
NetIron(config)# access-list 12 permit any
NetIron(config)# ssh access-group 12
NetIron(config)# write memory
```

Syntax: [no] ssh access-group {<*num*> **|** <*name*> **| ipv6** <*ipv6-acl-name*>}

Use the **ipv6** parameter if you are applying an IPv6 access list.

The <*num*> variable specifies the number of a standard IPv4 ACL, 1 – 99.

The <*name*> variable specifies the standard IPv4 access list name.

The <*ipv6-acl-name*> variable specifies the IPv6 access list name.

These commands configure ACL 12, then apply the ACL as the access list for SSH access. The device denies SSH access from the IPv4 addresses listed in ACL 12 and permits SSH access from all other IP addresses. Without the last ACL entry for permitting all packets, this ACL would deny SSH access from all IP addresses.

NOTE
In this example, the **command ssh access-group 10** could have been used to apply the ACL configured in the example for Telnet access. You can use the same ACL multiple times.

Using ACLs to restrict SNMP access

To restrict SNMP access to the device using ACLs, enter commands such as the following.

NOTE
The syntax for using ACLs for SNMP access is different from the syntax for controlling Telnet, SSH, and Web management access using ACLs.

```
NetIron(config)# access-list 25 deny host 209.157.22.98
NetIron(config)# access-list 25 deny 209.157.23.0 0.0.0.255
NetIron(config)# access-list 25 deny 209.157.24.0 0.0.0.255
NetIron(config)# access-list 25 permit any
NetIron(config)# access-list 30 deny 209.157.25.0 0.0.0.255
NetIron(config)# access-list 30 deny 209.157.26.0/24
NetIron(config)# access-list 30 permit any
NetIron(config)# snmp-server community public ro 25
NetIron(config)# snmp-server community private rw 30
NetIron(config)# write memory
```

These commands configure ACLs 25 and 30, then apply the ACLs to community strings. ACL 25 is used to control read-only access using the "public" community string. ACL 30 is used to control read-write access using the "private" community string.

Syntax: [no] **snmp-server community** <*string*> **{ro | rw} {**<*standard-acl-name*> **|** <*standard-acl-id*> **| ipv6** <*ipv6-acl-name*>**}**

The <*string*> variable specifies the SNMP community string the user must enter to gain SNMP access.

The **ro** parameter indicates that the community string is for read-only ("get") access. The **rw** parameter indicates the community string is for read-write ("set") access.

The **ipv6** parameter indicates that you are applying an IPv6 access list.

The <*standard-acl-name*> or <*standard-acl-id*> or <*ipv6-acl-name*> variable specifies which ACL will be used to filter incoming SNMP packets.

The <*standard-acl-id*> variable specifies the number of a standard IPv4 ACL, 1 – 99.

The <*standard-acl-name*> variable specifies the standard IPv4 access list name.

The <*ipv6-acl-name*> variable specifies the IPv6 access list name.

NOTE
When **snmp-server community** is configured, all incoming SNMP packets are validated first by their community strings and then by their bound ACLs. Packets are permitted if no filters are configured for an ACL.

Defining the console idle time

By default, a PowerConnect router does not time out serial console sessions. A serial session remains open indefinitely until you close it. You can however define how many minutes a serial management session can remain idle before it is timed out.

To configure the idle time for a serial console session, use the following command.

```
NetIron(config)# console timeout 120
```

Syntax: [no] **console timeout** <*0 – 240*>

- Possible values: 0 – 240 minutes
- Default value: 0 minutes (no timeout)

NOTE
The standard for the idle-timeout RADIUS attribute is for it to be implemented in seconds as opposed to the minutes that the PowerConnect router uses. If this attribute is used for setting idle time instead of this configuration, the value from the idle-timeout RADIUS attribute will be converted from seconds to minutes and truncated to the nearest minute.

Restricting remote access to the device to specific IP addresses

By default, a PowerConnect router does not control remote management access based on the IP address of the managing device. You can restrict remote management access to a single IP address for the following access methods:

- Telnet access
- SNMP access

In addition, if you want to restrict all three access methods to the same IP address, you can do so using a single command.

The following examples show the CLI commands for restricting remote access. You can specify only one IP address with each command. However, you can enter each command ten times to specify up to ten IP addresses.

NOTE
You cannot restrict remote management access using the Web Management Interface.

Restricting Telnet access to a specific IP address

To allow Telnet access to the PowerConnect router only to the host with IP address 209.157.22.39, enter the following command.

```
NetIron(config)# telnet client 209.157.22.39
```

Syntax: [no] telnet client <*ip-addr*>

Restricting SSH access to a specific IP address

To allow SSH access to the PowerConnect router only to the host with IP address 209.157.22.39, enter the following command.

```
NetIron(config)# ip ssh client 209.157.22.39
```

Syntax: [no] ip ssh client <*ip-addr*>

Restricting SNMP access to a specific IP address

To allow SNMP access to the PowerConnect router only to the host with IP address 209.157.22.14, enter the following command.

```
NetIron(config)# snmp-client 209.157.22.14
```

Syntax: [no] snmp-client <*ip-addr*>

Restricting all remote management access to a specific IP address

To allow Telnet, and SNMP management access to the PowerConnect router only to the host with IP address 209.157.22.69, you can enter three separate commands (one for each access type) or you can enter the following command.

```
NetIron(config)# all-client 209.157.22.69
```

Syntax: [no] all-client <*ip-addr*>

Defining the Telnet idle time

You can define how many minutes a Telnet session can remain idle before it is timed out. An idle Telnet session is a session that is still sending TCP ACKs in response to keepalive messages from the device, but is not being used to send data.

To configure the idle time for a Telnet session, use the following command.

```
NetIron(config)# telnet timeout 120
```

Syntax: [no] telnet timeout <*0 – 240*>

Possible values: 0 – 240 minutes

Default value: 0 minutes (no timeout)

NOTE
The standard for the idle-timeout RADIUS attribute is for it to be implemented in seconds as opposed to the minutes that the PowerConnect router uses. If this attribute is used for setting idle time instead of this configuration, the value from the idle-timeout RADIUS attribute will be converted from seconds to minutes and truncated to the nearest minute.

Specifying the maximum login attempts for Telnet access

If you are connecting to the PowerConnect router using Telnet, the device prompts you for a username and password. By default, you have up to 4 chances to enter a correct username and password. If you do not enter a correct username or password after 4 attempts, the PowerConnect router disconnects the Telnet session.

You can specify the number of attempts a Telnet user has to enter a correct username and password before the PowerConnect router disconnects the Telnet session. For example, to allow a Telnet user up to 5 chances to enter a correct username and password, enter the following command.

```
NetIron(config)# telnet login-retries 5
```

Syntax: [no] telnet login-retries <*number*>

You can specify from 0 – 5 attempts. The default is 4 attempts.

Restricting remote access to the device to specific VLAN IDs

You can restrict management access to a PowerConnect router to ports within a specific port-based VLAN. VLAN-based access control applies to the following access methods:

- Telnet access
- SNMP access
- TFTP access

By default, access is allowed for all the methods listed above on all ports. Once you configure security for a given access method based on VLAN ID, access to the device using that method is restricted to only the ports within the specified VLAN.

VLAN-based access control works in conjunction with other access control methods. For example, suppose you configure an ACL to permit Telnet access only to specific client IP addresses, and you also configure VLAN-based access control for Telnet access. In this case, the only Telnet clients that can access the device are clients that have one of the IP addresses permitted by the ACL ***and*** are connected to a port that is in a permitted VLAN. Clients who have a permitted IP address but are connected to a port in a VLAN that is not permitted still cannot access the device through Telnet.

Restricting Telnet access to a specific VLAN

To allow Telnet access only to clients in a specific VLAN, enter a command such as the following.

```
NetIron(config)# telnet server enable vlan 10
```

The command configures the device to allow Telnet management access only to clients connected to ports within port-based VLAN 10. Clients connected to ports that are not in VLAN 10 are denied management access.

Syntax: [no] telnet server enable vlan <*vlan-id*>

Restricting SNMP access to a specific VLAN

To allow SNMP access only to clients in a specific VLAN, enter a command such as the following.

```
NetIron(config)# snmp-server enable vlan 40
```

The command configures the device to allow SNMP access only to clients connected to ports within port-based VLAN 40. Clients connected to ports that are not in VLAN 40 are denied access.

Syntax: [no] snmp-server enable vlan <*vlan-id*>

Restricting TFTP access to a specific VLAN

To allow TFTP access only to clients in a specific VLAN, enter a command such as the following.

```
NetIron(config)# tftp client enable vlan 40
```

The command in this example configures the device to allow TFTP access only to clients connected to ports within port-based VLAN 40. Clients connected to ports that are not in VLAN 40 are denied access.

Syntax: [no] tftp client enable vlan <*vlan-id*>

Enabling specific access methods

You can specifically enable the following access methods:

- Telnet access
- SNMP access

NOTE
If you do not enable Telnet access, you can access the CLI using a serial connection to the management module. If you do not enable SNMP access, you will not be able to use SNMP management applications.

Enabling Telnet access

Telnet access is disabled by default. You can use a Telnet client to access the CLI on the device over the network.

To enable Telnet operation, enter the following command.

```
NetIron(config)# telnet-server
```

If you do not plan to use the CLI over the network and want to disable Telnet access to prevent others from establishing CLI sessions with the device, enter the following command.

```
NetIron(config)# no telnet-server
```

Syntax: [no] telnet-server

Enabling SNMP access

SNMP is disabled by default on the PowerConnect devices. SNMP is required if you want to manage a PowerConnect router using SNMP Network Manager.

To enable SNMP management of the device.

```
NetIron(config)#snmp-server
```

To later disable SNMP management of the device.

```
NetIron(config)#no snmp-server
```

Syntax: [no] snmp-server

Setting passwords

Passwords can be used to secure the following access methods:

- Telnet access can be secured by setting a Telnet password. Refer to "Setting a Telnet password" on page 27.
- Access to the Privileged EXEC and CONFIG levels of the CLI can be secured by setting passwords for management privilege levels. Refer to "Setting passwords for management privilege levels" on page 27.

This section also provides procedures for enhancing management privilege levels, recovering from a lost password, and disabling password encryption.

NOTE
You also can configure up to 16 user accounts consisting of a user name and password, and assign each user account a management privilege level. Refer to "Setting up local user accounts" on page 31.

Setting a Telnet password

By default, the device does not require a user name or password when you log in to the CLI using Telnet.

To set the password "letmein" for Telnet access to the CLI, enter the following command at the global CONFIG level.

```
NetIron(config)# enable telnet password letmein
```

Syntax: [no] enable telnet password <*string*>

Suppressing Telnet connection rejection messages

By default, if a PowerConnect router denies Telnet management access to the device, the software sends a message to the denied Telnet client. You can optionally suppress the rejection message. When you enable the option, a denied Telnet client does not receive a message from the PowerConnect router. Instead, the denied client simply does not gain access.

To suppress the connection rejection message sent by the device to a denied Telnet client, enter the following command at the global CONFIG level of the CLI.

```
NetIron(config)# telnet server suppress-reject-message
```

Syntax: [no] telnet server suppress-reject-message

Setting passwords for management privilege levels

You can set one password for each of the following management privilege levels:

- **Super User level** – Allows complete read-and-write access to the system. This is generally for system administrators and is the only management privilege level that allows you to configure passwords.
- **Port Configuration level** – Allows read-and-write access for specific ports but not for global (system-wide) parameters.
- **Read Only level** – Allows access to the Privileged EXEC mode and CONFIG mode of the CLI but only with read access.

You can assign a password to each management privilege level. You also can configure up to 16 user accounts consisting of a user name and password, and assign each user account to one of the three privilege levels. Refer to "Setting up local user accounts" on page 31.

NOTE
You must use the CLI to assign a password for management privilege levels. You cannot assign a password using the Web Management Interface.

If you configure user accounts in addition to privilege level passwords, the device will validate a user's access attempt using one or both methods (local user account or privilege level password), depending on the order you specify in the authentication-method lists. Refer to "Configuring authentication-method lists" on page 73.

Follow the steps listed below to set passwords for management privilege levels.

1. At the opening CLI prompt, enter the following command to change to the Privileged level of the EXEC mode.

```
NetIron> enable
NetIron#
```

2. Access the CONFIG level of the CLI by entering the following command.

```
NetIron# configure terminal
NetIron(config)#
```

3. Enter the following command to set the Super User level password.

```
NetIron(config)# enable super-user-password <text>
```

NOTE
You must set the Super User level password before you can set other types of passwords. The Super User level password can be an alphanumeric string, but cannot begin with a number.

4. Enter the following commands to set the Port Configuration level and Read Only level passwords.

```
NetIron(config)# enable port-config-password <text>
NetIron(config)# enable read-only-password <text>
```

Syntax: enable super-user-password <*text*>

Syntax: enable port-config-password <*text*>

Syntax: enable read-only-password <*text*>

NOTE
If you forget your Super User level password, refer to "Recovering from a lost password" on page 29.

Augmenting management privilege levels

Each management privilege level provides access to specific areas of the CLI by default:

- Super User level provides access to all commands and displays.
- Port Configuration level gives access to the following:
  - The User EXEC and Privileged EXEC levels
  - The port-specific parts of the CONFIG level
  - All interface configuration levels
- Read Only level gives access to to the following:
  - The User EXEC and Privileged EXEC levels

You can grant additional access to a privilege level on an individual command basis. To grant the additional access, you specify the privilege level you are enhancing, the CLI level that contains the command, and the individual command.

NOTE
This feature applies only to management privilege levels on the CLI. You cannot augment management access levels for the Web Management Interface.

To enhance the Port Configuration privilege level so users also can enter IP commands at the global CONFIG level.

```
NetIron(config)# privilege configure level 4 ip
```

In this command, **configure** specifies that the enhanced access is for a command at the global CONFIG level of the CLI. The **level 4** parameter indicates that the enhanced access is for management privilege level 4 (Port Configuration). All users with Port Configuration privileges will have the enhanced access. The ip parameter indicates that the enhanced access is for the IP commands. Users who log in with valid Port Configuration level user names and passwords can enter commands that begin with "ip" at the global CONFIG level.

Syntax: [no] privilege <*cli-level*> **level** <*privilege-level*> <*command-string*>

The <*cli-level*> parameter specifies the CLI level and can be one of the following values:

- **exec** – EXEC level; for example, NetIron#
- **configure** – CONFIG level; for example, NetIron`(config)#`
- **interface** – Interface level; for example, NetIron`(config-if-e10000-6)#`
- **virtual-interface** – Virtual-interface level; for example, NetIron`(config-vif-6)#`
- **rip-router** – RIP router level; for example, NetIron`(config-rip-router)#`
- **ospf-router** – OSPF router level; for example, NetIron`(config-ospf-router)#`
- **bgp-router** – BGP4 router level; for example, NetIron`(config-bgp-router)#`
- **port-vlan** – Port-based VLAN level; for example, NetIron`(config-vlan)#`
- **protocol-vlan** – Protocol-based VLAN level
- **dot1x**
- **loopback-interface**
- **tunnel-interface**
- **vrrp-router**

The <*privilege-level*> indicates the number of the management privilege level you are augmenting. You can specify one of the following:

- **0** – Super User level (full read-write access)
- **4** – Port Configuration level
- **5** – Read Only level

The <*command-string*> parameter specifies the command you are allowing users with the specified privilege level to enter. To display a list of the commands at a CLI level, enter "?" at that level's command prompt.

Recovering from a lost password

Recovery from a lost password requires direct access to the serial port and a system reset.

NOTE
You can perform this procedure only from the CLI. This procedure should be performed with one primary management module installed. If both management modules are installed then the secondary will take over during the boot process, not allowing the password recovery process.

Follow the steps listed below to recover from a lost password.

1. Start a CLI session over the serial interface to the device.
2. Reboot the device.
3. At the initial boot prompt at system startup, enter **b** to enter the boot monitor mode.
4. Enter **no password** at the prompt. (You cannot abbreviate this command.) This command will cause the device to bypass the system password check.
5. Enter **boot system flash primary** at the prompt, and enter **y** when asked "Are you sure?".
6. After the console prompt reappears, assign a new password.

Displaying the SNMP community string

If you want to display the SNMP community string, enter the following commands.

```
NetIron(config)# enable password-display
NetIron(config)# show snmp server
```

The **enable password-display** command enables display of the community string, but only in the output of the **show snmp server** command. Display of the string is still encrypted in the startup configuration file and running configuration. Enter the command at the global CONFIG level of the CLI.

Disabling password encryption

When you configure a password, then save the configuration to the device's flash memory, the password is also saved to flash as part of the configuration file. By default, the passwords are encrypted so that the passwords cannot be observed by another user who displays the configuration file. Even if someone observes the file while it is being transmitted over TFTP, the password is encrypted.

If you want to remove the password encryption, you can disable encryption by entering the following command.

```
NetIron(config)# no service password-encryption
```

Syntax: [no] service password-encryption

Specifying a minimum password length

By default, the device imposes no minimum length on the Line (Telnet), Enable, or Local passwords. You can configure the device to require that Line, Enable, and Local passwords be at least a specified length.

For example, to specify that the Line, Enable, and Local passwords be at least 8 characters, enter the following command.

```
NetIron(config)# enable password-min-length 8
```

Syntax: [no] enable password-min-length <*number-of-characters*>

The <*number-of-characters*> can be from 1 – 48.

Setting up local user accounts

You can define up to 16 local user accounts on a PowerConnect router. User accounts regulate who can access the management functions in the CLI using the following methods:

- Telnet access
- SSH access
- Console access
- Web management access
- SNMP access

Local user accounts provide greater flexibility for controlling management access to the PowerConnect router than do management privilege level passwords and SNMP community strings of SNMP versions 1 and 2. You can continue to use the privilege level passwords and the SNMP community strings as additional means of access authentication. Alternatively, you can choose not to use local user accounts and instead continue to use only the privilege level passwords and SNMP community strings. Local user accounts are backward-compatible with configuration files that contain privilege level passwords. Refer to "Setting passwords for management privilege levels" on page 27.

If you configure local user accounts, you also need to configure an authentication-method list for Telnet access, Web management access, and SNMP access. Refer to "Configuring authentication-method lists" on page 73.

For each local user account, you specify a user name which can have up to 255 characters. You also can specify the following parameters:

- A password
- A management privilege level, which can be one of the following:
  - **Super User level** – Allows complete read-and-write access to the system. This is generally for system administrators and is the only privilege level that allows you to configure passwords. This is the default.
  - **Port Configuration level** – Allows read-and-write access for specific ports but not for global (system-wide) parameters.
  - **Read Only level** – Allows access to the Privileged EXEC mode and CONFIG mode but only with read access.

Configuring a local user account

To configure a local user account, enter a command such as the following at the global CONFIG level of the CLI.

```
NetIron(config)# username wonka password willy
```

This command adds a local user account with the user name "wonka" and the password "willy". This account has the Super User privilege level; this user has full access to all configuration and display features.

NOTE
If you configure local user accounts, you must grant Super User level access to at least one account before you add accounts with other privilege levels. You need the Super User account to make further administrative changes.

```
NetIron(config)# username waldo privilege 5 password whereis
```

This command adds a user account for user name “waldo”, password “whereis”, with the Read Only privilege level. Waldo can look for information but cannot make configuration changes.

Syntax: **[no] username** <*user-string*> **privilege** <*privilege-level*> **password | nopassword** <*password-string*>

Enter up to 255 characters for <*user-string*>.

The **privilege** parameter specifies the privilege level for the account. You can specify one of the following:

- **0** – Super User level (full read-write access)
- **4** – Port Configuration level
- **5** – Read Only level

The default privilege level is **0**. If you want to assign Super User level access to the account, you can enter the command without **privilege 0**, as shown in the command example above.

The **password | nopassword** parameter indicates whether the user must enter a password. If you specify **password**, enter the string for the user's password.

NOTE
You must be logged on with Super User access (privilege level 0) to add user accounts or configure other access parameters.

To display user account information, enter the following command.

```
NetIron(config)# show users
```

Syntax: show users

Note about changing local user passwords

The PowerConnect router stores not only the current password configured for a local user, but the previous two passwords configured for the user as well. The local user's password cannot be changed to one of the stored passwords.

Consequently, if you change the password for a local user, you must select a password that is different from the current password, as well as different from the previous two passwords that had been configured for that user.

For example, say local user waldo originally had a password of "whereis", and the password was subsequently changed to “whois”, then later changed to “whyis”. If you change waldo's password again, you cannot change it to "whereis", "whois", or "whyis".

The current and previous passwords are stored in the device’s running configuration file in encrypted form.

Example

```
NetIron# show run
...
username waldo password 8 $1$Ro2..Ox0$udBu7pQT5XyuaXMUiUHy9. history
$1$eq...T62$IfpxIcxnDWX7CSVQKIodu. $1$QD3..2Q0$DYxgxCI64ZOSsYmSSaA28/
...
```

In the running configuration file, the user's previous two passwords are displayed in encrypted form following the **history** parameter.

Enhancements to username and password

The following rules are enabled by default:

- Users are now required to accept the message of the day.
- Users are locked out (disabled) if they fail to login after three attempts. This feature is automatically enabled.

The following rules are disabled by default:

- Enhanced user password combination requirements
- You can configure the system to store up to 15 previously configured passwords for each user.
- A password can now be set to expire.

Enabling enhanced user password combination requirements

Enhancements to the username and password have been added to provide added security. The regular password rules for username and password creation are still the default condition but the strict password rules can be enabled using the new command: "**enable strict-password-enforcement**" .

Regular password rules

The following rules apply to passwords unless the **enable strict-password-enforcement** command is executed:

- A minimum of one character is required to create a password.
- The last 3 passwords are stored in the CLI.
- No password expiration.
- Users were not locked out (disabled) after failed login attempts.

Strict password rules

The following rules have been implemented to enhance the password features in the PowerConnect devices.They apply to passwords if the **enable strict-password-enforcement** command is executed.

- Users are now required to accept the message of the day.
- Users are locked out (disabled) if they fail to login in three login attempts.

- The last 15 passwords are now stored in the CLI.
- A password can now be set to expire.
- Passwords are masked during password creation.
- Passwords must not share 4 or more concurrent characters with any other password configured on the router.
- You cannot configure a password that was previously configured.

When you create an enable and a user password, you must enter a minimum of eight characters containing the following combinations:

- At least two upper case characters
- At least two lower case characters
- At least two numeric characters
- At least two special character

NOTE
Password minimum and combination requirements are strictly enforced.

Configuring the strict password rules

Use the enable strict-password-enforcement command to enable the password security feature. Enter a command such as the following.

```
NetIron(config)# enable strict-password-enforcement
```

Syntax: [no] enable strict-password-enforcement

This feature is disabled by default.

The passwords must not share 4 or more concurrent characters with any other password configured on the router. If the user tries to create a password with 4 or more concurrent characters, the following error message will be returned.

```
Error - The substring <str> within the password has been used earlier, please
choose a different password.
```

Also, if the user tries to configure a password that was previously configured, the Local User Account configuration will not be allowed and the following message will be displayed.

```
This password was used earlier for same or different user, please choose a
different password."
```

When you create a password, the characters you type are masked.

Example : To create a password for the enable login.

```
NetIron(config)# user sandy password TesT12$%
```

Syntax: [no] user <*username*> password <*password*>

Example : To assign a password for a user account.

```
NetIron(config)# username sandy password [Enter]
Enter password: ********
```

Syntax: [no] username <*name*> password

Enter a password such as TesT12$! that contains the required character combination.

Requirement to accept the message of the day

If a message of the day (MOTD) is configured, a user will be required to press the "Enter" key before he or she can login. To enable this requirement, enter the command as shown.

```
NetIron(config)# banner motd require-enter-key
```

Login lockout

The CLI has been enhanced to provide up to three login attempts. If a user fails to login after three attempts, that user is locked out (disabled). To re-enable the user, do one of the following:

- Rebooting the PowerConnect router to re-enable all disabled users.
- Enable the user by entering the following command.

```
NetIron(config)# username sandy enable
```

Syntax: [no] username <*name*> **enable**

The <*name*> variable specifies the user whose access you want to enable.

There are no new CLI commands for this feature however the **enable strict-password-enforcement** command must be configured for this feature to be enabled.

Password history

The CLI has been enhanced to keep the last 15 passwords used by the user. A user will be prevented from changing their password to one that has already been used. This is for security purposes so that users do not use the same passwords multiple times.

There are no new CLI commands for this feature.

Setting passwords to expire

You can set a user password to expire. Once a password expires, the administrator must assign a new password to the user.

To configure a user password to expire, enter the following.

```
NetIron(config)# enable strict-password-enforcement
NetIron(config)# username sandy expires 20
```

Syntax: [no] username <*name*> **expires** <*days*>

The <*name*> variable specifies the user that the expiration time is applied to.

The <*days*> variable specifies the number of day before the password will expire. The following values can be used 1 – 365 days. The default is 90 days.

NOTE
The **enable strict-password-enforcement** command must be enabled before this command is configured. Otherwise, the following message will be displayed: `"Password expire time is enabled only if strict-password-enforcement is set".`

The **show user** command can be used to display the expiration date as shown in **bold** in the following.

```
NetIron(config)#show user Username Password Encrypt Priv Status Expire Time
================================================================================
= sandy $1$Gz...uX/$wQ44fVGtsqbKWkQknzAZ6. enabled 0 enabled 20 days
```

Requirement to accept the message of the day

If a message of the day (MOTD) is configured, a user will be required to press the Enter key before he or she can login. MOTD is configured using the **banner motd** command.

There are no new CLI commands for this feature.

Enhanced login lockout

The CLI has been enhanced to provide up to three login attempts. If a user fails to login after three attempts, that user is locked out (disabled).

To re-enable a user that has been locked out, perform one of the following tasks:

- Reboot the PowerConnect to re-enable all disabled users.
- Enable the user by entering the following command.

  ```
  NetIron(config)# username sandy enable
  ```

Example

```
NetIron(config)# user sandy enable
PowerConnect(config)# show user
Username  Password                              Encrypt   Priv Status   Expire Time
=============================================================================

sandy     $1$Gz...uX/$wQ44fVGtsqbKWkQknzAZ6. enabled   0   enabled  90 days
```

Syntax: [no] username <*name*> **enable**

Setting passwords to expire

You can set a user password to expire. Once a password expires, the administrator must assign a new password to the user. To configure a user password to expire, enter the following.

```
NetIron(config)# username sandy expires 20
```

Syntax: [no] username <*name*> **expires <days>**

Enter 1 – 365 for number of days. The default is 90 days.

Example

```
NetIron(config)# username sandy expires 20
NetIron(config)# show user
Username     Password                              Encrypt   Priv  Status   Expire
Time
================================================================================
=
sandy       $1$Gz...uX/$wQ44fVGtsqbKWkQknzAZ6. enabled    0    enabled  20 days
```

Creating an encrypted all-numeric password

To create a password that is made up of all numeric values, use the command "**username** <*user-string*> **privilege** <*privilege-level*> **password** <*password-string*>." To allow backward compatibility with the **username** command, the new keyword **create-password** has been created and it is used as shown in the following.

```
NetIron# username customer1 create-password 9999
```

Syntax: [no] username <*user-string*> **create-password** <*password-string*>

The **create-password** option allows you to create a password with a numeric value in the <*password-string*> variable. The generated password will be encrypted. The **show running-config** command will display the password as shown.

```
username <user-string> 8 <encrypted-password>
```

Granting access by time of day

To configure an PowerConnect router to restrict access to a specified user to a specified time of day, use the following command.

```
NetIron(config)# username admin1 access-time 10:00:00 to 13:00:00
```

Syntax: [no] username <*user-string*> **access-time** <*hh:mm:ss*> **to** <*hh:mm:ss*>

The <*user-string*> variable specifies the user that you want to limit access time for.

The first instance of the <*hh:mm:ss*> variable specifies the start of the access time and the second instance of the <*hh:mm:ss*> variable specifies the end of the access time.

Configuring SSL security for the Web Management Interface

When enabled, the SSL protocol uses digital certificates and public-private key pairs to establish a secure connection to the PowerConnect router. Digital certificates serve to prove the identity of a connecting client, and public-private key pairs provide a means to encrypt data sent between the device and the client.

Configuring SSL for the Web Management Interface consists of the following tasks:

- Enabling the SSL server on the PowerConnect router
- Importing an RSA certificate and private key file from a client (optional)
- Generating a certificate

Enabling the SSL server on a PowerConnect router

To enable the SSL server on a PowerConnect router, enter the following command.

```
NetIron(config)# web-management https
```

Syntax: [no] web-management http | https

You can enable either the HTTP or HTTPs servers with this command. You can disable both the HTTP and HTTPs servers by entering the following command.

```
NetIron(config)# no web-management
```

Syntax: [no] web-management

Specifying a port for SSL communication

By default, SSL protocol exchanges occur on TCP port 443. You can optionally change the port number used for SSL communication.

For example, the following command causes the device to use TCP port 334 for SSL communication.

```
NetIron(config)# ip ssl port 334
```

Syntax: [no] ip ssl port <*port-number*>

The default port for SSL communication is 443.

Importing digital certificates and RSA private key files

To allow a client to communicate with the other PowerConnect router using an SSL connection, you configure a set of digital certificates and RSA public-private key pairs on the device. A digital certificate is used for identifying the server to the connecting client. It contains information about the issuing Certificate Authority, as well as a public key. You can either import digital certificates and private keys from a server, or you can allow the Dell device to create them.

If you want to allow the Dell device to create the digital certificates, refer to the next section, "Generating an SSL certificate". If you choose to import an RSA certificate and private key file from a client, you can use TFTP to transfer the files.

For example, to import a digital certificate using TFTP, enter a command such as the following.

```
NetIron(config)# ip ssl certificate-data-file tftp 192.168.9.210 certfile
```

Syntax: [no] ip ssl certificate-data-file tftp <*ip-addr*> <*certificate-filename*>

NOTE
If you import a digital certificate from a client, it can be no larger than 2048 bytes.

To import an RSA private key from a client using TFTP, enter a command such as the following.

```
NetIron(config)# ip ssl private-key-file tftp 192.168.9.210 keyfile
```

Syntax: [no] ip ssl private-key-file tftp <*ip-addr*> <*key-filename*>

The <*ip-addr*> is the IP address of a TFTP server that contains the digital certificate or private key.

Generating an SSL certificate

If you did not already import a digital certificate from a client, the device can create a default certificate. To do this, enter the following command.

```
NetIron(config)# crypto-ssl certificate generate
```

Syntax: [no] crypto-ssl certificate generate

Deleting the SSL certificate

To delete the SSL certificate, enter the following command.

```
NetIron(config)# crypto-ssl certificate zeroize
```

Syntax: [no] crypto-ssl certificate zeroize

Configuring TACACS or TACACS+ security

You can use the security protocol Terminal Access Controller Access Control System (TACACS) or TACACS+ to authenticate the following kinds of access to the PowerConnect devices:

- Telnet access
- SSH access
- Console access
- Web management access
- Access to the Privileged EXEC level and CONFIG levels of the CLI

NOTE
You cannot authenticate SNMP access to a PowerConnect router using TACACS or TACACS+.

The TACACS and TACACS+ protocols define how authentication, authorization, and accounting information is sent between a PowerConnect router and an authentication database on a TACACS or TACACS+ server. TACACS or TACACS+ services are maintained in a database, typically on a UNIX workstation or PC with a TACACS or TACACS+ server running.

How TACACS+ differs from TACACS

TACACS is a simple UDP-based access control protocol originally developed by BBN for MILNET. TACACS+ is an enhancement to TACACS and uses TCP to ensure reliable delivery.

TACACS+ is an enhancement to the TACACS security protocol. TACACS+ improves on TACACS by separating the functions of authentication, authorization, and accounting (AAA) and by encrypting all traffic between the PowerConnect router and the TACACS+ server. TACACS+ allows for arbitrary length and content authentication exchanges, which allow any authentication mechanism to be utilized with the PowerConnect router. TACACS+ is extensible to provide for site customization and future development features. The protocol allows the PowerConnect router to request very precise access control and allows the TACACS+ server to respond to each component of that request.

NOTE
TACACS+ provides for authentication, authorization, and accounting, but an implementation or configuration is not required to employ all three.

TACACS or TACACS+ authentication, authorization, and accounting

When you configure a PowerConnect router to use a TACACS or TACACS+ server for authentication, the device prompts users who are trying to access the CLI for a user name and password, then verifies the password with the TACACS or TACACS+ server.

If you are using TACACS+, it is recommended that you also configure ***authorization***, in which the PowerConnect router consults a TACACS+ server to determine which management privilege level (and which associated set of commands) an authenticated user is allowed to use. You can also optionally configure ***accounting***, which causes the PowerConnect router to log information on the TACACS+ server when specified events occur on the device.

NOTE
By default, a user logging into the device through Telnet or SSH would first enter the User EXEC level. The user can enter the **enable** command to get to the Privileged EXEC level.

NOTE
A user that is successfully authenticated can be automatically placed at the Privileged EXEC level after login. Refer to "Entering privileged EXEC mode after a console, Telnet or SSH login" on page 48.

TACACS authentication

NOTE
Also, multiple challenges are supported for TACACS+ login authentication.

The following events occur when TACACS authentication takes place.

1. A user attempts to gain access to the PowerConnect router by doing one of the following:
   - Logging into the device using console, Telnet, SSH, or the Web Management Interface
   - Entering the Privileged EXEC level or CONFIG level of the CLI
2. The user is prompted for a username and password.
3. The user enters a username and password.
4. The PowerConnect router sends a request containing the username and password to the TACACS server.
5. The username and password are validated in the TACACS server's database.
6. If the password is valid, the user is authenticated.

TACACS+ authentication

The following events occur when TACACS+ authentication takes place.

1. A user attempts to gain access to the PowerConnect router by doing one of the following:
   - Logging into the device using console, telnet, SSH, or the Web Management Interface
   - Entering the Privileged EXEC level or CONFIG level of the CLI
2. The user is prompted for a username.
3. The user enters a username.
4. The PowerConnect router obtains a password prompt from a TACACS+ server.
5. The user is prompted for a password.
6. The user enters a password.
7. The PowerConnect router sends the password to the TACACS+ server.

8. The password is validated in the TACACS+ server's database.
9. If the password is valid, the user is authenticated.

TACACS+ authorization

The PowerConnect devices support two kinds of TACACS+ authorization:

- Exec authorization determines a user's privilege level when they are authenticated.
- Command authorization consults a TACACS+ server to get authorization for commands entered by the user.

The following events occur when TACACS+ exec authorization takes place.

1. A user logs into the PowerConnect router using console, Telnet or SSH
2. The user is authenticated.
3. The PowerConnect router consults the TACACS+ server to determine the privilege level of the user.
4. The TACACS+ server sends back a response containing an A-V (Attribute-Value) pair with the privilege level of the user.
5. The user is granted the specified privilege level.

The following events occur when TACACS+ command authorization takes place.

1. A Telnet, SSH, or console interface user previously authenticated by a TACACS+ server enters a command on the PowerConnect router.
2. The PowerConnect router looks at its configuration to see if the command is at a privilege level that requires TACACS+ command authorization.
3. If the command belongs to a privilege level that requires authorization, the PowerConnect router consults the TACACS+ server to see if the user is authorized to use the command.
4. If the user is authorized to use the command, the command is executed.

TACACS+ accounting

The following steps explain the working of TACACS+ accounting.

1. One of the following events occur on the PowerConnect router:
    - A user logs into the management interface using console, Telnet or SSH
    - A user enters a command for which accounting has been configured
    - A system event occurs, such as a reboot or reloading of the configuration file
2. The PowerConnect router checks its configuration to see if the event is one for which TACACS+ accounting is required.
3. If the event requires TACACS+ accounting, the PowerConnect router sends a TACACS+ Accounting Start packet to the TACACS+ accounting server, containing information about the event.
4. The TACACS+ accounting server acknowledges the Accounting Start packet.
5. The TACACS+ accounting server records information about the event.

6. When the event is concluded, the PowerConnect router sends an Accounting Stop packet to the TACACS+ accounting server.
7. The TACACS+ accounting server acknowledges the Accounting Stop packet.

AAA operations for TACACS or TACACS+

The following table lists the sequence of authentication, authorization, and accounting operations that take place when a user gains access to a PowerConnect router that has TACACS or TACACS+ security configured.

User action	Applicable AAA operations
User attempts to gain access to the Privileged EXEC and CONFIG levels of the CLI	Enable authentication: aaa authentication enable default <*method-list*>
	Exec authorization (TACACS+): aaa authorization exec default tacacs+
	System accounting start (TACACS+): aaa accounting system default start-stop <*method-list*>
User logs in using console, Telnet, or SSH	Login authentication: aaa authentication login default <*method-list*>
	Exec authorization (TACACS+): aaa authorization exec default tacacs+
	Exec accounting start (TACACS+): aaa accounting exec default <*method-list*> System accounting start (TACACS+): aaa accounting system default start-stop <*method-list*>
User logs into the Web Management Interface	Web authentication: aaa authentication web-server default <*method-list*>
	Exec authorization (TACACS+): aaa authorization exec default tacacs+
User logs out of console, Telnet, or SSH session	Command accounting (TACACS+): aaa accounting commands <*privilege-level*> default start-stop <*method-list*> EXEC accounting stop (TACACS+): aaa accounting exec default start-stop <*method-list*>
User enters system commands (for example, **reload**, **boot system**)	Command authorization (TACACS+): aaa authorization commands <*privilege-level*> default <*method-list*>
	Command accounting (TACACS+): aaa accounting commands <*privilege-level*> default start-stop <*method-list*> System accounting stop (TACACS+): aaa accounting system default start-stop <*method-list*>

User action	Applicable AAA operations
User enters the command: [no] aaa accounting system default start-stop <*method-list*>	Command authorization (TACACS+): aaa authorization commands <*privilege-level*> default <*method-list*>
	Command accounting (TACACS+): aaa accounting commands <*privilege-level*> default start-stop <*method-list*> System accounting start (TACACS+): aaa accounting system default start-stop <*method-list*>
User enters other commands	Command authorization (TACACS+): aaa authorization commands <*privilege-level*> default <*method-list*>
	Command accounting (TACACS+): aaa accounting commands <*privilege-level*> default start-stop <*method-list*>

AAA Security for commands pasted Into the running configuration

If AAA security is enabled on a PowerConnect router, commands pasted into the running configuration are subject to the same AAA operations as if they were entered manually.

When you paste commands into the running configuration, and AAA command authorization or accounting is configured on the device, AAA operations are performed on the pasted commands. The AAA operations are performed before the commands are actually added to the running configuration. The server performing the AAA operations should be reachable when you paste the commands into the running configuration file. If the device determines that a pasted command is invalid, AAA operations are halted on the remaining commands. The remaining commands may not be executed if command authorization is configured.

TACACS or TACACS+ configuration considerations

Consider the following for configuring TACACS or TACACS+ servers:

- You must deploy at least one TACACS or TACACS+ server in your network.
- The PowerConnect router supports authentication using up to eight TACACS or TACACS+ servers. The device tries to use the servers in the order you add them to the device's configuration.
- You can select only one primary authentication method for each type of access to a device (CLI through Telnet, CLI Privileged EXEC and CONFIG levels). For example, you can select TACACS+ as the primary authentication method for Telnet CLI access, but you cannot also select RADIUS authentication as a primary method for the same type of access. However, you can configure backup authentication methods for each access type.
- You can configure the Dell device to authenticate using a TACACS or TACACS+ server, not both.

TACACS configuration procedure

Use the following procedure for TACACS configurations.

1. Enable TACACS. "Enabling SNMP traps for TACACS" on page 44.
2. Identify TACACS servers. Refer to "Identifying the TACACS or TACACS+ servers" on page 44.
3. Set optional parameters. Refer to "Setting optional TACACS or TACACS+ parameters" on page 46.
4. Configure authentication-method lists. Refer to "Configuring authentication-method lists for TACACS or TACACS+" on page 47.

TACACS+ configuration procedure

Use the following procedure for TACACS+ configurations.

1. Enable TACACS. "Enabling SNMP traps for TACACS" on page 44
2. Identify TACACS+ servers. Refer to "Identifying the TACACS or TACACS+ servers" on page 44.
3. Set optional parameters. Refer to "Setting optional TACACS or TACACS+ parameters" on page 46.
4. Configure authentication-method lists. Refer to "Configuring authentication-method lists for TACACS or TACACS+" on page 47.
5. Optionally configure TACACS+ authorization. Refer to "Configuring TACACS+ authorization" on page 49.
6. Optionally configure TACACS+ accounting. Refer to "Configuring TACACS+ accounting" on page 52.

Enabling SNMP traps for TACACS

To enable SNMP traps for TACACS or TACACS+ on a PowerConnect router, you must execute the enable **snmp config-tacacs** command as shown in the following.

```
NetIron(config)# enable snmp config-tacacs
```

Syntax: [no] enable snmp [config-radius | config-tacacs]

The **config-radius** parameter specifies that traps will be enabled for RADIUS. Generation of Radius traps is disabled by default.

The **config-tacacs** parameter specifies that traps will be enabled for TACACS. Generation of TACACS traps is disabled by default.

Identifying the TACACS or TACACS+ servers

To use TACACS or TACACS+ servers to authenticate access to a PowerConnect router, you must identify the servers to the PowerConnect router.

For example, to identify three TACACS or TACACS+ servers, enter commands such as the following.

```
NetIron(config)# tacacs-server host 207.94.6.161
NetIron(config)# tacacs-server host 207.94.6.191
NetIron(config)# tacacs-server host 207.94.6.122
```

Syntax: [no] tacacs-server host <*ip-addr*> **|**<*hostname*> **[auth-port** <*number*>**]**

The <*ip-addr*> |<*hostname*> parameter specifies the IP address or host name of the server. You can enter up to eight **tacacs-server host** commands to specify up to eight different servers.

NOTE
To specify the server's host name instead of its IP address, you must first identify a DNS server using the **ip dns server-address** <*ip-addr*> command at the global CONFIG level.

If you add multiple TACACS or TACACS+ authentication servers to the PowerConnect router, the device tries to reach them in the order you add them. For example, if you add three servers in the following order, the software tries the servers in the same order.

1. 207.94.6.161
2. 207.94.6.191
3. 207.94.6.122

You can remove a TACACS or TACACS+ server by entering **no** followed by the **tacacs-server** command. For example, to remove 207.94.6.161, enter the following command.

```
NetIron(config)# no tacacs-server host 207.94.6.161
```

NOTE
If you erase a **tacacs-server** command (by entering "**no**" followed by the command), make sure you also erase the **aaa** commands that specify TACACS or TACACS+ as an authentication method. (Refer to "Configuring authentication-method lists for TACACS or TACACS+" on page 47.) Otherwise, when you exit from the CONFIG mode or from a Telnet session, the system continues to believe it is TACACS or TACACS+ enabled and you will not be able to access the system.

The **auth-port** parameter specifies the UDP (for TACACS) or TCP (for TACACS+) port number of the authentication port on the server. The default port number is 49.

Specifying different servers for individual AAA TACACS functions

In a TACACS+ configuration, you can designate a server to handle a specific AAA task. For example, you can designate one TACACS+ server to handle authorization and another TACACS+ server to handle accounting. You can set the TACACS+ key for each server.

To specify different TACACS+ servers for authentication, authorization, and accounting, enter a command such as the following.

```
NetIron(config)# tacacs-server host 1.2.3.4 auth-port 49 authentication-only key
abc
NetIron(config)# tacacs-server host 1.2.3.5 auth-port 49 authorization-only key
define
NetIron(config)# tacacs-server host 1.2.3.6 auth-port 49 accounting-only key ghi
```

Syntax: [no] **tacacs-server host** <*ip-addr*> | <*server-name*> [**auth-port** <*number*> [**authentication-only** | **authorization-only** | **accounting-only** | **default**] [**key** <*string*>]]

The **host** <*ip-addr*> | <*server-name*> parameter is either an IP address or an ASCII text string.

The **auth-port** <*number*> parameter is the Authentication port number; it is an optional parameter.

Enter **accounting-only** if the server is used only for TACACS accounting. Enter **authentication-only** if the server is used only for TACACS authentication. Enter **authorization-only** if the server is used only for TACAC authorization. Enterint the **default** parameter causes the server to be used for all AAA TACACS functions.

After authentication takes place, the server that performed the authentication is used for authorization, accounting or both. If the authenticating server cannot perform the requested function, then the next server in the configured list of servers is tried; this process repeats until either a server that can perform the requested function is found, or every server in the configured list has been tried.

Enter **key** and configure a key for the server if an authentication key is to be used. By default, **key** is encrypted. If you want key to be in clear text, insert a **0** between **key** and <*string*>.

Example

```
NetIron(config)# tacacs-server host 1.2.3.5 auth-port 49 authorization-only key 0
report
```

The software adds a prefix to the authentication key string in the configuration. For example, the prefix "2" is added to the authorization key string in the following example.

```
tacacs-server host 1.2.3.6 auth-port 49 authorization-only key 2 $D?@d=8
```

The prefix can be one of the following:

- 0 = the key string is not encrypted and is in clear text
- 1 = the key string uses proprietary simple crytographic 2-way algorithm
- 2 = the key string uses proprietary base64 crytographic 2-way algorithm

Setting optional TACACS or TACACS+ parameters

You can set the following optional parameters in a TACACS or TACACS+ configuration:

- **TACACS+ key** – This parameter specifies the value that the Dell device sends to the TACACS+ server when trying to authenticate user access.
- **Retransmit interval** – This parameter specifies how many times the Dell device will resend an authentication request when the TACACS or TACACS+ server does not respond. The retransmit value can be from 1 – 5 times. The default is 3 times.
- **Dead time** – This parameter specifies how long the Dell device waits for the primary authentication server to reply before deciding the server is dead and trying to authenticate using the next server. The dead-time value can be from 1 – 5 seconds. The default is 3 seconds.
- **Timeout** – This parameter specifies how many seconds the Dell device waits for a response from a TACACS or TACACS+ server before either retrying the authentication request, or determining that the TACACS or TACACS+ servers are unavailable and moving on to the next authentication method in the authentication-method list. The timeout can be from 1 – 15 seconds. The default is 3 seconds.

Setting the TACACS+ key

The **key** parameter in the **tacacs-server** command is used to encrypt TACACS+ packets before they are sent over the network. The value for the **key** parameter on the PowerConnect router should match the one configured on the TACACS+ server. The key length can be from 1 – 64 characters and cannot include any space characters.

NOTE
The **tacacs-server key** command applies only to TACACS+ servers, not to TACACS servers. If you are configuring TACACS, do not configure a key on the TACACS server and do not enter a key on the PowerConnect router.

To specify a TACACS+ server key, enter the following command.

```
NetIron(config)# tacacs-server key rkwong
```

Syntax: [no] tacacs-server key [0 | 1] <*string*>

When you display the configuration of the PowerConnect router, the TACACS+ keys are encrypted.

Example

```
NetIron(config)# tacacs-server key 1 abc
NetIron(config)# write terminal
...
tacacs-server host 1.2.3.5 auth-port 49
tacacs key 1 $!2d
```

NOTE
Encryption of the TACACS+ keys is done by default. The **0** parameter disables encryption. The **1** parameter is not required; it is provided for backwards compatibility.

Setting the retransmission limit

The **retransmit** parameter specifies how many times the PowerConnect router will resend an authentication request when the TACACS or TACACS+ server does not respond. The retransmit limit can be from 1 – 5 times. The default is 3 times.

To set the TACACS or TACACS+ retransmit limit, enter the following command.

```
NetIron(config)# tacacs-server retransmit 5
```

Syntax: [no] tacacs-server retransmit <*number*>

Setting the timeout parameter

The **timeout** parameter specifies how many seconds the Dell device waits for a response from the TACACS or TACACS+ server before either retrying the authentication request, or determining that the TACACS or TACACS+ server is unavailable and moving on to the next authentication method in the authentication-method list. The timeout can be from 1 – 15 seconds. The default is 3 seconds.

```
NetIron(config)# tacacs-server timeout 5
```

Syntax: [no] tacacs-server timeout <*number*>

Configuring authentication-method lists for TACACS or TACACS+

You can use TACACS or TACACS+ to authenticate console, Telnet, or SSH access and access to Privileged EXEC level and CONFIG levels of the CLI. When configuring TACACS or TACACS+ authentication, you create authentication-method lists specifically for these access methods, specifying TACACS or TACACS+ as the primary authentication method.

Within the authentication-method list, TACACS or TACACS+ is specified as the primary authentication method and up to six backup authentication methods are specified as alternates. If TACACS or TACACS+ authentication fails due to an error, the device tries the backup authentication methods in the order they appear in the list. If a TACACS or TACACS+ server responds with a reject for a user, the system does not try the backup authentication methods.

When you configure authentication-method lists for TACACS or TACACS+ authentication, you must create a separate authentication-method list for Telnet or SSH CLI access, and for access to the Privileged EXEC level and CONFIG levels of the CLI.

To create an authentication-method list that specifies TACACS or TACACS+ as the primary authentication method for securing Telnet or SSH access to the CLI.

```
NetIron(config)# enable telnet authentication
NetIron(config)# aaa authentication login default tacacs+ local
```

NOTE
To enable AAA support for commands entered at the console you must follow the procedure described in "Configuring AAA on the console" on page 72.

The commands above cause TACACS or TACACS+ to be the primary authentication method for securing Telnet or SSH access to the CLI. If TACACS or TACACS+ authentication fails due to an error with the server, authentication is performed using local user accounts instead.

To create an authentication-method list that specifies TACACS or TACACS+ as the primary authentication method for securing access to Privileged EXEC level and CONFIG levels of the CLI.

```
NetIron(config)# aaa authentication enable default tacacs+ local none
```

The command above causes TACACS or TACACS+ to be the primary authentication method for securing access to Privileged EXEC level and CONFIG levels of the CLI. If TACACS or TACACS+ authentication fails due to an error with the server, local authentication is used instead. If local authentication fails, no authentication is used; the device automatically permits access.

For information on the command syntax, refer to page page 75 under "Examples of authentication-method lists".

NOTE
For examples of how to define authentication-method lists for types of authentication other than TACACS or TACACS+, refer to "Configuring authentication-method lists" on page 73.

Entering privileged EXEC mode after a console, Telnet or SSH login

By default, a user enters User EXEC mode after a successful login through console, Telnet or SSH. Optionally, you can configure the device so that a user enters Privileged EXEC mode after a console, Telnet or SSH login. To do this, use the following command.

```
NetIron(config)# aaa authentication login privilege-mode
```

Syntax: [no] aaa authentication login privilege-mode

The user's privilege level is based on the privilege level granted during login.

Configuring enable authentication to use enable password on TACACS+

TACACS+ server allows a common enable password to be configured on the TACACS+ server. To allow a user to authenticate against that enable password, instead of the login password, use this command.

```
NetIron(config)# aaa authentication enable implicit-user
```

Syntax: [no] aaa authentication enable implicit-user

Telnet or SSH prompts when the TACACS+ server is unavailable

When TACACS+ is the first method in the authentication method list, the device displays the login prompt received from the TACACS+ server. If a user attempts to login through Telnet or SSH, but none of the configured TACACS+ servers are available, the following takes place:

- If the next method in the authentication method list is “enable”, the login prompt is skipped, and the user is prompted for the Enable password (that is, the password configured with the **enable super-user-password** command).
- If the next method in the authentication method list is “line”, the login prompt is skipped, and the user is prompted for the Line password (that is, the password configured with the **enable telnet password** command).

Configuring TACACS+ authorization

The PowerConnect router supports TACACS+ authorization for controlling access to management functions in the CLI. Two kinds of TACACS+ authorization are supported:

- Exec authorization determines a user’s privilege level when they are authenticated
- Command authorization consults a TACACS+ server to get authorization for commands entered by the user

Configuring exec authorization

When TACACS+ exec authorization is performed, the PowerConnect router consults a TACACS+ server to determine the privilege level of the authenticated user.

To configure TACACS+ exec authorization on a PowerConnect router, enter the following command.

```
NetIron(config)# aaa authorization exec default tacacs+
```

Syntax: aaa authorization exec default tacacs+ | radius | none

If you specify **none**, or omit the **aaa authorization** exec command from the device’s configuration, no exec authorization is performed.

A user’s privilege level is obtained from the TACACS+ server in the “foundry-privlvl” A-V pair. If the **aaa authorization exec default tacacs** command exists in the configuration, the device assigns the user the privilege level specified by this A-V pair. If the command does not exist in the configuration, then the value in the “foundry-privlvl” A-V pair is ignored, and the user is granted Super User access.

NOTE
If the **aaa authorization exec default tacacs+** command exists in the configuration, following successful authentication the device assigns the user the privilege level specified by the "foundry-privlvl" A-V pair received from the TACACS+ server. If the **aaa authorization exec default tacacs+** command does not exist in the configuration, then the value in the "foundry-privlvl" A-V pair is ignored, and the user is granted Super User access.

Also note that in order for the **aaa authorization exec default tacacs+** command to work, either the **aaa authentication enable default tacacs+** command, or the **aaa authentication login default tacacs+** command must also exist in the configuration.

Configuring an attribute-value pair on the TACACS+ server

During TACACS+ exec authorization, the Dell device expects the TACACS+ server to send a response containing an A-V (Attribute-Value) pair that specifies the privilege level of the user. When the PowerConnect router receives the response, it extracts an A-V pair configured for the Exec service and uses it to determine the user's privilege level.

To set a user's privilege level, you can configure the "foundry-privlvl" A-V pair for the Exec service on the TACACS+ server.

Example

```
user=bob {
   default service = permit
   member admin
   # Global password
   global = cleartext "cat"
   service = exec {
     foundry-privlvl = 0
        }
}
```

In this example, the A-V pair `foundry-privlvl = 0` grants the user full read-write access. The value in the foundry-privlvl A-V pair is an integer that indicates the privilege level of the user. Possible values are 0 for super-user level, 4 for port-config level, or 5 for read-only level. If a value other than 0, 4, or 5 is specified in the foundry-privlvl A-V pair, the default privilege level of 5 (read-only) is used. The foundry-privlvl A-V pair can also be embedded in the group configuration for the user. Refer to your TACACS+ documentation for the configuration syntax relevant to your server.

If the foundry-privlvl A-V pair is not present, the PowerConnect router extracts the last A-V pair configured for the Exec service that has a numeric value. The PowerConnect router uses this A-V pair to determine the user's privilege level.

Example

```
user=bob {
   default service = permit
   member admin
   # Global password
   global = cleartext "cat"
   service = exec {
     priv-lvl = 15
        }
}
```

The attribute name in the A-V pair is not significant; the PowerConnect router uses the last one that has a numeric value. However, the PowerConnect router interprets the value for a non-"foundry-privlvl" A-V pair differently than it does for a "foundry-privlvl" A-V pair. The following table lists how the PowerConnect router associates a value from a non-"foundry-privlvl" A-V pair with a Dell privilege level.

TABLE 5 Dell equivalents for non-"foundry-privlvl" A-V pair values

Value for non-"foundry-privlvl" A-V pair	Privilege level
15	0 (super-user)
From 14 – 1	4 (port-config)
Any other number or 0	5 (read-only)

In the example above, the A-V pair configured for the Exec service is `priv-lvl = 15`. The PowerConnect router uses the value in this A-V pair to set the user's privilege level to 0 (super-user), granting the user full read-write access.

In a configuration that has both a "foundry-privlvl" A-V pair and a non-"foudnry-privlvl" A-V pair for the Exec service, the non-"foundry-privlvl" A-V pair is ignored.

Example

```
user=bob {
   default service = permit
   member admin
   # Global password
   global = cleartext "cat"
   service = exec {
     foundry-privlvl = 4
     priv-lvl = 15
        }
}
```

In this example, the user would be granted a privilege level of 4 (port-config level). The `privlvl = 15` A-V pair is ignored by the PowerConnect router.

If the TACACS+ server has no A-V pair configured for the Exec service, the default privilege level of 5 (read-only) is grated to the user.

Configuring command authorization

When TACACS+ command authorization is enabled, the PowerConnect router consults a TACACS+ server to get authorization for commands entered by the user.

You enable TACACS+ command authorization by specifying a privilege level whose commands require authorization. For example, to configure the PowerConnect router to perform authorization for the commands available at the Super User privilege level (that is, all commands on the device), enter the following command.

```
NetIron(config)# aaa authorization commands 0 default tacacs+
```

Syntax: [no] aaa authorization commands <*privilege-level*> **default tacacs+ | radius | none**

The <*privilege-level*> parameter can be one of the following:

- **0** – Authorization is performed for commands available at the Super User level (all commands)
- **4** – Authorization is performed for commands available at the Port Configuration level (port-config and read-only commands)

- **5** – Authorization is performed for commands available at the Read Only level (read-only commands)

NOTE
TACACS+ command authorization can be performed only for commands entered from Telnet or SSH sessions, or from the console. No authorization is performed for commands entered at the Web Management Interface or SNMP.

TACACS+ command authorization is not performed for the following commands:

- **At all levels: exit**, **logout**, **end**, and **quit**.
- **At the Privileged EXEC level: enable** or **enable** <*text*>, where <*text*> is the password configured for the Super User privilege level.

If configured, command accounting is performed for these commands.

NOTE
To enable AAA support for commands entered at the console you must follow the procedure described in "Configuring AAA on the console" on page 72.

Configuring TACACS+ accounting

The PowerConnect router supports TACACS+ accounting for recording information about user activity and system events. When you configure TACACS+ accounting on a PowerConnect router, information is sent to a TACACS+ accounting server when specified events occur, such as when a user logs into the device or the system is rebooted.

Configuring TACACS+ accounting for Telnet or SSH (shell) access

To send an Accounting Start packet to the TACACS+ accounting server when an authenticated user establishes a Telnet or SSH session on the PowerConnect router, and an Accounting Stop packet when the user logs out.

```
NetIron(config)# aaa accounting exec default start-stop tacacs+
```

Syntax: [no] aaa accounting exec default start-stop radius | tacacs+ | none

Configuring TACACS+ accounting for CLI commands

You can configure TACACS+ accounting for CLI commands by specifying a privilege level whose commands require accounting. For example, to configure the PowerConnect router to perform TACACS+ accounting for the commands available at the Super User privilege level (that is; all commands on the device), enter the following command.

```
NetIron(config)# aaa accounting commands 0 default start-stop tacacs+
```

An Accounting Start packet is sent to the TACACS+ accounting server when a user enters a command, and an Accounting Stop packet is sent when the service provided by the command is completed.

NOTE
If authorization is enabled, and the command requires authorization, then authorization is performed before accounting takes place. If authorization fails for the command, no accounting takes place.

Syntax: [no] aa accounting commands <*privilege-level*> **default start-stop radius | tacacs+ | none**

The <*privilege-level*> parameter can be one of the following:

- **0** – Records commands available at the Super User level (all commands)
- **4** – Records commands available at the Port Configuration level (port-config and read-only commands)
- **5** – Records commands available at the Read Only level (read-only commands)

Configuring TACACS+ accounting for system events

You can configure TACACS+ accounting to record when system events occur on the PowerConnect router. System events include rebooting and when changes to the active configuration are made.

The following command causes an Accounting Start packet to be sent to the TACACS+ accounting server when a system event occurs, and a Accounting Stop packet to be sent when the system event is completed.

```
NetIron(config)# aaa accounting system default start-stop tacacs+
```

Syntax: [no] aaa accounting system default start-stop radius | tacacs+ | none

Configuring an interface as the source for all TACACS or TACACS+ packets

You can designate the lowest-numbered IP address configured an Ethernet port, loopback interface, or virtual interface as the source IP address for all TACACS or TACACS+ packets from the PowerConnect router. Identifying a single source IP address for TACACS or TACACS+ packets provides the following benefits:

- If your TACACS or TACACS+ server is configured to accept packets only from specific links or IP addresses, you can use this feature to simplify configuration of the TACACS or TACACS+ server by configuring the Dell device to always send the TACACS or TACACS+ packets from the same link or source address.
- If you specify a loopback interface as the single source for TACACS or TACACS+ packets, TACACS or TACACS+ servers can receive the packets regardless of the states of individual links. Thus, if a link to the TACACS or TACACS+ server becomes unavailable but the client or server can be reached through another link, the client or server still receives the packets, and the packets still have the source IP address of the loopback interface.

The software contains separate CLI commands for specifying the source interface for Telnet, TACACS or TACACS+, and RADIUS packets. You can configure a source interface for one or more of these types of packets.

To specify an Ethernet, loopback, or virtual interface as the source for all TACACS or TACACS+ packets from the device, use the following CLI method. The software uses the lowest-numbered IP address configured on the port or interface as the source IP address for TACACS or TACACS+ packets originated by the device.

To specify the lowest-numbered IP address configured on a virtual interface as the device source for all TACACS or TACACS+ packets, enter commands such as the following.

```
NetIron(config)# int ve 1
NetIron(config-vif-1)# ip address 10.0.0.3/24
NetIron(config-vif-1)# exit
NetIron(config)# ip tacacs source-interface ve 1
```

The commands in this example configure virtual interface 1, assign IP address 10.0.0.3/24 to the interface, then designate the interface as the source for all TACACS or TACACS+ packets from the PowerConnect router.

Syntax: [no]ip tacacs source-interface ethernet <*portnum*> **| loopback** <*num*> **| ve** <*num*>

The <*num*> parameter is a loopback interface or virtual interface number. If you specify an Ethernet, the <*portnum*> is the port's number (including the slot number, if you are configuring a device).

Displaying TACACS or TACACS+ statistics and configuration information

The **show aaa** command displays information about all TACACS+ and RADIUS servers identified on the device.

Example

```
NetIron# show aaa
Tacacs+ key: powerconnect
Tacacs+ retries: 1
Tacacs+ timeout: 15 seconds
Tacacs+ dead-time: 3 minutes
Tacacs+ Server: 207.95.6.90 Port:49:
                opens=6 closes=3 timeouts=3 errors=0
                packets in=4 packets out=4
no connection
Radius key: networks
Radius retries: 3
Radius timeout: 3 seconds
Radius dead-time: 3 minutes
Radius Server:  207.95.6.90 Auth Port=1645 Acct Port=1646:
                opens=2 closes=1 timeouts=1 errors=0
                packets in=1 packets out=4
no connection
```

Syntax: show aaa

The following table describes the TACACS or TACACS+ information displayed by the **show aaa** command.

TABLE 6 Output of the show aaa command for TACACS or TACACS+

Field	Description
Tacacs+ key	The setting configured with the **tacacs-server key** command. At the Super User privilege level, the actual text of the key is displayed. At the other privilege levels, a string of periods (....) is displayed instead of the text.
Tacacs+ retries	The setting configured with the **tacacs-server retransmit** command.
Tacacs+ timeout	The setting configured with the **tacacs-server timeout** command.

TABLE 6 Output of the show aaa command for TACACS or TACACS+ (Continued)

Field	Description
Tacacs+ dead-time	The setting configured with the **tacacs-server dead-time** command.
Tacacs+ Server	For each TACACS or TACACS+ server, the IP address, port, and the following statistics are displayed: **opens** – Number of times the port was opened for communication with the server **closes** – Number of times the port was closed normally **timeouts** – Number of times port was closed due to a timeout **errors** – Number of times an error occurred while opening the port **packets in** – Number of packets received from the server **packets out** – Number of packets sent to the server
connection	The current connection status. This can be “no connection” or “connection active”.

The **show web** command displays the privilege level of Web Management Interface users.

Example

```
NetIron#show web
User                              Privilege       IP address
set                                      0       192.168.1.234
```

Syntax: **show web**

Configuring RADIUS security

You can use a Remote Authentication Dial In User Service (RADIUS) server to secure the following types of access to the PowerConnect devices:

- Telnet access
- SSH access
- Web management access
- Access to the Privileged EXEC level and CONFIG levels of the CLI

NOTE
The PowerConnect devices do not support RADIUS security for SNMP access.

RADIUS authentication, authorization, and accounting

When RADIUS authentication is implemented, the PowerConnect router consults a RADIUS server to verify usernames and passwords. Optionally, you can configure RADIUS authorization, in which the PowerConnect router consults a list of commands supplied by the RADIUS server to determine whether a user can execute a command that has been entered. You can also configure RADIUS accounting, which causes the PowerConnect router to log information on a RADIUS accounting server when specified events occur on the device.

NOTE
By default, a user logging into the device through Telnet or SSH first enters the User EXEC level. The user can then enter the **enable** command to get to the Privileged EXEC level.

NOTE
A user that is successfully authenticated can be automatically placed at the Privileged EXEC level after login. Refer to "Entering privileged EXEC mode after a Telnet or SSH login" on page 66.

RADIUS authentication

The following events occur when RADIUS authentication takes place.

1. A user triggers RADIUS authentication by doing one of the following:
   - Logging in to the device using Telnet or SSH
   - Entering the Privileged EXEC level or CONFIG level of the CLI
2. The user is prompted for a username and password.
3. The user enters a username and password.
4. The PowerConnect device sends a RADIUS Access-Request packet containing the username and password to the RADIUS server.
5. The RADIUS server validates the PowerConnect device using a shared secret (the RADIUS key).
6. The RADIUS server looks up the username in its database.
7. If the username is found in the database, the RADIUS server validates the password.
8. If the password is valid, then:
   a. If the RADIUS server is configured to use multi-factor authentication, it may send an Access-Challenge packet to the PowerConnect device. If so, the user may be asked for additional input (for example, an RSA SecurID PIN or RSA SecurID next tokencode) which the PowerConnect device will forward to the RADIUS server. If the additional input is valid, then the process moves to the next step.
   b. If the RADIUS server is configured to use single-factor authentication, then the process moves immediately to the next step.
9. The RADIUS server sends an Access-Accept packet to the PowerConnect device, authenticating the user. Within the Access-Accept packet are three Dell vendor-specific attributes that indicate:
   - The privilege level of the user
   - A list of commands
   - Whether the user is allowed or denied usage of the commands in the list

   The last two attributes are used with RADIUS authorization, if configured.
10. The user is authenticated, and the information supplied in the Access-Accept packet for the user is stored on the PowerConnect router. The user is granted the specified privilege level. If you configure RADIUS authorization, the user is allowed or denied usage of the commands in the list.

Multi-factor RADIUS authentication

The PowerConnect device supports multi-factor authentication (for example, RSA SecurID) via a RADIUS server. For access by Telnet, no further configuration is needed on the PowerConnect device to enable multi-factor RADIUS authentication. For multi-factor authentication when using SSH, the PowerConnect device must be configured for interactive authentication using the following command.

```
NetIron(config)# ip ssh interactive-authentication yes
```

Syntax: ip ssh interactive-authentication {**no** | **yes**}

The default is **yes** (interactive authentication is supported by default).

A sample interactive authentication session (with RSA SecurID) is shown below.

```
Telnet_DMT_MLXe_16k - 08-25-2010  -- 11:20:18  Session Log Start --
10.20.179.55|Telnet - 08-25-2010  -- 11:20:18

08-25-2010  -- 11:21:55
```

RADIUS authorization

The following events occur when RADIUS authorization takes place.

1. A user previously authenticated by a RADIUS server enters a command on the PowerConnect router.
2. The PowerConnect router looks at its configuration to see if the command is at a privilege level that requires RADIUS command authorization.
3. If the command belongs to a privilege level that requires authorization, the PowerConnect router looks at the list of commands delivered to it in the RADIUS Access-Accept packet when the user was authenticated. (Along with the command list, an attribute was sent that specifies whether the user is permitted or denied usage of the commands in the list.)

NOTE
After RADIUS authentication takes place, the command list resides on the PowerConnect router. The RADIUS server is not consulted again once the user has been authenticated. This means that any changes made to the user's command list on the RADIUS server are not reflected until the next time the user is authenticated by the RADIUS server, and the new command list is sent to the PowerConnect router.

4. If the command list indicates that the user is authorized to use the command, the command is executed.

RADIUS accounting

The following steps explain the working of RADIUS accounting.

1. One of the following events occur on a PowerConnect router:
   - A user logs into the management interface using Telnet or SSH
   - A user enters a command for which accounting has been configured
   - A system event occurs, such as a reboot or reloading of the configuration file
2. The PowerConnect router checks its configuration to see if the event is one for which RADIUS accounting is required.
3. If the event requires RADIUS accounting, the PowerConnect router sends a RADIUS Accounting Start packet to the RADIUS accounting server, containing information about the event.
4. The RADIUS accounting server acknowledges the Accounting Start packet.
5. The RADIUS accounting server records information about the event.
6. When the event is concluded, the PowerConnect router sends an Accounting Stop packet to the RADIUS accounting server.
7. The RADIUS accounting server acknowledges the Accounting Stop packet.

AAA operations for RADIUS

The following table lists the sequence of authentication, authorization, and accounting operations that take place when a user gains access to a PowerConnect router that has RADIUS security configured.

User action	Applicable AAA operations
User attempts to gain access to the Privileged EXEC and CONFIG levels of the CLI	Enable authentication: aaa authentication enable default <*method-list*>
	System accounting start: aaa accounting system default start-stop <*method-list*>
User logs in using Telnet or SSH	Login authentication: aaa authentication login default <*method-list*>
	EXEC accounting Start: aaa accounting exec default start-stop <*method-list*> System accounting Start: aaa accounting system default start-stop <*method-list*>
User logs into the Web Management Interface	Web authentication: aaa authentication web-server default <*method-list*>

User action	Applicable AAA operations
User logs out of Telnet or SSH session	Command authorization for **logout** command: aaa authorization commands <*privilege-level*> default <*method-list*>
	Command accounting: aaa accounting commands <*privilege-level*> default start-stop <*method-list*> EXEC accounting stop: aaa accounting exec default start-stop <*method-list*>
User enters system commands (for example, **reload**, **boot system**)	Command authorization: aaa authorization commands <*privilege-level*> default <*method-list*>
	Command accounting: aaa accounting commands <*privilege-level*> default start-stop <*method-list*> System accounting stop: aaa accounting system default start-stop <*method-list*>
User enters the command: [no] aaa accounting system default start-stop <*method-list*>	Command authorization: aaa authorization commands <*privilege-level*> default <*method-list*>
	Command accounting: aaa accounting commands <*privilege-level*> default start-stop <*method-list*> System accounting start: aaa accounting system default start-stop <*method-list*>
User enters other commands	Command authorization: aaa authorization commands <*privilege-level*> default <*method-list*>
	Command accounting: aaa accounting commands <*privilege-level*> default start-stop <*method-list*>

AAA security for commands pasted into the running configuration

If AAA security is enabled on the device, commands pasted into the running configuration are subject to the same AAA operations as if they were entered manually.

When you paste commands into the running configuration, and AAA command authorization or accounting is configured on the device, AAA operations are performed on the pasted commands. The AAA operations are performed before the commands are actually added to the running configuration. The server performing the AAA operations should be reachable when you paste the commands into the running configuration file. If the device determines that a pasted command is invalid, AAA operations are halted on the remaining commands. The remaining commands may not be executed if command authorization is configured.

NOTE
Since RADIUS command authorization relies on a list of commands received from the RADIUS server when authentication is performed, it is important that you use RADIUS authentication when you also use RADIUS command authorization.

RADIUS configuration considerations

Consider the following for configuring the RADIUS server:

- You must deploy at least one RADIUS server in your network.
- The PowerConnect router supports authentication using up to eight RADIUS servers. The device tries to use the servers in the order you add them to the device's configuration. If one RADIUS server is not responding, the device tries the next one in the list.
- You can select only one primary authentication method for each type of access to a device (CLI through Telnet, CLI Privileged EXEC and CONFIG levels). For example, you can select RADIUS as the primary authentication method for Telnet CLI access, but you cannot also select TACACS+ authentication as the primary method for the same type of access. However, you can configure backup authentication methods for each access type.

RADIUS configuration procedure

Use the following procedure to configure a PowerConnect router for RADIUS.

1. Configure Dell vendor-specific attributes on the RADIUS server. Refer to "Configuring Dell-specific attributes on the RADIUS server" on page 60.
2. Enabling Radius. Refer to "Enabling SNMP traps for RADIUS" on page 62.
3. Identify the RADIUS server to the PowerConnect router. Refer to "Identifying the RADIUS server to the PowerConnect router" on page 63.
4. Set RADIUS parameters. Refer to "Setting RADIUS parameters" on page 64.
5. Configure authentication-method lists. Refer to "Configuring authentication-method lists for RADIUS" on page 65.
6. Optionally configure RADIUS authorization. Refer to "Configuring RADIUS authorization" on page 67.
7. Optionally configure RADIUS accounting. "Configuring RADIUS accounting" on page 68.

Configuring Dell-specific attributes on the RADIUS server

During the RADIUS authentication process, if a user supplies a valid username and password, the RADIUS server sends an Access-Accept packet to the PowerConnect, authenticating the user. Within the Access-Accept packet, the RADIUS server could send attribute "Vendor-Specific" (26) whose value could inform the PowerConnect on the runtime enviornment for this session. This section will detail all the vendor specific attributes defined by Dell.

TABLE 7 Vendor-specific attributes for RADIUS

Attribute name	Attribute ID	Data type	Description
foundry-privilege-level	1	integer	Specifies the privilege level for the user. This attribute can be set to one of the following: **0** –**Super User level** – Allows complete read-and-write access to the system. This is generally for system administrators and is the only management privilege level that allows you to configure passwords. **4** – **Port Configuration level** – Allows read-and-write access for specific ports but not for global (system-wide) parameters. **5** – **Read Only level** – Allows access to the Privileged EXEC mode and CONFIG mode of the CLI but only with read access.
foundry-command-string	2	string	Specifies a list of CLI commands that are permitted or denied to the user when RADIUS authorization is configured. The commands are delimited by semi-colons (;). You can specify an asterisk (*) as a wildcard at the end of a command string. For example, the following command list specifies all **show** and **debug ip** commands, as well as the **write terminal** command: show *; debug ip *; write term*
powerconnect-command-exception-flag	3	integer	Specifies whether the commands indicated by the powerconnect-command-string attribute are permitted or denied to the user. This attribute can be set to one of the following: **0** – Permit execution of the commands indicated by powerconnect-command-string, deny all other commands. **1** – Deny execution of the commands indicated by powerconnect-command-string, permit all other commands.
foundry-INM-privilege	4	integer	Specifies the IronView Network Manager user privilege level. This attribute can take a value range from 0 to 15. In IronView Network Manager, this attribute value will be mapped to the preconfigured roles “AAA privilege level 0” through “AAA privilege level 15”. The admin user has to configure these roles with the appropriate sets of privileges in order for the AAA user to get the correct set of feature access.

TABLE 7 Vendor-specific attributes for RADIUS

Attribute name	Attribute ID	Data type	Description
foundry-access-list	5	string	Specifies the access control list to be used for RADIUS authorization. Enter the access control list in the following format. type=string, value="ipacl.[e|s].[in|out] = [<acl-name>|<acl-number>] <separator> macfilter.in = [<acl-name>|<acl-number>] Where: • separator can be a space, newline, semicolon, comma, or null characater • ipacl.e is extended ACL; ipacl.s is standard ACL. **NOTE:** Outbound MAC filters are not supported, but outbound ACLs with 802.1X authentication is supported.
foundry-MAC-authent-needs-802x	6	integer	Specifies whether or not 802.1x authentication is required and enabled. **0** - Disabled **1** - Enabled
foundry-802.1x-valid-lookup	7	integer	Specifies if 802.1x lookup is enabled: **0** - Disabled **1** - Enabled
foundry-MAC-based-VLAN-QOS	8	integer	Specifies the priority for MAC-based VLAN QOS: **0** - qos_priority_0 **1** - qos_priority_1 **2** - qos_priority_2 **3** - qos_priority_3 **4** - qos_priority_4 **5** - qos_priority_5 **6** - qos_priority_6 **7** - qos_priority_7
foundry-INM-Role-AOR-List	9	string	Specifies the list of Roles and Area of Responsibility (AOR) that are allowed for an IronView Network Manager user. These values are mapped to IronView Network Manager Roles and AORs when the user logs in. For example, to configure an IronView Network Manager user to have “Administrator” and”'Report User” roles and “New York Region” and “Santa Clara Region” AORs, specify “'InmRoles=Administrator, Report User; InmAORs=New York Region, Santa Clara Region”. The keys “InmRoles” and “InmAORs” are delimited by semi colon (;) and the values for the keys are delimited by a comma (,). Refer to the *IronView Network Manager User Guide* for details.

Enabling SNMP traps for RADIUS

To enable SNMP traps for RADIUS on a PowerConnect router, you must execute the **enable snmp config-radius** command as shown in the following.

```
NetIron(config)# enable snmp config-radius
```

Syntax: [no] enable snmp [config-radius | config-tacacs]

The **config-radius** parameter specifies that traps will be enabled for RADIUS. Generation of Radius traps is disabled by default.

The **config-tacacs** parameter specifies that traps will be enabled for TACACS. Generation of TACACS traps is disabled by default.

Identifying the RADIUS server to the PowerConnect router

To use a RADIUS server to authenticate access to a PowerConnect router, you must identify the server to the PowerConnect router.

```
NetIron(config)# radius-server host 209.157.22.99
```

Syntax: [no] radius-server host <*ip-addr*> | <*server-name*> [auth-port <*number*> acct-port <*number*>]

The **host** <*ip-addr*> | <*server-name*> parameter is either an IP address or an ASCII text string.

The <*auth-port*> parameter is the Authentication port number; it is an optional parameter. The default is 1812.

The <*acct-port*> parameter is the Accounting port number; it is an optional parameter. The default is 1813.

Specifying different servers for individual AAA functions

In a RADIUS configuration, you can designate a server to handle a specific AAA task. For example, you can designate one RADIUS server to handle authorization and another RADIUS server to handle accounting. You can specify individual servers for authentication and accounting, but not for authorization. You can set the RADIUS key for each server.

To specify different RADIUS servers for authentication and accounting, enter a command such as the following.

```
NetIron(config)# radius-server host 1.2.3.4 auth-port 1812 acct-port 1813
authentication-only key abc
NetIron(config)# radius-server host 1.2.3.6 auth-port 1812 acct-port 1813
accounting-only key ghi
```

Syntax: [no] radius-server host <*ip-addr*> | <*server-name*> [auth-port <*number*> acct-port <*number*> [authentication-only | accounting-only | default] [key [0|1|2] <*string*> [dot1x]]]

The **host** <*ip-addr*> | <*server-name*> parameter is either an IP address or an ASCII text string.

The **auth-port** <*number*> parameter specifies what port to use for RADIUS authentication. The default is 1812.

The **acct-port** <*number*>parameter specifies what port to use for RADIUS accounting. The default is 1813.

Enter **accounting-only** if the server is used only for accounting. Enter **authentication-only** if the server is used only for authentication. Entering the **default** parameter causes the server to be used for all AAA RADIUS functions.

NOTE
To specify which RADIUS function(s) the server supports, you must first enter the authentication port and accounting port parameters.

After authentication takes place, the server that performed the authentication is used for authorization, accounting, or both. If the authenticating server cannot perform the requested function, then the next server in the configured list of servers is tried; this process repeats until either a server that can perform the requested function is found, or every server in the configured list has been tried.

Enter **key** and configure a key for the server if an authentication key is to be used. By default, **key** is encrypted. If you want key to be in clear text, insert a **0** between **key** and <*string*>.

```
NetIron(config)# radius-server host 1.2.3.4 authentication-only key 0 abc
```

The software adds a prefix to the authentication key in the configuration. For example, the prefix "2" is added to the key string in the example below.

```
radius-server host 1.2.3.6 auth-port 1812 acct-port 1813 default key 2 $D?@d=8
```

The prefix can be one of the following:

- **0** = the key string is not encrypted and is in clear text
- **1** = the key string uses proprietary simple crytographic 2-way algorithm
- **2** = the key string uses proprietary base64 crytographic 2-way algorithm

Setting RADIUS parameters

You can set the following parameters in a RADIUS configuration:

- **RADIUS key** – This parameter specifies the value that the PowerConnect router sends to the RADIUS server when trying to authenticate user access.
- **Retransmit interval** – This parameter specifies how many times the PowerConnect router will resend an authentication request when the RADIUS server does not respond. The retransmit value can be from 1 – 5 times. The default is 3 times.
- **Timeout** – This parameter specifies how many seconds the PowerConnect router waits for a response from a RADIUS server before either retrying the authentication request, or determining that the RADIUS servers are unavailable and moving on to the next authentication method in the authentication-method list. The timeout can be from 1 – 15 seconds. The default is 3 seconds.

Setting the RADIUS key

The **key** parameter in the **radius-server** command is used to encrypt RADIUS packets before they are sent over the network. The value for the **key** parameter on the PowerConnect router should match the one configured on the RADIUS server. The key length can be from 1 – 64 characters and cannot include any space characters.

To specify a RADIUS server key, enter a command such as the following.

```
NetIron(config)# radius-server key mirabeau
```

Syntax: [no] radius-server key [0 | 1] <*string*>

When you display the configuration of the PowerConnect router, the RADIUS key is encrypted.

Example

```
NetIron(config)# radius-server key 1 abc
NetIron(config)# write terminal
...
radius-server host 1.2.3.5
radius key 1 $!2d
```

NOTE
Encryption of the RADIUS keys is done by default. The **0** parameter disables encryption. The **1** parameter is not required; it is provided for backwards compatibility.

Setting the retransmission limit

The **retransmit** parameter specifies the maximum number of retransmission attempts. When an authentication request times out, the software will retransmit the request up to the maximum number of retransmissions configured. The default retransmit value is 3 retries. The range of retransmit values is from 1 – 5.

To set the RADIUS retransmit limit, enter a command such as the following.

```
NetIron(config)# radius-server retransmit 5
```

Syntax: [no] radius-server retransmit <*number*>

Setting the timeout parameter

The **timeout** parameter specifies how many seconds the PowerConnect router waits for a response from the RADIUS server before either retrying the authentication request, or determining that the RADIUS server is unavailable and moving on to the next authentication method in the authentication-method list. The timeout can be from 1 – 15 seconds. The default is 3 seconds.

```
NetIron(config)# radius-server timeout 5
```

Syntax: [no] radius-server timeout <*number*>

Configuring authentication-method lists for RADIUS

You can use RADIUS to authenticate Telnet or SSH access and access to Privileged EXEC level and CONFIG levels of the CLI. When configuring RADIUS authentication, you create authentication-method lists specifically for these access methods, specifying RADIUS as the primary authentication method.

Within the authentication-method list, RADIUS is specified as the primary authentication method and up to six backup authentication methods are specified as alternates. If RADIUS authentication fails due to an error, the device tries the backup authentication methods in the order they appear in the list.

When you configure authentication-method lists for RADIUS, you must create a separate authentication-method list for Telnet or SSH CLI access and for CLI access to the Privileged EXEC level and CONFIG levels of the CLI.

To create an authentication-method list that specifies RADIUS as the primary authentication method for securing Telnet access to the CLI, enter the following command.

```
NetIron(config)# enable telnet authentication
NetIron(config)# aaa authentication login default radius local
```

The commands above cause RADIUS to be the primary authentication method for securing Telnet access to the CLI. If RADIUS authentication fails due to an error with the server, local authentication is used instead.

To create an authentication-method list that specifies RADIUS as the primary authentication method for securing access to Privileged EXEC level and CONFIG levels of the CLI, enter the following command.

```
NetIron(config)# aaa authentication enable default radius local none
```

The command above causes RADIUS to be the primary authentication method for securing access to Privileged EXEC level and CONFIG levels of the CLI. If RADIUS authentication fails due to an error with the server, local authentication is used instead. If local authentication fails, no authentication is used; the device automatically permits access.

For information on the command syntax, refer to page page 75 under “Examples of authentication-method lists”.

NOTE
For examples of how to define authentication-method lists for types of authentication other than RADIUS, refer to “Configuring authentication-method lists” on page 73.

Entering privileged EXEC mode after a Telnet or SSH login

By default, a user enters User EXEC mode after a successful login through Telnet or SSH. You can configure the device so that a user enters Privileged EXEC mode after a Telnet or SSH login. To do this, use the following command.

```
NetIron(config)# aaa authentication login privilege-mode
```

Syntax: [no] aaa authentication login privilege-mode

The user’s privilege level is based on the privilege level granted during login.

Configuring enable authentication to prompt for password only

If Enable authentication is configured on the device, by default, a user is prompted for a username and password. when the user attempts to gain Super User access to the Privileged EXEC and CONFIG levels of the CLI. You can configure the PowerConnect router to prompt only for a password. The device uses the username (up to 255 characters) entered at login, if one is available. If no username was entered at login, the device prompts for both username and password.

To configure the PowerConnect router to prompt only for a password when a user attempts to gain Super User access to the Privileged EXEC and CONFIG levels of the CLI, enter the following command.

```
NetIron(config)# aaa authentication enable implicit-user
```

Syntax: [no] aaa authentication enable implicit-user

Configuring RADIUS authorization

The PowerConnect router supports RADIUS authorization for controlling access to management functions in the CLI. Two kinds of RADIUS authorization are supported:

- Exec authorization determines a user's privilege level when they are authenticated
- Command authorization consults a RADIUS server to get authorization for commands entered by the user

Configuring Exec authorization

NOTE
Before you configure RADIUS exec authorization on a PowerConnect router, make sure that the **aaa authentication enable default radius** command exists in the configuration.

When RADIUS exec authorization is performed, the PowerConnect router consults a RADIUS server to determine the privilege level of the authenticated user.

To configure RADIUS exec authorization on a PowerConnect router, enter the following command.

```
NetIron(config)# aaa authentication login default radius
NetIron(config)# aaa authorization exec default radius
```

Syntax: [no] aaa authorization exec default radius | none

If you specify **none**, or omit the **aaa authorization exec** command from the device's configuration, no exec authorization is performed.

NOTE
If the **aaa authorization exec default radius** command exists in the configuration, following successful authentication the device assigns the user the privilege level specified by the powerconnect-privilege-level attribute received from the RADIUS server. If the **aaa authorization exec default radius** command does not exist in the configuration, then the value in the powerconnect-privilege-level attribute is ignored, and the user is granted Super User access.

For the **aaa authorization exec default radius** command to work, either the **aaa authentication login default radius** command, or the **aaa authentication enable default radius** command must also exist in the configuration.

Configuring command authorization

When RADIUS command authorization is enabled, the PowerConnect router consults the list of commands supplied by the RADIUS server during authentication to determine whether a user can execute a command he or she has entered.

You enable RADIUS command authorization by specifying a privilege level whose commands require authorization. For example, to configure the PowerConnect router to perform authorization for the commands available at the Super User privilege level (that is; all commands on the device), enter the following command.

```
NetIron(config)# aaa authorization commands 0 default radius
```

Syntax: [no] aaa authorization commands <*privilege-level*> **default radius | tacacs+ | none**

The <*privilege-level*> parameter can be one of the following:

- 0 – Authorization is performed (that is, the PowerConnect router looks at the command list) for commands available at the Super User level (all commands)
- 4 – Authorization is performed for commands available at the Port Configuration level (port-config and read-only commands)
- 5 – Authorization is performed for commands available at the Read Only level (read-only commands)

NOTE
RADIUS command authorization can be performed only for commands entered from Telnet or SSH sessions, or from the console. No authorization is performed for commands entered at the Web Management Interface or SNMP.

NOTE
Since RADIUS command authorization relies on the command list supplied by the RADIUS server during authentication, you cannot perform RADIUS authorization without RADIUS authentication.

Command authorization and accounting for console commands

The PowerConnect devices support command authorization and command accounting for CLI commands entered at the console. To configure the device to perform command authorization and command accounting for console commands, enter the following.

```
NetIron(config)# enable aaa console
```

Syntax: [no] enable aaa console

CAUTION
If you have previously configured the device to perform command authorization using a RADIUS server, entering the enable aaa console command may prevent the execution of any subsequent commands entered on the console.

NOTE
This happens because RADIUS command authorization requires a list of allowable commands from the RADIUS server. This list is obtained during RADIUS authentication. For console sessions, RADIUS authentication is performed only if you have configured Enable authentication and specified RADIUS as the authentication method (for example, with the **aaa authentication enable default radius** command). If RADIUS authentication is never performed, the list of allowable commands is never obtained from the RADIUS server. Consequently, there would be no allowable commands on the console.

Configuring RADIUS accounting

The PowerConnect devices support RADIUS accounting for recording information about user activity and system events. When you configure RADIUS accounting on a PowerConnect router, information is sent to a RADIUS accounting server when specified events occur, such as when a user logs into the device or the system is rebooted.

Configuring RADIUS accounting for Telnet or SSH (shell) access

To send an Accounting Start packet to the RADIUS accounting server when an authenticated user establishes a Telnet or SSH session on the PowerConnect router, and an Accounting Stop packet when the user logs out, enter the following command.

```
NetIron(config)# aaa accounting exec default start-stop radius
```

Syntax: [no] aaa accounting exec default start-stop radius | tacacs+ | none

Configuring RADIUS accounting for CLI commands

You can configure RADIUS accounting for CLI commands by specifying a privilege level whose commands require accounting. For example, to configure a PowerConnect router to perform RADIUS accounting for the commands available at the Super User privilege level (that is; all commands on the device), enter the following command.

```
NetIron(config)# aaa accounting commands 0 default start-stop radius
```

An Accounting Start packet is sent to the RADIUS accounting server when a user enters a command, and an Accounting Stop packet is sent when the service provided by the command is completed.

NOTE
If authorization is enabled, and the command requires authorization, then authorization is performed before accounting takes place. If authorization fails for the command, no accounting takes place.

Syntax: [no] aaa accounting commands <*privilege-level*> **default start-stop radius | tacacs | none**

The <*privilege-level*> parameter can be one of the following:

- 0 – Records commands available at the Super User level (all commands)
- 4 – Records commands available at the Port Configuration level (port-config and read-only commands)
- 5 – Records commands available at the Read Only level (read-only commands)

Configuring RADIUS accounting for system events

You can configure RADIUS accounting to record when system events occur on a PowerConnect router. System events include rebooting and when changes to the active configuration are made.

The following command causes an Accounting Start packet to be sent to the RADIUS accounting server when a system event occurs, and a Accounting Stop packet to be sent when the system event is completed.

```
NetIron(config)# aaa accounting system default start-stop radius
```

Syntax: [no] aaa accounting system default start-stop radius | tacacs+ | none

Configuring an interface as the source for all RADIUS packets

You can designate the lowest-numbered IP address configured an Ethernet port, loopback interface, or virtual interface as the source IP address for all RADIUS packets from the PowerConnect router. Identifying a single source IP address for RADIUS packets provides the following benefits:

- If your RADIUS server is configured to accept packets only from specific links or IP addresses, you can use this feature to simplify configuration of the RADIUS server by configuring the PowerConnect router to always send the RADIUS packets from the same link or source address.
- If you specify a loopback interface as the single source for RADIUS packets, RADIUS servers can receive the packets regardless of the states of individual links. Thus, if a link to the RADIUS server becomes unavailable but the client or server can be reached through another link, the client or server still receives the packets, and the packets still have the source IP address of the loopback interface.

The software contains separate CLI commands for specifying the source interface for Telnet, TACACS or TACACS+, and RADIUS packets. You can configure a source interface for one or more of these types of packets.

To specify an Ethernet or a loopback or virtual interface as the source for all RADIUS packets from the device, use the following CLI method. The software uses the lowest-numbered IP address configured on the port or interface as the source IP address for RADIUS packets originated by the device.

To specify the lowest-numbered IP address configured on a virtual interface as the device's source for all RADIUS packets, enter commands such as the following.

```
NetIron(config)# int ve 1
NetIron(config-vif-1)# ip address 10.0.0.3/24
NetIron(config-vif-1)# exit
NetIron(config)# ip radius source-interface ve 1
```

The commands in this example configure virtual interface 1, assign IP address 10.0.0.3/24 to the interface, then designate the interface as the source for all RADIUS packets from the PowerConnect router.

Syntax: [no] ip radius source-interface ethernet <*portnum*> **| loopback** <*num*> **| ve** <*num*>

The <*num*> parameter is a loopback interface or virtual interface number. If you specify an Ethernet port, the <*portnum*> is the port's number (including the slot number, if you are configuring a device).

Displaying RADIUS configuration information

The **show aaa** command displays information about all TACACS or TACACS+ and RADIUS servers identified on the device.

```
NetIron# show aaa
Tacacs+ key: powerconnect
Tacacs+ retries: 1
Tacacs+ timeout: 15 seconds
Tacacs+ dead-time: 3 minutes
Tacacs+ Server: 207.95.6.90 Port:49:
                opens=6 closes=3 timeouts=3 errors=0
                packets in=4 packets out=4
no connection
Radius key: networks
Radius retries: 3
Radius timeout: 3 seconds
Radius dead-time: 3 minutes
Radius Server:  207.95.6.90 Auth Port=1645 Acct Port=1646:
                opens=2 closes=1 timeouts=1 errors=0
                packets in=1 packets out=4
no connection
```

Syntax: show aaa

The following table describes the RADIUS information displayed by the **show aaa** command.

TABLE 8 Output of the show aaa command for RADIUS

Field	Description
Radius key	The setting configured with the **radius-server key** command. At the Super User privilege level, the actual text of the key is displayed. At the other privilege levels, a string of periods (....) is displayed instead of the text.
Radius retries	The setting configured with the **radius-server retransmit** command.
Radius timeout	The setting configured with the **radius-server timeout** command.
Radius dead-time	The setting configured with the **radius-server dead-time** command.
Radius Server	For each RADIUS server, the IP address, and the following statistics are displayed: **Auth Port** – RADIUS authentication port number (default 1645) **Acct Port** – RADIUS accounting port number (default 1646) **opens** – Number of times the port was opened for communication with the server **closes** – Number of times the port was closed normally **timeouts** – Number of times port was closed due to a timeout **errors** – Number of times an error occurred while opening the port **packets in** – Number of packets received from the server **packets out** – Number of packets sent to the server
connection	The current connection status. This can be “no connection” or “connection active”.

The **show web** command displays the privilege level of Web Management Interface users.

```
NetIron(config)# show web
User                              Privilege       IP address
set                                      0       192.168.1.234
```

Syntax: show web

Configuring AAA on the console

Only enable-level authentication is available on the console by default. Command authorization and accounting and exec accounting must be explicitly configured. To enable AAA support on the console, use the following command.

```
NetIron(config)# enable aaa console
```

Syntax: [no] enable aaa console

After this command is added, use the following procedure to test the configuration.

1. At the console, type "**end**" to go to the Privileged EXEC level.
2. Type "**exit**" to go to the User EXEC level.

   After the enable **aaa console** command is, a new command, "**exit**", is be available at the User EXEC level.
3. Enter "**exit**" to display the following login prompt on the console window.

   ```
   "Press Enter key to login".
   ```
4. Press the "Enter key," to begin the login process.

   The next prompt to appear is determined by the first method configured in the login authentication configuration. If it is not TACACS+, the default prompts are used.

NOTE
If you use the use the **aaa console** command to enable AAA, you must make sure that the method lists are configured to allow access. Otherwise, you will be locked out of the console.

Configuring AAA authentication-method lists for login

With AAA is enabled on the console, you must configure an authentication-method list to set the conditions for granting access to the console. The authentication methods supported on the PowerConnect devices include the following:

- enable
- line
- local
- radius
- tacacs
- tacacs+
- none

When a list is configured, the first method listed is attempted to provide authentication at login. If that method is not available, (for example, a TACACs server can not be reached) the next method is tried until a method in the list is available or all methods have been tried. You can place the method none at the end of a list to ensure that access will always be available if all active methods fail.

To configure a AAA authentication-method list for login, use the following command.

```
NetIron(config)# aaa authentication login default tacacs+ local none
```

In this configuration, tacacs+ would be tried first. If a tacacs+ server cannot be reached, the local system password would be used. If this method fails, authentication would default to none.

Syntax: [no] aaa authentication login default enable line local none radius tacacs tacacs+

The **enable** option uses the enable password configured on the router to grant access to the console.

The **line** option uses the line password configured on the router to grant access to the console.

The **local** option uses the local password configured on the router to grant access to the console.

The **radius** option uses authentication provided by a radius server to grant access to the console.

The **tacacs** option uses authentication provided by a tacacs server to grant access to the console.

The **tacacs+** option uses authentication provided by a tacacs+ server to grant access to the console.

The **none** option eliminates the requirement for any authentication method to grant access to the console.

Configuring authentication-method lists

To implement one or more authentication methods for securing access to the device, you configure authentication-method lists that set the order in which the authentication methods are consulted.

In an authentication-method list, you specify the access method (Telnet, Web, SNMP, and so on) and the order in which the device tries one or more of the following authentication methods:

- Local Telnet login password
- Local password for the Super User privilege level
- Local user accounts configured on the device
- Database on a TACACS or TACACS+ server
- Database on a RADIUS server
- No authentication

NOTE
The TACACS or TACACS+, RADIUS, and Telnet login password authentication methods are not supported for SNMP access.

NOTE
To authenticate Telnet access to the CLI, you also must enable the authentication by entering the **enable telnet authentication** command at the global CONFIG level of the CLI. You cannot enable Telnet authentication using the Web Management Interface.

NOTE
You do not need an authentication-method list to secure access based on ACLs or a list of IP addresses. Refer to "Using ACLs to restrict remote access" on page 20 or "Restricting remote access to the device to specific IP addresses" on page 23.

In an authentication-method list for a particular access method, you can specify up to seven authentication methods. If the first authentication method is successful, the software grants access and stops the authentication process. If the access is rejected by the first authentication method, the software denies access and stops checking.

However, if an error occurs with an authentication method, the software tries the next method on the list, and so on. For example, if the first authentication method is the RADIUS server, but the link to the server is down, the software will try the next authentication method in the list.

NOTE
If an authentication method is working properly and the password (and user name, if applicable) is not known to that method, this is not an error. The authentication attempt stops, and the user is denied access.

The software will continue this process until either the authentication method is passed or the software reaches the end of the method list. If the Super User level password is not rejected after all the access methods in the list have been tried, access is granted.

NOTE
If a user cannot be authenticated using local authentication, then the next method on the authentication methods list is used to try to authenticate the user. If there is no method following local authentication, then the user is denied access to the device.

Configuration considerations for authentication-method lists

The configuration considerations for authentication-method lists are as follows:

- For CLI access, you must configure authentication-method lists if you want the device to authenticate access using local user accounts or a RADIUS server. Otherwise, the device will authenticate using only the locally based password for the Super User privilege level.
- When no authentication-method list is configured specifically for Web management access, the device performs authentication using the SNMP community strings:
  - For read-only access, you can use the user name “get” and the password “public”. The default read-only community string is “public”.
  - There is no default read-write community string. Thus, by default, you cannot open a read-write management session using the Web Management Interface. You first must configure a read-write community string using the CLI. Then you can log on using “set” as the user name and the read-write community string you configure as the password. Refer to “Configuring TACACS or TACACS+ security” on page 39.
- If you configure an authentication-method list for Web management access and specify “local” as the primary authentication method, users who attempt to access the device using the Web Management Interface must supply a user name and password configured in one of the local user accounts on the device. The user ***cannot*** access the device by entering “set” or “get” and the corresponding SNMP community string.

- For devices that can be managed using SNMP, the default authentication method (if no authentication-method list is configured for SNMP) is the CLI Super User level password. If no Super User level password is configured, then access through IronView Network Manager is not authenticated. To use local user accounts to authenticate access through SNMP, configure an authentication-method list for SNMP access and specify “local” as the primary authentication method.

Examples of authentication-method lists

The following example shows how to configure authentication-method lists for the Web Management Interface, SNMP, and the Privileged EXEC and CONFIG levels of the CLI. In this example, the primary authentication method for each is “local”. The device will authenticate access attempts using the locally configured user names and passwords first.

To configure an authentication-method list for the Web Management Interface, enter a command such as the following.

```
NetIron(config)# aaa authentication web-server default local
```

This command configures the device to use the local user accounts to authenticate access to the device through the Web Management Interface. If the device does not have a user account that matches the user name and password entered by the user, the user is not granted access.

To configure an authentication-method list for SNMP Network Manager, enter a command such as the following.

```
NetIron(config)# aaa authentication snmp-server default local
```

This command configures the device to use the local user accounts to authenticate access attempts through any network management software, such as SNMP Network Manager.

To configure an authentication-method list for the Privileged EXEC and CONFIG levels of the CLI, enter the following command.

```
NetIron(config)# aaa authentication enable default local
```

This command configures the device to use the local user accounts to authenticate attempts to access the Privileged EXEC and CONFIG levels of the CLI.

Example

To configure the device to consult a RADIUS server first to authenticate attempts to access the Privileged EXEC and CONFIG levels of the CLI, then consult the local user accounts if the RADIUS server is unavailable, enter the following command.

```
NetIron(config)# aaa authentication enable default radius local
```

Syntax: **[no] aaa authentication snmp-server | web-server | enable | login | dot1x default** <*method1*> [<*method2*>] [<*method3*>] [<*method4*>] [<*method5*>] [<*method6*>] [<*method7*>]

The **snmp-server | web-server | enable | login | dot1x** parameter specifies the type of access this authentication-method list controls. You can configure one authentication-method list for each type of access.

NOTE
If you configure authentication for Web management access, authentication is performed each time a page is requested from the server. When frames are enabled on the Web Management Interface, the browser sends an HTTP request for each frame. The Dell device authenticates each HTTP request from the browser. To limit authentications to one per page, disable frames on the Web Management Interface.

NOTE
TACACS or TACACS+ and RADIUS are not supported with the **snmp-server** parameter.

The <*method1*> parameter specifies the primary authentication method. The remaining optional <*method*> parameters specify additional methods to try if an error occurs with the primary method. A method can be one of the values listed in the Method Parameter column in Table 9.

TABLE 9 Authentication method values

Method parameter	Description
line	Authenticate using the password you configured for Telnet access. The Telnet password is configured using the **enable telnet password...** command. Refer to "Setting a Telnet password" on page 27.
enable	Authenticate using the password you configured for the Super User privilege level. This password is configured using the **enable super-user-password...** command. Refer to "Setting passwords for management privilege levels" on page 27.
local	Authenticate using a local user name and password you configured on the device. Local user names and passwords are configured using the **username...** command. Refer to "Configuring a local user account" on page 31.
tacacs	Authenticate using the database on a TACACS server. You also must identify the server to the device using the **tacacs-server** command.
tacacs+	Authenticate using the database on a TACACS+ server. You also must identify the server to the device using the **tacacs-server** command.
radius	Authenticate using the database on a RADIUS server. You also must identify the server to the device using the **radius-server** command.
none	Do not use any authentication method. The device automatically permits access.

Configuring Basic Parameters 3

Overview

The following Basic Parameters features are supported by NetIron MLX Series devices:

- Simple Network Management (SNMP) traps
- SNMP ifIndex
- Optical Monitoring
- Optics Compatibility Checking
- New encryption code for passwords, authentication keys, and community strings
- Designating an Interface as the source for packets
- Simple Network Time Protocol (SNTP) server
- Setting the systemclock
- Command Alias
- Limiting broadcast, multicast, or unknown-unicast rates
- CLI banners
- Terminal display
- Modifying system parameter default settings
- System low memory prevention and reporting
- Layer 2 switching
- MAC age time
- Static ARP entries
- Configurable CAM size for IPv4 and IPv6 multicast entries
- Switch fabric fault monitoring
- Automatic switch fabric module shutdown
- Switch fabric utilization monitoring
- Verifying an image checksum
- Displaying information for an interface for an Ethernet port
- Displaying statistics Information for an Ethernet port
- Real-time monitoring

This chapter describes how to configure basic system parameters.

NOTE
For information about the Syslog buffer and messages, refer to Appendix A, “Using Syslog”.

The PowerConnect router is configured with default parameters to allow you to begin using the basic features of the system immediately. However, many advanced features, such as VLANs or routing protocols for the router, must first be enabled at the system (global) level before they can be configured.

You can find system level parameters at the Global CONFIG level of the CLI.

NOTE
Before assigning or modifying any router parameters, you must assign the IP subnet (interface) addresses for each port.

Entering system administration information

You can configure a system name, contact, and location for the PowerConnect router and save the information locally in the configuration file for future reference. The information is not required for system operation but recommended. When you configure a system name, it replaces the default system name in the CLI command prompt.

To configure a system name, contact, and location, enter commands such as the following.

```
NetIron(config)# hostname home
home(config)# snmp-server contact Suzy Sanchez
home(config)# snmp-server location Centerville
home(config)# end
home# write memory
```

The system name you configure **home** replaces the system name PowerConnect.

Syntax: [no] hostname <*string*>

Syntax: [no] snmp-server contact <*string*>

Syntax: [no] snmp-server location <*string*>

The name, contact, and location each can be up to 255 alphanumeric characters. The text strings can contain blanks. The SNMP text strings do not require quotation marks when they contain blanks but the host name does.

Configuring Simple Network Management (SNMP) traps

This section explains how to do the following:

- Specify an SNMP trap receiver.
- Specify a source address and community string for all traps that the PowerConnect router sends.
- Change the holddown time for SNMP traps.
- Disable individual SNMP traps. (All traps are enabled by default.)
- Disable traps for CLI access that is authenticated by a local user account, a RADIUS server, or a TACACS or TACACS+ server.

NOTE
To add and modify "get" (read-only) and "set" (read-write) community strings, refer to "Securing Access to Management Functions" on page 17.

Specifying an SNMP trap receiver

You can specify a trap receiver to ensure that all SNMP traps sent by the PowerConnect router go to the same SNMP trap receiver or set of receivers, typically one or more host devices on the network. When you specify the host, you also specify a community string. The PowerConnect router sends all the SNMP traps to the specified hosts and includes the specified community string. Administrators can therefore filter for traps from a PowerConnect router based on IP address or community string.

If the string is in the clear format, the system will internally encrypt it. When you display or save the configuration, the encrypted string is used.

To specify an SNMP trap receiver, enter a command such as the following.

```
NetIron(config)# snmp-server host 2.2.2.2 mypublic port 200
```

The command adds trap receiver 2.2.2.2 and designates the UDP port that will be used to receive traps.

Syntax: [no] snmp-server host <*ip-addr*> <*string*> **[port** <*value*>**]**

The <*ip-addr*> parameter specifies the IP address of the trap receiver.

The <*string*> parameter specifies an SNMP community string configured on the PowerConnect router. It is not used to authenticate access to the trap host, but it is a useful method for filtering traps on the host. For example, if you configure each of your PowerConnect devices that use the trap host to send a different community string, you can easily distinguish among the traps from the devices based on the community strings.

By default, <*string*> is encrypted. If you want <*string*> to be in clear text, insert a **0** preceding <*string*>.

Example

```
NetIron(config)# snmp-server host 2.2.2.2 0 mypublic port 200
```

The software adds a prefix to the string in the configuration. For example, the following portion of the code has the encrypted code "2".

```
snmp-server host 2.2.2.2 version v2c 2 $Si2^=d
```

The prefix can be one of the following:

- 0 = the key string is not encrypted and is in clear text
- 1 = the key string uses simple encryption
- 2 = the key string uses base64 encryption format

The **port** <*value*> parameter specifies the UDP port that will be used to receive traps. This parameter allows you to configure several trap receivers in a system. With this parameter, SNMP Network Manager and another network management application can coexist in the same system. The PowerConnect devices can be configured to send copies of traps to more than one network management application.

Specifying a single trap source

You can specify a single trap source to ensure that all SNMP traps sent by the PowerConnect router use the same source IP address. When you configure the SNMP source address, you specify the Ethernet port, loopback interface, or virtual routing interface that is the source for the traps. The PowerConnect router then uses the lowest-numbered IP address configured on the port or interface as the source IP address in the SNMP traps it sends.

Identifying a single source IP address for SNMP traps provides the following benefits:

- If your trap receiver is configured to accept traps only from specific links or IP addresses, you can simplify configuration of the trap receiver by configuring the PowerConnect router to always send the traps from the same link or source address.
- If you specify a loopback interface as the single source for SNMP traps, SNMP trap receivers can receive traps regardless of the states of individual links. Thus, if a link to the trap receiver becomes unavailable but the receiver can be reached through another link, the receiver still receives the trap, and the trap still has the source IP address of the loopback interface.

To configure the PowerConnect router to send all SNMP traps from the first configured IP address on port 4/11, enter the following commands.

```
NetIron(config)# snmp-server trap-source ethernet 4/11
NetIron(config)# write memory
```

Syntax: [no] snmp-server trap-source loopback <*num*> **| ethernet** <*slot/port*> **| ve** <*num*>

The <*num*> parameter is a loopback interface or virtual routing interface number.

If you do not configure this command, the device will use the device router ID as the source IP address of the notification packet. The router ID of the device can be obtained from the “show ip” command output.

To specify a loopback interface as the device’s SNMP trap source, enter following commands.

```
NetIron(config)# int loopback 1
NetIron(config-lbif-1)# ip address 10.0.0.1/24
NetIron(config-lbif-1)# exit
NetIron(config)# snmp-server trap-source loopback 1
```

The commands configure loopback interface 1, gives it IP address 10.00.1/24, then designate it as the SNMP trap source for the PowerConnect router. Regardless of the port the PowerConnect uses to send traps to the receiver, the traps always arrive from the same source IP address.

Setting the SNMP trap holddown time

When a PowerConnect router starts up, the software waits for Layer 2 convergence (STP) and Layer 3 convergence (OSPF) before beginning to send SNMP traps to external SNMP servers. Until convergence occurs, the PowerConnect router might not be able to reach the servers, in which case the messages are lost.

By default, the PowerConnect router uses a one-minute holddown time to wait for the convergence to occur before starting to send SNMP traps. After the holddown time expires, the PowerConnect router sends the traps, including traps such as “cold start” or “warm start” that occur before the holddown time expires.

You can change the holddown time to a value from one second to ten minutes.

To change the holddown time for SNMP traps, enter a command such as the following at the global CONFIG level of the CLI.

```
NetIron(config)# snmp-server enable traps holddown-time 30
```

The command changes the holddown time for SNMP traps to 30 seconds. The PowerConnect router waits 30 seconds to allow convergence in STP and OSPF before sending traps to the SNMP trap receiver.

Syntax: [no] snmp-server enable traps holddown-time <*secs*>

The <*secs*> parameter specifies the number of seconds (1 – 600). The default is 60.

Disabling SNMP traps

The PowerConnect router comes with SNMP trap generation enabled by default for all traps.

NOTE
By default, all SNMP traps are enabled at system startup.

You can selectively disable one or more of the following traps:

- SNMP authentication key
- Temperature
- Power supply failure
- Fan failure
- Cold start
- Link up
- Link down
- Bridge new root
- Bridge topology change
- Module insert
- Module remove
- Redundant module
- Metro-ring
- MPLS
- BGP4
- OSPF
- VRRP
- VSRP

To stop link down occurrences from being reported, enter the following command.

```
NetIron(config)# no snmp-server enable traps link-down
```

Syntax: [no] snmp-server enable traps <*trap-type*>

A list of traps is available in the *IronWare MIB Reference*.

Disabling Syslog messages and traps for CLI access

The PowerConnect router sends Syslog messages and SNMP traps when a user logs into or out of the User EXEC or Privileged EXEC level of the CLI. The feature, enabled by default, applies to users whose access is determined by the AAA engine.

NOTE
The Privileged EXEC level is sometimes called the "Enable" level, because the command for accessing this level is **enable**.

Examples of Syslog messages for CLI access

When a user whose access is authenticated by a local user account, a RADIUS server, or a TACACS or TACACS+ server logs into or out of the CLI's User EXEC or Privileged EXEC mode, the software generates a Syslog message and trap containing the following information:

- The time stamp
- The user name
- Whether the user logged in or out
- The CLI level the user logged into or out of (User EXEC or Privileged EXEC level)

NOTE
Messages for accessing the User EXEC level apply only to access through Telnet. The device does not authenticate initial access through serial connections but does authenticate serial access to the Privileged EXEC level. Messages for accessing the Privileged EXEC level apply to access through the serial connection or Telnet.

The following examples show login and logout messages for the User EXEC and Privileged EXEC levels of the CLI.

```
NetIron(config)# show logging
Syslog logging: enabled (0 messages dropped, 0 flushes, 0 overruns)
Buffer logging: level ACDMEINW, 12 messages logged
level code: A=alert C=critical D=debugging M=emergency E=error
I=informational N=notification W=warning
Static Log Buffer:
Dec 15 19:04:14:A:Fan 1, fan on right connector, failed

Dynamic Log Buffer (50 entries):
Oct 15 18:01:11:info:dg logout from USER EXEC mode
Oct 15 17:59:22:info:dg logout from PRIVILEGE EXEC mode
Oct 15 17:38:07:info:dg login to PRIVILEGE EXEC mode
Oct 15 17:38:03:info:dg login to USER EXEC mode
```

Syntax: show logging

The first message (the one on the bottom) indicates that user "dg" logged in to the CLI's User EXEC level on October 15 at 5:38 PM and 3 seconds (Oct 15 17:38:03). The same user logged into the Privileged EXEC level four seconds later.

The user remained in the Privileged EXEC mode until 5:59 PM and 22 seconds. (The user could have used the CONFIG modes as well. Once you access the Privileged EXEC level, no further authentication is required to access the CONFIG levels.) At 6:01 PM and 11 seconds, the user ended the CLI session.

Example : Direct Telnet access without a password check.

```
00:48:53:I:Security: telnet login from src IP 172.16.2.100 to USER EXEC mode
00:48:59:I:Security: telnet logout from src IP 172.16.2.100 to USER EXEC mode
```

Example : Telnet access using a local user.

```
Oct 30 01:06:30:I:Security: telnet login by sunil from src IP 172.16.2.100 to
USER EXEC mode
```

Example : SSH access.

```
Oct 30 01:08:58:I:Security: ssh login by sunil from src IP 172.16.2.100 to USER
EXEC mode
```

Disabling the Syslog messages and traps

Logging of CLI access is enabled by default. To disable logging of CLI access, enter the following commands.

```
NetIron(config)# no logging enable user-login
```

Syntax: [no] logging enable user-login

Refer to the MIB Guide for a list of traps.

Configuring SNMP ifIndex

This section explains how ifIndex values are assigned on PowerConnect devices.

On NetIron MLX Series devices only

On **NetIron MLX Series** devices, SNMP Management Information Base (MIB) uses Interface Index (ifIndex) to assign a unique value to each port on a module or slot. The number of indexes that can be assigned per module is 20, 40, or 64, depending on the number of ports on the module.

Enter the following to change the number of indexes per module.

```
NetIron(config)# snmp-server max-ifindex-per-module 40
```

Syntax: [no] snmp-server max-ifindex-per-module [20 | 40 | 64]

20 is the default.

You cannot change the maximum ifIndex per module to a number less than the number of ports.

After this command is issued the following are generated:

- “System: IfIndex assignment was changed” is logged in the Syslog.
- The snTrapIfIndexAssignmentChanged trap is generated.

Configuration notes for the Product Name

Note the following if you are upgrading the software on the Product Name:

- If you are running an earlier version of the software and you will not be installing the NI-MLX-1Gx48-T module, you do not need to change your ifIndex allocation scheme. The current definition is maintained. The maximum ifIndex per module can remain at 20 or 40.
- If you are running an earlier version of the software and you will be installing the NI-MLX-1Gx48-T module on you Product Name, you must configure the maximum ifIndex per module to 64. **You must change the ifIndex allocation before installing the NI-MLX-1Gx48-T module**; otherwise, the module status remains in the Offline state.
- If you have a new Product Name (no previous software installed), but will not be installing an NI-MLX-1Gx48-T module, it is recommended that you configure the maximum ifIndex per module to 64 to avoid future ifIndex problems in case an NI-MLX-1Gx48-T module is installed in the future.
- If you have a new Product Name (no previous software installed), and you will be installing an NI-MLX-1Gx48-T module, you **must** configure the maximum ifIndex per module to 64; otherwise, the module remains in the Offline state.

Configuring optical monitoring

You can configure your PowerConnect router to monitor XFPs or SFPs in the system either globally or by specified port. If monitoring is enabled, console messages, syslog messages, and SNMP traps are sent when XFP or SFP operating conditions warrant it and a port is enabled.

Configure all XFP and SFP ports for optical monitoring, using the following command.

```
NetIron(config)# optical-monitor
```

Configure a specific XFP or SFP port for optical monitoring, using the following command.

```
NetIron(config)# interface ethernet 1/1
NetIron(config-if-e10000-1/1)# optical-monitor
```

Configure a range of XFP or SFP ports for optical monitoring, using the following command.

```
NetIron(config)# interface ethernet 1/1 to 1/2
NetIron(config-mif-e10000-1/1-1/2)# optical-monitor
```

Syntax: [no] optical-monitor <*alarm-interval*>

The optional <*alarm-interval*> variable sets the interval in minutes between which alarms or messages are sent. The default interval is 3 minutes.

You can view the XFP optical monitoring information using the show optic command as displayed in the following.

```
NetIron#show optic 4
 Port  Temperature   Tx Power     Rx Power     Tx Bias Current
+----+-----------+----------+------------+------------------+
4/1   30.8242 C  -001.8822 dBm -002.5908 dBm   41.790 mA
       Normal       Normal         Normal         Normal
4/2   31.7070 C  -001.4116 dBm -006.4092 dBm   41.976 mA
       Normal       Normal         Normal         Normal
4/3   30.1835 C                -000.5794 dBm    0.000 mA
       Normal      Low-Alarm      Normal        Low-Alarm
4/4    0.0000 C                                 0.000 mA
       Normal       Normal         Normal         Normal
```

For Temperature, Tx Power, Rx Power, and Tx Bias Current, values are displayed along with one of the following status values: Low-Alarm, Low-Warn, Normal, High-Warn or High-Alarm. The thresholds that determine these status values are set by the manufacturer of the XFPs. Table 10 describes each of these status values.

TABLE 10 Status value description

Status value	Description
Low-alarm	The monitored level has dropped below the "low-alarm" threshold set by the XFP or SFP manufacturer.
Low-warn	The monitored level has dropped below the "low-warn" threshold set by the XFP or SFP manufacturer.
Normal	The monitored level is within the "normal" range" set by the XFP or SFP manufacturer.
High-warn	The monitored level has climbed above the "high-warn" threshold set by the XFP or SFP manufacturer.
High-alarm	The monitored level has climbed above the "high-alarm" threshold set by the XFP or SFP manufacturer.

NOTE
This function takes advantage of information stored and supplied by the SFP or XFP device. This information is an optional feature of the Multi-Source Agreement standard defining the SFP or XFP interface. Not all component suppliers have implemented this feature set. In such cases where the SFP or XFP device does not supply the information, a “Not Available” message will be displayed for the specific port that the device is installed

Displaying media information

To display media information for SFP and XFP devices installed in a specific slot, enter the following command at any CLI level.

```
NetIron#show media slot 3
Port 2/1:
    Type  : 10GBASE-SR/SW 850.00nm (XFP)
    Vendor:     FOUNDRY NETWORKS, Version:                    00
    Part# :     FTLX8511D3-F1   , Serial#:     A9C01ED
Port 2/2:
    Type  : 10GBASE-SR 850.00nm (XFP)
    Vendor:     Foundry Networks, Version:                    01
    Part# :     AFBR-720XPDZ-FD1, Serial#:     AVAGCN0933MD10U
.
.
```

```
.
All show media done
```

The example above displays all optical devices on slot 3.

Syntax: show media slot <*slot-number*>

To display media information for SFP and XFP devices installed in an ethernet port, enter the following command at any CLI level.

```
NetIron#show media ethernet 3/4
Port 3/4:
    Type  : 10GBASE-SR/SW 854.00nm (XFP)
    Vendor:     Foundry Networks, Version:                   02
    Part# :     JXPR01SW05306   , Serial#:     F74340380372
```

Syntax: show media [ethernet <*slot-port*> **[to** <*slot-port*>**]]**

You can display media information for all ports in an NetIron router by using the **show media** command without options.

The **ethernet** <*slot-port*> parameter limits the display to a single port.

The **to** <*slot-port*> parameter displays information for a range of ports.

This results displayed from this command provide the Type, Vendor, Part number, Version and Serial number of the SFP or XFP optical device installed in the port.

If no SFP or XFP device is installed in a port, the “Type” field will display “N/A”, the “Vendor” field will be empty and the other fields will display “Unknown”.

Multi-rate optical transceivers are supported. In this case, if a multi-rate optical transceiver is inserted in an Interface module, the “Type” parameter will display the transmission code for the correct value for the port as determined by either the Interface module type or the configuration of the port. There is one exception to this rule however. If a port is in the disabled state only one type will be displayed. Once the port is enabled, the correct “Type” will be displayed in accordance with the configuration.

Optics compatibility checking

This feature checks the installation of the following optical transceivers into Interface module ports and shuts down the port if the transceiver is incompatible with the port:

- **10 GbE XFP** – This interface is brought up if the XFP is compliant with Ethernet transmission compliance.
- **10 Gbe SFP+** - This interface is brought up if the SFP+ is compliant with Ethernet transmission.
- 1 Gb (100/1000) Ethernet interface will be enabled if the SFP is Ethernet capable.

If the interface is incompatible with the optical transceiver installed, the port will not come up and the syslog message “**Incompatible optical trans-receiver detected on port** <*n*>” is displayed. An SNMP trap is also generated and the port is described as “down” because of “(incompatible transceiver)” in the output from the **show interface** command.

Multi-rate optical transceivers (XFP and SFP) are supported as described in the following:

- In Multi-rate SFPs and XFPs, the EEPROM is programmed for multi-rate.
- Multi-rate SFPs and XFPs are supported. The system software checks for transmission compatibility against the interface configuration.

- The **show media** command described in "Configuring optical monitoring" on page 84 continues to show only one transmission rate even for multi-rate SFPs and XFPs. If the interface is enabled and the SFP or XFP is compatible, the **show media** command only displays the compatible transmission code in the "Type" field. If the interface is disabled, the **show media** display depends on the module type. For Ethernet interface modules, the Ethernet compliance code is shown.

Disabling transceiver type checking

When transceiver type checking is disabled, the syslog message "**Incompatible optical trans-receiver detected on port** <*n*>" is still displayed but the port is not shut down. You can disable transceiver type checking with the **no transceiver-type-check** command as shown in the following.

```
NetIron(config)# no transceiver-type-check
```

Syntax: [no] transceiver-type-check

Transceiver type checking is on by default and the command is not included in the configuration.

The **no** option of the **transceiver-type-check** command, disables transceiver type checking as described, sends a syslog message and places the command in the configuration.

Using the **transceiver-type-check** command without the no option, enables transceiver type checking, sends a syslog message and removes the command from the configuration.

Designating an interface as the packet source

The software uses the lowest-numbered IP address configured on an interface as the source IP address for all Telnet, SSH, SNTP, TFTP, TACACS or TACACS+, or RADIUS packets originated from the PowerConnect router.

You can specify the source interface for one or more of these types of packets.

Configuring an interface as the source for all Telnet packets

Identifying a single source IP address for Telnet packets provides the following benefits:

- If your Telnet server is configured to accept packets only from specific links or IP addresses, you can simplify configuration of the Telnet server by configuring the PowerConnect router to always send the Telnet packets from the same link or source address.
- If you specify a loopback interface as the single source for Telnet packets, Telnet servers can receive the packets regardless of the states of individual links. Thus, if a link to the Telnet server becomes unavailable but the client or server can be reached through another link, the client or server still receives the packets, and the packets still have the source IP address of the loopback interface.

To specify the lowest-numbered IP address configured on a loopback interface as the device's source for all Telnet packets, enter commands such as the following.

```
NetIron(config)# int loopback 2
NetIron(config-lbif-2)# ip address 10.0.0.2/24
NetIron(config-lbif-2)# exit
NetIron(config)# ip telnet source-interface loopback 2
```

The commands configure loopback interface 2, assign IP address 10.0.0.2/24 to it, then designate it as the source for all Telnet packets from the PowerConnect router.

Syntax: [no] ip telnet source-interface ethernet <*portnum*> **| loopback** <*num*> **| ve** <*num*>

The following commands configure an IP interface on an Ethernet port and designate the address port as the source for all Telnet packets from the PowerConnect router.

```
NetIron(config)# interface ethernet 1/4
NetIron(config-if-e10000-1/4)# ip address 209.157.22.110/24
NetIron(config-if-e10000-1/4)# exit
NetIron(config)# ip telnet source-interface ethernet 1/4
```

Cancelling an outbound Telnet session

If you want to cancel a Telnet session from the console to a remote Telnet server (for example, if the connection is frozen), you can terminate the Telnet session by performing the tasks listed below.

1. At the console, press Ctrl-^ (Ctrl-Shift-6).
2. Press the X key to terminate the Telnet session.

Pressing Ctrl-^ twice in a row causes a single Ctrl-^ character to be sent to the Telnet server. After you press Ctrl-^, pressing any key other than X or Ctrl-^ returns you to the Telnet session.

Configuring an interface as the source for all SSH packets

You can configure the PowerConnect router to use the lowest-numbered IP address configured on a loopback interface, virtual routing interface, or Ethernet port as the source for the SSH packets it sends.

For example, to specify an Ethernet port as the interface whose lowest-numbered IP address will be the source address for the SSH packets originated from the PowerConnect router, enter commands such as the following.

```
NetIron(config)# interface ethernet 1/5
NetIron(config-if-e10000-1/5)# ip address 209.157.22.111/24
NetIron(config-if-e10000-1/5)# exit
NetIron(config)# ip ssh source-interface ethernet 1/5
```

The commands configure Ethernet port 1/5, assign IP address 209.157.22.111/24 to it, then designate it as the source interface.

Syntax: [no] ip ssh source-interface ethernet <*portnum*> **| loopback** <*num*> **| ve** <*num*>

Configuring an interface as the source for all SNTP packets

You can configure the PowerConnect router to use the lowest-numbered IP address configured on a loopback interface, virtual routing interface, or Ethernet port as the source for the SNTP packets it sends.

For example, to specify a virtual routing interface as the interface whose lowest-numbered IP address will be the source address for the SNTP packets originated from the PowerConnect router, enter commands such as the following.

```
NetIron(config)# int ve 1
NetIron(config-vif-1)# ip address 10.0.0.3/24
NetIron(config-vif-1)# exit
NetIron(config)# ip sntp source-interface ve 1
```

The commands configure virtual routing interface 1, assign IP address 10.0.0.3/24 to it, then designate it as the source interface.

Syntax: [no] ip sntp source-interface ethernet <*portnum*> **| loopback** <*num*> **| ve** <*num*>

Configuring an interface as the source for all TFTP packets

You can configure the PowerConnect router to use the lowest-numbered IP address configured on a loopback interface, virtual routing interface, or Ethernet port as the source for all TFTP packets it sends.

For example, to specify the lowest-numbered IP address configured on a virtual routing interface as the PowerConnect's source for all TFTP packets, enter commands such as the following.

```
NetIron(config)# int ve 1
NetIron(config-vif-1)# ip address 10.0.0.3/24
NetIron(config-vif-1)# exit
NetIron(config)# ip tftp source-interface ve 1
```

The commands configure virtual routing interface 1, assign IP address 10.0.0.3/24 to it, then designate the address as the source address for all TFTP packets.

Syntax: [no] ip tftp source-interface ethernet <*portnum*> **| loopback** <*num*> **| ve** <*num*>

The default is the lowest-numbered IP address configured on the port through which the packet is sent. The address therefore changes, by default, depending on the port.

Configuring an interface as the source for all TACACS or TACACS+ packets

You can configure the PowerConnect router to use the lowest-numbered IP address configured on a loopback interface, virtual routing interface, or Ethernet port as the source for the TACACS or TACACS+ packets it sends.

For example, to specify a virtual routing interface as the interface whose lowest-numbered IP address will be the source address for the TACACS or TACACS+ packets originated from the PowerConnect router, enter commands such as the following.

```
NetIron(config)# int ve 1
NetIron(config-vif-1)# ip address 10.0.0.3/24
NetIron(config-vif-1)# exit
NetIron(config)# ip tacacs source-interface ve 1
```

The commands configure virtual routing interface 1, assign IP address 10.0.0.3/24 to it, then designate it as the source interface.

Syntax: [no] ip tacacs source-interface ethernet <*portnum*> **| loopback** <*num*> **| ve** <*num*>

Configuring an interface as the source for all RADIUS packets

You can configure the PowerConnect router to use the lowest-numbered IP address configured on a loopback interface, virtual routing interface, or Ethernet port as the source for the RADIUS packets it sends.

For example, to specify an Ethernet port as the interface whose lowest-numbered IP address will be the source address for the RADIUS packets originated from the PowerConnect router, enter the following commands.

```
NetIron(config)# interface ethernet 1/5
NetIron(config-if-e10000-1/5)# ip address 209.157.22.111/24
NetIron(config-if-e10000-1/5)# exit
NetIron(config)# ip radius source-interface ethernet 1/5
```

The commands configure Ethernet port 1/5, assign IP address 209.157.22.111/24 to it, then designate it as the source interface.

Syntax: **[no] ip radius source-interface ethernet** <*portnum*> **| loopback** <*num*> **| ve** <*num*>

Specifying a Simple Network Time Protocol (SNTP) server

The PowerConnect can be configured both as an SNTP server and as an SNTP client. This section describes how to configure the PowerConnect device as an SNTP client, consulting upstream SNTP servers for the current system time and date.

You can configure the device to consult up to 3 SNTP servers to establish the current system time and date. The first server configured will be used unless it becomes unreachable, in which case the device will attempt to synchronize with the other SNTP servers (if any) in the order in which they were configured.

NOTE
While the PowerConnect device does retain time and date information across power cycles, the system time can drift and should ideally be synchronized with a reliable external clock source. Therefore Dell recommends that you use the SNTP feature as described below.

To identify an SNTP server with IP address 208.99.8.95 to act as the clock reference for a PowerConnect, router enter the following command.

```
NetIron(config)# sntp server 208.99.8.95
```

Syntax: **[no] sntp server** { <*ip-address*> | <*hostname*> | **ipv6** <*ipv6-address*> } [<*sntp-version*>] [**authentication-key** <*key-ID*> <*key-string*>]

- The <*sntp-version*> parameter specifies the SNTP version the server is running and can be from 1 – 4. The default is 4. You can configure up to three SNTP servers by entering three separate **sntp server** commands.
- The order in which the SNTP servers are configured is the order in which they are consulted. The server that was configured first is the first server consulted after the poll cycle; the next server will be consulted only if a positive ACK is not received from the first one.

- To specify an IPv6 address for the SNTP server, use the **ipv6** option.
- The **authentication-key** option allows you to configure an authentication key for communication with the SNTP server. The <*key-ID*> is the symmetric key shared with the upstream server, and accepts values from 1 to 4,294,967,295. The <*key-string*> is the authentication string itself, and can take up to 16 characters.

Modification of the authentication key fields is not supported. To change the key ID or key string, remove the time server using the **no sntp server...** command, then reconfigure the server with the new key.

```
NetIron(config)# sntp poll-interval 900
```

Syntax: [no] sntp poll-interval <*1-65535*>

To display information about SNTP associations, enter the following command.

```
NetIron# show sntp associations
  address                 ref clock       st  when  poll    delay     disp
*~10.50.2.121             10.60.2.100      3     4  1800    0.000    0.000
 ~216.218.254.202         CDMA             1   119  1800    0.000    0.000
 ~10.51.3.123             0.0.0.0         16    -1  1800    0.000    0.000
* synced, ~ configured
```

Syntax: show sntp associations

The following table describes the information displayed by the **show sntp associations** command.

TABLE 11 Output from the show sntp associations command

This field...	Displays...
(leading character)	One or both of the following: * Synchronized to this peer ~ Peer is statically configured
address	IP address of the peer
ref clock	IP address of the peer's reference clock, or the reference ID of the external clock source if the peer is stratum 1. Examples of external clock source IDs: GPS, CDMA, WWV (Ft.Collins US Radio 2.5, 5, 10, 15 MHz), CESM (calibrated Cesium clock), etc.
st	NTP stratum level of the peer
when	Amount of time since the last NTP packet was received from the peer. A negative number indicates the system has never received any synchcronization message from the specified server.
poll	Poll interval in seconds
delay	Round trip delay in milliseconds
disp	Dispersion in seconds

To display information about SNTP status, enter the following command.

```
NetIron# show sntp status
Clock is synchronized, stratum = 3, reference clock = 10.50.2.121
precision is 2**-20
reference time is 3478372757.0
clock offset is 144.23966407 msec, root delay is 0.000 msec
root dispersion is 0.000 msec, peer dispersion is 0.000 msec
```

Syntax: show sntp status

The following table describes the information displayed by the **show sntp status** command.

TABLE 12 Output from the show sntp status command

This field...	Indicates...
unsynchronized	System is not synchronized to an NTP peer.
synchronized	System is synchronized to an NTP peer.
stratum	NTP stratum level of the upstream time server
reference clock	IP Address of the peer (if any) to which the unit is synchronized
precision	Precision of this system's clock (in Hz)
reference time	Reference time stamp
clock offset	Offset of clock to synchronized peer
root delay	Total delay along the path to the root clock
root dispersion	Dispersion of the root path
peer dispersion	Dispersion of the synchronized peer

Configuring the device as an SNTP server

You can configure the PowerConnect device to function as an SNTP server to its downstream clients. When using the device as an SNTP server, you can also set it to use its own internal clock as the reference source if an upstream server becomes unavailable.

To use the device as a an SNTP server, enter a command such as the following at the Privileged EXEC level.

```
NetIron(config)# sntp server-mode use-local-clock authentication-key abc123
NetIron(config)# write memory
```

The above example configures the device to operate as an SNTP server with the local clock as a reference backup and an authentication key of “abc123” and writes the configuration changes to memory.

Syntax: [**no**] **sntp server-mode** [**use-local-clock** [**stratum** <*stratum-number*>]] [**authentication-key** <*key-string*>]

- The **use-local-clock** option causes the PowerConnect device to use the local clock as a reference source if an upstream reference source becomes unavailable. The SNTP stratum number is set to 1 by default. You may specify a different stratum number using the **stratum** option; <*stratum-number*> must be between 1 and 15. When the internal clock is serving as the SNTP reference source, the device will use the specified stratum number (or the default value of 1). When it is synchronized with the upstream server, the device will use the upstream server’s stratum number plus 1.
  If you do not include the **use-local-clock** option the device will function as specified by RFC 4330: when the device loses upstream synchronization, it will respond to client SNTP requests with a “kiss-of-death” response (stratum value=0).

NOTE
To enable the **use-local-clock** option, you must set the device internal clock either by SNTP synchronization (see "Specifying a Simple Network Time Protocol (SNTP) server" on page 90) or by using the **clock set** command (see "Setting the system clock" on page 94). Until the internal clock is set, the device will continue to rely exclusively on an upstream SNTP server if one is reachable. If none, the PowerConnect SNTP server is disabled (down).

- To require a code string for authentication of SNTP communication from clients, use the **authentication-key** option and enter a key string of up to 16 characters. When this option is used, authentication parameters are required in clients' SNTP request messages. If authentication fails, the device will reply with stratum 0 and a reference ID code of "CRYP" (cryptographic authentication or identification failed), and messages received without the required parameters will be dropped.

NOTE
Once entered, the authentication key cannot be viewed. Using the **show running-config** command will show output similar to the following when an authentication key has been set:

```
sntp server-mode authentication-key 2 $QHMiR3NzQA=
```

The **2** indicates that the key is encrypted using base-64 encryption; the characters following the 2 are the encrypted authentication string.

NOTE
You cannot enable or disable the **use-local-clock** option (or its stratum number) or change the authentication string when the SNTP server is up. To change these settings after enabling SNTP server mode, you must disable server mode using the command **no sntp server-mode**, then re-enable it with the new parameters.

Displaying SNTP server information

Use the following command to display the status of the SNTP server and its configuration.

```
NetIron# show sntp server-mode
Status            : up
Stratum           : 4
Authentication    : md5
Clock source      : 10.50.2.121
Last upstream sync: 15:55:00 Pacific Sun Jul 5 2009

Last 5 unique responses sent to downstream clients :
Client Address           Reference Time
10.1.50.23               16:10:32 Pacific Sun Jul 5 2009
10.1.52.34               15:50:40 Pacific Sun Jul 5 2009
10.1.50.41               10:22:08 Pacific Fri Jul 3 2009
10.1.50.10               06:21:03 Pacific Fri Jul 3 2009
10.1.50.29               21:17:39 Pacific Fri Jul 2 2009
```

Syntax: show sntp server-mode

TABLE 13 Output from the **show sntp server-mode** command

This field...	Displays...
status	The operational state of the SNTP server. "**Up**" means that the SNTP port is open; "**down**" means that the SNTP port is closed. (If sntp server-mode is disabled, the **show sntp server-mode** command will display the message "SNTP server is not operational.)
stratum	Stratum number of this server. If the PowerConnect is synchronized to an upstream SNTP server, this will show that server's stratum number +1. If the PowerConnect is unsynchronized and using the **use-local-clock** option, this will show the user-specified stratum number (or the default value of "**1**" if no stratum has been configured).
authentication	Authentication key used. If authentication has been configured successfully, this displays "**md5**." If not, it displays "**none**."
clock source	The source of the reference time. When the reference source is an upstream SNTP server, this will show the IP address of the upstream server. When the device internal clock is being used as the reference, this will show "**local-clock**."
last upstream sync	The last upstream time-server synchronization, displayed in timestamp format. This field is not displayed if the time source is the local clock.
last responses sent to clients	The last responses sent to downstream clients (maximum of five unique clients), displayed in reverse chronological order. Each entry shows the IP address of the client and the timestamp sent.

Setting the system clock

In addition to supporting SNTP, the PowerConnect device also allows you to manually set the system clock. Using the **clock set** command starts the system clock with the time and date you specify. The time counter setting is retained across power cycles but is not automatically synchronized with an SNTP server.

NOTE
To synchronize the time counter with your SNTP server time, enter the **sntp sync** command from the Privileged EXEC level of the CLI.

NOTE
Unless you identify an SNTP server for the system time and date, system time is not guaranteed to be reliable.

For more details about SNTP, refer to "Specifying a Simple Network Time Protocol (SNTP) server" on page 90.

To set the system time and date to 10:15:05 on October 15, 2005, enter the following command.

```
NetIron# clock set 10:15:05 10-15-05
```

Syntax: [no] clock set <*hh:mm:ss*> <*mm-dd-yy*> | <*mm-dd-yyyy*>

By default, the PowerConnect router does not change the system time for daylight savings time. To enable daylight savings time, enter the following command.

```
NetIron# clock summer-time
```

Syntax: [no] clock summer-time

Although SNTP servers typically deliver the time and date in Greenwich Mean Time (GMT), you can configure the PowerConnect router to adjust the time for any one-hour offset from GMT or for one of the following U.S. time zones:

- US Pacific (default)
- Alaska
- Aleutian
- Arizona
- Central
- East-Indiana
- Eastern
- Hawaii
- Michigan
- Mountain
- Pacific
- Samoa

The default is US Pacific.

To change the time zone to Australian East Coast time (which is normally 10 hours ahead of GMT), enter the following command.

```
NetIron(config)# clock timezone gmt gmt+10
```

Syntax: [no] clock timezone gmt gmt | us <*time-zone*>

You can enter one of the following values for <*time-zone*>:

- US time zones (**us**): alaska, aleutian, arizona, central, east-indiana, eastern, hawaii, michigan, mountain, pacific, samoa.
- GMT time zones (**gmt**): gmt+12, gmt+11, gmt+10...gmt+01, gmt+00, gmt-01...gmt-10, gmt-11, gmt-12.

DST “change" notice for networks using US time zones

The new Daylight Saving Time (DST) change that went into effect on March 11, 2007 affects networks in the US time zones. Because of this change, your network clock might not be correct. If your network uses US time zones, and it needs to maintain the correct time, you must enable the following command.

```
NetIron(config)# clock timezone us pacific
```

Syntax: [no] clock timezone us {pacific | eastern | central | mountain}

NOTE
This command must be configured on every device that uses the US DST.

To verify the change, use the following command.

```
NetIron(config)# show clock
```

For more information, refer to the Marketing web site.

Creating a command alias

Use the **alias** command to create an alias for a command and to save that alias within the router's configuration.

To create the alias "shro" for the **show ip routes** command, use the following command.

```
NetIron(config)# alias shro = show ip routes
NetIron(config)# write memory
```

Syntax: [no] alias [<*name*> **=** <*command*> **]**

The <*name*> variable is the name that you want to assign to the alias.

The <*command*> variable is the syntax for the command you want to create an alias for.

The **write** memory command is used to save the alias within the configuration.

Removing an alias

You can remove an alias using the **no** version of the alias command as shown in the following.

```
NetIron(config)# no alias shro
```

Alternately, you can use the **unalias** command as shown in the following.

```
NetIron(config)# unalias shro
```

Syntax: [no] unalias

If the alias you try to remove does not exist, the following error will be displayed.

```
NetIron(config)# unalias wrs
Error: Alias wrs does not exist, unalias failed
```

Displaying a list of all configured alias

The following command allows you to display a list of all configured alias.

```
NetIron# alias
#alias
             savemem    write memory
             shro       show ip routes
```

Syntax: [no] alias

Limiting broadcast, multicast, or unknown unicast rates

The PowerConnect router can forward all traffic at wire speed. However, some third-party networking devices cannot handle high forwarding rates for broadcast, multicast, or unknown unicast packets.

The limits are individually configurable for broadcasts, multicasts, and unknown unicasts. You can configure limits globally to apply to each individual inbound interface module. The valid range is 1 – 4294967295 packets per second. The default is 0, which disables limiting.

Limiting broadcasts

To globally limit the number of broadcast packets a PowerConnect router forwards to 100,000 per second, enter the following command at the global CONFIG level of the CLI.

```
NetIron(config)# broadcast limit 100000
NetIron(config)# write memory
```

Syntax: [no] broadcast limit <*number*>

Limiting multicasts

To globally limit the number of multicast packets a PowerConnect router forwards to 120,000 per second, enter the following command at the global CONFIG level of the CLI.

```
NetIron(config)# multicast limit 120000
NetIron(config)# write memory
```

Syntax: [no] multicast limit <*number*>

NOTE
The multicast limit is configured at the global level, but the value you enter applies to each interface module (slot) installed on the device.

Limiting unknown unicasts

To globally limit the number of unknown unicast packets a PowerConnect router forwards to 110,000 per second, enter the following command at the global CONFIG level of the CLI.

```
NetIron(config)# unknown-unicast limit 110000
NetIron(config)# write memory
```

Syntax: [no] unknown-unicast limit <*number*>

NOTE
Only the **unknown-unicast limit** is configured on the global level, but the value you enter applies to each interface module (slot) installed on the device.

Configuring CLI banners

The PowerConnect router can be configured to display a greeting message on users' terminals when they enter the Privileged EXEC CLI level or access the device through Telnet. In addition, a PowerConnect router can display a message on the Console when an incoming Telnet CLI session is detected.

Setting a message of the day banner

You can configure the PowerConnect router to display a message on a user's terminal when he or she establishes a Telnet CLI session. For example, to display the message "Welcome to PowerConnect!" when a Telnet CLI session is established, enter the following.

```
NetIron(config)# banner motd $(Press Return)
Enter TEXT message, End with the character '$'.
Welcome to PowerConnect! $
```

A delimiting character is established on the first line of the **banner motd** command. You begin and end the message with this delimiting character. The delimiting character can be any character except "(double-quotation mark) and cannot appear in the banner text. In this example, the delimiting character is $(dollar sign). The text in between the dollar signs is the contents of the banner. The banner text can be up to 2048 characters long and can consist of multiple lines. To remove the banner, enter the **no banner motd** command.

Syntax: [no] banner <*delimiting-character*> **| [motd** <*delimiting-character*>**]**

NOTE
The **banner** <*delimiting-character*> command is equivalent to the **banner motd** <*delimiting-character*> command.

NOTE
The size of the MOTD banner will be restricted (truncated) to 1850 characters when using an SSH client.

Setting a privileged EXEC CLI level banner

You can configure the PowerConnect router to display a message when a user enters the Privileged EXEC CLI level.

Example

```
NetIron(config)# banner exec_mode # (Press Return)
Enter TEXT message, End with the character '#'.
You are entering Privileged EXEC level
Don't foul anything up! #
```

As with the **banner motd** command, you begin and end the message with a delimiting character; in this example, the delimiting character is # (pound sign). To remove the banner, enter the **no banner exec_mode** command.

Syntax: [no] banner exec_mode <*delimiting-character*>

Displaying a message on the console when an incoming Telnet session Is detected

You can configure the PowerConnect router to display a message on the Console when a user establishes a Telnet session. This message indicates where the user is connecting from and displays a configurable text message.

Example

```
NetIron(config)# banner incoming $(Press Return)
Enter TEXT message, End with the character '$'.
Incoming Telnet Session! $
```

When a user connects to the CLI using Telnet, the following message appears on the Console.

```
Telnet from 209.157.22.63
Incoming Telnet Session!
```

Syntax: [no] banner incoming <*delimiting-character*>

To remove the banner, enter the **no banner incoming** command.

Configuring terminal display

You can configure and display the number of lines displayed on a terminal screen during the current CLI session.

The **terminal length** command allows you to determine how many lines will be displayed on the screen during the current CLI session. This command is useful when reading multiple lines of displayed information, especially those that do not fit on one screen.

To specify the maximum number of lines displayed on one page, enter a command such as the following.

```
NetIron(config)# terminal length 15
```

Syntax: [no] terminal length <*number-of-lines*>

The <*number-of-lines*> parameter indicates the maximum number of lines that will be displayed on a full screen of text during the current session. If the displayed information requires more than one page, the terminal pauses. Pressing the space bar displays the next page.

The default for <*number-of-lines*> is 24. Entering a value of 0 prevents the terminal from pausing between multiple output pages:

Checking the length of terminal displays

The **show terminal** command specifies the number of lines that will be displayed on the screen as specified by the **terminal length**, **page display**, and **skip-page-display** commands. It also shows if the **enable skip-page-display** command has been configured. The **enable skip-page-display** command allows you to use the skip-page-display to disable the configured page-display settings.

```
NetIron(config)# show terminal
Length: 24 lines
Page display mode (session): enabled
Page display mode (global): enabled
```

Syntax: show terminal

Enabling or disabling routing protocols

The Multi-Service IronWare supports the following protocols:

- BGP4

- DVMRP
- IP
- ISIS
- MPLS
- MSDP
- OSPF
- PIM
- RIP
- VRRP
- VRRPE

By default, IP routing is enabled on the PowerConnect router. All other protocols are disabled, so you must enable them to configure and use them.

To enable a protocol on a PowerConnect router, enter **router** at the global CONFIG level, followed by the protocol to be enabled. The following example shows how to enable OSPF.

```
NetIron(config)# router ospf
```

Syntax: [no] router bgp | dvmrp | ospf | pim | rip | vrrp | vrrpe

Displaying and modifying default settings for system parameters

The Multi-Service IronWare has default table sizes for the following parameters. The table sizes determine the maximum number of entries the tables can hold. You can adjust individual table sizes to accommodate your configuration needs:

- MAC address entries
- VLANs supported on a system
- Virtual interfaces
- Spanning tree instances
- RSTP instances
- IP cache size
- ARP entries
- IP routes
- IP ACL filter entries
- L2 ACL entries per ACL table
- Size for management port ACL
- IP subnets per port and per device
- IPv6 Multicast routes
- IPv6 PIM mcache
- Layer 4 sessions supported
- Number of VPLS’s

- VPLS MAC entries
- IP VRF routes
- IPv6 cache
- IPv6 routes
- Number of tunnels
- Number of LAGs
- Configuration file size

The tables you can configure as well the defaults and valid ranges for each table differ depending on the PowerConnect router you are configuring.

NOTE
If you increase the number of subnet addresses you can configure on each port to a higher amount, you might also need to increase the total number of subnets that you can configure on the device.

NOTE
Changing the table size for a parameter reconfigures the device's memory. Whenever you reconfigure the memory on a PowerConnect router, you must save the change to the startup configuration file, then reload the software to place the change into effect.

To display the configurable tables and their defaults and maximum values, enter the following command at any level of the CLI.

FIGURE 1 Output for the Product Name

```

The following table describes the system-max values of the **show default values** command for NetIron MLX Series devices.

TABLE 14 Display of show default values for system parameters

This field...	Displays...
Default	The default value for the system-max element. This value is used in the following conditions: a)There is no system-max configured for the corresponding element. b) If the system-max element configuration is reverted at bootup time (if it is a revertible element).
Maximum	The maximum value that this element can be configured at.
Current	The most current configured value for the system-max element. If the system-max element is configured in the running system, then the value under this column will change to reflect this value. **NOTE:** The new value does not take affect until the node is reloaded.
Actual	The system-max value that is used by the target application of the running system. If system-max elements are reverted at bootup, then only the Actual column is affected. The Application is now using default values and will be displayed in the Actual column. Please refer to the example on the next page for more information. The Current and Bootup values are still configured on the system, and are not affected by the reversion of system-max elements at bootup.
Bootup	The system-max value that was read from the configuration when the system was booting up. If the read values are found to be acceptable, and not reverted, then the values in this column, and in the “Actual” column will have the same values. However, if the values were reverted during bootup, then the values are different for the “Revertible” elements.
Revertible	This column displays which corresponding system-max element is revertible or not. If “Yes” is displayed then the value is changed to a default value. If ‘No” is displayed then there no change to the value.

If system-max elements are reverted at bootup time, then the following message will display on the CLI.

```
NetIron#show default values
...

NOTE: All the Revertible Elements were Reverted During System Bringup.

System Parameters  Default    Maximum    Current    Actual     Bootup   Revertible
mac                  131072     2097152    2097152    131072     2097152    Yes
vlan                   512        4095       512        512        512        No
spanning-tree          32         128        32         32         32         No
rstp                   32         128        32         32         32         No
ip-arp                 8192       65536      65536      65536      65536      No
multicast-route (IPv6) 8192       153600     8192       8192       8192       Yes
pim-mcache (IPv6)      4096       4096       4096       4096       4096       Yes
ip-cache               204800     1048576    524288     204800     524288     Yes
...
```

Information for the configurable tables appears under the columns shown in bold type. To simplify configuration, the command parameter you enter to configure the table is used for the table name.

Example : To increase the capacity of the IP route table

```
NetIron(config)# system-max ip-route 120000
NetIron(config)# write memory
NetIron(config)# exit
NetIron# reload
```

NOTE
If you enter a value that is not within the valid range of values, the CLI will display the valid range for you.

To increase the number of IP subnet interfaces you can configure on each port on a PowerConnect router to 64, enter the following commands.

```
NetIron(config)# system-max ip-subnet-port 64
NetIron(config)# write memory
NetIron(config)# exit
NetIron# reload
```

Syntax: [no] system-max ip-subnet-port <*num*>

The <*num*> parameter specifies the maximum number of subnet addresses per port. The minimum, maximum and default values for this parameter are described in Table 15.

To increase the size of the IP route table, enter the following command.

```
PowerConnect(config)# system-max ip-static-route 400000
```

Syntax: [no] system-max ip-route <*num*>

The minimum, maximum and default values for this parameter are described in Table 15.

NOTE
You must reload the software for the change to take effect.

Enabling or disabling layer 2 switching

By default, PowerConnect devices supports routing over layer 2 switching. You can enable layer 2 switching globally or on individual port using the **no route-only** command.

The **no route-only** and **route-only** commands prompts you for whether or not you want to change the "route-only" behavior. You must enter **y** if you want to proceed or **n** if you do not. The prompt is displayed as shown in the following examples of the **no route-only** and **route-only** commands.

To enable Layer 2 switching globally, enter the following.

```
NetIron(config)# no route-only
This will change the route-only behavior at the global level.
Are you sure? (enter 'y' or 'n'): y
Global 'route-only' committed.
```

To globally disable Layer 2 switching on a PowerConnect router and return to the default (route-only) condition, enter commands such as the following:

```
NetIron(config)# route-only
This will change the route-only behavior at the global level.
Are you sure? (enter 'y' or 'n'): y
Global 'no route-only committed.
```

Syntax: [no] route-only

To enable Layer 2 switching only on a specific interface, go to the Interface configuration level for that interface, and add the **no route-only** command. The following commands show how to enable Layer 2 switching on port 3/2.

```
NetIron(config)# interface ethernet 3/2
NetIron(config-if-e10000-3/2)# no route-only
```

Syntax: [no] route-only

To re-enable the default **route-only** condition on port 3/2, enter the **route-only** command as shown.

```
NetIron(config-if-e10000-3/2)# route-only
```

The default route-only condition, unknown unicast packets are not sent to the CPU and are dropped locally by the hardware.

Configuring static MAC addresses

You can assign static MAC addresses to ports of a PowerConnect router.

You can manually input the MAC address of a device to prevent it from being aged out of the system address table, to prevent traffic for a specific device, such as a server, from flooding the network with traffic when it is down, and to assign higher priorities to specific MAC addresses.

Static MAC addresses are configured within a specified VLAN including the default VLAN 1. Optionally you can specify a port priority (QoS).

The default and maximum configurable MAC table sizes can differ depending on the device. To determine the default and maximum MAC table sizes for your device, display the system parameter values. Refer to "Displaying and modifying default settings for system parameters" on page 100.

The ability of the CAM to store depends on the following:

- The number of source MAC address being learned by the CAM.
- The number of destination MAC addresses being forwarded by the CAM
- The distribution of the MAC address entries across ports. For example, it one port is learning all the source MAC addresses, the available of the CAM for that port will be depleted.

Example

In the following example, a static MAC address of 1145.5563.67FF with a priority of 7 is assigned to port 2 of module 1 in VLAN 200.

```
NetIron(config)# vlan 200
NetIron(config)# static-mac-address 1145.5563.67FF e 1/2 priority 7
```

Syntax: [no] static-mac-address <*mac-addr*> **ethernet** <*portnum*> **[priority** <*number*>**]**

The <*mac-addr*> variable specifies the MAC address that you assigning.

The **portnum** variable specifies the Ethernet port that the MAC address is being assigned to.

Using the **priority** option, you can assign a value to the <*number*> variable of 0 – 7

Changing the MAC age time

The MAC age time sets the aging period for ports on the device, defining how long (how many seconds) a port address remains active in the address table.

To change the aging period for MAC addresses from the default of 300 seconds to 600 seconds.

```
NetIron(config)# mac-age-time 600
```

Syntax: [no] mac-age-time <*age-time*>

The <*age-time*> can be 0 or a number from 67 – 65535. The zero results in no address aging. The default is 300 (seconds).

Configuring static ARP entries

When you create a static ARP entry, the PowerConnect router automatically creates a static MAC entry.

NOTE
To delete the static MAC entry, you must delete the static ARP entry first.

Configuring system max values

The system max values for the several system parameters of the NetIron MLX Series devices are described in Table 15

TABLE 15 System max values for NetIron MLX Series routers

Parameter	Minimum value for MLXe	Maximum value for MLXe	Default value for MLXe
config-file-size	2097152	16777216	8388608
gre-tunnels	1	8192	256
hw-flooding	0	4095	0
ifl-cam	0	81920	0
ip-arp	2048	65536	8192
ip-cache	8192	524288	102400
ip-filter-system	1024	40960	4096
ip-route	4096	524288	102400
ipv4-mcast-cam	0	32768	4096
ip-subnet-port	24	128	24
ip-vrf-route	128	262143	5120
ipv6-cache	8192	102400	32768
ipv6-mcast-cam	0	8192	1024
ipv6-route	4096	114688	32768
l2-acl-table-entries	64	256	64

TABLE 15 System max values for NetIron MLX Series routers (Continued)

Parameter	Minimum value for MLXe	Maximum value for MLXe	Default value for MLXe
mac	4000	1048576	32768
mgmt-port-acl-size	1	100	20
receive-cam	512	8192	1024
rstp	1	128	32
session-limit	1024	40960	8192
spanning-tree	1	128	32
virtual-interface	40	4095	255
vlan	2	4095	512
vpls-mac	32	262144	2048
vpls-num	512	4096	512

To configure system-max values, use the following command.

Syntax: [no] system-max config-file-size | gre-tunnels | hw-flooding | ip-arp | ip-cache |ip-filter-sys | ip-route | ip-static-arp | ipv4-mcast-cam | ip-subnet-port | ip-tunnels| ip-vrf| ip-vrf-route | ipv6-cache | ipv6-mcast-cam | ipv6-route | l2-acl-table-entries |ifl-cam | mac | mgmt-port-acl-size | receive-cam | rstp | session-limit | spanning-tree | trunk-num | virtual-interface | vlan | vpls-mac | vpls-num

The **gre-tunnels** parameter sets the maximum number of GRE tunnels.
For minimum, maximum and default values for this parameter refer to Table 15.

The **config-file-size** parameter sets the allowed running and startup-config file sizes. Refer to the appropriate table for your platform. For minimum, maximum and default values for this parameter refer to Table 15.

The **hw-flooding** parameter sets the maximum number of hardware flooding entries.
For minimum, maximum and default values for this parameter refer to Table 15. T

NOTE
The dynamic growth of the protocol and flooding sub-partitions in the L2 CAM to grant them a higher priority has been enhanced. Because of this enhancement, the **system-max hw-flooding** command is no longer required and has been retired from the software. If you already have the **system-max hw-flooding** command in your configuration, it will automatically be upgraded to the current functionality and the command will be deleted from the configuration file.

The **ifl-cam** parameter sets the maximum number of Internal Forwarding Lookup Indentifiers. These are used when configuring a Local VLL for Dual Tagging. The default value for the **ifl-cam** parameter is 8K. The maximum values for this parameter are different depending on which CAM partition you have configured on your system. For minimum, maximum and default values by CAM partition for this parameter, refer to Table 16.

The **ip-arp** parameter sets the maximum number of ARP entries.
For minimum, maximum and default values for this parameter refer to Table 15.

The **ip-cache** parameter sets the maximum size of the IP cache.
For minimum, maximum and default values for this parameter refer to Table 15.

The **ip-filter-sys** parameter sets the maximum number of IP ACL entries.
For minimum, maximum and default values for this parameter refer to Table 15.

The **ip-route** parameter sets the maximum number of IP Route entries.
For minimum, maximum and default values for this parameter refer to Table 15.

NOTE
There is no need to configure a system-max value for static ARP entries.

The **ip-static-arp** parameter sets the maximum number of static ARP entries.
For minimum, maximum and default values for this parameter refer to Table 15.

The **ipv4-mcast-cam** parameter allows you to configure the maximum CAM size for an IPv4 multicast group. For minimum, maximum and default values for this parameter refer to Table 4.5. To configure the CAM size of an IPv4 multicast group, refer to "Configuring CAM size for an IPv4 multicast group" on page 109.

The **ip-subnet-port** parameter sets the maximum number of IP subnets per port.
For minimum, maximum and default values for this parameter refer to Table 15.

The **ip-vrf-route** parameter sets the maximum number of IP VRF routes per VRF instance.
For minimum, maximum and default values for this parameter refer to Table 15.

The **ipv6-cache** parameter sets the maximum size of the IPv6 cache.
For minimum, maximum and default values for this parameter refer to Table 15.

The **ipv6-mcast-cam** parameter allows you to configure the maximum CAM size for an IPv6 multicast group. For minimum, maximum and default values for this parameter refer to Table 14. To configure the CAM size of an IPv6 multicast group, refer to "Configuring CAM size for an IPv6 multicast group" on page 110.

The **ipv6-route** parameter sets the maximum number of IPv6 routes.
For minimum, maximum and default values for this parameter refer to Table 15.

NOTE
The **system-max ipv6-route** command can be configured with a maximum value of 114688 on the Product Name, however the PowerConnect system will only support a maximum value of 114687 for ipv6 routes.

The **l2-acl-table-entries** parameter sets the maximum number of layer-2 ACL entries per ACL table.
For minimum, maximum and default values for this parameter refer to Table 15.

The **mac** parameter sets the maximum number of MAC entries.
For minimum, maximum and default values for this parameter refer to Table 15.

The **mgmt-port-acl-size** parameter sets the maximum size for a management port ACL.
For minimum, maximum and default values for this parameter refer to Table 15.

The **receive-cam** parameter sets the maximum number of IP Receive ACL software CAM entries.
For minimum, maximum and default values for this parameter refer to Table 15.

The **rstp** parameter sets the maximum number of RSTP instances.
For minimum, maximum and default values for this parameter refer to Table 15.

The **session-limit** parameter sets the maximum number of sessions.
For minimum, maximum and default values for this parameter refer to Table 15.

The **spanning-tree** parameter sets the maximum number of spanning-tree instances. For minimum, maximum and default values for this parameter refer to Table 15.

The **virtual-interface** parameter sets the maximum number of virtual interfaces. For minimum, maximum and default values for this parameter refer to Table 15.

The **vlan** parameter sets the maximum number of VLANs. For minimum, maximum and default values for this parameter refer to Table 15.

The **vpls-mac** parameter sets the maximum number of VPLS MAC Entries. For minimum, maximum and default values for this parameter refer to Table 15.

The **vpls-num** parameter sets the maximum number of Virtual Private LAN Services (VPLS). For minimum, maximum and default values for this parameter refer to Table 15

TABLE 16 System max **ifl-cam** values available by CAM profile on PowerConnect B-MLXe

CAM profile	Minimum value	Maximum value	Default value
Default	0	57344	8192
ipv4	0	114688	8192
ipv6	0	16384	8192
l2-metro	0	114688	8192
mpls-l3vpn	0	114688	8192
mpls-vpls	0	114688	8192
multi-service	0	49152	8192
multi-service-2	0	81920	8192
vpn-vpls	0	114688	8192
ipv4-vpn	0	114688	8192
l2-metro-2	0	114688	8192
mpls-l3vpn-2	0	114688	8192
mpls-vpls-2	0	114688	8192
ipv4-ipv6	0	114688	8192
ipv4-vpls	0	114688	8192
ipv4-ipv6-2	0	81920	8192

Configuring CAM size for an IPv4 multicast group

To configure the CAM size of an IPv4 multicast group, enter the following command.

```
NetIron(config)# system-max ipv4-mcast-cam
```

Syntax: [no] system-max [ipv4-mcast-cam]

By default, no system-max parameter is configured.

The **ipv4-mcast-cam** parameter allows you to specify the maximum CAM size you want for an IPv4 multicast group.

The **decimal** parameter specifies the range that is supported for configuring the CAM size. On the PowerConnect B-MLXe, the minimum value supported is 0, and the maximum value supported is 32768. The default value is 4096.

Upon configuration, the NetIron system will verify the input value with the amount of CAM resources that are available. If the PowerConnect system is unable to allocate requested space, it will display the following error message on the Product Name.

```
NetIron(config)# system-max ipv4-mcast-cam 32768
Error - IPV4 Multicast CAM (32768) exceeding available CAM resources
Total IPv4 ACL CAM:             49152(Raw Size)
IPv4 Receive ACL CAM:           2048(Raw Size)
IPv4 Source Guard CAM:          0(Raw Size)
Reserved IPv4 Rule ACL CAM:     1024(Raw Size)
Available IPv4 Multicast CAM:   46080(Raw Size)  23040(User Size)
```

If there is not enough CAM resources available to change the cam-partition profile from IPv4 to IPv6, the following message is displayed.

```
NetIron(config)# cam-partition profile ipv4-ipv6
Error - IPv4 Receive ACL CAM (1024) exceeding available CAM resources
Total IPv4 ACL CAM:                 49152(Raw Size)
    IPv4 Multicast CAM:             65536(Raw Size)
    IPv4 Source Guard CAM:          0(Raw Size)
    Reserved IPv4 Rule ACL CAM:     1024(Raw Size)
    Available IPv4 Receive ACL CAM: 0(Raw Size) 0(User Size)
Error - Failed to select this CAM profile
```

This error message is also displayed on the Product Name.

After you issue the system-max command, with ipv4-mcast-cam parameter included, additional information will display on the Product Name as shown in the following example.

```
NetIron(config)#system-max ipv4-mcast-cam 60000
Reload required. Please write memory and then reload or power cycle.
Failure to reload could cause system instability on failover.
Newly configured system-max will not take effect during hitless-reload.
```

NOTE
You must write this command to memory and perform a system reload for this command to take effect.

Configuring CAM size for an IPv6 multicast group

To configure the CAM size of an IPv6 multicast group, enter the following command.

```
NetIron(config)# system-max ipv6-mcast-cam
```

Syntax: [no] system-max [ipv6-mcast-cam]

By default, no system-max parameter is configured.

The **ipv6-mcast-cam** parameter allows you to specify the maximum CAM size you want for an IPv6 multicast group.

The **decimal** parameter specifies the range that is supported for configuring the CAM size. On the Product Name, the minimum value supported is 0, and the maximum value supported is 8192. The default value is 1024.

Upon configuration, the NetIron system will verify the input value with the amount of CAM resources that are available. If the PowerConnect system is unable to allocate requested space, it will display the following error messages on the Product Name:

On the Product Name.

```
NetIron MLX(config)#system-max ipv6-mcast-cam 8000
Error - IPV6 Multicast CAM (8000) exceeding available CAM resources
Total IPv6 ACL CAM: 16384(Raw Size)
Reserved IPv6 Rule ACL CAM: 1024(Raw Size)
Available IPv6 Multicast CAM: 15360(Raw Size) 1920(User Size)
```

After you issue the system-max command, with ipv6-mcast-cam parameter included, additional information will display on the Product Name as shown in the following example.

```
NetIron MLX(config)#system-max ipv6-mcast-cam 1000
Reload required. Please write memory and then reload or power cycle.
Failure to reload could cause system instability on failover.
Newly configured system-max will not take effect during hitless-reload.
```

NOTE
You must write this command to memory and perform a system reload for this command to take effect.

Configuring profiles with a zero-size IPv4 or IPv6 ACL

When a profile is configured to a zero-size IPv4 or IPv6 ACL, the minimum value of 512 for IPv4, and the minimum value of 128 for IPv6 is disabled.

If the system-max value for multicast is configured, and you select a value of 0 for IPv4 or IPV6 ACL, the system-max value will be ignored. There is minimal checking for errors. The following warning message is displayed.

```
NetIron MLXe-MLX(config)#cam-partition profile mpls-vpls-2
Warning - Changing to a profile with zero Ipv6 ACL CAM size, ignoring system-max
value check and minimum-guarantee checks.
Reload required. Please write memory and then reload or power cycle.
Failure to reload could cause system instability on failover.
Newly configured system-max will not take effect during hitless-reload.
```

NOTE
You must write this command to memory and perform a system reload for this command to take effect.

The system-max value is retained in the configuration so that it can be reused later when you want to change the CAM profile.

Maintaining system-max configuration with available system resources

When system-max values are configured, the PowerConnect system checks for available system resources. The system resources are required in order to maintain dynamic memory allocation. System-max values are checked at the configuration time, and at the bootup time. If there are insufficient system resources available on the Management Module, this will cause the configuration to be rejected during card bootup. On the Interface Module, insufficient system resources will lead to failure in booting up the card.

Configuration time

When system-max values are configured, the Management Module calculates the memory required to accept the value. The resulting value is checked against the Known-Available-Memory value, and calculated against the Highest Required Memory value for both the Management Module and the Interface Module.

The Known-Available-Memory is a value with the Lowest Supported Available Memory on a node. For example, if a node can accept a 1 Gigabyte LP, and a 512 MB LP, then the 512 MB LP will be used. The Highest Required Memory is a value with most amount of memory available on a node. For example, if a node has both 2 PPCR LP, and 1 PPCR LP, then the 2 PPCR LP will be used.

If the new system-max value is accepted, then the configuration will also be accepted. The following information will display.

```
NetIron(config)#system-max mac 4000
Reload required. Please write memory and then reload or power cycle.
Failure to reload could cause system instability on failover.
Newly configured system-max will not take effect during hitless-reload.
```

NOTE
You must write this command to memory and perform a system reload for this command to take effect.

If the new system-max value is not accepted, then the configuration is rejected. The following error message is printed on the console.

```
NetIron(config)# system-max ipv4 10000
ERROR: Configured System-max value cannot be accommodated.
```

Bootup time

At bootup time, the Management Module will repeat the same process as done in the Configuration time. The Management Module calculates the memory required to accept the system-max configuration. The resulting value is checked against the Known-Available-Memory value for both the Management Module and the Interface Module.

After the new system-max value is configured, there are three possible configuration outcomes. The three possible configuration outcomes are described below.

1. The configuration can be accommodated, but leaves only 10% of Available Memory

   In this configuration, a check is made against 90% of Available Memory. If the difference between the Required Available Memory and the Available Memory is less than 10% of Available Memory, then the configuration is accepted. The following warning message is displayed on the console if it affects the Management Module or Interface Module.

   The following warning message is displayed on the Management Module.

   ```
   WARNING: Configured System-max Leaves less than 10 percent Free Memory
   Available on MP.
   ```

   The following warning message is displayed on the Interface Module.

   ```
   WARNING: Configured System-max Leaves less than 10 percent Free Memory
   Available on LP.
   ```

   A syslog message showing the required memory versus the available memory is generated, and a similar warning message is displayed on the Management Module and Interface Module as shown in the following example.

```
NetIron# show log
…
Jan 17 22:55:55:N: WARN: Configured System-max Leaves less than 10 percent Free
Memory Available on MP (162529285 req vs 1625292800 available)
Jan 17 22:55:55:N: WARN: Configured System-max Leaves less than 10 percent Free
Memory Available on LP (162529285 req vs 1625292800 available)
```

NOTE
When the system is booted up again, the percent of free memory is discretionary and is only an estimate.

NOTE
Even if all elements are configured with the maximum allowed value, you may not see the reversion of system-max values that occur on any given Interface Module.

NOTE
Notifications and traps are sent with the same message.

2. The configuration can be easily accommodated.

   In this configuration, the Management Module continues to use the configured system-max value, and send the same value to the installed Interface Modules.

3. The configuration cannot be accommodated.

   If the configured system-max value cannot be used, the Management Module will locate the elements that can be reverted to a default value. These system-max elements will revert to a default value, and the following message will display on the console.

   ```
   WARN: Configured System-max cannot be accommodated. Resetting revertible
   elements to default values.
   ```

A syslog message is generated, and a similar warning message is displayed on the Management Module and Interface Module as shown in the following example.

```
NetIron# show log
…
Jan 17 22:55:55:N: WARN: Configured System-max cannot be accommodated on MP
(1625292801 req vs 1625292800 available). Resetting revertible elements to
default
values.
Jan 17 22:55:55:N: WARN: Configured System-max cannot be accommodated on LP
(1625292801 req vs 1625292800 available). Resetting revertible elements to
default
values.
```

NOTE
Once the system-max have been reverted, a user might not be able to configure any system-max until configuration for some or all of the revertible system-max elements is removed using "no system-max" CLI.

NOTE
Notifications and traps are sent with the same message.

The following tables show which elements are revertible (Yes or No) in each element category.

L2 elements

TABLE 17 L2 elements

L2 elements	Revertible: yes or no
Mac	yes
Vlan	no
Spanning-tree	no
Rstp	no

IPv6 MCAST CAM	no
SERVER_TRUNKS	no
CONFIG_FILE_SIZE	no

Monitoring dynamic memory allocation

After a configured system-max value is accepted, it is possible that the dynamic memory allocation may fail in a running system. To monitor the amount of available memory on the Management Module and the Interface Module, a timer will check the memory every 10 seconds. If the available memory falls below 5 percent of the total installed memory, the timer will log the following warning message.

```
NetIron# show log
…
Jan 17 22:55:55:N: WARN: Current Total Free Memory on MP is below 5 percent of
Installed Memory.
…
Jan 17 23:53:55:N: WARN: Current Total Free Memory on LP 8 is below 5 percent of
Installed Memory.
```

The warning message is displayed at a frequency of 1 log per 5 minutes.

NOTE
Notifications and traps are sent.

When the memory allocation fails, an alert message is logged immediately. The alert message is displayed at a frequency of 1 log per 5 minutes. The following example below displays an alert message on the Management Module and the Interface Module.

```
NetIron# show log
…
Jan 17 22:55:55:A: ALERT: Failed to allocate memory on MP
…
Jan 17 23:52:55:A: ALERT: Failed to allocate memory on LP 8
…
```

The NULL value is returned to the calling routine. The calling routine will decide how to proceed after the memory allocation fails.

NOTE
Notifications and traps are sent.

At any time, you can display the status of all recorded memory that is available on the Management Module by entering the **show memory** command. The amount of available memory is displayed in percentage values.The following example displays a show memory output on a Management Module.

```
NetIron# show memory
==========================================================================
NetIron MLX active MP slot 33:
Total SDRAM         :  1073741824 bytes

```

Switch fabric fault monitoring

With this feature, you can display information about the current status of links between the switch fabric modules (SFM) and interface modules in a PowerConnect B-MLXe chassis. This feature also provides log messages to the console when there is a change in the “UP” or “DOWN” status of links to the SFM and when an individual fabric element (FE) cannot be accessed by the management module. The router can also be configured to automatically shut down an SFM when failure is detected. The following sections describe the capabilities of this feature.

Displaying switch fabric information

You can display information about the current status of links between the SFMs and interface modules in a PowerConnect B-MLXe chassis using the following command. Each line represents a link between an SFM and an interface module (LP).

```
NetIron#show sfm-links all
 SFM#/FE# | FE link#  | LP#/TM# | TM link#  | link state
----------+-----------+---------+-----------+---------
  2 / 1   |    32     | 3 / 1   |    13     |      UP
  2 / 1   |    31     | 3 / 2   |    01     |      UP
  2 / 1   |    11     | 3 / 1   |    01     |      UP
  2 / 1   |    12     | 3 / 2   |    13     |      UP

  2 / 3   |    32     | 3 / 1   |    19     |      UP
  2 / 3   |    31     | 3 / 2   |    07     |      UP
  2 / 3   |    11     | 3 / 1   |    07     |      UP
  2 / 3   |    12     | 3 / 2   |    19     |      UP

  3 / 1   |    32     | 3 / 1   |    16     |      UP
  3 / 1   |    31     | 3 / 2   |    04     |      UP
  3 / 1   |    11     | 3 / 1   |    04     |      UP
  3 / 1   |    12     | 3 / 2   |    16     |      UP

  3 / 3   |    32     | 3 / 1   |    22     |      UP
  3 / 3   |    31     | 3 / 2   |    10     |      UP
  3 / 3   |    11     | 3 / 1   |    10     |      UP
  3 / 3   |    12     | 3 / 2   |    22     |      UP

WARN: LP 3 has 8 links up, less than minimum to guarantee line rate traffic
forwarding
```

Syntax: show sfm-links <*sfm-number*> **| all [errors]**

The <*sfm-number*> variable specifies an SFM that you want to display link information for.

The **all** option displays link information for all SFMs in the chassis.

The **errors** option only displays information for SFM links that are in the DOWN state.

The output of this command can also be filtered using an output modifier. To use an output modifier, type a vertical bar (**|**) followed by a space and one of the following parameters:

- **begin** - begin output with the first matching line
- **exclude** - exclude matching lines from the output
- **include** - include only matching lines in the output

A warning statement is sent if the number of operational links falls below the minimum threshold. This warning is displayed to warn users that the line rate traffic will not be maintained.

The **show sfm-links** command displays the following information.

TABLE 21 CLI display of SFM link information

This field...	Displays...
SFM#	The switch fabric module number.
FE#	The FE number.
FE link#	The number of the interconnect between the SFM and the FE.
LP#	The slot number where the Interface module (LP) is installed.
TM#	The number of the traffic manager used in the link.
TM link#	The link number on the traffic manager.
link state	The link state is either: UP – In an operating condition DOWN – In a non-operational condition

Displaying switch fabric module information

To display the state of all switch fabric modules in the chassis, enter the following command at any level of the CLI.

```
NetIron> show module
M1 (upper): NI-MLX-MR Management Module Active
M2 (lower): NI-MLX-MR Management Module Standby (Ready State)
F1: NI-X-SF Switch Fabric Module Powered off (By Health Monitoring)
F2:
F3:
F4: NI-X-HSF Switch Fabric Module Active
...
```

Syntax: show module

The **show module** command displays the modules currently connected to the chassis and their state. For switch fabric modules, the command shows “Active” if the module is operational or “Powered off” and the reason for the shutdown.

Powering a switch fabric link on or off manually

To manually power on a switch fabric link, use a command such as the following.

```
NetIron# power-on snm-link sfm 3 fe 3 link 37
```

To manually power off a switch fabric link, use a command such as the following.

```
NetIron# power-off snm-link sfm 3 fe 3 link 37
```

Syntax: [no] power-on snm-link sfm <*sfm-number*> **fe** <*fe-number*> <*link-number*>

Syntax: [no] power-off snm-link sfm <*sfm-number*> **fe** <*fe-number*> <*link-number*>

Powering a switch fabric module off automatically on failure

To configure the router to automatically power off a switch fabric module (SFM) or high speed switch fabric module (hSFM) on which an access error has been detected, enter the following command at the CONFIG level of the CLI.

```
NetIron(config)# system-init fabric-failure-detection
```

Syntax: [no] system-init fabric-failure-detection

NOTE
You must restart the router for automatic SFM shutdown to take effect.

Once you have configured automatic SFM shutdown on the router and restarted it, the management module will automatically detect access failure (see "Access failure messages" on page 120) and shut down the unresponsive SFM. You can restart the SFM at any time (manually, by removing and re-inserting the module, or by initiating a system restart), but if another access error is detected, the management module will shut the SFM down again. If an SFM is automatically powered down, SFM power-off status (and the associated reason) are synced to the standby management module, and in the event of failover the standby module will keep the faulty SFM powered off.

Switch fabric log messages

Information about the state of each switch fabric module and whether it can be accessed by the Management Module is also provided in the form of syslog messages.

Link up/down messages

The Switch Fabric modules (SFM) in an PowerConnect chassis send a log message when they first become operational or when they change state between "UP" and "DOWN". The following is an example of the message sent when a link first becomes operational (UP) or when it changes state from non-operational (DOWN) to operational (UP).

```
Apr  6 10:57:20:E: Fabric Monitoring Link Up : SFM 3/FE 3/Link 37, LP 5/TM 1
```

The following is an example of the message sent when a link is detected going from operational (UP) to non-operational (DOWN).

```
Apr  6 10:56:00:E: Fabric Monitoring Link Down : SFM 3/FE 3/Link 37, LP 5/TM 1
```

Once a link had been detected as going down, it is automatically shut down by the Multi-Service IronWare software. The following is an example of the message sent when a link is either brought down automatically or manually using the command described in "Powering a switch fabric link on or off manually" on page 118.

```
Apr  6 10:56:00:E: Fabric Monitoring Link Admin Shut Down : SFM 3/FE 3/Link 37, LP
5/TM 1
```

This contents of the message are defined as described in the following.

`Apr  6 10:57:20:` – The time that the link changed state.

`Fabric Monitoring Link Up` – the link went "UP"
`Fabric Monitoring Link Down` – the link went "DOWN"

`SFM 3` – The switch fabric module (SFM) number

`FE 3` – The Fabric Element number

`Link 37` – The number of the interconnect between the SFM and the FE

`LP 5` – The slot number where the Interface Module (LP) is installed.

`TM 1` – The number of the traffic manager (TM) used in the link.

Access failure messages

The management module attempts to access each fabric element for every poll period (1 second by default). If the number of access failures in a poll window (default 10 seconds) exceeds the threshold (3 by default), the management module sends a log message similar to the following:

```
Apr 6 20:33:57:A:System: Health Monitoring: FE access failure detected on SFM 2/FE
1
```

The contents of the message are defined as described in the following.

`Apr 6 20:33:57:` – the time at which the error threshold was exceeded

`FE access failure detected` – the management module failed to access the specified FE

`SFM 2` – the switch fabric module (SFM) number

`FE 1`– the Fabric Element (FE) number

If the router has been configured to shut down a switch fabric module when failure is detected (see"Powering a switch fabric module off automatically on failure" on page 119), the management module will shut down the failed switch fabric module, then send a log message similar to the following:

```
Oct 4 20:33:57:A:System: Health Monitoring: Switch fabric 2 powered off due to
failure detection
```

The message above indicates that a failure was detected in attempting to access switch fabric module 2, and the module was powered off on October 4th at 20:33:57.

Switch fabric utilization monitoring

With this feature, you can monitor the percentage of the total bandwidth used on the SFM for the timing intervals of 1 sec, 5 sec, 1 min, and 5 min. For example, to display bandwidth usage on all SFMs on the device, enter the following command.

```
NetIron#show sfm-utilization all
SFM#2
----------+----------+---------+----------+---------
last 1 second utilization = 0.4%
last 5 seconds utilization = 0.3%
last 1 minute utilization = 0.1%
last 5 minutes utilization = 0.0%
SFM#3
----------+----------+---------+----------+---------
last 1 second utilization = 0.4%
last 5 seconds utilization = 0.4%
last 1 minute utilization = 0.1%
last 5 minutes utilization = 0.0%
```

To display bandwidth usage on one SFM, enter the following command.

```
NetIron#show sfm-utilization 2
SFM#2
----------+----------+---------+----------+---------
last 1 second  utilization = 0.4%
last 5 seconds utilization = 0.3%
last 1 minute  utilization = 0.1%
last 5 minutes utilization = 0.0%
```

Syntax: show sfm-utilization [<*sfm-number*> **| all]**

The <*sfm-number*> variable specifies an SFM that you want to utilization information for.

The **all** option displays utilization information for all SFMs in the chassis.

Verifying an image checksum

Use the **image-checksum** command to verify the checksum of the application, boot, or monitor images that are saved in code flash and PCMCIA cards.

To check a monitor image, use the following command.

```
NetIron# image-checksum monitor
OK
```

Syntax: [no] image-checksum <*file-name*>

The <*file-name*> variable specifies the image file that you want to verify the checksum for.

The following output can be generated by this command

TABLE 22 Output from image-checksum command

Output	Description
File not found	The router failed to locate the specified file.
Failed to read file	The router failed to obtain the file length from the file system.
Not an image file	The specified file is not an image file.
File read failed	The specified file's actual length is different form the file length stored in the file system.
Checksum failed	The image has a checksum error.
OK	The checksum has been verified for the specified image file.

Displaying information for an interface for an Ethernet port

To display information for a show interface for an ethernet port, enter the following command at any CLI level.

```
NetIron# show interface ethernet 9/1
GigabitEthernet2/3 is up, line protocol is up
  STP Root Guard is disabled, STP BPDU Guard is disabled
  Hardware is GigabitEthernet, address is 0012.f298.4900 (bia 0012.f298.492a)
  Configured speed auto, actual 1Gbit, configured duplex fdx, actual fdx
 Member of VLAN 1 (untagged), 5 L2 VLANS (tagged), port is in dual mode (default
vlan), port state is Forwarding
  STP configured to ON, Priority is level0, flow control enabled
  Priority force disabled, Drop precedence level 0, Drop precedence force disabled
  arp-inspection-trust configured to OFF
  mirror disabled, monitor disabled
  Not member of any active trunks
  Not member of any configured trunks
  Port name is ->7.blade1.shelf1.access.aprd
  MTU 1544 bytes, encapsulation ethernet
  300 second input rate: 1509512 bits/sec, 713 packets/sec, 0.15% utilization
  300 second output rate: 1992071 bits/sec, 751 packets/sec, 0.20% utilization
  712896623 packets input, 204984611768 bytes, 0 no buffer
  Received 1315502 broadcasts, 53313 multicasts, 711527808 unicasts
  0 input errors, 0 CRC, 0 frame, 0 ignored
  0 runts, 29433839 giants
  NP received 712896745 packets, Sent to TM 712839428 packets
  NP Ingress dropped 57317 packets
  796106728 packets output, 366570033985 bytes, 0 underruns
  Transmitted 2045784 broadcasts, 32330616 multicasts, 761730328 unicasts
  0 output errors, 0 collisions
  NP transmitted 796106833 packets, Received from TM 796534170 packets
```

Syntax: show interface [ethernet <*slot-port*> **[to** <*slot-port*> **]]**

You can display information for all ports in a router by using the **show interface** command without options, or use the **ethernet** <*slot-port*> option to limit the display to a single port, or add the **to** <*slot-port*> option for a range of ports.

Displaying the full port name for an Ethernet interface

To display the full port name for an ethernet interface using the CLI, enter the following command..

```
NetIron# show interface brief wide
Port  Link L2 State  Speed Tag MAC            Name
2/1   Up   Forward   10G   No  0012.f2f7.0230 port-connected-to-chicago
2/2   DisabNone      None  No  0012.f2f7.0231
2/3   DisabNone      None  No  0012.f2f7.0232
2/4   DisabNone      None  No  0012.f2f7.0233

Port  Link L2 State  Speed Tag MAC            Name
mgmt1 Up   Forward   100M  Yes 0012.f2f7.0200

Port  Link L2 State  Speed Tag MAC            Name
lb1   Up   N/A       N/A   N/A N/A
NetIron#
```

Syntax: show interface brief wide

TABLE 23 Display of show interface ethernet port

This field...	Displays...
<*Module type*> <*Port#*> is <*State*>	The <*module type*> variable specifies a type of interface module, such as 10GigabitEthernet. The <*port#*> variable specifies the port number for the interface module. The <*state*> variable if the interface module is up or down.
Line protocol is <*status*>	The <*status*> variable specifies if the line protocol is up or down. If the interface is down due to Remote Fault, the reason is indicated as: "(remote fault)". If a port is down because of a Local Fault, the reason is indicated as: "(local fault)".
STP Root Guard is <*status*>	The <*status*> variable specifies if the STP Root Guard is enabled or disabled.
STP BPDU Guard is <*status*>	The <*status*> variable specifies if the STP BPDU Guard is enabled or disabled.
Hardware is <*module type*>	The <*module type*> variable specifies a type of interface module, such as <#>GigabitEthernet.
Address is <*MAC- address*>	The <*MAC- address*> variable specifies the MAC addess of the port.
Configured speed and actual speed	The speed that the module has been configured to operate at, and the actual speed it is currently operating at.
Configured port speed and actual duplex	The port capacity that the module has been configured to operate at, and the actual speed it is currently operating at.
Member of <*VLAN #*> (untagged) <*port#*> L2 VLANS (tagged) Port is in <dual mode/untagged/tagged> mode Port state is <*status*>	The <*VLAN#*> (untagged) variable specifies a port that is a member of only 1 VLAN. The <*port#*> L2 VLANS (tagged) variable specifies a port that is a member of multiple ports and untagged. A port is in <*dual- mode*> specifies member VLAN ports as untagged and tagged. The default mode is dual-mode. The <*status*> variable identifies the flow of traffic as forwarding or disabled.
STP configured to <*status*> Priority level Flow control <*status*>	The <*status*> variable specifies if the STP is ON or OFF. The priority level assigned to the port-based VLAN. The priority level is on scale from 0-7. The default is 0. The <*status*> variable is enabled or disabled.
Priority force <*status*>	The <*status*> variable specifies if the priority force on a port is disabled on enabled.
Drop precedence level <*value*>	Identifies the TOS or DSCP value in the IPv4 or IPv6 packet header. The <*value*> variable specifies the drop precedence on a scale from 0-3. Packets that contain a DSCP value of 0 are least likely to be dropped and packets with a value of 3 are most likely to be dropped. The default value is 0.
Drop precedence force <*status*>	The <*status*> variable specifies the drop precedence force as enabled or disabled. Identifies the drop precedence if the force command is configured for a specific ingress port.
arp-inspection-trust configured to <*status*>	The <*status*> variable specifies if arp-inspection-trust feature is configured ON or OFF. The default trust setting for a port is untrusted.
Mirror <*status*>	The <*status*> variable specifies if the port mirror command is configured as enabled or disabled.
Monitor <*status*>	The <*status*> variable specifies if the port monitor command is configured as enabled or disabled.

TABLE 23 Display of show interface ethernet port (Continued)

This field...	Displays...
<*Trunk membership*>	The <*Trunk membership*> variable identifies the interface module as a member of a primary or seconday port. This specifies members of an active port or not a member of an active port.
<*Configured trunk membership*>	The <*Configured trunk membership*> variable identifies the interface module as a member of any configured trunk or not a member of a configured trunk.
<*Port name*>	The <*port name*> variable identifies the name assigned to the port.
MTU <*# bytes*>, encapsulation ethernet	Maximum Transmision Unit (MTU) refers to the size of the largest packet or frame that a known layer can pass forward. The <*# bytes*> variable refers to size of the packet or frame.
<*#seconds*> input rate: <*value*> bits/sec, <*value*> packets/sec, <%> utilization	The <*#second*> input rate refers to: • The <*value*> of bits received per second. • The <*value*> of packets received per second. • The <%> utilization specifies the port's bandwidth used by received traffic.
<*# seconds*> output rate: <*value*> bits/sec, <*value*> packets/sec, <%> utilization	The <*#second*> output rate refers to: • The <*value*> of bits transmitted per second. • The <*value*> of packets transmitted per second. • The <%> utilization specifies the port's bandwidth used by transmitted traffic.
<*value*> packets input, <*value*> bytes, <*value*> no buffer	• The <*value*> variable specifies the number of packets received. • The <*value*> variable specifies the number of bytes received. • The <*value*> no buffer variable specifies the total number of packets that have been discarded by the MAC device, due to temporary inability to store the packets before forwarding to the Network Processor (NP).
Received <*value*> broadcasts, <*value*> multicasts, <*value*> unicasts	The <*value*> variable specifies the amount of traffic the interface module is receiving on broadcasts, multicasts, and unicast traffic.
<*value*> input errors, <*value*> CRC, <*value*> frame, <*value*> ignored	• The <*value*> input errors variable specifies the number of received packets with errors. • The <*value*> CRC variable specifies the number of packets discarded by the MAC device due to detected CRC error. • The <*value*> variable specifies the number of received packets with alignment errors. • The <*value*> variable specifies the number of received packets that are discarded. These parameters are not currently supported and will always display 0.
<*value*> runts, <*value*> giants	The <*value*> runts variable specifies the number of small packets that are less than 64 bytes. The <*value*> giants variable specifies the number of large packets greater than 1518 bytes. These parameters are not currently supported and will always display 0.
NP received	The number of packets received on the Network Processer (NP).
NP transmitted	The number of packets sent from the Network Processor to the Traffic Manager (TM).
NP Ingress dropped	The number of ingress packets dropped on the Network Processor.

TABLE 23 Display of show interface ethernet port (Continued)

This field...	Displays...
<*value*> packets output <*value*> bytes	• The <*value*> variable specifies the number of transmitted packets. • The <*value*> variable specifies the number of transmitted bytes.
Transmitted <*value*> broadcasts, <*value*> multicasts, <*value*> unicasts	The <*value*> variable specifies the amount of traffic the interface module transmitted on broadcasts, multicasts, and unicast traffic.
<*value*> output errors, <*value*> collisions	• The <*value*> variable specifies the number of transmitted packets with errors. • The <*value*> variable specifies the number of packets that experienced muli-access collisions. These parameters are not currently supported and will always display 0.
Network Processor transmitted <*value*> packets Received from Traffic Manager <*value*> packets	The <*value*> variable specifies the number of packets transmitted from the Network Processor. The <*value*> variable specifies the number of packets received by the Network Processor from the Traffic Manager.

Displaying statistics information for an Ethernet port

You can view statistical information about the traffic passing through a specified Ethernet port in one of two ways. The **monitor** commands allow you to monitor traffic statistics in real time, while the **show statistics** command provides a snapshot of the most recent traffic statistics.

Monitoring Ethernet port statistics in real time

You can monitor Ethernet traffic statistics in real time for a single port or traffic counters for all Ethernet ports using the **monitor** commands. When you execute a **monitor** command it retrieves and displays traffic statistics once per polling interval (2 seconds by default) until you pause or stop the display. The terminal window is fully occupied by the real-time display, and the command prompt is replaced by a footer listing options for pausing, canceling or modifying the display. When real-time monitoring is canceled, the command prompt is restored and the CLI resumes normal operation.

The following considerations affect the use of the **monitor** commands:

- Real-time monitor commands can be executed via Telnet, SSH, or a console session. Because of the slower communication rate in a console session, Dell recommends executing the **monitor** commands *only* from a Telnet or SSH session. The default poll interval for telnet and SSH is 2 seconds, but the default polling interval for a console session is 8 seconds. If you execute **monitor** commands from a console session, flickering of the display may occur.
- If the **monitor** command is executed in a console session, console debug messages will not be displayed on the console screen.
- When the **monitor** command is executed via telnet or SSH, debug messages will not be displayed during execution of the command even with a **debug destination telnet** <*session*> configuration present.

- **monitor** commands, in general, display two kinds of statistics: aggregated (counted since system startup or since last cleared using a **clear** command) and delta (counted since start of this **monitor** command or since last cleared using the **c** footer option on the monitor screen).
- Resizing of the terminal window is not supported during real-time statistics display. You must stop the execution of the command before resizing the terminal window.
- Terminal display size must be at least 80 characters wide by 24 lines in order to avoid garbled or truncated display.
- Execution of the **monitor** commands is unaffected by Telnet or SSH idle timeouts; as long as the **monitor** command is running, the terminal is not idle.
- There can be a noticeable impact on CPU utilization if the polling interval (monitor refresh interval) is short and multiple sessions are simultaneously executing **monitor** commands. When monitoring takes place by way of multiple simultaneous sessions, increase the polling interval to minimize impact on the CPU. (The polling interval/refresh rate ranges from 2 to 30 seconds, with a default value of 2 seconds for SSH or telnet connections and 8 seconds for a console session.)
- When you quit the **monitor** command, the CLI command prompt will usually be displayed at the bottom of the screen. If it appears instead in the middle of the screen, clear the screen using the command **cls** before executing further commands.

Real-time monitoring of traffic statistics for a specific Ethernet port

To monitor traffic statistics for a specific Ethernet port, enter the following command at the Privileged EXEC level of the CLI.

```
NetIron# monitor statistics ethernet 1/2
```

Syntax: monitor statistics ethernet <*slot/port*>

The <*slot/port*> variable specifies the port for which you want to display statistics.

The **monitor statistics** command uses page mode display to show a detailed, port-specific traffic statistics screen which is updated every poll interval. You can modify the display using the commands shown in the footer. (Note that when you enter footer options they are not executed immediately but will be interpreted by the monitor engine during the next polling cycle.) The footer commands and their effects are described in Table 24.

TABLE 24 Footer commands for **monitor statistics** display

t	Displays the transmit/output statistics (the default) and continues the execution of the original command.
r	Displays the receive/input statistics and continues the execution of the original command.
n	Continues the execution of the command for the next available Ethernet interface. If there is no next interface available, the monitor continues to display statistics for the current interface.
p	Continues the execution of the command for the previous Ethernet interface. If there is no next interface available, the monitor continues to display statistics for the current interface.
c	Clears the current delta counters and continues the execution of the original command. To clear the aggregate counters, use the appropriate **clear** command.
f	Freezes the execution of the command; pauses retrieval and display of the statistics. While display is frozen, the only valid commands are **s** and **q**: you can restart or quit the monitor, but any other command will be ignored.

TABLE 24 Footer commands for **monitor statistics** display

s	Restarts the execution of the command; resumes retrieval and display of the statistics.
F	Decreases the polling interval (monitor refresh interval) by one second and continues the execution of the original command with the new refresh interval. This option will decrease the refresh interval until it is equal to 2 seconds, the minimum supported refresh interval value. The default value is 2 seconds. This command is not displayed in the footer of the statistics screen.
S	Increases the polling interval (monitor refresh interval) by one second and continues the execution of the original command with the new refresh interval. This option will increase the refresh interval until it is equal to 30 seconds, the maximum supported refresh interval value. The default value is 2 seconds. This command is not displayed in the footer of the statistics screen.
q or **escape** or **^c**	Quits the execution of the command and returns to the command prompt.
u	**MLX only**: Displays the first page of the multipage display (page-up operation).
d	**MLX only**: Displays the second page of the multipage display (page-down operation).

NetIron MLX Series example

```
NetIron# monitor statistics ethernet 4/1

                            Seconds: 8         poll: 8  Time: Aug 19 16:10:59

```

The previous output shows the first and second pages of the detailed traffic statistics display for Ethernet port 4/1 from a PowerConnect B-MLXe, displaying transmit counters (the default).

Real-time monitoring of traffic statistics for all Ethernet ports

To monitor summary traffic data (total packets or bytes sent and received) for all Ethernet ports (displaying up to 16 ports per screen), enter the following command at the Privileged EXEC level of the CLI.

```
NetIron# monitor interface traffic

                          Seconds: 248          Time: Mar 11 20:12:08
Interface traffic statistics:
                 InPackets           Delta           OutPackets           Delta
  e1/1               24615            4004                24308            3986
  e1/2                   0               0                    0               0
  e1/3                   0               0                    0               0
  e1/4                   0               0                    0               0
  e1/5                   0               0                    0               0
  e1/6                   0               0                    0               0
  e1/7                   0               0                    0               0
  e1/8                   0               0                    1               1
  e1/9                   0               0                    0               0
 e1/10                   0               0                    0               0
 e1/11                   0               0                    0               0
 e1/12                   0               0                    0               0
 e1/13                   0               0                    0               0
 e1/14                   0               0                    0               0
 e1/15                   0               0                    0               0
 e1/16                   0               0                    0               0

Packets=p or Bytes=b, Delta=d or Rate=r, Clear=c, Next=n :Freeze=f/s Quit=q
```

Syntax: monitor interface traffic [**ethernet** <*slot/port*>]

The **monitor interface traffic** command uses page mode display to produce an updating statistics screen which is updated every poll interval and which can be modified using the commands shown at the bottom of the display. (Note that when you enter footer options they are not executed immediately but will be interpreted by the monitor engine during the next polling cycle.) Normally the display begins with the lowest numbered Ethernet port; the **ethernet** <*slot/port*> option starts the display instead with the specified port.

The footer commands and their effects are described inTable 25.

TABLE 25 Footer commands for **monitor interface traffic** display

p	Displays input/output packets instead of bytes and continues the execution of the original command.
b	Displays input/output bytes instead of packets and continues the execution of the original command.
d	Displays delta counters instead of rate counters and continues the execution of the original command.
r	Displays rate counters instead of delta counters and continues the execution of the original command.
c	Clears the current delta counters and continues the execution of the original command. To clear the aggregate counters, use the appropriate **clear** command.
n	Moves to the next group of interfaces and continues the execution of the original command.
f	Freezes the execution of the command; pauses retrieval and display of the statistics. While display is frozen, the only valid commands are **s** and **q**: you can restart or quit the monitor, but any other command will be ignored.
s	Restarts the execution of the command; resumes retrieval and display of the statistics.
F	Decreases the polling interval (monitor refresh interval) by one second and continues the execution of the original command with the new refresh interval. This option will decrease the refresh interval until it is equal to 2 seconds, the minimum supported refresh interval value. The default value is 2 seconds. This command is not displayed in the footer of the statistics screen.
S	Increases the polling interval (monitor refresh interval) by one second and continues the execution of the original command with the new refresh interval. This option will increase the refresh interval until it is equal to 30 seconds, the maximum supported refresh interval value. The default value is 2 seconds. This command is not displayed in the footer of the statistics screen.
q or **escape** or **^c**	Quits the execution of the command and returns to the command prompt.

Displaying recent traffic statistics for an Ethernet port

To display information from the **show statistics** command for an Ethernet port, enter the following command at any CLI level.

```
NetIron# show statistics ethernet 9/1
PORT 9/1 Counters:
          InOctets       210753498112           OutOctets      210753550720
             InPkts        1646511726              OutPkts        1646512119
     InBroadcastPkts                 0     OutBroadcastPkts                0
     InMulticastPkts                 0    OutMulticastPkts                0
       InUnicastPkts        1646511726      OutUnicastPkts        1646512142
          InDiscards                 0         OutDiscards                0
           InErrors                  0          OutErrors                 0
        InCollisions                 0       OutCollisions                0
                                         OutLateCollisions                0
           Alignment                 0                  FCS                0
           GiantPkts                 0           ShortPkts                 0
         InBitsPerSec        3440829770        OutBitsPerSec        3440686411
         InPktsPerSec           3360185        OutPktsPerSec           3360085
        InUtilization             39.78%     OutUtilization             39.78%
```

Syntax: show statistics ethernet <*slot/port*>

The <*slot/port*> variable specifies the port that you want to display statistics for.

This field...	Displays...
InOctets	The total number of good octets and bad octets received.
OutOctets	The total number of good octets and bad octets transmitted.
InPkts	The total number of packets received. The count includes rejected and local packets that are not transmitted to the switching core for transmission.
OutPkts	The number of good packets received. The count includes unicast, mulicast, and broadcasts packets.
InBroadcastPkts	The total number of good broadcast packets received.
OutBroadcastPkts	The total number of good braodcast packets transmitted.
InMulticastPkts	The total number of good multicast packets received.
OutMulticastPkts	The total number of good multicast packets transmitted.
InUnicastPkts	The total number of good unicast packets received.
OutUnicastPkts	The total number of good unicast packets transmitted.
InDiscards	The total number of packets that were received and then dropped due to a lack of receive buffers.
OutDiscards	The total number of packets that were transmitted and then dropped due to a lack of transmit buffers.
InErrors	The total number of packets received that had Alignment errors or phy errors.
OutErrors	The total number of packets transmitted that had Alignment errors or phy errors.
InCollisions	The total number of packets received in which a Collision event was detected.
OutCollisions	The total number of packets transmitted in which a Collision event was detected.
OutLateCollisions	The total number of packets transmitted in which a Collision event was detected, but for which a receive error (Rx Error) event was not detected.
Alignment	The total number of packets received that were from 64 – 1518 octets long, but had either a bad FCS with an integral number of octets (FCS Error) or a bad FCS with a non-integral number of octets (Alignment Error).

This field...	Displays...
FCS	The Frame Checksum error.
GiantPkts	The total number of packets for which all of the following was true: • The data length was longer than the maximum allowable frame size. • No Rx Error was detected. This counter is only for 10GbE interfaces.
ShortPkts	The total number of packets received for which all of the following was true: • The data length was less than 64 bytes. • No Rx Error was detected. • No Collision or late Collision was detected.
InBitsPerSec	The number of bits received per second.
OutBitsPerSec	The number of bits transmitted per second.
InPktsPerSec	The number of packets received per second.
OutPktsPerSec	The number of packets transmitted per second.
InUtilization	The percentage of the port's bandwidth used by received traffic.
OutUtilization	The percentage of the port's bandwidth used by transmitted traffic.

Configuring SNMP to revert ifType to legacy values

The ifType for all Ethernet interfaces (10/100/1G/10G) returns the value ethernetCsmacd(6) as mandated by RFC 2665. If you want ifType to return gigabitEthernet (117) or fastEther(62) for Ethernet interfaces, enter the following command.

```
NetIron(config)# snmp-server legacy iftype
```

Syntax: [no] snmp-server legacy iftype

When this command is configured, the values gigabitEthernet (117) or fastEther(62) are returned for ifType. If you issue a **no snmp-server legacy iftype,** ifType returns ethernetCsmacd(6) for Ethernet interfaces.

Configuring snAgentConfigModuleType to return original values

Enumeration values for snAgentConfigModuleType object in the SNMP MIB have been changed for the Product Name to resolve enumeration conflicts with other hardware modules in the IronWare enterprise MIB. For example, an SNMP get of the snAgentConfigModuleType of the 10x1GC module returned mlxe20PortGigCopperSPModule(84). The snAgentConfigModuleType returns fdryMlxe20PortGigCopperSPModule(1084) for the 10x1GC module.

If you want snAgentConfigModuleType to return the enumeration values, configure the following command.

```
NetIron(config)# snmp-server legacy module-type
```

Syntax: [no] snmp-server legacy module-type

Refer to the *IronWare MIB Reference* for details on snAgentConfigModuleType.

Preserving interface statistics in SNMP

By default, statistics for an interface is cleared from both the CLI and SNMP when the following commands are entered on the CLI:

- **clear statistics ethernet** *slot-number/port-number*
- **clear statistics pos** *slot-number/port-number*
- **clear rmon statistics**
- **clear statistics log** *slot-number/port-number*

If you want to preserve interface statistics in SNMP when these commands are entered, configure the following command at the Global level of the CLI.

```
NetIron(config)# snmp-server preserve-statistics
```

Syntax: [no] snmp-server preserve-statistics

For details on which interface statistics are preserved in SNMP, refer to the "Preserved interface statistics for SNMP" section of the "Supported Standard MIBs" chapter in the *IronWare MIB Reference*.

NOTE
Statistics for an interface will be different between the CLI and SNMP if **snmp-server preserve-statistics** is configured and the clear commands listed above are executed.

Configuring Interface Parameters 4

Overview

The following Interface Parameters features are supported by the NetIron MLX Series devices.

- Assigning Port Name
- Assigning an IP Address to a Port
- Modifying Port Speeds
- Default Gigabit Negotiation Mode
- Flow Control
- Port Transition Hold Timer
- Port Flap Dampening
- Mirror Port and Monitor Ports
- ACL-based Inbound Mirroring
- Setting IP VPN Packets
- 10G WAN PHY Fault and Performance Management
- 10G Interface Numbering
- Wait for all Cards
- CAM Sharing
- Link Fault Signaling
- 10G Port Local Fault
- LFS or RFN Counters for 10G LAN PHY
- Displaying Network Processor Statistics
- Port loop detection
- Auto negotiation speed limit

NOTE
To modify Layer 2, Layer 3, or Layer 4 features on a port, refer to the appropriate section in this chapter or other chapters. For example, to modify Spanning Tree Protocol (STP) parameters for a port, refer to "Changing STP port parameters" on page 374.

All PowerConnect ports are pre-configured with default values that allow the device to be fully operational at initial startup without any additional configuration. However, in some cases, changes to the port parameters may be necessary to adjust to attached devices or other network requirements.

Assigning a port name

A port name can be assigned to help identify interfaces on the network. You can assign a port name to physical ports, virtual routing interfaces, and loopback interfaces.

To assign a name to a port, enter the following command.

```
NetIron(config)# interface e 2/8
NetIron(config-if-e10000-2/8)# port-name Marsha Markey
```

Syntax: [no] port-name <*text*>

The <*text*> parameter is an alphanumeric string. The name can have up to 255 characters on a PowerConnect and can include blanks. You do not need to use quotation marks around the string, even when it contains blanks.

Assigning an IP address to a port

To assign an IP address to an interface, enter the following commands.

```
NetIron(config)# interface e 1/8
NetIron(config)# ip address 192.45.6.110 255.255.255.0
```

Syntax: [no] ip address <*ip-addr*> <*ip-mask*>

or

Syntax: [no] ip address <*ip-addr*>/<*mask-bits*>

NOTE
You also can enter the IP address and mask in CIDR format, as follows.

```
NetIron(config)# ip address 192.45.6.1/24
```

Modifying port speed

Each of the 10/100/1000BaseTX ports is designed to auto-sense and auto-negotiate the speed and mode of the connected device. If the attached device does not support this operation, you can manually enter the port speed to operate at either 10 Mbps or 100 Mbps. The default value is 10 or 100 half- or full-duplex.

NOTE
Modifying the port speed of a port that has a pre-configured rate limit policy may result in the inability to remove the port's rate limit policy.

To change the port speed of interface 1/8 from the default of 10/100 auto-sense to 10 Mbps operating at full-duplex, first disable the port. Then, enter the following.

```
NetIron(config)# interface e 1/8
NetIron(config-if-e10000-1/8)# speed-duplex 10-full
```

Syntax: [no] speed-duplex <*value*>

The <*value*> can be one of the following:

- 10-full
- 10-half
- 100-full
- 100-half
- 1000-full
- 1000-half
- auto

The default is auto.

NOTE
An auto negotiation port must be connected to another auto negotiation port. If you connect an auto negotiation port to a fixed speed or duplex port, the behavior is undefined.

Also, ports must be disabled before changing speed.

Modifying port mode

You can configure a port to accept either full-duplex (bi-directional) or half-duplex (uni-directional) traffic. Port duplex mode and port speed are modified by the same command.

To change the port speed of interface 1/8 from the default of 10/100 auto-sense to 10 Mbps operating at full-duplex, enter the following command.

```
NetIron(config)# interface e 1/8
NetIron(config-if-e10000-1/8)# speed-duplex 10-full
```

Syntax: speed-duplex <*value*>

The <*value*> can be one of the following:

- 10-full
- 10-half
- 100-full
- 100-half
- 1000-full
- 1000-half
- auto

The default is auto.

Auto Negotiation Speed Limit

Auto-negotiation is an active method of determining the link mode. Each interface is expected to transmit specific information in a specific format. If an interface that is expecting to use auto-negotiation does not receive this information from the other side, it assumes the other side cannot detect or change its mode.

One of the most common causes of performance issues on 10/100/1000 Mb Ethernet links occurs when one port on the link operates at half-duplex while the other port operates at full-duplex. This occurs when one or both ports on a link are reset and the auto-negotiation process does not result in both link partners having the same configuration. It also can occur when users reconfigure one side of a link and forgets to reconfigure the other side. Both sides of a link should have auto-negotiation on, or both sides should have it off.

The auto negotiation speed limit feature allows the user to reduce or limit the port speed when auto- negoiation is configured. You can set the port to automatically reduce the speed from 1000Mb to 100Mb or 10Mb. The **down-shift** option will reduce the port speed to 100Mb from 1000Mb automatically once a 2-wire cable is detected.

The auto negotiation speed limit feature is supported only on FIXED (non SFP) copper ports when auto-neg is ON.

```
NetIron(config)# interface e 1/8
NetIron(config-if-e10000-1/8)# auto
NetIron(config-if-e10000-1/8)# link-config gig copper autoneg-control down-shift
```

Syntax: [no] link-config gig copper autoneg-control [down-shift|100m|10m]

The **10m** option will limit the port to negotiation to speeds and duplex of 10mb.

The **100m** option will limit the port to negotiation of speeds and duplex below 100mb.

Disabling or re-enabling a port

The port can be made inactive (disable) or active (enable) by selecting the appropriate status option. he default value for a port is disabled.

To disable port 8 on module 1 of a PowerConnect router, enter the following command.

```
NetIron(config)# interface e 1/8
NetIron(config-if-e10000-1/8)# disable
```

Syntax: [no] disable

Syntax: [no] enable

You also can disable or re-enable a virtual routing interface. To do so, enter commands such as the following.

```
NetIron(config)# interface ve v1
NetIron(config-vif-1)# disable
```

Syntax: [no] disable

To re-enable a virtual routing interface, enter the **enable** command at the Interface configuration level. For example, to re-enable virtual routing interface v1, enter the following command.

```
NetIron(config-vif-1)# enable
```

Syntax: [no] enable

Disabling Source Address Learning on a port

The default operation is for Source Address (SA) Learning to be enabled on all ports. It can be useful to disable SA Learning on a port in situations where high CPU usage is occuring because a large number of packets are being sent to the CPU for SA Learning. For example, it can be useful to disable SA Learning on physical ports that are part of a Virtual Ethernet (VE) interface that has no need to switch packets.

SA Learning can be disabled on a port using the **sa-learning-disable** command as shown in the following.

```
NetIron(config)# interface e 1/8
NetIron(config-if-e10000-1/8)# sa-learning-disable
```

Syntax: [no] sa-learning-disable

Changing the default Gigabit negotiation mode

You can configure the default Gigabit negotiation mode to be one of the following:

- **neg-full-auto** – The port first tries to perform a negotiation its peer port to exchange capability information. If the other port does not respond, the port reverts to the Negotiation-off state.
- **auto-gig** – The port tries to performs a negotiation with its peer port to exchange capability information. This is the default state.
- **neg-off** – The port does not try to perform a negotiation with its peer port.

Unless the ports at both ends of a Gigabit Ethernet link use the same mode (either **auto-gig** or **neg-off**), the ports cannot establish a link. An administrator must intervene to manually configure one or both sides of the link to enable the ports to establish the link.

Changing the negotiation mode

You can change the negotiation mode for individual ports as shown in the following.

```
NetIron(config)# interface ethernet 4/1 to 4/4
NetIron(config-mif-4/1-4/4)# gig-default neg-off
```

This command changes the default **auto-gig** setting and sets the negotiation mode to neg-off for ports 4/1 – 4/4.

Syntax: [no] gig-default neg-full-auto | auto-gig | neg-off

The **neg-full-auto, auto-gig**, and **neg-off** options are as described above.

Disabling or re-enabling flow control

You can configure full-duplex ports on a system to operate with or without flow control (802.3x).

NOTE
The **flow-control** command has been deprecated, and will no longer be accepted except at system bootup time.

The new command is **system global-flow-control** command. The **system global-flow-control** command is enabled by default.

To disable flow control on full-duplex ports on a system, enter the following command.

```
NetIron(config)# no system global-flow-control
```

To turn the feature back on, enter the following command.

```
NetIron(config)# system global-flow-control
```

Syntax: [no] system global-flow control

Specifying threshold values for flow control

The 802.3x flow control specification provides a method for slowing traffic from a sender when a port is receiving more traffic than it can handle. Specifically, the receiving device can send out 802.3x PAUSE frames that request that the sender stop sending traffic for a period of time.

The PowerConnect router generates 802.3x PAUSE frames when the number of buffers available to a module's Buffer Manager (BM) drops below a threshold value. A module's BM can start running out of buffers when a port receives more traffic than it can handle. In addition, the device drops the lowest priority traffic when the number of available buffers drops below a second threshold. When the number of available buffers returns to a higher level, the device sends out another PAUSE frame that tells the sender to resume sending traffic normally. You can specify values for both thresholds, as well as the module where the thresholds are to take effect.

NOTE
sflow is implemented in the default VRF only. Therefore, sflow data is only accessible by the sflow collector (sflow destination host(s)) defined in the default VRF.

NOTE
To use this feature, 802.3x flow control must be enabled globally on the device. By default, 802.3x flow control is enabled on the PowerConnect router, but can be disabled with the **no flow-control** command.

To specify threshold values for flow control, enter the following command.

```
NetIron(config)# qd-flow sink 75 sunk 50 slot 1
```

Syntax: [no] qd-flow sink <*sinking-threshold*> **sunk** <*sunk-threshold*> **slot** <*slot*>

The threshold values are percentages of the total number of buffers available to a module's Buffer Manager.

When the <*sinking-threshold*> is reached, the PowerConnect router sends out 802.3x PAUSE frames telling the sender to stop sending traffic for a period of time.

When the <*sunk-threshold*> is reached, the PowerConnect router drops traffic at the specified priority level.

The <*slot*> parameter specifies the location of the module where the thresholds are to take effect.

Modifying port priority (QoS)

You can give preference to the inbound traffic on specific ports by changing the Quality of Service (QoS) level on those ports. For information and procedures, refer to 9, “Configuring Quality of Service for the NetIron MLX”.

Setting IP VPN packets with a TTL value of 1 to be dropped

This command is for IP VPN packets only. Under normal conditions IP VPN packets with a TTL value equal to 0 are always dropped in hardware regardless of the setting of this command. With this command set, IP VPN packets with TTL value equal to one will also be dropped in hardware.

To enable this command use the following command.

```
NetIron(config)# interface ethernet 4/1 to 4/4
NetIron(config-if-4/1)# hw-drop-bad-ttl-pkt
```

Syntax: [no] hw-drop-bad-ttl-pkt

The default value is off.

Port transition hold timer

Using the **delay-link-event** command will delay the sending of port "up" or "down" events to Layer 2 protocols. While link down events are reported immediately in syslog, their effect on higher level protocols such as OSPF is delayed according to how the delay-link-event is configured. This command affects the physical link events. However, the resulting logical link events are also delayed. This is a per-interface command.

For example, if VSRP is enabled on the port, the ownership will not change until the port status has remained up or down for the configured amount of time to ensure that minor transient states of a link do not unintentionally cause a disruptive topology change in the network.

NOTE
All LAG ports must have the same delayed-link-down-event configuration.

The following command will delay the sending of port "down" event for 100ms when a port state is detected "down". If the port state is detected "up" afterwards within 100ms, the delayed "down" event is cancelled; otherwise, the "down" event is sent after 100ms. This allows the upper layer applications not to be affected by a port state flapping.

```
NetIron (config-if-e1000-1/2)# delay-link-event 2 down
```

Syntax: [no] delay-link-event <*time*> **up | down**

The <*time*> parameter is the number of 50-ms units. The default is 0. The valid range is from 0 to 200.

The **up** parameter means only "up" events are delayed.

The **down** parameter means that only the down events are delayed.

If neither the **up** or **down** parameter is specified, both up and down events are delayed. This is the default.

Port flap dampening

The port flap dampening feature allows you to configure a wait period before a port, whose link goes down then up, becomes enabled.

If the port link state toggles (from down to up or from up to down) for a specified number of times within a specified period, the interface is physically disabled for the specified wait period. Once the wait period expires, the port's link state is re-enabled. However, if the wait period is set to zero (0) seconds, or you want to re-enable the port before the wait period expires, the port must be manually re-enabled as described in "Re-enabling a port disabled by port link dampening" on page 140.

Configuring port link dampening on an interface

This feature is configured at the interface level.

```
NetIron(config)#interface ethernet 2/1
NetIron(config-if-e10000-2/1)#link-error-disable 10 3 10
```

Syntax: [no] link-error-disable <*toggle-threshold*> <*sampling-time-in-sec*> <*wait-time-in-sec*>

The <*toggle-threshold*> is the number of times a port's link state goes from up to down and down to up before the wait period is activated. The default is 0. Enter a valid value range from 1-50.

The <*sampling-time-in-sec*> is the amount of time during which the specified toggle threshold can occur before the wait period is activated. The default is 0 seconds. Enter a value between 1 and 65565 seconds.

The <*wait-time-in-sec*> is the amount of time the port remains disabled (down) before it becomes enabled. Entering 0 indicates that the port will stay down until an administrative override occurs. Enter a value between 0 and 65565 seconds.

Configuring port link dampening on a LAG

You can configure the port link dampening feature on the primary port of a LAG at the interface level using the **link-error-disable** command. Once configured on the primary port of the LAG, the feature is enabled on all port that are members of the LAG. You cannot disable the feature from a member of the LAG.

Enter commands such as the following on the primary port of a LAG.

```
NetIron(config)#interface ethernet 2/1
NetIron(config-if-e10000-2/1)#link-error-disable 10 3 10
```

Re-enabling a port disabled by port link dampening

A port disabled by the port link dampening is automatically re-enabled once the wait period expires; however, if the wait period is set to zero (0) seconds or you want to re-enable the port before the configured wait period expires, you must re-enable the port by entering the **link-error-disable** command on the disabled port as shown in the following.

```
NetIron(config)#interface ethernet 2/1
NetIron(config-if-e10000-2/1)#link-error-disable 10 3 10
```

NOTE
You must enter the **link-error-disable** command with the <*toggle-threshold*> <*sampling-time-in-sec*> and <*wait-time-in-sec*> variables defined to re-enable the port. Using the **link-error-disable** command without the variables, will not bring the port back up.

Displaying ports configured with port link dampening

Ports that have been disabled due to the port link dampening feature are not identified in a **show running-config** command.

Use the **show interface link-error-disable** to display the ports that have the port link dampening feature enabled.

```
NetIron(config-if-e10000-8/1)#show interfaces link-error-disable
Port 8/1: link-error-disabled (Config: 2 toggles per 3 sec, wait time 1 sec)
Port 8/3: not link-error-disabled (Config: 2 toggles per 2 sec, wait time 30 sec)
Port 8/4: not link-error-disabled (Config: 2 toggles per 2 sec, wait time 30 sec)
```

TABLE 26 link-error-disable

Displays...	Description...
port	The port that has been configured
link-error-disabled	The port that has been disabled by this feature
not link-error-disabled	The “not” means the port has not been disabled due to this feature
toggle	The number of times a port’s link state goes from up to down and down to up before the wait period is activated
wait time	The amount of time the port remains disabled (down) before it becomes enabled

Issuing the **disabled-only** with the command displays only the ports that have been disabled by the port link dampening feature.

```
NetIron(config-if-e10000-8/1)#show interfaces link-error-disable disabled-only
Port 8/1: link-error-disabled (Config: 2 toggles per 3 sec, wait time 1 sec)
```

Syntax: show interface link-error-disable [disabled-only]

Entering the **show interface link-error-disable** displays all the ports that have the port link dampening feature enabled. Add the **disabled-only** keyword for a list of ports disabled by this feature.

Port loop detection

This feature allows the Dell device to disable a port that is on the receiving end of a loop by sending test packets. You can configure the time period during which test packets are sent.

Strict mode and Loose mode

There are two types of loop detection; Strict Mode and Loose Mode. In Strict Mode, a port is disabled only if a packet is looped back to that same port. Strict Mode overcomes specific hardware issues where packets are echoed back to the input port. In Strict Mode, loop detection must be configured on the physical port.

In Loose Mode, loop detection is configured on the VLAN of the receiving port. Loose Mode disables the receiving port if packets originate from any port or VLAN on the same device. The VLAN of the receiving port must be configured for loop detection in order to disable the port.

Recovering disabled ports

Once a loop is detected on a port, it is placed in a disabled state. The port will remain disabled until one of the following occurs:

- You manually disable and enable the port at the Interface Level of the CLI
- You enter the command **clear loop-detection**. The **clear loop-detection** command clears the loop detection statistics and enables all disabled ports
- The device automatically re-enables the port. To set your device to automatically re-enable disabled ports, refer to "Configuring the device to automatically re-enable ports" on page 144.

Disable duration and loop detection interval

By default, the ports are shutdown permanently until user enables it manually. You can configure the disable duration from 1 minute to 1440 minutes (24 hours)

By default. the Loop Detection time Interval between the loop detection BPDU is 1 second. You can configure the loop detection PDU interval from 100ms to 10 seconds.

Configuration notes

Loopback detection packets are sent and received on both tagged and untagged ports. Therefore, this feature cannot be used to detect a loop across separate devices.

The following information applies to Loose Mode loop detection:

- Loop detection is configured on the VLAN. Different VLANs may disable different ports. A disabled port affects every VLAN using it.
- Loose Mode disables the receiving port if packets originate from any port or member port of a VLAN on the same device
- The VLAN of the receiving port must be configured for loop detection in order to disable the port.
- Loose Mode floods test packets to the entire VLAN. This can impact system performance if too many VLANs are configured for Loose Mode loop detection.

The following information applies to Strict Mode loop detection:

- A port is disabled only if a packet is looped back to that same port.
- Loop detection must be configured on the physical port.
- Strict Mode overcomes specific hardware issues where packets are echoed back to the input port.

NOTE
Dell recommends that you limit the use of Loose Mode. If you have a large number of VLANS or VLAN groups, configuring loop detection on all of them can significantly affect system performance because of the flooding of test packets to all configured VLANs. An alternative to configuring loop detection in a VLAN-group of many VLANs is to configure a separate VLAN with the same tagged port and configuration, and enable loop detection on this VLAN only.

NOTE
When loop detection is used with L2 loop prevention protocols, such as spanning tree (STP), the L2 protocol takes higher priority. Loop detection cannot send or receive probe packets if ports are blocked by L2 protocols, so it does not detect L2 loops when STP is running because loops within a VLAN have been prevented by STP. Loop detection running in Loose Mode can detect and break L3 loops because STP cannot prevent loops across different VLANs. In these instances, the ports are not blocked and loop detection is able to send out probe packets in one VLAN and receive packets in another VLAN. In this way, loop detection running in Loose Mode disables both ingress and egress ports.

Enabling loop detection

Use the loop-detection command to enable loop detection on a physical port (Strict Mode) or a VLAN (Loose Mode). Loop detection is disabled by default. The following example shows a Strict Mode configuration.

```
NetIron(config)#interface ethernet 1/1
NetIron(config-if-e1000-1/1)#loop-detection
```

The following example shows a Loose Mode configuration.

```
NetIron(config)#vlan 20
NetIron(config-vlan-20)#loop-detection
```

The following example shows a Loose Mode configuration for a VLAN group.

```
NetIron(config)#vlan-group 10
NetIron(config-vlan-group-10)#add-vlan 1 to 100
NetIron(config-vlan-group-10)#loop-detection
```

By default, the port will send test packets every one second, or the number of seconds specified by the **loop-detection-interval** command. Refer to "Configuring a global loop detection interval."

Syntax: [**no**] **loop-detection**

Use the [**no**] form of the command to disable loop detection.

Configuring a global loop detection interval

The loop detection interval specifies how often a test packet is sent on a port. When loop detection is enabled, the loop detection time unit is 0.1 second, with a default of 10 (one second). The range is from 1 (one tenth of a second) to 100 (10 seconds). You can use the show loop-detection status command to view the loop detection interval.

To configure the global loop detection interval, enter a command such as the following.

```
NetIron(config)#loop-detection-interval 50
```

This command sets the loop-detection interval to 5 seconds (50 x 100ms).

To revert to the default global loop detection interval of 10, enter one of the following.

```
NetIron(config)#loop-detection-interval 10
```
OR
```
NetIron(config)#no loop-detection-interval 50
```

Syntax: [**no**] **loop-detection-interval** <*number*>

Where <*number*> is a value from 1 to 100. The system multiplies your entry by 0.1 to calculate the interval at which test packets will be sent.

Configuring the device to automatically re-enable ports

To configure the Dell device to automatically re-enable ports that were disabled because of a loop detection, enter the following command The default is 0.

```
NetIron(config)#loop-detection disable-duration 1440
```

The above command will cause the Dell device to automatically re-enable ports that were disabled for a duration of 24 hours because of a loop detection. This configuration applies to all the ports that are configured the loop detection (strict or loose).

Syntax: [**no**] **loop-detection disable-duration** <num>

Use the [**no**] form of the command to disable this feature.

Where <*num*> is the number of minutes from 0 to 1440. When 0 is specified, it is permanently off.

Clearing loop-detection

To clear loop detection statistics and re-enable all ports that are in disabled state because of a loop detection, enter the following command.

```
NetIron #clear loop-detection
```

Syntax: **clear loop-detection** [vlan | ethernet] <vlanid/port-num>

Where **port-num** enables the specified port.

Where **vlan-id** enables all the ports disabled by loop detection for this VLAN

Displaying loop-detection information

Use the **show loop-detection** command to display the loop detection status.

```
NetIron(config-vlan-100)#show loop-detection

loop detection packets interval: 10 (unit 100 msec)
loop detection disable duration: 10 (In minutes, 0 means permanently disabled)

Ports mode loop detection
=========================
port-num   disable-count

1/12       0
1/11       0

Vlan mode loop detection
========================
vlan-id    disable-count

100        2
10          0
200        0

Ports disabled by loop detection
================================
port       age(minutes) disable cause

 1/11  1            Disabled by VLAN: 100 loopdetect 1/11
 1/12  1            Disabled by VLAN: 100 loopdetect 1/12
```

Syntax: show loop-detection

TABLE 27 Port loop detection output description

Parameter	Description
loop detection packets interval	Specifies how often a test packet is sent on a port.
loop detection disable duration	Specifies the device to automatically re-enable ports that were disabled for the configured duration because of a loop detection
ports mode	The VLAN or port that port loop detection was configured on.
loop detection disabled ports	The ports that are disabled by port loop detection. • port - The port number that was disabled by port loop detection. • age - The time duration after which port will be automatically re-enabled. If the age is “0”, it means port is not configured to be automatically re-enabled. • disable cause - specifies all the ports that were disabled by loop detection (either strict or loose).

Syslog message

The following message is logged when a port is disabled due to loop detection. This message will also appear on the console.

```
SYSLOG: Jan 27 18:16:42:<14>Jan 27 18:16:42 LOOP_DETECT LOG: Port Down 1/10 -
Loop detected on VLAN: 150
```

Mirroring and Monitoring

You can monitor traffic on PowerConnect router ports by configuring another port to “mirror” the traffic on the ports you want to monitor. By attaching a protocol analyzer to the mirror port, you can observe the traffic on the monitored ports.

Monitoring traffic on a port is a two-step process:

- Enable a port to act as the mirror port. This is the port to which you connect your protocol analyzer.
- Enable monitoring on the ports you want to monitor.

You can monitor input traffic, output traffic, or both.

Any port on a module can operate as a mirror port and you can configure more than one mirror port. You can configure the mirror ports on different modules and you can configure more than one mirror port on the same module.

Configuration guidelines for monitoring traffic

Use the following considerations when configuring mirroring for inbound and outbound traffic:

- Any port can be mirrored and monitored except for the management port.
- Only one inbound mirror port can be configured for any inbound monitor port.
- Only one outbound mirror port can be configured for any outbound monitor port.
- A LAG port can be configured as either an inbound or outbound monitor port.
- A LAG port cannot be configured as either an inbound or an outbound mirror port.
- Both input and output monitoring are supported.
- Monitoring for LAG ports is supported.
- sFlow and monitoring can be enabled concurrently on the same port.
- ACL-based inbound mirroring is supported.
- ACL-based inbound sFlow is not concurrently supported.

Assigning a mirror port and monitor ports

To configure ethernet port 3/1 for port mirroring, enter the following command.

```
NetIron(config)# mirror-port ethernet 3/1
```

Syntax: [no] **mirror-port ethernet** <*slot*>/<*portnum*> | **pos** <*slot*>/<*portnum*>

POS ports can be monitored. However, because a POS port cannot be configured as a monitor port using the **monitor ethernet** command described below, the monitored POS port must be mirrored through an Ethernet port.

NOTE
If a port is configured as a mirror port, all traffic sent from that port will retain the encapsulation of the port being monitored and not add the encapsulation of the Egress port.

Enter the slot and port number of the port that will be the mirrored.

```
NetIron(config)# interface ethernet 4/1
NetIron(config-if-4/1)# monitor ethernet 3/1
```

Syntax: [no] monitor ethernet <*slot*>/<*portnum*> **both | input | output**

Enter the slot and port number of the port that will serve as the monitor port. This port cannot be the same as the mirror port.

NOTE
A mirror port must be an Ethernet port. While a a POS port can be monitored, a POS port cannot be used as a mirror port. Also, POS control packets and IS-IS control packets transmitted or received at a POS port cannot be mirrored.

Specify input if the port will monitor incoming traffic, output to monitor outgoing traffic, or both to monitor both types of traffic.

NOTE
In VPLS, when an unknown unicast traffic is handled, it uses the corresponding VLAN Forwarding ID to flood the packets to the VLAN domain which contains both the monitored port as well as the mirroring port. But in VLL, there is no such flood handling mechanism and hence, there is a discrepancy in the output of the **show statistic brief** command in terms of the **Packet Transmit** count on the mirroring port.

Displaying mirror and monitor port configuration

To display the inbound and outbound traffic mirrored to each mirror port, enter the following command at any level of the CLI.

```
NetIron# show monitor config
Monitored Port 3/1
    Input traffic mirrored to: 2/1
    Output traffic mirrored to: 1/1
Monitored Port 4/1
    Input traffic mirrored to: 1/2
    Output traffic mirrored to: 2/1
```

Syntax: show monitor config

To display the actual traffic mirrored to each mirror port, enter the following command at any level of the CLI.

```
NetIron# show monitor actual
Monitored Port 3/1
    Output traffic mirrored to: 1/1
Monitored Port 4/1
    Input traffic mirrored to: 1/2
```

Syntax: show monitor actual

This output displays the output traffic mirrored to mirror port 1/1 from port 3/1 and input traffic mirrored to mirror port 1/2 from port 4/1, which are explicitly configured.

ACL-based inbound mirroring

The Multi-Service IronWare software supports using an ACL to select traffic for mirroring from one port to another. Using this feature, you can monitor traffic in the mirrored port by attaching a protocol analyzer to it. The **acl-mirror-port** command is supported for POS interfaces. A user can configure a POS port to be monitored and then mirrored to an Ethernet port. Traffic cannot however be mirrored *to* a POS port.

Considerations when configuring ACL-based inbound mirroring

The following must be considered when configuring ACL-based inbound mirroring:

- Configuring a common destination ACL mirror port for all ports of a PPCR (see below)
- Support with ACL CAM sharing enabled (see below)
- The **mirror** and **copy-sflow** keywords are mutually exclusive on a per-ACL clause basis.
- ACL-based inbound mirroring and port-based inbound mirroring are mutually exclusive on a per-port basis.
- ACL-based mirroring must be configured at the LAG level for individual LAG member ports (see "Configuring ACL-based mirroring" on page 223).
- Configuring ACL-based mirroring at the port level on the primary port of a LAG mirrors all traffic on that LAG to the monitor port.

Configuring a Common Destination ACL mirror port for all ports of a PPCR

All ports using the same PPCR must have a common destination ACL mirror port when configuring ACL-based inbound mirroring. For Example, where ports 4/1 and 4/2 belong to the same PPCR, the following configuration that configures them with different destination ACL mirror ports will fail and generate an error message as shown.

```
NetIron(config)# interface ethernet 4/1
NetIron(config-if-e10000-4/1)# acl-mirror-port ethernet 6/1
NetIron(config-if-e10000-4/1)# interface ethernet 4/2
NetIron(config-if-e10000-4/2)# acl-mirror-port ethernet 6/2
Error: 4/2 and 4/1 should have the same ACL mirror port
```

Support with ACL CAM sharing enabled

For ACL CAM sharing to function, either one of the following conditions must be true:

- All ports that belong to a PPCR have the **acl-mirror-port** command configured to direct mirrored traffic to the same port.
- None of the ports that belong to the PPCR have the **acl-mirror-port** command configured.

ACL CAM sharing cannot function with the configuration shown in the following example because port 4/1 has ACL port mirroring configured and port 4/2 does not.

```
NetIron(config)# enable-acl-cam-sharing
NetIron(config)# interface ethernet 4/1
NetIron(config-if-e10000-4/1)# ip access-group 101 in
NetIron(config-if-e10000-4/1)# acl-mirror-port ethernet 6/1
NetIron(config-if-e10000-4/1)# interface ethernet 4/2
NetIron(config-if-e10000-4/2)# ip access-group 101 in
```

Configuring ACL-based inbound mirroring

The following sections describe how to configure ACL-based Inbound Mirroring on a PowerConnect router:

- Creating an ACL with a mirroring clause
- Applying the ACL to an interface
- Specifying a destination mirror port
- Specifying the desintation mirror port for physical ports
- Specifying the destination mirror port for a LAG
- Configuring ACL-based mirroring for ACLs bound to virtual interfaces
- Specifying the destination mirror port for IP receive ACLs

Creating an ACL with a mirroring clause

The **mirror** keyword in IPv4, L2 and IPv6 ACL clauses directs traffic that matches the clause criteria to be mirrored to another port. In the following examples, the ACL is used to direct IP traffic to a mirror port.

Example : ACL-based Mirroring Supported for IPv4 ACLs.

```
access-list 101 permit ip any any mirror
access-list 101 permit ip any any
```

Example : ACL-based Mirroring supported for IPv6 Inbound ACLs.

```
ipv6 access-list gem
   permit tcp 1000:1::/64 2000:1::/64 mirror
   permit udp 1000:1::/64 2000:1::/64 mirror
   permit icmp 1000:1::/64 2000:1::/64 mirror
   permit ipv6 any any
```

Example : ACL-based Mirroring supported for Layer-2 Inbound ACLs.

```
access-list 400 permit 0000.0000.0010 ffff.ffff.ffff 0000.0000.0020
           ffff.ffff.ffff.ffff any mirror
access-list 400 permit 0000.0000.0050 ffff.ffff.ffff 0000.0000.0020
           ffff.ffff.ffff.ffff any mirror
access-list 400 permit any any any
```

The **mirror** parameter directs selected traffic to the mirrored port. Traffic can only be selected using the **permit** clause. The mirror parameter is supported on rACLs.

NOTE
As with any ACL, the final clause must permit desired traffic to flow: be sure to add an appropriate **permit any any** clause to the end of any ACL intended to mirror (and not filter) traffic. Failure to include the **permit** clause will result in disruption of traffic through any interface to which the ACL is applied.

Applying the ACL to an interface

You must apply the ACL to an interface using the **ip access-group command** as shown in the following.

```
NetIron(config)# interface ethernet 1/1
NetIron(config-if-e10000-1/1)# ip access-group 101 in
```

Specifying the destination mirror port

You can specify physical ports or a LAG to mirror traffic from. The following sections describe how to perform each of these configurations.

Specifying the destination mirror port for physical ports

You must specify a destination port for traffic that has been selected by ACL-based Inbound Mirroring. This configuration is performed at the Interface Configuration of the port whose traffic you are mirroring. In the following example, ACL mirroring traffic from port 1/1 is mirrored to port 1/3.

```
NetIron(config)# interface ethernet 1/1
NetIron(config-if-e10000-1/1)# acl-mirror-port ethernet 1/3
```

You can also use the ACL-mirroring feature to mirror traffic from multiple ports to a single port using the Multiple Interface Configuration (MIF) mode as shown in the following example.

```
NetIron(config)# interface ethernet 1/1 to 1/2
NetIron(config-mif-e10000-1/1-1/2)# acl-mirror-port ethernet 1/3
```

Syntax: [no] acl-mirror-port ethernet [slot/port]

The [slot/port] variable specifies port that ACL-mirror traffic from the configured interface will be mirrored to.

Specifying the destination mirror port for a LAG

You can mirror the traffic that has been selected by ACL-based inbound mirroring from all ports in a LAG by configuring a destination (monitor) port for the LAG at the interface configuration level of the LAG's primary port. Configuring mirroring on the primary port of the LAG causes ACL-selected traffic from all ports in the LAG to be mirrored to the monitor port. For example, in the following configuration all traffic on LAG "mylag" will be mirrored to port 10/4:

```
NetIron(config)# lag mylag static
NetIron(config-lag-mylag)# ports ethernet 10/1 to 10/3
NetIron(config-lag-mylag)# primary-port 10/1
NetIron(config-lag-mylag)# deploy
NetIron(config-lag-mylag)# exit
NetIron(config)# interface ethernet 10/1
NetIron(config-if-e1000-10/1)# acl-mirror-port ethernet 10/4
```

Syntax: [no] acl-mirror-port ethernet <*slot/port*>

The **ethernet** <*slot/port*> variable specifies the port that ACL-mirror traffic from the LAG will be mirrored to.

The following considerations apply when configuring ACL-based mirroring with LAGs:

- You must configure ACL-mirroring for an individual member port from the LAG configuration level (see "Configuring ACL-based mirroring" on page 223). Attempting to configure ACL-mirroring at the interface level for an individual member port will fail and display the following message.

  ```
  Error: please use  config level to configure ACL based mirroring on  port.
  ```

- If an individual port is configured for ACL-based mirroring, you cannot add it to a LAG. If you want to add it to a LAG, you must remove it from ACL-based mirroring first. Then you can add it to a LAG. It can then be configured for either ACL-based LAG mirroring or for mirroring an individual port within a LAG.

  If you attempt to add a port that is configured for ACL-based mirroring to a LAG, the following message will display.

  ```
  ACL port is configured on port 2/1, please remove it and try again.
   transaction failed:  Config Vetoed
  ```

- When a LAG with ACL-based mirroring configured on it is deleted or undeployed, the ACL-based mirroring configuration is removed from each of the individual ports that made up the LAG, including the primary port.

Configuring ACL-based mirroring for ACLs bound to virtual interfaces

For configurations that have an ACL bound to a virtual interface, you must configure the **acl-mirror-port** command on a port for each PPCR that is a member of the virtual interface. For example, in the following configuration ports 4/1 and 4/2 share the same PPCR while port 4/3 uses another PPCR.

```
NetIron(config)# vlan 10
NetIron(config-vlan-10)# tagged ethernet 4/1 to 4/3
NetIron(config-vlan-10)# router-interface ve 10

NetIron(config)# interface ethernet 4/1
NetIron(config-if-e10000-4/1)# acl-mirror-port ethernet 5/1
NetIron(config)# interface ve 10
NetIron(config-vif-10)# ip address 10.10.10.254/24
NetIron(config-vif-10)# ip access-group 102 in

NetIron(config)# access-list 101 permit ip any any mirror
```

In this configuration, the **acl-mirror-port** command is configured on port 4/1 which is a member of ve 10. Because of this, ACL-based mirroring will apply to VLAN 10 traffic that arrives on ports 4/1 and 4/2. It will not apply to VLAN 10 traffic that arrives on port 4/3 because that port uses a different PPCR than ports 4/1 and 4/2. To make the configuration apply ACL-based mirroring to VLAN 10 traffic arriving on port 4/3, you must add the following command to the configuration.

```
NetIron(config)# interface ethernet 4/3
NetIron(config-if-e10000-4/3)# acl-mirror-port ethernet 5/1
```

If the ve contains LAG ports, configuration of acl-mirror-port command on an individual LAG port will also apply to other LAG ports that are in the same PPCR. For example, in the following configuration the acl-mirror-port command is configured for LAG port 10/2, which is a member of ve.

```
NetIron(config)# lag mylag static
NetIron(config-lag-mylag)# ports ethernet 10/1 to 10/4
NetIron(config-lag-mylag)# primary-port 10/1
NetIron(config-lag-mylag)# deploy
NetIron(config-lag-mylag)# acl-mirror-port ether-port-monitored 10/2 ethe 11/3

NetIron(config)# vlan 10
NetIron(config-vlan-10)# tagged ethe 10/1 to 10/4
NetIron(config-vlan-10)# router-interface ve 10
```

The ACL-based mirroring will apply to VLAN 10 traffic incoming on ports 10/1 and 10/2 since they are in the same PPCR and are members of a virtual interface. However it will not apply to VLAN 10 traffic incoming on 10/3 and 10/4 since they are in a different PPCR. To apply ACL-based mirroring on VLAN 10 traffic incoming on 10/3 and 10/4, you will have to additionally configure the acl-mirror-port ethe-port-monitored 10/3 ethe 11/3 command under the LAG.

Specifying the destination mirror port for IP Receive ACLs

When specifying a destination port for IP Receive ACLs, you must configure the **acl-mirror-port** command on all ports supported by the same PPCR. For example, if you are using mirroring traffic for an rACL on a 4 x 10G interface module and you want to mirror traffic incoming on the first PPCR, you have to configure the **acl-mirror-port** command on both ports 1 and 2. If you want to mirror IP Receive ACL permit traffic incoming on all ports of the module, you have to configure the **acl-mirror-port** command on all ports of the module.

10G WAN PHY fault and performance management

This feature provides fault and performance management features like alarm detection, alarm generation and performance monitoring on 10 GbE WAN PHY interfaces. It only applies to 10 GbE interfaces configured in the WAN PHY mode.

Using this feature, you can gather fault and performance management information and display it for the current 15 minute interval or for any of the previous 15 minute intervals. In addition, this feature allows you to create a path trace between WAN PHY interfaces to ensure correct connection.

Setting a 10 GbE interface to WAN PHY mode

To set a 10 GbE interface to WAN PHY mode, use the following command.

```
NetIron(config)# interface ethernet 3/1
NetIron(config-if-e10000-3/1)# phy-mode wan
```

Syntax: [**no**] **phy-mode** { **wan** | **28k** }

The **wan** parameter sets the PHY mode to WAN.

The **28k** parameter sets the PHY mode to 28k (provided for compatibility with Bay Networks hardware).

The default setting is LAN PHY mode; to reset PHY mode to LAN, use the command **no phy-mode**.

Turning alarm interfaces on and off

When a 10 GbE port is to WAN PHY mode, alarm monitoring is set on by default. You can turn alarm monitoring off for an individual port as shown in the following.

```
NetIron(config)# interface ethernet 3/1
NetIron(config-if-e10000-3/1)# no alarm-monitoring
```

Syntax: [no] alarm-monitoring

Configuring path trace

You can configure a character string to be carried in the SONET overhead as a method of detecting mis-connection of ports between two routers connected over the WAN PHY. The routers compare the configured character string with the received character string to determine if the connection is valid.

You can configure an PowerConnect router with the character string "test1" using the following command.

```
NetIron(config)# overhead j0-transmit test1
```

Syntax: [no] overhead [j0-transmit <*string*> **] | [j1-transmit** <*string*>**]**

The <*string*> variable is the character string used to detect mis-connection of ports it must be configured with the same value on each side of the WAN PHY connection.

Displaying status of alarms on an interface

You can display the current status of WAN PHY alarms as shown in the following.

```
NetIron# show control1er curr15min e 3/1
----------------------------------------------------------
10g wan phy alarms statistics  - PORT e3/1
----------------------------------------------------------
ACTIVE ALAMRS : LOS
ACTIVE DEFECTS : LOF-S AIS-L AIS-P

Elapsed time [0 min 13 secs]
Format [alarm type = count]
FM-PARAMS
 Section
  LOS = 1  LOF = 1
Line
  AIS-L = 1 RDI-L = 0
Path
  AIS-P = 1  LOP = 0 PLM = 0 AIS-PFE = 0 PLM-PFE = 0
PM-PARAMS
 Section
  CV = 2  ES = 1  SES = 0  SEFS = 0
 Line
  CV = 3  ES = 1  SES = 0 UAS = 0
  CV-FE  = 0  ES-FE = 0  SES-FE = 0 UAS-FE = 0
 Path
   CV = 4  ES = 1  SES = 0 UAS = 0
   CV-FE  = 0  ES-FE = 0  SES-FE = 0 UAS-FE = 0
```

Syntax: show controller [curr15min <*port no***> | <***slot no***>] | [day <***port no***> | <***slot no***>] | [prev15min <** *interval***> <***port no***> | <***slot no***>]**

The **curr15min** parameter specifies that you want to display WAN PHY alarm and performance information for the current 15 minute interval for either the port number ***<portno>*** or slot number ***<slotno>*** specified.

The **day** parameter specifies that you want to display WAN PHY alarm and performance information for the current day for either the port number ***<portno>*** or slot number ***<slotno>*** specified.

The **prev15min** parameter specifies that you want to display WAN PHY alarm and performance information for the a past 15 minute interval as specified by the ***<interval>*** variable for either the port number ***<portno>*** or slot number ***<slotno>*** specified.
Possible values for ***<interval>*** are 1 - 31 and indicates which previous 15 minute interval you want to display information from. The closest previous interval is 1 and the farthest is 31.

The <*port no*> variable specifies the port that you want to display WAN PHY alarm and performance information for.

The <*slot no*> variable specifies the slot that you want to display WAN PHY alarm and performance information for.

This display shows the following information.

TABLE 28 WAN PHY display parameters

Parameter	Description.
Loss of signal (LOS)	LOS is raised when the synchronous signal (STS-N) level drops below the threshold at which a BER of 1 in 103 is predicted. It could be due to a cut cable, excessive attenuation of the signal, or equipment fault. LOS state clears when two consecutive framing patterns are received and no new LOS condition is detected.
Out of frame (OOF) alignment or SEF (Severely errored Frame)	OOF state occurs when four or five consecutive SONET frames are received with invalid (errored) framing patterns (A1 and A2 bytes). The maximum time to detect OOF is 625 microseconds. OOF state clears when two consecutive SONET frames are received with valid framing patterns.
Loss of frame (LOF) alignment	LOF state occurs when the OOF state exists for a specified time in milliseconds. LOF state clears when an in-frame condition exists continuously for a specified time in milliseconds.
Loss of pointer (LOP)	LOP state occurs when N consecutive invalid pointers are received or N consecutive new data flags (NDFs) are received (other than in a concatenation indicator), where N = 8, 9, or 10. LOP state clears when three equal valid pointers or three consecutive AIS indications are received. LOP can be identified as follows: • STS path loss of pointer (SP-LOP) · • VT path loss of pointer (VP-LOP)

TABLE 28 WAN PHY display parameters (Continued)

Parameter	Description.
Alarm indication signal (AIS)	The AIS is an all-ones characteristic or adapted information signal. It is generated to replace the normal traffic signal when it contains a defect condition in order to prevent consequential downstream failures being declared or alarms being raised. Line AIS defect is detected as a "111" pattern in bits 6, 7, and 8 of the K2 byte in five consecutive frames. Line AIS defect is terminated when bits 6, 7, and 8 of the K2 byte do not contain the code "111" for five consecutive frames. STS-Path AIS defect is detected as all ones in bytes H1 and H2 in three contiguous frames. STS-Path AIS defect is terminated when a valid STS Pointer is detected with the NDF set to "1001" (inverted) for one frame, or "0110" (normal) for three contiguous frames. AIS can also be identified as follows: • Line alarm indication signal (AIS-L) · • STS path alarm indication signal (SP-AIS) · • VT path alarm indication signal (VP-AIS)
Remote error indication (REI)	This is an indication returned to a transmitting node (source) that an errored block has been detected at the receiving node (sink). This indication was formerly known as far end block error (FEBE). REI can also be identified as the following: • Line remote error indication (REI-L) · • STS path remote error indication (REI-P) · • VT path remote error indication (REI-V)
Remote defect indication (RDI)	This is a signal returned to the transmitting terminating equipment upon detecting a loss of signal, loss of frame, or AIS defect. RDI was previously known as FERF. RDI can also be identified as the following: • Line remote defect indication (RDI-L) · • STS path remote defect indication (RDI-P) · • VT path remote defect indication (RDI-V)
B1 error (coding violation, CV)	Parity errors evaluated by byte B1 (BIP-8) of an STS-N are monitored. If any of the eight parity checks fail, the corresponding block is assumed to be in error.
B2 error (coding violation, CV)	Parity errors evaluated by byte B2 (BIP-24 x N) of an STS-N are monitored. If any of the N x 24 parity checks fail, the corresponding block is assumed to be in error.
B3 error (coding violation, CV)	Parity errors evaluated by byte B3 (BIP-8) of a VT-N (N = 3, 4) are monitored. If any of the eight parity checks fail, the corresponding block is assumed to be in error.
Errored Seconds (ES)	At each layer, an Errored Second (ES) is a second with one or more Coding Violations at that layer OR one or more incoming defects (e.g., SEF, LOS, AIS, LOP) at that layer has occurred. Far end - This is an indication returned to a transmitting node (source) that an errored block has been detected at the receiving node (sink). And Errored seconds - far end indicate this error in terms of errored seconds. ES can be identified as follows: • Section Errored seconds (ES-S)· • Line Errored seconds (ES-L), Line Errored seconds- Far end (ES-LFE)· • Path Errored seconds (ES-P), Path Errored seconds- Far end (ES-PFE)

TABLE 28 WAN PHY display parameters (Continued)

Parameter	Description.
Severely Errored seconds (SES)	At each layer, an Severely Errored Second (SES) is a second with x or more CVs at that layer, or a second during which at least one or more incoming defects at that layer has occurred. Values of x vary depending on the line rate and the Bit Error Rate. SES can be identified as follows: • Section Severely Errored seconds (SES-S). • Line Severely Errored seconds (SES-L), Line Errored seconds- Far end (SES-LFE). • Path Severely Errored seconds (SES-P), Path Errored seconds- Far end (SES-PFE)
Severely errored frame seconds (SEFS)	A Severely Errored Framing Second (SEFS) is a seconds with containing one or more SEF events. This counter is only counted at the Section Layer.
Unavailable seconds (UAS)	At the Line, Path, and VT layers, an unavailable second is calculated by counting the number of seconds that the interface is unavailable. At each layer, the SONET or SDH interface is said to be unavailable at the onset of 10 contiguous SESs. The 10 SESs are included in unavailable time. Once unavailable, the SONET or SDH interface becomes available at the onset of 10 contiguous seconds with no SESs. The 10 seconds with no SESs are excluded from unavailable time. With respect to the SONET or SDH error counts at each layer, all counters at that layer are incriminated while the SONET or SDH interface is deemed available at that layer. While the interface is deemed unavailable at that layer, the only count that is incriminated is UASs at that layer. UAS can be identified as follows: • Line Unavailable seconds (UAS-L), Line Unavailable seconds at far end (UAS-LFE). • Path Unavailable seconds (UAS-P), Path Unavailable seconds (UAS-PFE)

Wait for all cards feature

During a system reload, an Interface module comes up after it completes its initialization process. After an Interface module is up, its ports can come up. Since 10G modules have more packet processors to initialize, 1G ports are up earlier than 10G ports.

The **wait-for-all-cards** command directs all ports to come up at the same time. This is done by waiting for all Interface modules to come up first, before allowing for ports to come up. This command is shown in the following.

```
NetIron(config)# wait-for-all-cards
```

Syntax: [no] wait-for-all-cards

NOTE
With the **wait-for-all-cards** command enabled,10G ports will come up before 1G ports because Multi-Service IronWare software processes 10G port's state changes first.

Link fault signaling

You can enable link fault signaling on 1 or 10 gigabit interfaces. Link fault signalling (LFS) is a physical layer protocol that enables communication on a link between two 1 or 10 Gigabit Ethernet devices. When configured on a 1 or 10 Gigabit Ethernet port, the port can detect and report fault conditions on transmit and receive ports.

If LFS is configured on an interface, the following Syslog messages are generated when that interface go up or down or when the TX or RX fiber is removed from one or both sides of the link that has LFS configured:

- Interface ethernet1/1, state down - link down
- Interface ethernet1/1, state up

The Link and Activity LEDs on the module turn on when there is traffic transiting the link after the fiber is installed. To configure LFS, enter commands such as the following.

```
NetIron(config)# interface ethernet 1/4
NetIron(config-if-e1000-1/4)# link-fault-signal
```

Syntax: [no] link-fault-signal

LFS is disabled by default.

To display if LFS is configured on an interface, enter the following command.

```
NetIron#show link-fault-signaling
Global Remote Fault : OFF
PORT #: REMOTE FAULT:
PORT 1/1: OFF
PORT 1/2: OFF
PORT 1/3: OFF
PORT 1/4: ON
PORT 1/5: OFF
PORT 1/6: OFF
PORT 1/7: OFF
PORT 1/8: OFF
PORT 1/9: OFF
```

Displaying and clearing remote fault counters

To display Remote Fault Notification (RFN) counters on 10GbE LAN physical interface, enter the following command .

```
NetIron# show remote-fault ethernet 1/1 to 1/4
Port      RFN Detected           Remote-fault count     time last RFN detected
----       -----------------    ----------------------  --------------------------
1/1            Yes                        15             Sep 29 22:03:03
1/2            No                          0                  -
1/3            No                         12             Aug 20 13:22:14
1/4            No                           0                 -
** remote-fault counters are only supported for ports in LAN PHY mode on 10GE
modules. **
```

The example above displays remote fault notification counters with slot 1 as a 10GbE module, and ports 1/1, 1/2, 1/3, and 1/4 in LAN mode.

If the user enters a slot number that is not a 10 GbE port, or if any port in the port range is not a 10GbE port in LAN mode, the following error message is displayed.

```
NetIron# show remote-fault slot 3
remote-fault counters are only supported for ports in LAN PHY mode on 10 GE
modules.
```

To clear remote fault notification counters on a 10 GbE LAN physical interface, enter the following command.

```
NetIron#clear remote-fault slot 1
```

Syntax: show or clear remote-fault [ethernet <*slot#/port#*> **[to** <*slot#/port*>**] | slot** <*slot#*>**]**

You can display information for remote fault notification counters in a PowerConnect router by using the **show remote-fault** command without options,

Use the ethernet <*slot#/port#*> option to limit the display to a single ethernet port.

Use the to <*slot#/port*> option for a range of ports.

Use the slot <*slot#*> option to limit the display to a single slot.

The following table describes the output of the **show remote-fault** command

TABLE 29 Display of show remote-fault output

This field...	Displays...
Port	The <*port#*> variable specifies the port number for the interface module.
RFN Detected	The remote-fault notification is detected on a given interface. If “Yes” is displayed, then the remote-fault notification is detected on the given port at the time of inquiry. If “No” is displayed, then no remote-fault notification is detected on the given port at the time of inquiry.
Remote-fault count	The Remote-fault count displays the number of times the remote-fault notification is detected on a given interface. The number of times, include: • The time since the Interface Module was last powered on. • The time since the count was last cleared by the user. • The time since the interface was last configured as a LAN mode.
time last RFN detected	The time the remote-fault notification was last detected on a given interface.

Limits and restrictions

Current implementation with this feature has the following limitations:

- Works only on a 10GbE LAN interface. Information for ports in a WAN interface at the time of inquiry is not displayed. Information for a port that does not belong to 10 GbE module is not displayed.
- In a Management Module switchover state, the remote fault notification counts and detection time are maintained.
- The RFN counts of a port only reset to zero in the following conditions:
  - At slot initialization (power on).
  - When the **clear remote-fault** command is enabled on 10 GbE LAN interface.
  - When configuring a 10GbE port into WAN mode.

Local fault event detection and counters

Local fault event detection and counters are enabled for ports on 10GbE LAN physical interfaces when link fault signaling is enabled on the interface. If both local fault and remote fault events are detected on the same interface, then the remote fault event is reported.

If a port is down because of a local fault event, then a syslog message is generated to inform you of this event. The syslog message will display "(local fault)" in the dynamic log buffer. For more information on local fault syslog messages, refer to "Syslog messages system" on page 2264. The local fault event is also indicated in the **show interface** command. In the **show interface** command, the reason is displayed as "(local fault)". For more information on the **show interface** command, refer to "Displaying information for an interface for an Ethernet port" on page 121.

Displaying and clearing local fault counters

To display local fault counters on 10GbE LAN physical interface, enter the following command.

```
NetIron# show local-fault ethernet 2/1 to 2/2
Port  Local Fault Detected   Local-Fault Count     time last Local Fault detected
---- ---------------------  ------------------  -----------------------------
2/1        yes                 1                   Apr  3 18:06:28
2/2         yes                1                   Apr  3 18:06:28
```

The example above displays local fault counters for ports 2/1 and 2/2 in LAN physical mode.

To clear local fault counters on a 10 GbE LAN physical interface, enter the following command.

```
NetIron# clear local ethernet 2/1 to 2/2
Local-fault stats for port 2/1 is cleared.
Local-fault stats for port 2/2 is cleared.
```

The example above displays ports 2/1 and 2/2 cleared for local-fault statistics.

Syntax: show or clear local [ethernet <*slot#/port#*> **[to** <*slot#/port*>**] | slot** <*slot#*>**]**

You can display information for local fault counters in a PowerConnect router by using the **show local-fault** command without options,

Or use the ethernet <*slot#/port#*> option to limit the display to a single ethernet port.

Or use the to <*slot#/port*> option for a range of ports.

Use the slot <*slot#*> option to limit the display to a single slot.

The following table describes the output of the **show local-fault** command.

TABLE 30 Display of show local-fault output

This field...	Displays...
Port	The <*port#*> variable specifies the port number for the interface module.
Local Fault Detected	The local-fault is detected on a given interface. If "Yes" is displayed, then the local-fault event is detected on the given port at the time of inquiry. If "No" is displayed, then no local-fault event is detected on the given port at the time of inquiry.
Local-fault count	The local-fault count displays the number of times the local-fault event is detected on a given interface. The number of times, include: • The time since the Interface Module was last powered on. • The time since the count was last cleared by the user. • The time since the interface was last configured as a LAN mode.
time last Local Fault detected	The time the local-fault event was last detected on a given interface.

Displaying Network Processor statistics

The Network Processor (NP) counters track the packets and bytes that enter the ingress NP and exit the egress NP. Counts displayed are since the last time the **clear np statistics** command was issued.

The **show np statistics command** displays the NP statistics for all interface modules within a router or for an interface in a specified slot or port. A routed packet drop counter is added to the **show np statistics** command. For more information on the routed packet drop counter, see Table 31 on page 161. The following example displays an output from the **show np statistics** command on the Product Name.

Output of the Product Name is as follows.

```
NetIron MLXe# show np statistics ethernet 10/4
NP STATs IPC reply from slot 10 length =1608
Port 10/4 RX
NP Rx Raw Good Packet          = (115458)
NP Rx Forward Packet            = (115458)
NP Rx Discard Packet           = (0)
NP Rx Unicast Packet           = (44571)
NP Rx Broadcast Packet         = (0)
NP Rx Multicast Packet         = (70887)
NP Rx Send to TM Packet        = (115458)
NP Rx Bad Packet               = (0)
NP Rx Lookup Unavailable       = (0)

NP Rx IPv6 RPF Drop Count      = (0)
NP Rx IPv4 Byte                = (0)
NP Rx IPv6 Byte                = (0)
NP Rx POS Ctrl Protocol Packet = (0)
NP Rx POS Link Drop            = (0)
NP Rx Routed Packet Drop     = (0)
Port 10/4 TX
NP Tx Sent to MAC Packet       = (1365518)
NP Tx Raw Good Packet          = (1365518)
NP Tx Source Port Supress Drop = (0)
NP Tx Bad Packet Count         = (0)
NP Tx Unicast Packet           = (1324427)
NP Tx Broadcast Packet         = (1)
NP Tx Multicast Packet         = (41090)
NP Tx IPX HW Forwarded Packet  = (41090)
NP Tx Receive from TM          = (1365518)
NP Tx ACL Drop                 = (0)
NP Tx IPv4 Packet              = (0)
NP Tx IPv6 Packet              = (0)
NP Tx IPv4 Byte                = (0)
NP Tx IPv6 Byte                = (0)
NP Tx POS Ctrl Protocol Packet = (0)
NP Tx POS Link Drop            = (0)
```

Syntax: show np statistics [ethernet <*slot/port*> **] [pos** <*slot/port*> **] [slot** <*slot-num*> **]**

You can use the **ethernet** or **pos** options and specify a <*slot/port*> variable to display NP statistics for an individual port.

You can use the slot option and specify a <*slot-num*> variable to display NP statistics for an individual interface module.

The **Tx** and **Rx** counters displayed are described in the following tables.

TABLE 31 Rx counters

Rx counter (per port)	Explanation
Rx Raw Good Packet	Number of good packets received from MAC
Rx Forward Packet	Number of forwarded packets by packet evaluation engine
Rx Discard Packet	Number of packets flagged for discard by packet evaluation engine
Rx Unicast Packet	Number of unicast (indicated by MAC DA) packets received
Rx Broadcast Packet	Number of broadcast (indicated by MAC DA) packets received
Rx Multicast Packets	Number of multicast (indicated by MAC DA) packets received
Rx Send to TM Packets	Number of packets sent to TM (= Rx Forward Packet – RL drops)
Rx Bad Packets	Number of packets that have MAC to NP interface errors
Rx Loopup Unavailable	Number of packets that have been dropped due to unavailability of the CAM interface for packet lookups
Rx ACL Drop	Drop counter for ACL drop on the ingress path
Rx Priority 0/1 Drop	Drop counter for ingress priority 0,1 packets
Rx Priority 2/3 Drop	Drop counter for ingress priority 2,3 packets

TABLE 31 Rx counters

Rx counter (per port)	Explanation
Rx Priority 4/5 Drop	Drop counter for ingress priority 4,5 packets
Rx Priority 6/7 Drop	Drop counter for ingress priority 6,7 packets
Rx Supress RPF Drop	Counter for suppressed RPF drops on the ingress path due to ACL override
Rx RPF Drop	Counter for RPF drop on the ingress
Rx IPv4 Packet	Raw packet count that have IPv4 EType (0x0800) and IP version of 0x4
Rx IPv6 Packet	Raw packet count that have IPv6 EType (0x86DD) and IP version of 0x6
Rx IPv6 Supress RPF Drop	Counter for IPv6 suppressed RFP drops on the ingress path due to ACL override
Rx IPv6 RPF Drop Count	Counter for IPv6 drop on the ingress
NP Rx Route-only Drop	Counts packets that have been dropped due to Route-Only configuration during MAC-DA processing.
Rx IPv4 Byte	Raw packet Bytes (+FCS) that have IPv4 etype (0x0800) and IP version equals 0x4
Rx IPv6 Byte	Raw packet Bytes (+FCS) that have IPv6 etype (0x86DD) and IP version equals 0x6
Rx POS Ctrl Protocol Packet	Number of control protocol packets received in POS mode
Rx POS Link Drop	Number of packets dropped due to link state in POS mode
Rx Routed Packet Drop	Number of received IPv4 or IPv6 routed packets that are dropped because the TTL is 0, or because routing is not enabled on the given virtual interface.

TABLE 32 Tx counters

TX counter (per port)	Explanation
Tx Sent to MAC Packet	Total number of packets sent to MAC for transmit
Tx Raw Good Packet	Total number of packets sent to egress processing logic that pass the initial length checks (min, max, offsets, bad packet etc.)
Tx Source Port Suppression Drop	Number of packets dropped because of transmit source port suppression
Tx Bad Packet Count	Total number of packets dropped in egress logic that fail the initial length checks (min, max, bad packet etc.)
Tx Unicast Packet	Number of unicast packets transmitted (from MAC DA)
Tx Broadcast Packet	Number of broadcast packets transmitted (from MAC DA)
Tx Multicast Packet	Number of multicast packets transmitted (from MAC DA)
Tx Receive From TM	Number of packets received from TM
Tx ACL Drop	Number of packets that have been dropped by the Outbound ACL Logic
Tx IPv4 Packet	Number of IPv4 packets transmitted out the port (Etype==0x0800 & IPver == 0x4)
Tx IPv6 Packet	Number of IPv6 packets transmitted out the port (Etype==0x86DD & IPver == 0x6)
Tx IPv4 Byte	Counts packet Bytes (+FCS) that have IPv4 etype (0x0800) and IP version equals 0x4
Tx IPv6 Byte	Counts packet Bytes (+FCS) that have IPv6 etype (0x86DD) and IP version equals 0x6
Tx POS Ctrl Protocol Packet	Number of control protocol packets sent in POS mode
Tx POS Link Drop	Number of packets dropped due to link state in POS mode

Relationships between some counters

Some of the values for counters displayed using the **show np statistics** command are the result of adding the contents of more than one counter. Table 33 and Table 34 describe these relationships between NP counters displayed.

TABLE 33 Relationships between RX counters

Total RX Packets	=	Rx Bad Packets + Rx Lookup Unavailable Packets + Rx Raw Good Packets
Rx Raw Good Packets	= = =	Rx Unicast Packets + Rx Multicast Packets + Rx Broadcast Packets Rx IPv4 Packets + Rx IPv6 Packets + Rx Other Packets Rx Forward Packets + Rx Discard Packets
Rx Forward Packets	=	Rx Sent to TM Packets + Rx RL drop packets
Rx Discard Packets	=	ACL drop + TTL drop + route-only drop + RPF drop + tag mismatch drop + VLAN blocking drop + segment filtering drop + drop by packet evaluation decisions +miscellaneous
Rx Priority Drops	=	RL drop + Rx Discard Packets

TABLE 34 Relationships between TX counters

Tx Raw Good Packets	= =	Tx Receive From TM Packets - Tx Bad Packets Tx Unicast Packets + Tx Broadcast Packets + Tx Multicast Packets + Tx Source Port Suppression Drop
Tx Sent to MAC	= =	Tx IPv4 Packets + Tx IPv6 Packets + Tx Others Tx Raw Good Packets – Tx Source Port Suppression Drop – Tx ACL drop - Tx RL Drop – Tx Multicast TTL drop

Clearing the NP statistics counters

You can clear the NP statistics counters for an entire router or selectively by port or slot using the **clear np statistics** command as shown in the following.

```
NetIron# clear np statistics
```

Syntax: clear np statistics [ethernet <*slot/port*> **] [pos** <*slot/port*> **] [slot** <*slot-num*> **]**

You can use the **ethernet** or **pos** options and specify a <*slot/port*> variable to clear NP statistics for an individual port.

You can use the **slot** option and specify a <*slot-num*> variable to clear NP statistics for an individual interface module.

Enabling the Foundry Discovery Protocol (FDP) and Reading Cisco Discovery Protocol (CDP) Packets

5

Overview

The following features are supported by NetIron MLX Series devices.

- Foundry Discovery Protocol (FDP)
- Reading Cisco Discovery Protocol (CDP)
- Displaying FDP Information
- Displaying CDP Information

NOTE
On platforms that support the Ethernet Service Instance (ESI) framework: FDP and CDP may be configured in the default ESI. FDP and CDP are not supported under user-defined ESIs.

This chapter discusses the following features:

- **Foundry Discovery Protocol (FDP)** – a protocol used by Dell devices to advertise themselves to other Dell devices
- **Cisco Discovery Protocol (CDP)** – a protocol used by Cisco devices to advertise themselves to other Cisco devices. Dell devices use this protocol to learn device and interface information for Cisco devices in the network

Using FDP

FDP enables Dell devices to advertise themselves to other Dell devices on the network. When you enable FDP on a Dell device, the device periodically advertises information including the following:

- Hostname (device ID)
- Product platform and capability
- Software version
- VLAN and Layer 3 protocol address information for the port sending the update.

A device running FDP sends FDP updates on Layer 2 to MAC address 01-E0-52-CC-CC-CC. Other devices listening on that address receive the updates and can display the information in the updates.

FDP is disabled by default.

NOTE
If FDP is not enabled on a device that receives an FDP update or the device is running a software release that does not support FDP, the update passes through the device at Layer 2. Also, FDP should not be used if VPLS is enabled.

Configuring FDP

The following sections describe how to enable FDP and how to change the FDP update and hold timers.

Enabling FDP globally

To enable a Dell device to globally send FDP packets, enter the following command at the global CONFIG level of the CLI.

```
NetIron(config)# fdp run
```

Syntax: [no] **fdp run**

The feature is disabled by default.

Enabling FDP at the interface level

You can enable FDP at the interface level by entering the following commands.

```
NetIron(config)# int e 2/1
NetIron(config-if-e10000-2/1)# fdp enable
```

Syntax: [no] **fdp enable**

By default, the feature is enabled on an interface once FDP is enabled on the device.

Changing the FDP update timer

By default, a device enabled for FDP sends an FDP update every 60 seconds. You can change the update timer to a value from 5 – 900 seconds.

To change the FDP update timer, enter a command such as the following at the global CONFIG level of the CLI.

```
NetIron(config)# fdp timer 120
```

Syntax: [no] **fdp timer** <*secs*>

The <*secs*> parameter specifies the number of seconds between updates and can be from 5 – 900 seconds. The default is 60 seconds.

Changing the FDP hold time

By default, a device that receives an FDP update holds the information until one of the following events occurs:

- The device receives a new update.
- 180 seconds have passed since receipt of the last update. This is the hold time.

Once either of these events occurs, the device discards the update.

To change the FDP hold time, enter a command such as the following at the global CONFIG level of the CLI.

```
NetIron(config)# fdp holdtime 360
```

Syntax: [**no**] **fdp holdtime** <*secs*>

The <*secs*> parameter specifies the number of seconds a device that receives an FDP update can hold the update before discarding it. You can specify from 10 – 255 seconds. The default is 180 seconds.

Displaying FDP information

You can display the following FDP information:

- FDP entries for neighbors
- Individual FDP entries
- FDP information for an interface on the device you are managing
- FDP packet statistics

NOTE
If the device has intercepted CDP updates, the CDP information is also displayed.

Displaying neighbor information

To display a summary of all the neighbors that have sent FDP updates to this device, enter the following command.

```
NetIronA# show fdp neighbor
Capability Codes: R - Router, T - Trans Bridge, B - Source Route Bridge
                  S - Switch, H - Host, I - IGMP, r - Repeater
(*) indicates a CDP device

   Device ID      Local Int    Holdtm Capability Platform    Port ID
   -------------- ------------ ------ ---------- ----------- -------------
   NetIronB    Eth 2/9      178    Router     NetIron Rou Eth 2/9
```

Syntax: **show fdp neighbor** [**ethernet** <*slot*>/<*portnum*>] [**detail**]

The **ethernet** <*slot*>/<*portnum*> parameter lists the information only for updates received on the specified interface.

The **detail** parameter lists detailed information for each device.

The **show fdp neighbor** command, without optional parameters, displays the following information.

TABLE 35 Summary FDP and CDP neighbor information

This line...	Displays...
Device ID	The hostname of the neighbor.
Local Int	The interface on which this device received an FDP or CDP update for the neighbor.
Holdtm	The maximum number of seconds this device can keep the information received in the update before discarding it.
Capability	The role the neighbor is capable of playing in the network.
Platform	The product platform of the neighbor.
Port ID	The interface through which the neighbor sent the update.

To display detailed information, enter the following command.

```
NetIronA# show fdp neighbor detail
Device ID: PowerConnectB configured as default VLAN1, tag-type8100
Entry address(es):
Platform: PowerConnect Router,  Capabilities: Router
Interface: Eth 2/9
Port ID (outgoing port): Eth 2/9 is TAGGED in following VLAN(s):
 9 10 11
Holdtime : 176 seconds
Version :
Brocade Router, IronWare Version 07.6.01b1T53 Compiled on Aug 29
2002 at 10:35:21 labeled as B2R07601b1
```

The **show fdp neighbor detail** command displays the following information.

TABLE 36 Detailed FDP and CDP neighbor information

This line...	Displays...
Device ID	The hostname of the neighbor. In addition, this line lists the VLAN memberships and other VLAN information for the neighbor port that sent the update to this device.
Entry address(es)	The Layer 3 protocol addresses configured on the neighbor port that sent the update to this device. If the neighbor is a Layer 2 Switch, this field lists the management IP address.
Platform	The product platform of the neighbor.
Capabilities	The role the neighbor is capable of playing in the network.
Interface	The interface on which this device received an FDP or CDP update for the neighbor.
Port ID	The interface through which the neighbor sent the update.
Holdtime	The maximum number of seconds this device can keep the information received in the update before discarding it.
Version	The software version running on the neighbor.

Displaying FDP entries

To display the detailed neighbor information for a specific device, enter a command such as the following.

```
NetIronA# show fdp entry NetIronB
Device ID: NetIronB configured as default VLAN1, tag-type8100
Entry address(es):
Platform: NetIron Router,  Capabilities: Router
Interface: Eth 2/9
Port ID (outgoing port): Eth 2/9 is TAGGED in following VLAN(s):
 9 10 11
Holdtime : 176 seconds
Version :
Brocade Router, IronWare Version 07.6.01b1T53 Compiled on Aug 29
2002 at 10:35:21 labeled as B2R07601b1
```

Syntax: show fdp entry * | <*device-id*>

The * | <*device-id*> parameter specifies the device ID. If you enter *, the detailed updates for all neighbor devices are displayed. If you enter a specific device ID, the update for that device is displayed. For information about the display, refer to Table 36 on page 168.

Displaying FDP information for an interface

To display FDP information for an interface, enter a command such as the following.

```
NetIronA# show fdp interface ethernet 2/3
FastEthernet2/3 is up, line protocol is up
  Encapsulation ethernet
  Sending FDP packets every 5 seconds
  Holdtime is 180 seconds
```

This example shows information for Ethernet port 2/3. The port sends FDP updates every 5 seconds. Neighbors that receive the updates can hold them for up to 180 seconds before discarding them.

Syntax: show fdp interface [**ethernet** <*slot*>/<*portnum*>]

The **ethernet** <*slot*>/<*portnum*> parameter lists the information only for the specified interface.

Displaying FDP and CDP statistics

To display FDP and CDP packet statistics, enter the following command.

```
NetIronA# show fdp traffic
CDP/FDP counters:
  Total packets output: 6, Input: 5
  Hdr syntax: 0, Chksum error: 0, Encaps failed: 0
  No memory: 0, Invalid packet: 0, Fragmented: 0
  Internal errors: 0
```

Syntax: show fdp traffic

Clearing FDP and CDP information

You can clear the following FDP and CDP information:

- Information received in FDP and CDP updates
- FDP and CDP statistics

The same commands clear information for both FDP and CDP.

Clearing FDP and CDP neighbor information

To clear the information received in FDP and CDP updates from neighboring devices, enter the following command.

```
NetIron# clear fdp table
```

Syntax: clear fdp table

NOTE
This command clears all the updates for FDP and CDP.

Clearing FDP and CDP statistics

To clear FDP and CDP statistics, enter the following command.

```
NetIron# clear fdp counters
```

Syntax: clear fdp counters

Reading CDP packets

Cisco Discovery Protocol (CDP) packets are used by Cisco devices to advertise themselves to other Cisco devices. By default, a device forwards these packets without examining their contents. You can configure a device to intercept and display the contents of CDP packets. This feature is useful for learning device and interface information for Cisco devices in the network.

Dell devices support intercepting and interpreting CDP version 1 and 2 packets.

NOTE
The device can interpret only the information fields that are common to both CDP version 1 and CDP version 2.

NOTE
When you enable interception of CDP packets, the device drops the packets. As a result, Cisco devices will no longer receive the packets.

Enabling interception of CDP packets globally

To enable the device to intercept and display CDP packets, enter the following command at the global CONFIG level of the CLI.

```
NetIron(config)# cdp run
```

Syntax: [no] cdp run

The feature is disabled by default.

Enabling interception of CDP packets on an interface

You can disable and enable CDP at the interface level.

You can enter the following commands.

```
NetIron(config)# int e 2/1
NetIron(config-if-e10000-2/1)# cdp enable
```

Syntax: [no] cdp enable

By default, the feature is enabled on an interface once CDP is enabled on the device.

Displaying CDP information

You can display the following CDP information:

- Cisco neighbors
- CDP entries for all Cisco neighbors or a specific neighbor
- CDP packet statistics

Displaying neighbors

To display the Cisco neighbors the device has learned from CDP packets, enter the following command.

```
NetIron# show fdp neighbors
Capability Codes: R - Router, T - Trans Bridge, B - Source Route Bridge
                  S - Switch, H - Host, I - IGMP, r - Repeater
(*) indicates a Cisco device

   Device ID      Local Int    Holdtm Capability Platform    Port ID
   -------------- ------------ ------ ---------- ----------- -------------
(*)Router         Eth 1/1      124    R          cisco RSP4
FastEthernet5/0/0
```

Syntax: show fdp neighbors [**detail** | **ethernet** <*portnum*>]

To display detailed information for the neighbors, enter the following command.

```
NetIron# show fdp neighbors detail
Device ID: Router
Entry address(es):
  IP address: 207.95.6.143
Platform: cisco RSP4,  Capabilities: Router
Interface: Eth 1/1,  Port ID (outgoing port): FastEthernet5/0/0
Holdtime : 150 seconds
Version :
Cisco Internetwork Operating System Software
IOS (tm) RSP Software (RSP-JSV-M), Version 12.0(5)T1,  RELEASE SOFTWARE
(fc1)
Copyright (c) 1986-1999 by cisco Systems, Inc.
Compiled Thu 19-Aug-99 04:12 by cmong
```

To display information about a neighbor attached to a specific port, enter a command such as the following.

```
NetIron# show fdp neighbors ethernet 1/1
Device ID: Router
Entry address(es):
  IP address: 207.95.6.143
Platform: cisco RSP4,  Capabilities: Router
Interface: Eth 1/1,  Port ID (outgoing port): FastEthernet5/0/0
Holdtime : 127 seconds
Version :
Cisco Internetwork Operating System Software
IOS (tm) RSP Software (RSP-JSV-M), Version 12.0(5)T1,  RELEASE SOFTWARE
(fc1)
Copyright (c) 1986-1999 by cisco Systems, Inc.
Compiled Thu 19-Aug-99 04:12 by cmong
```

Displaying CDP entries

To display CDP entries for all neighbors, enter the following command.

```
NetIron# show fdp entry *
Device ID: Router
Entry address(es):
  IP address: 207.95.6.143
Platform: cisco RSP4,  Capabilities: Router
Interface: Eth 1/1,  Port ID (outgoing port): FastEthernet5/0/0
Holdtime : 124 seconds
Version :
Cisco Internetwork Operating System Software
IOS (tm) RSP Software (RSP-JSV-M), Version 12.0(5)T1,  RELEASE SOFTWARE
(fc1)
Copyright (c) 1986-1999 by cisco Systems, Inc.
Compiled Thu 19-Aug-99 04:12 by cmong
```

Syntax: show fdp entry * | <*device-id*>

For example, to display CDP entries for a specific device, specify the device ID.

```
NetIron# show fdp entry Router1
Device ID: Router1
Entry address(es):
  IP address: 207.95.6.143
Platform: cisco RSP4,  Capabilities: Router
Interface: Eth 1/1,  Port ID (outgoing port): FastEthernet5/0/0
Holdtime : 156 seconds
Version :
Cisco Internetwork Operating System Software
IOS (tm) RSP Software (RSP-JSV-M), Version 12.0(5)T1,  RELEASE SOFTWARE
(fc1)
Copyright (c) 1986-1999 by cisco Systems, Inc.
Compiled Thu 19-Aug-99 04:12 by cmong
```

Displaying CDP statistics

To display CDP packet statistics, enter the following command.

```
NetIron# show fdp traffic
CDP counters:
  Total packets output: 0, Input: 3
  Hdr syntax: 0, Chksum error: 0, Encaps failed: 0
  No memory: 0, Invalid packet: 0, Fragmented: 0
```

Syntax: show fdp traffic

Clearing CDP information

You can clear the following CDP information:

- Cisco Neighbor information
- CDP statistics

To clear the Cisco neighbor information, enter the following command.

```
NetIron# clear fdp table
```

Syntax: clear fdp table

To clear CDP statistics, enter the following command.

```
NetIron# clear fdp counters
```

Syntax: clear fdp counters

Using a Redundant Management Module 6

Overview

The following Redundant Management Module features are supported by NetIron MLX Series devices.

- Management Module Switchover
- Default Active Chassis Slot
- Synchronization Between Active and Standby Management Modules
- Manually Switching Over to the Standby Management Module
- Monitoring Management Module Redundancy
- Flash Memory and PCMCIA Flash Card File Management
- Option to delete old file first upon image download if MP Flash full
- Enhanced Syslog for Module State Changes

You can install a redundant management module in slot M1 or M2 of a PowerConnect chassis. (By default, the system considers the module in slot M1 to be the active management module and the module in slot M2 to be the redundant, or standby module. If the active module becomes unavailable, the standby module automatically takes over management of the system.

This chapter describes the redundant management module, how it works with the active module, and how to configure and manage it.

How management module redundancy works

This section explains the following:

- How management module redundancy works under normal operating conditions
- Events that cause a standby management module to assume the role of the active module (switchover)
- System implications when a switchover occurs

Management module redundancy overview

When you apply power to or reload a PowerConnect router with two management modules installed, by default, the management module in slot M1 becomes the active module and the module in slot M2 becomes the standby module. (You can change the default active slot from M1 to M2 using the **active-management** command. Refer to "Changing the default active chassis slot" on page 178.)

After the active and standby modules are determined, both modules boot from the source specified for the active module. The active module can boot from the following sources:

- The flash memory on the active management module
- A PCMCIA flash card in a PCMCIA slot on the active management module.

Once the modules boot, the system compares the flash code and system-config files on the standby module to the files on the active module. If the files are not the same, the files on the standby module are synchronized with those on the active module.

During normal operation, the active module handles tasks such as obtaining network topology and reachability information and determining the best paths to known destinations. The active module also monitors the standby module.

The standby module functions in an active standby mode. Configuration changes made from the CLI to the active management module are also written to the standby management module even if they are not written to flash memory. Synchronizing the system-config and running-config files on both modules allows the standby module to assume the role of active module seamlessly, if necessary.

The interface modules are not reset, and continue to forward traffic while the standby management module takes over operation of the system. The new now-active management module receives updates from the interface modules and sends verification information to the interface modules to ensure that they are synchronized. If the new active management module becomes out of sync with an interface module, information on the interface module may be overwritten, which can cause an interruption of traffic forwarding. An out of sync state should only occur if there is a layer 3 topology change elsewhere in the network during the management failover. PowerConnect devices support Layer 3 hitless failover with restart for high-availability routing in protocols such as BGP and OSPF. With these high-availability features enabled, when a router experiences a failover or restart, forwarding disruptions are minimized, and route flapping diminished to provide continuous service.

Management module switchover

The following events cause the standby management module to become the active module, which is called a ***switchover***:

- The active module becomes unavailable
- You perform a manual switchover
- You remove and replace the active management module

The following sections explain how the switchover occurs for each event.

Unavailable active module

The following events cause an active module to become unavailable and a switchover to occur:

- An active module experiences a problem significant enough to cause a reset of the module
- The active module loses power

Before a switchover occurs, the active module resets itself and sends an interrupt signal to the standby module. The standby module then becomes the active module and the interface modules continue to forward traffic.

The new active module begins to manage the system. When the original active module becomes available again or is replaced, it assumes the role of standby module.

Manual switchover

In some situations, you may want to manually switch the active module to the standby module. You can perform a manual switchover using the **switchover** command. For information about performing this task, refer to "Manually switching over to the standby management module" on page 181.

When the switchover occurs, the standby module becomes active and the active module becomes standby.

Removal and replacement of a management module

For information about how to remove and replace a management module, refer to "Replacing a Management Module" in the *PowerConnect B-MLXe Hardware Installation Guide.*

This section explains how management module redundancy is affected when you remove and replace an active or standby management module.

Removal and replacement of an active management module

If you remove the active management module, the standby module automatically assumes the active role. When you insert a replacement module in the slot from which the original active module was removed, the replacement module assumes the standby role. This module boots from a source specified for the active module, for example:

- The flash memory on the active management module
- A PCMCIA flash card installed in the active management module

When the replacement module boots, the system compares the flash code and system-config files on the standby module to the files on the active module. If differences exist, the files on the standby module are synchronized to match those on the active module.

Removal and replacement of a standby management module

You can remove a standby management module without causing a switchover to occur. The active module continues to function normally. When the new module is installed, it assumes the role of standby, and boots from a source specified for the active module, for example:

- The flash memory on the active management module
- A PCMCIA flash card installed in the active management module

The system compares the flash code and system-config files on the replacement module to the files on the active module. If differences exist, the files on the standby module are synchronized to match those on the active module.

Switchover implications

When a switchover occurs between the active and standby modules, the following areas may be affected:

- Management sessions
- Syslog and SNMP traps
- BGP Peer Notification – Described in "BGP4 Peer notification during a management module switchover" on page 1005

The following sections explain the implications for these areas.

Management sessions

You can establish management sessions using the management port on the active management module. If a switchover occurs, the management port on the original active module shuts down and all open CLI, Web Management Interface, and SNMP Network Manager sessions with that port close. You can open new sessions with the new active module, if this module has the same management port connections.

For example, if you were accessing the Web Management Interface through a PC connected to the original active management port, you can open a new session if a PC is connected to the new active management port. Open a new session using the same IP address you used before the switchover. (If a switchover occurs, the IP address you configured on the original active module is automatically assumed by the new active module.)

Syslog and SNMP traps

When a switchover occurs, the PowerConnect system sends a Syslog message to the local Syslog buffer and to the Syslog server, if you have configured the system to use one. The system also sends an SNMP trap to the receiver, if one is configured.

When system power is restored, or the system is reset normally, a cold start message and trap are sent. However, if the system is reset as the result of switchover to the standby management module, the system sends a warm start message and trap.

Management module redundancy configuration

Configuring management module redundancy consists of performing one optional task (changing the default active chassis slot) as described in the following section.

Changing the default active chassis slot

By default, the PowerConnect system considers the module installed in slot M1 to be the active management module. However, you can change the default active chassis slot to M2 using the **active-management** command.

The **active-management** command determines which management module will become active after a power cycle. By default, the top management module of the PowerConnect B-MLXe-16, PowerConnect B-MLXe-4 and PowerConnect B-MLXe-8 become active after a power cycle. This information is stored in the chassis's backplane EPROM and not in the configuration file.

To change the default active chassis slot from the default state of M1 to M2, enter the following commands.

```
NetIron(config)# redundancy
NetIron(config-redundancy)# active-management mgmt-2
```

Syntax: active-management <*mgt-module*>

The <*mgt-module*> parameter specifies the management module, either mgmt-1 or mgmt-2.

NOTE
This configuration has no effect on the **reload** and **boot** commands. it only applies to the power cycle when both management modules are installed in a chassis.

Managing management module redundancy

You can perform the following management tasks related to management module redundancy for PowerConnect devices:

- Perform immediate synchronization of files
- Perform a manual switchover to the standby module
- Reboot the standby module

File synchronization between active and standby management modules

Each active and standby management module contains the following files that can be synchronized between the two modules:

- **Flash code** – The flash code can include the following files:
  - monitor, which contains the Real Time Operating System (RTOS) for the management module
  - primary, which contains the primary Multi-Service IronWare image for the management module
  - secondary, which contains the secondary Multi-Service IronWare image for the management module

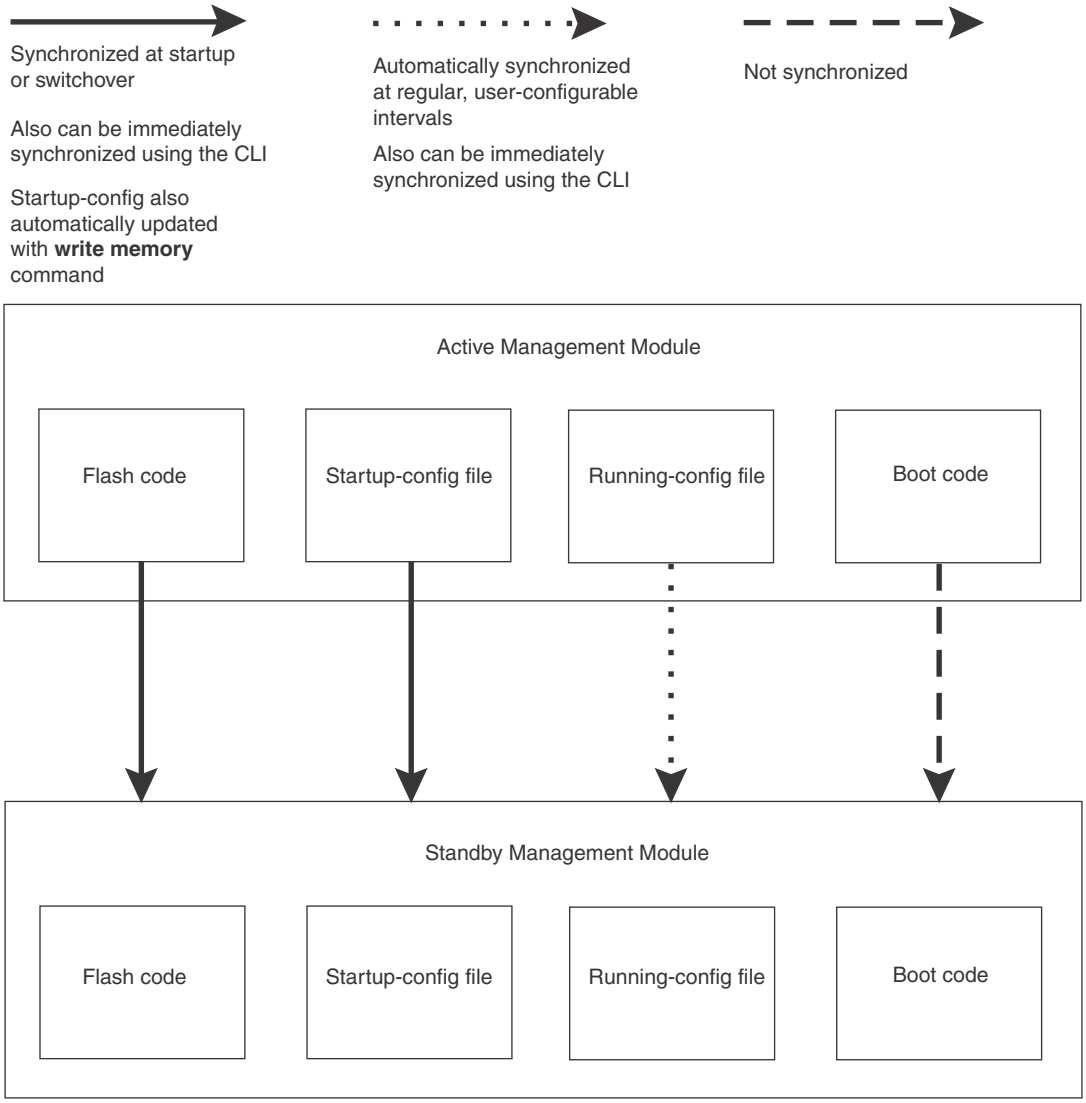
  A PowerConnect Multi-Service IronWare image contains layer 1 – 3 software used by the management module.

  During startup or switchover, the flash code on the active module is compared to the flash code on the standby module. If the files differ, the files on the standby module are synchronized to the files on the active module. If you update the flash code on the active module, the flash code on the standby module is automatically synchronized (without comparison) to the new file on the active module.
- **System-config file** – The flash code includes the system-config file. During startup or switchover, the system-config file on the active module is compared to the system-config file on the standby module. If the files are different, the system-config file on the standby module is synchronized with that of the active module. When you save changes to the system-config file on the active module, the system-config file on the standby module is automatically (without comparison) synchronized to match the system-config file on the active module.
- **Running-config** – The running-config file resides in the PowerConnect system memory, and is automatically synchronized (without comparison) between the active and the standby module at regular intervals. The default interval is 7 seconds.

Each active and standby management module also includes boot code that is run when a module boots. The boot code resides in the boot flash of each module. Boot code is not synchronized between the active and standby modules, which allows the system to use an older version of boot code on the standby module if desired.

Figure 2 shows how the files are synchronized between the active module and the standby module.

FIGURE 2 Active and standby management module file synchronization



The PowerConnect system allows you to perform the following file synchronization tasks:

- Compare files on the active module with files on the standby module and immediately synchronize any files that are different.
- Immediately synchronize all files between the active and standby modules.

The following sections explain how to perform these tasks.

Comparing and synchronizing files

You can initiate a comparison of the flash code, system-config, and running-config files on the active management module with these files on the standby module and synchronize the files immediately if differences exist. When you synchronize the files, the active module files are copied to the standby module, replacing the standby module files.

To compare and immediately synchronize files between the active and standby modules, enter the following command at the Privileged EXEC level.

```
NetIron# sync-standby
```

Synchronizing files without comparison

You can synchronize the flash code, system-config file, and running-config file immediately without comparison. When you synchronize the files, active module files are copied to the standby module, replacing the files on the standby module.

To immediately synchronize the files between the active and standby modules, enter the following command at the Privileged EXEC level.

```
NetIron# force-sync-standby
```

Manually switching over to the standby management module

You can cause the PowerConnect system to switch over to the standby module (and thus make it the active module). Enter the **switchover** command at the Privileged EXEC level.

```
NetIron# switchover
```

You are presented with the question **"Are you sure?"** after the switchover command is executed. At this question, you can either type **y** to proceed with the switchover or type **n** to abort the switchover.

The following is an example of the new switchover procedure.

```
NetIron#switchover
Are you sure? (enter 'y' or 'n'): y
```

NOTE
The switchover command should not be used immediately after downloading new code to the PowerConnect systems with redundant management modules.

Upon switchover to the standby management module, a software image is downloaded. The following error message is displayed on the console:

```
Warning: There is an outstanding software download. Do you want to continue?
(enter 'y' or 'n')
```

If you want to continue with downloading the image, enter yes. If you do not want to download the image, enter no.

Rebooting the active and standby management modules

You can reboot management modules, while maintaining the active and standby roles, using the **boot system** or **reload** commands. You can also reboot the standby module only, maintaining the standby role, using the **reboot-standby** command.

For example, to reboot the active and standby management modules from the primary PowerConnect Multi-Service IronWare image in the management module flash memory, enter the following command at the Privileged EXEC level.

```
NetIron# boot system flash primary
NetIron# Are you sure? (enter 'y' or 'n'): y
```

Syntax: [no] **boot system bootp | [flash primary | flash secondary] | slot** <*number*> <*filename*> | **tftp** <*ip-address*> <*filename*>

The **flash primary** keyword specifies the primary PowerConnect Multi-Service IronWare image in the management module flash memory. The **flash secondary** keyword specifies the secondary PowerConnect Multi-Service IronWare image in the flash memory.

For the <*number*> parameter, specify 1 for PCMCIA slot 1 on the active management module and 2 for PCMCIA slot 2 on the active management module. For the <*filename*> parameter, specify the name of the image on the PCMCIA flash card.

The **tftp** keyword directs the PowerConnect router to boot from an PowerConnect Multi-Service IronWare image on a TFTP server located at <*ip-address*> with the specified <*filename*>.

For example, to reboot the active and standby management modules, enter the following command at the Privileged EXEC level.

```
NetIron# reload
```

To reboot the standby module only, enter the following command at the Privileged EXEC level.

```
NetIron# reboot-standby
```

Upon rebooting the active and standby management module, a software image is downloaded. The following error message is displayed on the console:

```
Warning: There is an outstanding software download. Do you want to continue?
(enter 'y' or 'n')
```

If you want to continue with downloading the image, enter yes. If you do not want to download the image, enter no.

Monitoring management module redundancy

You can monitor the following aspects of management module redundancy:

- The status of the management modules (if a module is in active or standby mode)
- The switchover history for the management modules

The following sections explain how to monitor the management modules.

Determining management module status

You can determine the status of a management module in the following ways:

- **LEDs** – LEDs on the management module indicate whether a module is active or standby, and if the module has power.
- **Module information in software** – The module information displayed by the software indicates whether a module is active or standby.

Status LED

You can determine which management module is currently active and which is standby by observing the Active LED on each module. If this LED is on (green), the module is the active module. If this LED is off, the module is the standby module.

You can also observe the Pwr LED on each module. If this LED is on (green), the module is receiving power. If the LED is off, the module is not receiving power. (A module without power will not function as either the active or standby module.)

For information about what to do if these LED indicators are not what you expect, refer to the *PowerConnect B-MLXe Hardware Installation Guide.*

Software

To display the status of the management modules using the software, enter the following command at any level.

```
NetIron# show module
        Module                              Status      Ports  Starting MAC
M1 (left): NI-MLXe-MR Management Module     Active
M2 (right): NI-MLXe-MR Management Module    Standby (Ready)
)
...
```

The Status column indicates the module status. The management module status can be one of the following:

- **ACTIVE** – Current active management module
- **STANDBY** – Current standby management module.

  The status of the standby module can be one of the following:

  - **Init** – Currently initializing as the standby module
  - **Ready** – Ready to take over as the active module, if necessary
  - **Wait** – Waiting for boot information from the active management module
  - **Sync** – Active module is currently synchronizing files on the standby module

Monitoring the status change of a module

The NetIron system now logs the status change of a module. The status change of a module is logged when the module becomes:

- **Up or Ready** - The module is running or ready to run.
- **Down** - The module is not running normally.

Upon the status change of a module, a message is logged in the syslog memory. At the CLI level, type the **show log** command to view the logged messages.

The following example displays a syslog message on an Interface Module in the Down state.

```
Feb  5 12:16:17:N:System: Module down in slot 1, reason REBOOTED. Error Code 0
```

The following example displays a syslog message on a Standby Management Module in the Down state.

```
Feb  5 14:38:58:N:System: Standby Management Module was down, reason Heartbeat
Loss. Error Code 5
```

Displaying temperature information

All management, interface and switch fabric modules contain temperature sensors. By default, the PowerConnect system polls module temperature every 60 seconds. You can display the current temperature of the modules by entering either of the following commands:

- show chassis
- show temperature

For information about these commands, refer to the *PowerConnect B-MLXe Hardware Installation Guide.*

Displaying switchover information

You can display the following information about a switchover:

- Redundancy parameter settings and statistics, including the number of switchovers that have occurred
- System log or traps logged on an SNMP trap receiver, including Information about whether a switchover has occurred.

To view the redundancy parameter settings and statistics, enter the following command at any level of the CLI.

```
NetIron# show redundancy
=== MP Redundancy Settings ===
Default Active Slot = M1 (upper)
Running-Config Sync Period = 7 seconds

=== MP Redundancy Statistics ===
Current Active Session:
Active Slot=M2(lower),Standby Slot=M1(upper)(Ready State), Switchover Cause = No
Switchover
Start Time = 1900-0-0  0:6:21 (Monday)

Previous Active Session #1:
Active Slot=M1(upper), Standby Slot=M2(lower), Switchover Cause = MP Upgrade to
Ver3.7.0T163
Start Time = 1900-0-0  0:3:4 (Monday), End Time = 1900-0-0  0:6:21 (Monday)

Previous Active Session #2:
Active Slot = M2 (lower), Standby Slot = M1(upper), Switchover Cause = Active
Rebooted
Start Time = 1900-0-0  0:1:1 (Monday), End Time = 1900-0-0  0:3:4 (Monday)

Previous Active Session #3:
Active Slot = M1 (upper), Standby Slot = M2(lower), Switchover Cause = MP Upgrade
to Ver3.7.0T163
Start Time = 2036-2-6  6:43:54 (Wednesday), End Time = 1900-0-0  0:1:1 (Monday)
...
```

This output displays that the default active chassis slot is configured as slot M1 and the automatic synchronization interval is configured for 7 seconds. It also displays that in the current active session, the module installed in M2 is the active module, the module installed in M1 is the standby module, which is in Ready state, and no switchovers have occurred.

However, in three previous sessions, switchovers occurred. In sessions #1 and #3, the switchovers occurred because the software was upgraded to "Ver3.7.0T163". In session #2 the switchover occurred because the active module was rebooted. In sessions #1 and #3, the modules installed in M1 were the active modules, while the modules installed in M2 were the standby modules. In session #2, the module installed in M2 was the active module, while the module installed in M1 was the standby module.

To view the system log or traps logged on an SNMP trap receiver, enter the following command at any level.

```
NetIron# show log
Syslog logging: enabled (0 messages dropped, 0 flushes, 0 overruns)
    Buffer logging: level ACDMEINW, 24 messages logged
    level code: A=alert C=critical D=debugging M=emergency E=error
                I=informational N=notification W=warning

Static Log Buffer:
Sep 28 11:31:25:A:Power Supply 1, 1st left, not installed
Sep 28 11:31:25:A:Power Supply 3, middle left, not installed
Sep 28 11:31:25:A:Power Supply 4, middle right, failed
Sep 28 11:31:25:A:Power Supply 5, 2nd right, not installed

Dynamic Log Buffer (50 lines):
Sep 27 18:06:58:I:Interface ethernet6/2, state up
Sep 27 18:06:57:I:Interface ethernet3/2, state up
Sep 27 15:39:42:I:Interface ethernet3/2, state up
Sep 27 15:39:42:I:Interface ethernet6/2, state up
...
Sep 27 14:23:45:N:Module up in slot 6
Sep 27 14:23:45:N:Module up in slot 3
Sep 27 14:23:27:A:Management module at slot 9 state changed from standby to
active
```

This output indicates that one switchover occurred.

Flash memory and PCMCIA flash card file management commands

The PowerConnect system supports file systems in the following locations:

- Flash memory on the management module
- A PCMCIA flash card inserted in management module slots 1 or 2

Table 37 outlines the root directory for each file system.

TABLE 37 PowerConnect file system root directories

File system	Root directory
Flash memory	/flash/
PCMCIA flash card in slot 1	/slot1/
PCMCIA flash card in slot 2	/slot2/

This section describes commands that manage the files in flash memory and on the flash cards. Use the file management commands to perform the following tasks:

- Format a flash card
- Determine the current management focus
- Switch the management focus
- Display a directory of files
- Display the contents of a file
- Display the hexadecimal output of a file
- Create a subdirectory
- Remove a subdirectory
- Rename a file
- Change the read-write attribute of a file
- Delete a file
- Recover (undelete) a file
- Append one file to another (join two files)
- Perform copy operations using the **copy** command
- Perform copy operations using the **cp** command
- Load the system software from flash memory, a flash card, or other sources during system reboot
- Change the save location of the startup-config file from the default location (flash memory) to a flash card in slot 1 or 2

You can access all file management commands at the Privileged EXEC level of the CLI.

CAUTION

Do not add or remove a flash card while a file operation involving the slot where the flash card is installed is in progress. Doing so can result in corruption of the flash card. If this occurs, you may need to reformat the flash card to make it usable again. Reformatting erases all data stored on the card.

Verifying available flash space on the management module before an image is copied

The Management Module of the NetIron system accommodates 32 MB of flash space. However, as the size of the Interface Module, Management Module, and FPGA images increase, the Management Module flash may not have enough space to accommodate these images. The space in the Management Module flash is too small to hold more than two images (primary and secondary) and hence, downloading a new image is not possible without deleting one of the images that is already present in the flash.

Before an image is copied onto the Management Module or Interface Module, the software now checks to refer to if there is enough space available in the Management Module flash to support the copy operation. If there is not enough free space available on the Management Module flash, the following error message will display on the user interface.

The 32 MB flash space is capable of holding two image. However, during the TFTP copy operation, it needs more buffer space. It is not possible to copy or update an existing image to a 32 MB flash, if there are two images in the flash already. If you try to copy or update an image, the following error message is displayed.

For TFTP copy operation, the following error message is displayed.

```
NetIron#copy tftp flash 10.20.10.62 mlxe04001b1.bin primary
There is not enough space on MP flash. Please clean up MP flash and retry, or use
"delete-first" option.
TFTP: Download to primary flash failed - Flash is full
```

For SCP copy operation, the following error message is displayed.

```
C:\>scp xm04001b1.bin lab@10.22.2.21:image:primary
There is not enough space on MP flash. Please clean up MP flash and retry, or use
"delete-first" option.
C:\>
```

In the example above the copy procedure is cancelled because there is not enough space on Management Module flash to copy the image. To make space for an image to be copied, you must clean up the flash space on the Management Module, and then retry copying the image again. You may also use the delete-first option, along with the CLI copy command, to make space for an image to be copied. The delete-first option allows you to delete existing target files on the Management Module flash.

The example below displays how the delete-first option is used. In this example, the existing secondary file image is removed from the flash to make space for a new image to be copied. The TFTP copy operation is able to successfully download the new image to the secondary flash.

```
NetIron#copy tftp flash 10.53.1.82 mlxe04001b1.bin secondary delete-first
Removing secondary from flash.
.....................................................................
........TFTP: Download to secondary flash done.
```

When the delete-first option is used, the existing target files are deleted only if there is enough free space to accommodate the copy operation. If, after the delete-first option is used and there is still a shortage of free space then the following error message will display.

```
NetIron#copy tftp flash 10.53.1.82 mlxe04001b1.bin secondary delete-first
There will not be enough space on MP flash even after deleting the target files.
Please clean up MP flash and retry.
```

Management focus

The **management focus** determines the default file system (flash memory or the flash card inserted in slot 1 or 2) to which a file management operation applies. When you power on or reload a PowerConnect system, by default, the management focus is on flash memory.

You can change the management focus from flash memory to a slot and subdirectory using the **cd** or **chdir** command. (For more information, refer to "Switching the management focus" on page 191.)

To determine the slot and subdirectory that have the current management focus, enter the **pwd** command. (For more information about this command, refer to "Determining the current management focus" on page 191.)

Most file management commands provide the option of specifying the file system to which the command applies. If you want the command to apply to the file system that has the current management focus, you do not need to specify the file system. If you want the operation to apply to the file system that does not have the current management focus, you must specify one of the following keywords:

- **flash** – indicates flash memory
- **slot1** – indicates the flash card inserted in slot 1
- **slot2** – indicates the flash card inserted in slot 2

For example, if you want to display a directory of files in flash memory and flash memory has the current management focus, you do not need to specify the **flash** keyword. However, if you want to display a directory of files for slot 1 and flash memory has the current focus, you must specify the **slot1** keyword.

Flash memory file system

The flash memory file system is flat, which means that it does not support subdirectories. As a result, you cannot create or delete subdirectories in this file system using the **md**/**mkdir** and **rd**/**rmdir** commands, respectively. Also, when specifying the syntax for the various file management commands, you will not need to specify a pathname to a subdirectory because it is not possible for a subdirectory to exist.

File naming conventions

A file name in the flash memory file system can contain a maximum of 31 characters. File name are case sensitive. The flash memory file system does not accept spaces as part of a file name.

The following characters are valid in file names:

- All upper and lowercase letters
- All digits
- Any of the following special characters:
  - $
  - %
  - '
  - -
  - _
  - @
  - ~
  - `
  - !
  - (
  -)
  - {
  - }
  - ^

- #
- &

PCMCIA flash card file system

The PCMCIA flash card file system is hierarchical, which means that it supports subdirectories. Therefore, you can create or delete subdirectories in this file system using the **md**/**mkdir** and **rd**/**rmdir** commands, respectively. Also, when specifying the syntax for the various file management commands, you may need to specify a pathname to a subdirectory as appropriate to manipulate a file in a subdirectory.

PCMCIA flash card subdirectories

The full path name for the location of a file can be a maximum of 256 characters. You can nest subdirectories as deep as you want as long as the full path name is 256 characters or less.

When you include a subdirectory path in a file management command, use a slash between each level. For example, to create a subdirectory for flash code and copy a flash image file to the subdirectory, enter commands such as the following.

```
NetIron# mkdir slot1 /switchCode/initial-release
```

These commands create two levels of subdirectories on the flash card in PCMCIA slot 1.

File and subdirectory naming conventions

The PCMCIA slots supports file names of up to 32 characters . File names are not case sensitive. Thus, the software considers the name “test.cfg” and “TEST.CFG” to be the same.

Files and subdirectory names can be up to 32 characters long, including spaces and the special characters listed. The following characters are valid in file and subdirectory names:

- All upper and lowercase letters
- All digits
- Spaces
- Any of the following special characters:
  - $
  - %
  - '
  - -
  - _
  - @
  - ~
  - `
  - !
  - (
  -)
  - {

- }
- ^
- #
- &

You can use spaces in a file or subdirectory name if you enclose the name in double quotes. For example, to specify a subdirectory name that contains spaces, enter a string such as the following: “a long subdirectory name”.

A subdirectory or file name can be a maximum of 256 characters long. A complete subdirectory path name cannot contain more than 256 characters.

There is no maximum file size. A file can be as large as the available flash card space.

Wildcards

Commands to display a directory of files, to change the read-write attribute of a file, or to delete files accept wildcards in the file name (<*file-name*>). With these commands, you can use “*” (asterisk) as a wildcard for any part of the name. For example, all the following values are valid for <*file-name*>:

- teststartup.cfg
- test*.cfg
- nmb02200.bin
- *.bin
- m*.bin
- m*.*

Formatting a flash card

The flash cards shipped with a management module are pre-formatted for the 16 FAT file system used by the modules. If you want to use a flash card that is not formatted for the 16 FAT file system, you need to reformat the flash card before you can store files on it.

CAUTION

Make sure the flash card is empty or does not contain files you want to keep. Formatting a flash card completely erases all files on the card.

CAUTION

Once you start the formatting process, you cannot stop it. Even if you enter CTRL-C to stop the CLI output and a new prompt appears, the formatting continues. Make sure you want to format the card before you enter the command.

To reformat a flash card in slot 2 on the management module, for example, enter the following command.

```
NetIron# format slot2
```

```
.................................................
.................................................
.................................................
.................................
 80809984 bytes total card space.
 80809984 bytes available on card.
     2048 bytes in each allocation unit.
    39458 allocation units available on card.
```

Syntax: format slot1 | slot2

The **slot1 | slot2** keyword specifies the PCMCIA slot that contains the flash card you are formatting.

Determining the current management focus

For conceptual information about management focus, refer to "Management focus" on page 187.

To determine which file system has the current management focus, enter the following command.

```
NetIron# pwd
Flash /flash/
```

In this example, the management focus is the flash memory.

In the following example, the management focus is the root directory of the flash card in slot 1.

```
NetIron# pwd
/slot1/
```

In the following example, the management focus is a subdirectory called "test" on the flash card in slot 1.

```
NetIron# pwd
/slot1/test/
```

Switching the management focus

The effect of file management commands depends on the file system that has the current management focus. For example, if you enter a command to delete a file and do not specify the location of the file, the software attempts to delete the file from the location that currently has the management focus.

By default, the management focus is on the flash memory on the management module. You can switch the focus from flash memory to flash cards in slot 1 or slot 2 on the management module using the **cd** or **chdir** commands, which have the same syntax and function exactly the same.

For example, to switch the focus from flash memory to the flash card in slot 2, enter the following command.

```
NetIron# cd /slot2
NetIron#
```

When you enter this command, the software changes the management focus to slot 2 then displays a new command prompt. If a slot you specify does not contain a flash card, the software displays the message shown in the following example.

```
NetIron# cd /slot2
Device not present
```

Syntax: **cd** <*directory-pathname*>

Syntax: chdir <*directory-pathname*>

For the <*directory-pathname*> parameter for both **cd** and **chdir** commands, specify /slot1 or /slot2 to switch the focus to slot 1 or slot 2, respectively. Specify /flash to switch the focus to flash memory.

After you have switched the focus to slot 2, you can specify the <*directory-pathname*> parameter to switch the focus to a subdirectory on a flash card inserted in slot 2. For example, to switch the focus from the root directory level (/) of slot 2 to the subdirectory named "PLOOK," enter the following command.

```
NetIron# cd /PLOOK
```

If you specify an invalid subdirectory path, the CLI displays a message such as the following.

```
NetIron# cd /PLOOK
Path not found
```

If you are certain the path you specified exists, make sure you are at the correct level to reach the path. For example, if you are already at the PLOOK level, the CLI cannot find the subdirectory "/PLOOK" because it is not a subdirectory from the level that currently has the management focus.

To change the management focus back to flash memory, enter the following command.

```
NetIron# cd /flash
NetIron#
```

Displaying a directory of the files

You can display a directory of the files in the flash memory on the management module, or on a flash card inserted in management module slot 1 or slot 2 using the **dir** or **ls** commands.

The software displays the directory of the file system that has the current management focus. By default, flash memory has the management focus. However, you do not need to change the focus to list the files on the file system that does not currently have management focus. In this case, you can specify the /<*path-name*>/ parameter with the **dir** or **ls** commands to display the directory of the desired file system.

For example, to display a directory of the files in flash memory, if flash memory has the management focus, enter the following command.

```
NetIron# dir
Directory of /flash/

07/28/2003 15:57:45              3,077,697 1060.tmp
07/28/2003 15:56:10              3,077,697 14082.tmp
07/28/2003 16:00:08              3,077,697 2084.tmp
07/25/2003 18:00:23                292,701 boot
00/00/0    00:00:00                     12 boot.ini
07/28/2003 14:40:19                840,007 lp-primary-0
07/28/2003 15:18:18                840,007 lp-secondary-0
07/28/2003 09:56:16                391,524 monitor
07/28/2003 15:08:12              3,077,697 primary
07/28/2003 16:02:23                  1,757 startup-config
07/25/2003 18:02:14                  1,178 startup.sj2
07/28/2003 14:28:47                  1,662 startup.spa
07/26/2003 12:16:29                  1,141 startup.vso
07/25/2003 18:11:01                  1,008 startup.vsr
07/28/2003 09:40:54                  1,554 startup.vsrp.ospf

               15 File(s)       14,683,339 bytes
                0 Dir(s)        15,990,784 bytes free
```

Syntax: dir | ls [<*path-name*>]

You can enter either **dir** or **ls** for the command name.

Specify the <*path-name*> parameter to display the following:

- The files that match the value for a flash memory directory, or flash card directory/subdirectory you specify
- The files that match the value for a name you specify

For example, to list only files that contain a .tmp suffix in flash memory, if flash memory is the current management focus, enter a command such as the following.

```
NetIron# dir *.tmp
Directory of /flash/
07/28/2003 15:57:45              3,077,697 1060.tmp
07/28/2003 15:56:10              3,077,697 14082.tmp
07/28/2003 16:00:08              3,077,697 2084.tmp

                3 File(s)        9,292,701 bytes
                0 Dir(s)        15,990,784 bytes free
```

For example, to display a directory of the files on the flash card in slot 2, if flash memory has the management focus, enter the following command.

```
NetIron# dir /slot2/
Directory of /slot2/

08/01/2003 18:25:28              3,092,508 PRIMARY
08/01/2003 18:28:06              3,092,508 primary.1234

08/01/2003 18:28:30                389,696 MONITOR1
08/01/2003 18:28:01                389,696 MONITOR2
08/01/2003 18:28:03                389,696 MONITOR3
08/01/2003 18:29:04                389,696 MONITOR4
08/01/2003 18:29:12   <DIR>                DIR1
08/01/2003 18:32:03                389,696 1234567890.12345
08/01/2003 18:32:08                389,696 123456.123
08/01/2003 18:32:11                389,696 123456.123
08/01/2003 18:32:14                389,696 123456.123
08/01/2003 18:32:17                389,696 123456.123

               12 File(s)       10,081,976 bytes
                1 Dir(s)       114,577,408 bytes free
```

The following information is displayed for each file.

TABLE 38 CLI display of directory information

This field...	Displays...
File date	The date on which the file was placed in the flash memory or card, if the device system clock is set.
Time of day	The time of day at which the file was placed in the flash memory or card, if the device system clock is set.
File size	The number of bytes in the file.
Read-write attribute	If you have set the read-write attribute of the file to read-only, "R" appears before the file name. If the read-write attribute of the file is read-write (the default), no value appears in this column. For information, refer to "Changing the read-write attribute of a file" on page 198.
File name	The file name.
Long file name	This field applies to files on a flash card only. The longer file name applies if the file was created on a PC and the name is longer than the 8.3 format.

The directory also lists the total number of files that match the parameters you specified, the total number of bytes used by all the files, and the number of bytes still free.

Displaying the contents of a file

You can display the contents of a file in the flash memory on the management module or on a flash card inserted in management module slot 1 or slot 2.

The software displays the specified file in the file system that has the current management focus (flash memory by default). However, you do not need to change the focus to display the file in a file system that does not currently have management focus. In this case, you can specify the */<directory>/ <path-name>* parameter with the **more** command to display the file in the desired file system.

For example, to display the contents of a file in flash memory, if flash memory has the current management focus, enter a command such as the following.

```
NetIron# more cfg.cfg
```

Syntax: more [/<*directory*>/]<*file-name*>

Use the <*directory*> parameter to specify a directory in a file system that does not have current management focus.

Use the <*path-name*> parameter to specify the file you want to display.

For example, to display the contents of a file on the flash card in slot 2, if flash memory has the current management focus, enter a command such as the following.

```
NetIron# more /slot2/cfg.cfg
```

Displaying the hexadecimal output of a file

You can display the hexadecimal output of a file in flash memory on the management module or on a flash card inserted in management module slot 1 or slot 2.

The software displays the hexadecimal output of a specified file in the file system that has the current management focus (flash memory by default). However, you do not need to change the focus to display the hexadecimal output of a file in a file system that does not currently have management focus. In this case, you can specify the /<*directory*>/<*file-name*> parameter with the **hd** command to display the output of the file in the desired file system.

For example, to display the hexadecimal output of a file in flash memory, if flash memory has the current management focus, enter the following command.

```
NetIron# hd cfg.cfg
```

Syntax: [no] hd [/<*directory*>/]<*file-name*>

Use the <*directory*> parameter to specify a directory in a file system that does not have current management focus.

Use the <*file-name*> parameter to specify a file for which you want to display the hexadecimal output.

For example, to display the hexadecimal output of a file in a flash card inserted in slot 2, if flash memory has the current management focus, enter the following command.

```
NetIron# hd /slot2/cfg.cfg
```

Creating a subdirectory

Create a subdirectory in the flash card file system using the **md** and **mkdir** commands, which have the same syntax and function exactly the same.

NOTE
You cannot create subdirectories in the flash memory file system. Therefore, the **md** and **mkdir** commands do not apply to the flash memory file system.

The software creates a subdirectory in the file system that has the current management focus (flash memory by default). However, you do not need to change the focus to create a subdirectory in a file system that does not currently have management focus. In this case, you can specify the **slot1** or **slot2** keyword with the **md** or **mkdir** command to create the subdirectory in the desired file system.

For example, to create a subdirectory on the flash card inserted in slot 2, if the flash memory has current management focus, enter a command such as the following.

```
NetIron# mkdir slot2 TEST
```

Syntax: [no] md | mkdir [slot1 | slot2] <*dir-name*>

You can enter either **md** or **mkdir** for the command name.

Specify the **slot1** or **slot2** keyword to create a subdirectory on the flash card in slot 1 or slot 2, respectively. If you do not specify one of these parameters, the command applies to the file system that currently has the management focus.

The <*dir-name*> parameter specifies the subdirectory name. You can enter a name that contains any combination of the following characters. Do not enter a slash " / " in front of the name. Remember, a file name preceded by a slash represents the absolute path name (/flash, /slot1, or /slot2).

- All upper and lowercase letters
- All digits
- Spaces
- Any of the following special characters:
  - $
  - %
  - '
  - -
  - _
  - @
  - ~
  - `
  - !
  - (
  -)
  - {
  - }
  - ^
  - #
  - &

You can use spaces in a subdirectory name if you enclose the name in double quotes. For example, to specify a subdirectory name that contains spaces, enter a string such as the following: "a long subdirectory name".

A subdirectory name can be a maximum of 256 characters long. A complete subdirectory path name cannot contain more than 260 characters.

The name is not case sensitive. You can enter upper- or lowercase letters, however the CLI displays the name using uppercase letters.

To verify successful creation of the subdirectory, enter a command such as the following to change to the new subdirectory level.

```
NetIron# chdir /slot2/TEST
Current directory of slot2 is: /TEST
```

For information about changing the directory using the **cd** and **chdir** commands, refer to "Switching the management focus" on page 191.

Removing a subdirectory

You can remove a subdirectory from the flash card file system using the **rd** and **rmdir** commands, which have the same syntax and function exactly the same.

NOTE
You cannot remove subdirectories from the flash memory file system. Therefore, the **rd** and **rmdir** commands do not apply to the flash memory file system.

NOTE
You can remove a subdirectory only if the subdirectory does not contain files or other subdirectories.

The software will remove a subdirectory from the file system that has the current management focus (flash memory by default). However, you do not need to change the focus to remove a subdirectory from a file system that does not currently have management focus. In this case, you can specify the **slot1** or **slot2** keyword with the **rd** or **rmdir** command to remove the subdirectory from the desired file system.

For example, to remove a subdirectory from the flash card inserted in slot 2, if the flash memory has current management focus, enter a command such as the following.

```
NetIron# rmdir slot2 TEST
```

Syntax: [no] rd | rmdir [slot1 | slot2] <*dir-name*>

You can enter either **rd** or **rmdir** for the command name.

Specify the **slot1** or **slot2** keyword to remove a subdirectory on the flash card in slot 1 or slot 2, respectively. If you do not specify one of these parameters, the command applies to the file system that currently has the management focus.

The <*dir-name*> parameter specifies the subdirectory you want to delete. You can enter a path name if the subdirectory is not in the current directory.

If you receive a message such as the following, enter the **pwd** command to verify that the management focus is at the appropriate level of the directory tree.

```
NetIron# rmdir TEST
rmdir /slot1/test/dir1/temp failed - File not found
```

For information about using the **pwd** command, refer to "Determining the current management focus" on page 191.

Renaming a file

You can rename a file in the flash memory on the management module or on a flash card inserted in management module slot 1 or slot 2 using the **rename** or **mv** command.

The software renames the file in the file system that has the current management focus flash memory by default). However, you do not need to change the focus to rename the file in a file system that does not currently have management focus. In this case, you can specify the */<directory>/<old-file-name>* /<directory>/*<new-file-name>* parameter with the **rename** or **mv** command to rename the file in the desired file system.

For example, to rename a file in flash memory, if flash memory has the current management focus, enter a command such as the following.

```
NetIron# rename oldname newname
```

If the command is successful, the CLI displays a new command prompt.

Syntax: [no] rename | mv *[/<directory>/]<old-file-name> [/<directory>/]<new-file-name>*

You can enter either **rename** or **mv** for the command name.

The */<directory>/* parameter specifies a directory in a file system that does not have current management focus.

The *<old-file-name>* parameter specifies the original filename that you want to change.

The *<new-file-name>* parameter specifies the new filename that you want to assign to the original file.

For example, to rename a file on the flash card inserted in slot 2, if flash memory has the current management focus, enter a command similar to the following.

```
NetIron# rename /slot2/oldname /slot2/newname
```

Changing the read-write attribute of a file

You can specify the read-write attribute of a file on a flash card as follows:

- **Read-only** – You can display or copy the file but you cannot replace (copy over) or delete the file.
- **Read-write** – You can replace (copy over) or delete the file. This is the default.

NOTE
All files in flash memory are set to the read-write attribute, which cannot be changed. You cannot change this attribute. Therefore, the **attrib** command does not apply to the flash memory file system.

To determine the current setting of the read-write attribute for a file, use the **dir** command to list the directory information for the file. Files set to read-only are listed with "R" in front of the file name. For information about the **dir** command, refer to "Displaying a directory of the files" on page 192.

The software will change the read-write attribute of the file in the file system that has the current management focus (flash memory by default). However, you do not need to change the focus to change this file attribute in a file system that does not currently have management focus. In this case, you can specify the **slot1** or **slot2** keyword with the **attrib** command to change the attribute of the file in the desired file system.

For example, to change the attribute of a file in slot2 to read-only, if flash memory has the management focus, enter a command similar to the following.

```
NetIron# attrib slot2 ro goodcfg.cfg
```

Syntax: [no] attrib [slot1 | slot2] ro | rw *<file-name>*

Specify the **slot1** or **slot2** keyword to change the attribute of a file on the flash card in slot 1 or slot 2, respectively. If you do not specify one of these keywords, the command applies to the file system that currently has the management focus.

The **ro** parameter specifies that the attribute of the file is set to read-only. The **rw** parameter specifies that the attribute of the file is set to read-write.

The *<file-name>* parameter specifies the file for which to change the attribute.

For example, to change the attribute of all files on the flash card in slot 2 to read-only, if flash memory has the current management focus, enter a command similar to the following.

```
NetIron# attrib slot2 ro *.*
```

Deleting a file

You can delete a file from flash memory or a flash card inserted in slot 1 or slot 2 on the management module using the **delete** or **rm** command.

NOTE
The **delete** or **rm** command deletes all files in a file system unless you explicitly specify the files you want to delete.

NOTE
The software does not support an undelete option for the flash memory file system. Be sure you really want to delete the file before you execute this command.

The software will delete the file in the file system that has the current management focus. By default, flash memory has the management focus. However, you do not need to change the focus to delete the file in a file system that does not currently have management focus. In this case, you can specify the */<directory>/<file-name>* parameter with the **delete** or **rm** command to delete the file in the desired file system.

For example, to delete a file in flash memory, if flash memory has the current management focus, enter a command similar to the following.

```
NetIron# delete cfg.cfg
```

If the command is successful, the CLI displays a new command prompt.

Syntax: delete | rm [slot1 | slot2] [*<directory>] [<file-name>*]

You can enter either **delete** or **rm** for the command name.

Specify the **slot1** or **slot2** keywords to delete all files on the flash card in slot 1 or slot 2, respectively.

The *<directory>* parameter specifies the directory in a file system that does not have the current management focus.

The *<file-name>* parameter specifies the file that you want to delete.

For example, to delete all files with names that start with “test” from flash memory, if flash memory has the current management focus, enter a command similar to the following.

```
NetIron# delete test*.*
```

For example, to delete all files on the flash card in slot 2, if flash memory has the current management focus, you can enter one of the following commands.

```
NetIron# delete /slot2/
```

or

```
NetIron# delete slot2
```

Recovering ("undeleting") a file

You can recover or undelete a file you have deleted from a flash card file system using the **undelete** command.

NOTE
You can not recover or undelete a file from the flash memory file system. Therefore, the **undelete** command does not apply to the flash memory file system.

The software will recover the file in the file system that has the current management focus (flash memory by default). If you want to recover a file in a file system that does not have the current management focus, you must switch the management focus to the desired file system using the **cd** command. For more information about switching the management focus, refer to "Switching the management focus" on page 191.

For example, to undelete a file on the flash card in slot 2, if flash memory has the current management focus, enter a command such as the following.

```
NetIron# cd slot2
NetIron# undelete
Undelete file ?RIMARY ? (enter y or n) :y
Input one character: P
File recovered successfully and named to PRIMARY
```

For each file that can be undeleted from the flash card in slot 2, the CLI displays the remaining name entry in the file directory and prompts you for the first character of the file name. You can enter any valid file name character. You do not need to enter the character that was used before in the deleted file name.

Once you enter a character and the CLI undeletes the file, the CLI continues with the next file that can be undeleted. For each file, specify "y" or "n", and specify a first character for the files that you select to undelete.

NOTE
When you delete a file from a flash card, the CLI leaves the file intact but removes the first letter in the file name from the file directory. However, if you save file changes or new files that use part of the space occupied by the deleted file, you cannot undelete the file. The **undelete** command lists only the files that can be undeleted.

To end the undelete process, enter CTRL + C.

Appending a file to another file

You can append a file in flash memory or on a flash card to the end of another file in one of these file systems.

The software will append one file to another in the file system that has the current management focus (flash memory by default). However, you do not need to change the focus to append one file to another in a file system that does not currently have management focus. In this case, you can specify the /<*source-dir-path*>/ or /<*dest-dir-path*>/ parameters with the **append** command to append one file to another in the desired file system.

To append one file to another in flash memory, if flash memory has the current management focus, enter a command similar to the following.

```
NetIron# append newacls.cfg startup-config.cfg
```

Syntax: [no] **append** [<*source-file-system*> <*dest-file-system*>]
[/<*source-dir-path*>/]<*source-file-name*> [/<*dest-dir-path*>/]<*dest-file-name*>

Specify the <*source-file-system*> and <*dest-file-system*> parameters when you are appending a file on one file system to a file on another file system.

The [/<*source-dir-path*>/] <*source-file-name*> parameter specifies the file you are appending to the end of another file. If the file is not located in the current subdirectory (the subdirectory that currently has the management focus), specify the subdirectory path in front of the file name.

The [/<*dest-dir-path*>/]<*dest-file-name*> parameter specifies the file to which you are appending the other file. If the file is not located in the current subdirectory, specify the subdirectory path in front of the file name.

For example, to append a file in the root directory of slot 1 to another file in a subdirectory of slot 2, enter a command similar to the following.

```
NetIron# append slot1 slot2 newacls.cfg /TEST/startup-config.cfg
```

Copying files using the copy command

For information about copying files using the **copy** command while upgrading software images, refer to "Basic Tasks in the Software Upgrade Process" in the *PowerConnect B-MLXe Hardware Installation Guide.*

You can perform the following additional copy operations using the **copy** command:

- Copy files from one flash card to the other
- Copy files between a flash card and the flash memory on the management module
- Copy software images between active and standby management modules
- Copy files from a management module to an interface module
- Copy management module PowerConnect Multi-Service IronWare images from flash memory to a TFTP server
- Copy files between a flash card and a TFTP server
- Copy a startup-config file between a flash card and flash memory on the management module
- Copy a startup-config file between flash memory on the management module and a TFTP server
- Copy the running-config to a flash card or a TFTP server
- Load a running-config from a flash card or TFTP server into the running-config (loading ACLs only) on the device

NOTE
Since the copy options require you to explicitly specify the flash card, you can perform a copy regardless of the flash card that currently has the management focus.

Copying files from one flash card to the other

To copy a file from one flash card to the other, enter the following command.

```
NetIron# copy slot1 slot2 sales.cfg
```

Syntax: copy <*from-card*> <*to-card*> [/<*from-dir-path*>/]<*from-name*> [/<*to-dir-path*>/][<*to-name*>]

For the <*from-card*> and <*to-card*> parameters, you can specify **slot1** or **slot2**.

The command shown in the example copies a file from the flash card in slot 1 to the flash card in slot 2. In this case, the software uses the same name for the original file and for the copy. Optionally, you can specify a different file name for the copy.

Copying files between a flash card and flash memory

To copy a file from a flash card to the primary area in flash memory, enter a command similar to the following.

```
NetIron# copy slot1 flash nmpr02200.bin primary
```

Syntax: copy slot1 | slot2 flash [/<*from-dir-path*>/]<*from-name*> **monitor | primary | secondary**

To copy a file from flash memory to a flash card, enter a command similar to the following.

```
NetIron# copy flash slot2 nmpr02200.bin primary
```

Syntax: copy flash slot1 | slot2 <*source-name*> **monitor | primary | secondary | startup-config** [<*dest-name*>]

The command in this example copies a PowerConnect Multi-Service IronWare image file from the primary area in flash memory onto the flash card in slot 2. In this case, the software uses the same name for the source file and for the destination file. Optionally, you can specify a different file name for the destination file.

Copying software images between active and standby management modules

To copy the monitor image from flash memory of the active management module to flash memory of the standby module, enter the following command.

```
NetIron# copy flash flash monitor standby
```

To copy the PowerConnect Multi-Service IronWare image from the secondary location in flash memory on the active management module to the primary location in flash memory, enter the following command.

```
NetIron# copy flash flash primary
```

Syntax: copy flash flash primary [standby]

Specify the optional **standby** keyword to copy the PowerConnect Multi-Service IronWare image from the secondary location in flash memory on the active management module to the primary location in flash memory on the standby module.

To copy the PowerConnect Multi-Service IronWare image from the primary location in flash memory on the active management module to the secondary location in flash memory on the active module, enter the following command.

```
NetIron# copy flash flash secondary
```

Syntax: copy flash flash secondary [standby]

Specify the optional **standby** keyword to copy the PowerConnect Multi-Service IronWare image from the primary location in the flash memory on the active management module to the secondary location in the flash memory on the standby module.

Copying files from a management module to an interface module

You can copy a software image or other type of file from flash memory on the management module to the flash memory on one or all interface modules.

For example, to copy the monitor image on the interface module from the management module to all interface modules, enter a command similar to the following.

```
NetIron# copy flash lp nlb02200.bin monitor all
```

Syntax: copy flash lp <*source-file*> **monitor | primary | secondary** <*slot-number*> **| all**

For example, to copy a file called test.cfg from the management module to the interface module in chassis slot 1, enter a command similar to the following.

```
NetIron# copy flash lp test.cfg lptest.cfg 1
```

Syntax: copy flash lp <*source-file*> <*dest-file*> <*slot-number*> **| all**

Copying PowerConnect Multi-Service IronWare images from flash memory to a TFTP Server

You can copy PowerConnect Multi-Service IronWare images from the primary and secondary locations in flash memory on the management module to a TFTP server.

For example, to copy the PowerConnect Multi-Service IronWare image in the secondary location in flash memory to a TFTP server, enter a command similar to the following.

```
NetIron# copy flash tftp 10.10.10.1 secondary.bak secondary
```

Syntax: copy flash tftp <*ip-addr*> <*dest-file-name*> **primary | secondary**

Copying files between a flash card and a TFTP server

Use the following methods to copy files between a flash card and a TFTP server.

NOTE
The PowerConnect system must have network access to the TFTP server.

To copy a file from a flash card to a TFTP server, enter a command similar to the following.

```
NetIron# copy slot1 tftp 192.168.1.17 notes.txt
```

Syntax: copy slot1 | slot2 tftp <*ip-addr*> [/<*from-dir-path*>/]<*source-file*> [<*dest-file*>]

The command in this example copies a file from slot 1 to a TFTP server. In this case, the software uses the same name for the source file and for the destination file. Optionally, you can specify a different file name for the destination file.

To copy a software image from a TFTP server to a flash card, enter a command similar to the following.

```
NetIron# copy tftp slot1 192.168.1.17 nmpr02200.bin primary
```

Syntax: copy tftp slot1 | slot2 <*ip-addr*> [/<*from-dir-path*>/]<*source-file*> <*path-name*> **| monitor | primary | secondary**

The command in this example copies the primary PowerConnect Multi-Service IronWare image from a TFTP server to a flash card in slot 1.

Copying the startup-config file between a flash card and flash memory

Use the following methods to copy a startup-config file between flash memory and a flash card. By default, the PowerConnect router uses the startup-config in the primary area of flash memory when you boot or reload the device.

NOTE
The PowerConnect router cannot configure from a startup-config file on a flash card. You cannot boot or reload from a flash card.

To copy a startup-config file from a flash card to flash memory, enter a command similar to the following.

```
NetIron# copy slot1 startup-config test2.cfg
```

Syntax: copy slot1 | slot2 startup-config [/<*from-dir-path*>/]<*file-name*>

This command copies a startup configuration named test2.cfg from the flash card in slot 1 into the flash memory on the device. The next time you reboot or reload, the device uses the configuration information in test2.cfg.

To copy the startup-config file on the device from flash memory onto a flash card, enter a command similar to the following.

```
NetIron# copy startup-config slot1 mfgtest.cfg
```

Syntax: copy startup-config slot1 | slot2 [/<*to-dir-path*>/]<*to-name*>

This command copies the startup configuration from the flash memory on the device to a flash card in slot 1 and names the file mfgtest.cfg.

Copying the startup-config file between flash memory and a TFTP server

Use the following methods to copy a startup-config between flash memory and a TFTP server to which the PowerConnect system has access. By default, the device configures from the startup-config in the primary area of flash memory when you boot or reload the device.

To copy the startup-config on the device from flash memory to a TFTP server, enter a command similar to the following.

```
NetIron# copy startup-config tftp 10.10.10.1 /backups/startup.cfg
```

Syntax: copy startup-config tftp <*ip-addr*> [/<*to-dir-path*>]<*to-name*>

To copy a startup-config file from a TFTP server to flash memory, enter a command similar to the following.

```
NetIron# copy tftp startup-config 10.10.10.1 test.cfg
```

Syntax: copy tftp startup-config <*ip-addr*> [/<*from-dir-path*>]<*from-name*>

Copying the running-config to a flash card or a TFTP server

Use the following method to copy the config file on the PowerConnect router to a flash card or a TFTP server. The running-config contains currently active configuration information for the device. When you copy the running-config to a flash card or TFTP server, you are making a copy of the current configuration, including any configuration changes you have not saved to the startup-config.

To copy the running configuration for the device into a file on a flash card, enter a command similar to the following.

```
NetIron# copy running-config slot1 runip.1
```

Syntax: copy running-config slot1 | slot2 [/<*to-dir-path*>/]<*to-name*>

To copy the running configuration for the device into a file on a TFTP server, enter a command such as the following.

```
NetIron# copy running-config tftp 10.10.10.1 runip.1
```

Loading a running-config from a flash card or a TFTP server

Use the following method to load configuration commands into the active configuration for the PowerConnect router.

NOTE
A configuration file that you create must follow the same syntax rules as the startup-config the device creates. Refer to "Dynamic Configuration Loading" in the *PowerConnect B-MLXe Hardware Installation Guide.*

To copy a running-config from a flash card, enter a command such as the following.

```
NetIron# copy slot2 running-config runacl.2
```

Syntax: copy slot1 | slot2 running-config [/<*from-dir-path*>/]<*from-name*>

The command in this example changes the active configuration for the device based on the information in the file.

To copy a running-config from a TFTP server, enter a command similar to the following.

```
NetIron# copy tftp running-config 10.10.10.1 run.cfg overwrite
```

Syntax: copy tftp running-config <*ip-addr*> [/<*from-dir-path*>/]<*from-name*> **[overwrite]**

This command copies a running-config from a TFTP server and overwrites the active configuration for the device.

NOTE
You cannot use the overwrite option from non-console sessions, as it will disconnect the session.

Copying files using the cp command

Use the **cp** command to do the following:

- Copy files from flash memory to flash memory
- Copy files from flash memory to a flash card or vice versa
- Copy files from one flash card to another flash card

The software will copy a file in a file system to another location in the file system that has the current management focus (flash memory by default). However, you do not need to change the focus to copy a file from one location to another in a file system that does not currently have management focus. In this case, you can specify the /<*source-dir-path*>/ or /<*dest-dir-path*>/ parameters with the **cp** command to copy a file to or from a file system that does not have current management focus.

For example, to copy a file from flash memory, which has the current management focus, to flash memory, enter a command similar to the following.

```
NetIron# cp primary primary2
```

For example, to copy a file from flash memory, which has the current management focus, to the flash card in slot 2, enter a command similar to the following.

```
NetIron# cp new.cfg /slot2/cfg/new.cfg
```

Syntax: **cp** [<*source-dir-path*>]<*source-file-name*> [<*dest-dir-path*>]<*dest-file-name*>

The <*source-dir-path*> parameter specifies the directory pathname of the source file. Specify this parameter if the source file is in a file system that does not have current management focus. The <*source-file-name*> specifies the name of the file you want to copy.

The <*dest-dir-path*> parameter specifies the directory pathname of the destination file. Specify this parameter if you want to copy the source file to a file system that does not have current management focus. The <*dest-file-name*> specifies the name of the file you copied to a new destination.

For example, to copy a file from a flash card in slot 2 to flash memory, which has current management focus, enter the following command.

```
NetIron# cp /slot2/cfg/new.cfg new.cfg
```

For example, to copy a file from a flash card in slot 1 to a flash card in slot 2, neither of which has current management focus, enter the following command.

```
NetIron# cp /slot1/cfg/new.cfg /slot2/cfg/new.cfg
```

Loading the software

By default, the management module loads an PowerConnect Multi-Service IronWare image from the primary location in flash memory. You can change the PowerConnect Multi-Service IronWare image source for the system to one of the following sources for a single reboot or for all future reboots:

- The secondary location in flash memory
- A flash card inserted in slot 1 or 2
- A TFTP server
- A BOOTP server

If you specify a source other than the primary location in flash memory and for some reason the source or the PowerConnect Multi-Service IronWare image is unavailable, the system uses the primary location in flash memory as a default backup source.

Rebooting from the system

To use a source besides the IronWare image in the primary location in flash memory for a single reboot, enter a command similar to the following at the Privileged EXEC level of the CLI.

```
NetIron# boot system slot1 /slot1/mlxe03000.bin
```

The command in this example reboots the system using the image mlxe03000.bin located on the flash card in slot 1. This example assumes that the flash card in slot 1 is not the management focus.

Syntax: boot system slot1 | **slot2** [/<*dir-path*>/]<*file-name*>

The **slot1** | **slot2** keywords specify the flash card slot.

The <*file-name*> parameter specifies the file name. If the file is in a subdirectory, specify the subdirectory path in front of the file name. If the file name you specify is not a full path name, the CLI assumes that the name (and path, if applicable) you enter are relative to the subdirectory that currently has the management focus.

NOTE
This command also is supported at the boot PROM.

For example, to reboot the system using the image mlxe03000.bin on a TFTP server, enter a command similar to the following.

```
NetIron# boot system tftp 10.10.10.1 mlxe03000.bin
```

Syntax: boot system tftp <*ip-address*> <*file-name*>

The <*ip-address*> parameter specifies the address of the TFTP server on which the desired image resides.

The <*file-name*> parameter specifies the name of the PowerConnect Multi-Service IronWare image on the TFTP server.

For example, to reboot the system using the secondary location in flash memory, enter the following command.

```
NetIron# boot system flash secondary
NetIron# Are you sure? (enter 'y' or 'n'): y
```

Syntax: boot system flash secondary

To reboot the system from a BOOTP server, enter the following command.

```
NetIron# boot system bootp
```

Syntax: boot system bootp

Configuring the boot source for future reboots

To change the PowerConnect Multi-Service IronWare image source from the primary location in flash memory to another source for future reboots, enter a command similar to the following at the global CONFIG level of the CLI.

```
NetIron(config)# boot system slot1 mlxe03000.bin
```

The command in this example sets PCMCIA slot 1 as the primary boot source for the PowerConnect router. When you reload the software or power cycle the device, the device will look for the PowerConnect Multi-Service IronWare image on the flash card in slot 1.

Syntax: **boot system slot1** <*file-name*> | **slot2** <*file-name*> | **flash secondary** | **tftp** <*ip-address*> <*file-name*> | **bootp**

NOTE
The command syntax is the same for immediately reloading and for changing the primary source, except the <*file-name*> must be the full path name. You cannot specify a relative path name. If the first character in the path name is not a slash (/), the CLI treats the name you specify as relative to the root directory.

How the device responds to the command depends on whether you enter the command at the Privileged EXEC level or the global CONFIG level.

If you enter multiple **boot system** commands at the global CONFIG level, the software places them in the running-config in the order you enter them, and saves them to the startup-config in the same order when you save the configuration. When you reload or power cycle the device, the device tries the boot sources in the order they appear in the startup-config and running-config.

Saving configuration changes

You can configure the PowerConnect system to save configuration changes to a startup-config in flash memory or on a flash card in slot 1 or 2.

Displaying the current location for saving configuration changes

Enter the following command at the Privileged EXEC level of the CLI to display the current save location for the startup-config.

```
NetIron# locate startup-config
Startup-config data location is flash memory
```

Specifying the location for saving configuration changes

By default, when you save configuration changes, the changes are saved to the startup-config in flash memory.
To change the save location to a flash card in slot 1 or 2, enter a command similar to the following.

```
NetIron# locate startup-config slot1 router1.cfg
NetIron# write memory
```

The first command in this example sets the device to save configuration changes to the file named “switch1.cfg” in the flash card in slot 1. The second command saves the running-config to the router1.cfg file on the flash card in slot 1.

NOTE
In this example, after you save the configuration changes using the **write memory** command, the router1.cfg file will include the command that designates slot 1 as the save location for configuration changes.

Syntax: **locate startup-config [slot1 | slot2 | flash-memory] [/**<*dir-path-name*>**/]**<*file-name*>

The **locate** command is used only for saving the startup-config file to a different location. But once after reload, the system always picks up the startup-config file from the flash memory.

The **slot1**, **slot2**, and **flash-memory** keywords specify the flash card in slot 1 or slot 2 or flash memory as the save location for configuration changes.

Specify the <*dir-path-name*> parameter if you want to save the configuration changes to a directory other than the root directory of a flash card file system.

The <*file-name*> parameter indicates the name of the saved configuration file.

To change the save location back to flash memory, enter a command similar to the following.

```
NetIron# locate startup-config flash-memory router1.cfg
NetIron# write memory
```

File management messages

The following table lists the messages the CLI can display in response to file management commands.

TABLE 39 Flash card file management messages

This message...	Means...
File not found	You specified a file name that the software could not find. Verify the command you entered to make sure it matches the source and destination you intended for the file operation.
Current directory is: <*dir-path*>	You have successfully changed the management focus to the slot and subdirectory indicated by the message.
Path not found	You specified an invalid path.
There is not enough space on the card	The flash card does not have enough space to hold the file you are trying to copy to it.
Access is denied	You tried to copy or delete a file that has the read-only attribute.
A duplicate file name exists	You tried to rename a file using a name that is already in use by another file.
Fatal error, can not read or write media	A hardware error has occurred. One possible cause of this message is removing the flash card while a file operation involving the card was in progress.
There is sharing conflict between format command and other read/write operations	The flash card is currently undergoing formatting. This message also appears if you enter a command to format the card while the card is being accessed for another file operation.
Invalid DOS file name	A filename you entered contains an invalid character (for example, ":" or "\").
File recovered successfully and named <*file-name*>	A file you tried to recover was successfully recovered under the name indicated in the message

6 Verifying available flash space on the management module before an image is copied

NetIron MLX Link Aggregation 7

Overview

This chapter describes how to configure Link Aggregation Groups (LAG) for the NetIron MLX. You can use a single interface to configure any of the following LAG types:

- **Static LAGs** – These LAG groups are manually-configured aggregate links containing multiple ports.
- **Dynamic LAGs** – This LAG type uses the Link Aggregation Control Protocol (LACP), to maintain aggregate links over multiple port. LACP PDUs are exchanged between ports on each router to determine if the connection is still active. The LAG then shuts down ports whose connection is no longer active.
- **Keep Alive LAGs** – In a Keep Alive LAG a single connection between a single port on 2 PowerConnect routers is established. In a keep alive LAG, LACP PDUs are exchanged between the 2 ports to determine if the connection between the routers is still active. If it is determined that the connection is no longer active, the ports are blocked.

LAG formation rules

The LAG formation rules are mentioned below:

- You cannot configure a port concurrently as a member of a static, dynamic, or keep-alive LAG.
- Any number or combination of ports between 1 and 32 within the same chassis can be used to configure a LAG. The maximum number of LAG ports is checked when adding ports to a LAG.
- All ports configured in a LAG must be of equal bandwidth. For example all 10 G ports.
- All ports configured in a LAG must be configured with the same port attributes.
- LAG formation rules are checked when a static or dynamic LAG is deployed.
- A LAG must have its primary port selected before it can be deployed.
- All ports configured in a LAG must be configured in the same VLAN.
- All ports must have the same PBR configuration before deployment. During deployment, the configuration on the primary port is replicated to all ports. On undeployment, each port inherits the same PBR configuration.
- VLAN and inner-VLAN translation

  The LAG is rejected if any LAG port has VLAN or inner-VLAN translation configured
- Layer 2 requirements:

  The LAG is rejected if the LAG ports:

  - Do not have the same untagged VLAN component.
  - Do not share the same SuperSpan customer ID (CID).

  - Do not share the same VLAN membership or do not share the same uplink VLAN membership
  - Do not share the same protocol-VLAN configuration
  - Are configured as mainly primary and secondary interfaces
- Layer 3 requirements:

  The LAG is rejected if any of the secondary LAG port has any Layer 3 configurations, such as IPv4 or IPv6 address, OSPF, RIP, RIPNG, IS-IS, and so on.
- Layer 4 (ACL) requirements:
  - All LAG ports must have the same ACL configurations; otherwise, the LAG is rejected.
  - A LAG cannot be deployed if any of the member ports has ACL-based mirroring configured on it.
  - A port with ACL-based mirroring configured on it cannot be added to a LAG.
- The router can support up to 256 LAGs, and each LAG can contain up to 32 member ports. If the router is configured to support 64 LAGs by using the **system-max trunk-num** command, the maximum number of LAG ports is 32. If the system-max trunk-num is set to 256, the maximum number of LAG ports supported is 8. The default system-max trunk-num is set to 128, and each LAG can have up to 16 member ports.
- Ports can be in only one LAG group. All the ports in a LAG group must be connected to the same device at the other end. For example, if port 1/4 and 1/5 in Device 1 are in the same LAG group, both ports must be connected to ports in Device 2 or in Device 3. You cannot have one port connected to Device 2 and another port connected to Device 3.
- All LAG member properties must match the primary port of the LAG with respect to the following parameters:
  - Port tag type (untagged or tagged port)
  - Port speed and duplex
  - TOS-based Configuration – All ports in the LAG must have the same TOS-based QoS configuration before LAG deployment, During deployment the configuration on the primary port is replicated to all ports and on undeployment, each port inherits the same TOS-based QoS configuration.

  To change port parameters, you must change them on the primary port. The software automatically applies the changes to the other ports in the LAG.
- The router can support the following LAG/member port configurations:
  - 256 LAGs with each containing 8 member ports.
  - 128 LAGs with each containing 16 member ports.
  - 64 LAGs with each containing 32 member ports.
  - 32 LAGs with each containing 64 member ports.

  You can change the number of LAGs and member ports by using the **system-max trunk-num** *num* command. The valid values are 32, 64, 128, and 256. By default, the router is configured to support 128 LAGs with each containing 16 member ports.
- Make sure the device on the other end of the LAG link can support the same number of ports in the link.

Figure 3 displays an example of a valid, Keep ALIVE LAG link between two devices. This configuration does not aggregate ports but uses the LACP PDUs to maintain the connection status between the two ports.

FIGURE 3 Example of a 1-port keep alive LAG

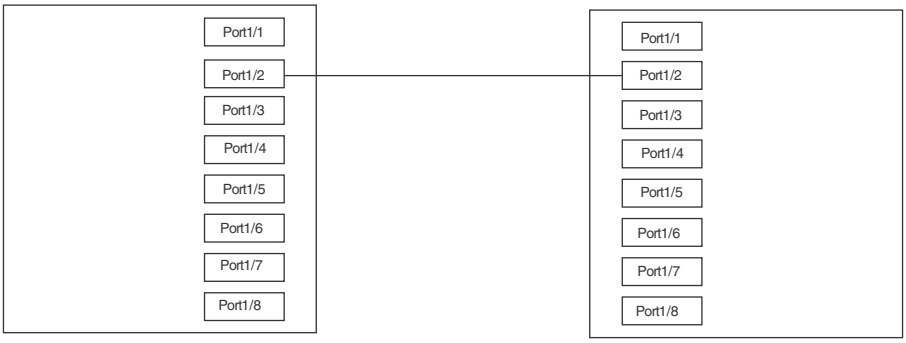

Figure 4 shows an example of a valid 2-port LAG link between devices where the ports on each end are on the same interface module. Ports in a valid 2-port LAG on one device are connected to two ports in a valid 2-port LAG on another device.

FIGURE 4 Example of 2-port LAG

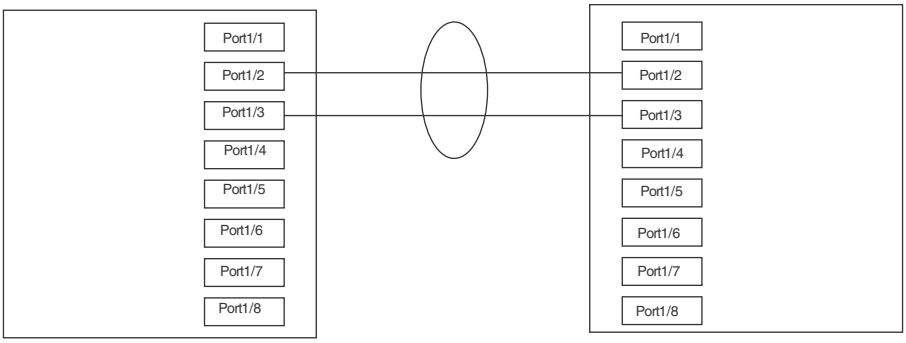

Figure 5 shows an example of two devices connected over a 4 port LAG where the ports on each end of the LAG are on different interface modules.

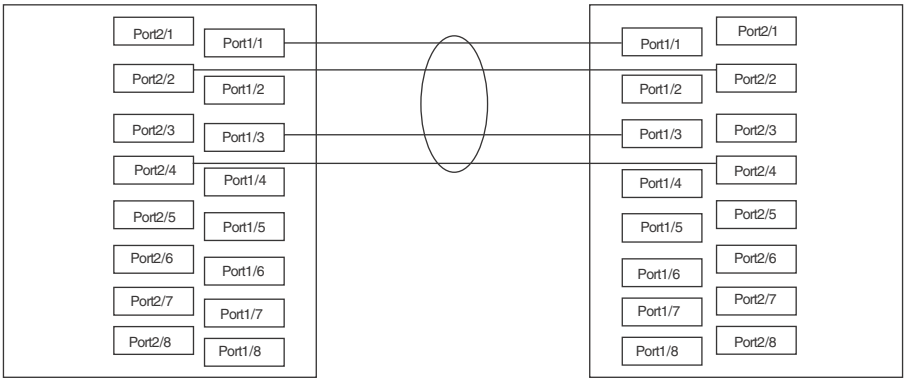
FIGURE 5 Examples of multi-slot, multi-port LAG



LAG load sharing

PowerConnect devices can be configured for load sharing over a LAG by either of the following methods:

- Hash Based Load Sharing
- Per Packet Load Sharing

Each of these methods, that are described in the following sections, are configured per LAG using the **trunk-type** command as described in "Configuring load sharing type" on page 220.

Hash based load sharing

The PowerConnect router shares the traffic load evenly across the ports in LAG group, while ensuring that packets in the flow are not reordered. Individual flows are assigned a LAG index to identify them. Hash based load sharing algorithm was introduced with the following enhancements:

- Better Distribution
- Support for 32-port LAGs
- An increased number of fields in the packet header that can be used for load balancing
- Enhanced load sharing in configurations of ECMP with LAGs.

Traffic from each flow is then distributed across the ports in the LAG group using a hash index as follows:

- For L2 switching, the hash index is based on the following:
  - IPv4 or IPv6 traffic: source MAC address and destination MAC address, IPv4v6 source and destination address, VLAN-ID, IPv4 protocol number or IPv6 next header and TCP or UDP source port and TCP or UDP destination port.

NOTE
TCP or UDP Destination and Source port is used under the following conditions:
– Packet is non-fragmented and without option, and packet is a TCP or UDP packet
– or, the **load-balance force-l4-hashing** command is configured.

  - Layer-2 packets with an MPLS payload: source MAC address and destination MAC address, VLAN ID, Inner VLAN ID (for double-tagged packets), Ethertype, and up to 3 MPLS Labels.

NOTE
For double-tagged packets, Ethertype is not used and the TPID of the inner TAG must be 0x8100 to be considered a double-tagged packet.

  - GRE encapsulated IPv4 traffic: source MAC address and destination MAC address, IPv4 source and destination address, IPv4 protocol number. VLAN-ID, and TCP or UDP source port and TCP or UDP destination port. Also, inner IPv4 source address and inner destination IPv4 address are used if there is at least one GRE or IPv6 tunnel configured.

NOTE
TCP or UDP Destination and Source port is used under the following conditions:
– Packet is non-fragmented and without option, and packet is a TCP or UDP packet
– or, the **load-balance force-l4-hashing** command is configured.

- IPv6 tunnel encapsulated IPv6 traffic: source MAC address and destination MAC address, IPv6 source and destination address, TCP or UDP source port and TCP or UDP destination port, and IPv6 next header. and VLAN-ID.

NOTE
TCP or UDP Destination and Source port is used under the following conditions:
– Packet is a TCP or UDP packet
– or, the **load-balance force-l4-hashing** command is configured.
For 6over4 encapsulated packets, inner IPv6 destination address and inner IPv6 source address
are used if there is at least one GRE or IPv6 tunnel configured.

- Layer-2, non-IPv4.IPv6 or non-MPLS packets: source MAC address, destination MAC address, VLAN ID, Ethertype and Inner VLAN ID (for double-tagged packets).

- For L3-Routing, the hash index is based on the following:
  - IPv4 or IPv6 traffic: source MAC address and destination MAC address, IPv4v6 source and destination address, VLAN-ID, IPv4 protocol number or IPv6 next header and TCP or UDP source port and TCP or UDP destination port.

NOTE
TCP or UDP Destination and Source port is used under the following conditions:
– Packet is non-fragmented and without option, and packet is a TCP or UDP packet
– or, the **load-balance force-l4-hashing** command is configured.

  - GRE encapsulated IPv4 traffic: source MAC address and destination MAC address, IPv4 source and destination address, IPv4 protocol number. VLAN-ID, and TCP or UDP source port and TCP or UDP destination port. Also, inner IPv4 source address and inner destination IPv4 address are used if there is at least one GRE or IPv6 tunnel configured.

NOTE
TCP or UDP Destination and Source port is used under the following conditions:
– Packet is non-fragmented and without option, and packet is a TCP or UDP packet
– or, the **load-balance force-l4-hashing** command is configured.

  - IPv6 tunnel encapsulated IPv6 traffic: source MAC address and destination MAC address, IPv6 source and destination address, TCP or UDP source port and TCP or UDP destination port, and IPv6 next header. and VLAN-ID.

NOTE
TCP or UDP Destination and Source port is used under the following conditions:
– Packet is a TCP or UDP packet
– or, the **load-balance force-l4-hashing** command is configured.
For 6over4 encapsulated packets, inner IPv6 destination address and inner IPv6 source address
are used if there is at least one GRE or IPv6 tunnel configured.

- For MPLS Switching, the hash index is based on the following:
  - L2VPN traffic: outer source MAC address and outer destination MAC address, up to two MPLS Labels, VLAN ID, inner source MAC address and inner destination MAC address, If packet payload is an IPv4 or v6 packet: IPv4v6 source and destination address, IPv4 Protocol Number or IPv6 Next Header ID of the payload are used.

- L3VPN traffic or IP shortcut traffic: outer source MAC address and outer destination MAC address, VLAN ID, inner source IPv4v6 address and inner destination IPv4v6 address, IPv4 Protocol Number or IPv6 Next Header ID, TCP source port and TCP destination port, UDP source port and UDP destination port, and up to two MPLS Labels.
- MPLS packets with 3 labels: outer source MAC address and outer destination MAC address, VLAN ID, and all 3 MPLS Labels.

NOTE
For transit LSR's please note the following:
The **load-balance speculate-mpls-ip** command must be active. It is on by default.

If the **load-balance speculate-mpls-ip** command has been configured to be inactive, and the **load-balance speculate-mpls-enet** command is active, the packet will be processed like an L2VPN packet.

If both commands are configured to be inactive, no inner Layer-2 or Layer-3 headers are considered
but up to 3 MPLS labels are used for hashing.

Options for hash based load sharing

The following options can be used to refine the hash calculations used for LAGs:

- Speculate UDP or TCP Headers
- Mask Layer-4 Source and Destination Port Information
- Hash Diversification

Each of these options when configured apply to both IP Load Sharing and LAG Load sharing. They are described in detail in "Options for IP load sharing and LAGs" on page 734.

Load sharing for MPLS LAGs

Load sharing on MPLS LAG involves traffic flows that include the MPLS Inner and Outer Labels. These can be used exclusively or in combination with the IP and MAC source and destination addresses to determine the LAG index for a traffic flow. The following additional CLI commands can be added to restrict the hashing to just **MPLS-ip** and **MPLS-enet** respectively.

Using IP source and destination addresses for load sharing

You can use the **load-balance speculate-mpls-ip** command to include the IP source and destination addresses in the calculation of the LAG index for a traffic flow within MPLS LAGs, as shown in the following.

```
NetIron(config)# load-balance speculate-mpls-ip all
```

Syntax: [no] load-balance speculate-mpls-ip [all | <*slot-number*> **|** <*slot-number*> <*np-id*> **]**

The **all** option applies the command to all ports within the router.

Specifying a slot number using the <*slot-number*> variable limits the command to an individual module.

Specifying a slot number and a network processor ID using the <*slot-number*> and <*np-id*> variables limits the command to the ports supported by the specified network processor on the specified interface module.

NOTE
The **load-balance speculate-mpls-ip** command will hash only on the IP portion.

Using MAC source and destination addresses for load sharing

You can use the **load-balance speculate-mpls-enet** command to include the MAC source and destination addresses in the calculation of the LAG index for a traffic flow within MPLS LAGs, as shown in the following.

```
NetIron(config)# load-balance speculate-mpls-enet all
```

Syntax: [no] load-balance speculate-mpls-enet [all | <*slot-number*> **|** <*slot-number*> <*np-id*> **]**

The **all** option applies the command to all ports within the router.

Specifying a slot number using the <*slot-number*> variable limits the command to an individual module.

Specifying a slot number and a network processor ID using the <*slot-number*> and <*np-id*> variables limits the command to the ports supported by the specified network processor on the specified interface module.

NOTE
The **load-balance speculate-mpls–enet** command will hash only on the Ethernet header portion.

Per packet server LAG load sharing

Per packet LAG load balancing is a type of LAG that load balances traffic on a per-packet basis, as compared to traditional server LAG load-balancing which balances traffic based on packet content such as source or destination addresses. In per packet server LAG load balancing, the packet processor (PPCR) on each module selects a port in the per packet server LAG to forward traffic in a round-robin fashion. For example, if the first port of the per packet server LAG is currently selected, the second port of the per-packet server LAG will be used next, and so on. Consequently, traffic is evenly distributed among all of the ports that are configured in a per packet server LAG.

Traffic that can be forwarded out of a per-packet LAG includes L2 switching traffic, L3 routing traffic, L3VPN (2547) traffic, VLL and VPLS traffic.

Configuring a LAG

The following configuration procedures are used to configure a LAG. Depending upon whether you are configuring a static, dynamic or keep-alive LAG, the configuration procedures may or may not apply as described:

- **Creating a Link Aggregation Group** – Required for all static, dynamic or keep alive LAGs.
- **Adding Ports to a LAG** – Required for all static, dynamic, or keep alive LAGs. A keep alive LAG contains only one port with static and dynamic LAGs can have 2 to 32 ports.
- **Configuring the Primary Port for a LAG** – Required for all static and dynamic LAGs. Since a keep alive LAG contains only one port, it is unnecessary to configure this parameter.
- **Configuring the Load Sharing Type** – Optional for all static and dynamic LAGs. Since a keep alive LAG contains only one port, it is unnecessary to configure this parameter.

- **Specifying the LAG Threshold for a LAG Group** – Optional for static and dynamic LAGs. Since a keep alive LAG contains only one port, it is unnecessary to configure this parameter.
- **Configuring LACP Port Priority** – Optional for dynamic and keep alive LAGs. Because static LAGs do not support LACP, it is unnecessary to configure this parameter.
- **Configuring an LACP Timeout** – Optional for dynamic and keep alive LAGs. Because static LAGs do not support LACP, it is unnecessary to configure this parameter.

Creating a Link Aggregation Group (LAG) using the LAG ID option

Before setting-up ports or configuring any other aspects of a LAG, you must create it first.

You can either assign a LAG **ID** explicitly or it will be automatically generated by the system. The LAG **ID** stays the same across system reload and hitless upgrade.

The command to configure LAGs allows explicit configuration of the LAG ID for static and dynamic LAGs.

To create a LAG with the LAG ID option, enter a command such as the following.

```
NetIron(config)# lag blue static
NetIron(config-lag-blue)#
```

Syntax: [no] lag <*name*> **[static | dynamic] [id** <*number*>**]**

The **ID** parameter is optional. The value of the **ID** parameter that you can enter is from 1 to 256. If you do not enter a LAG **ID**, the system will generate one automatically. Once the LAG **ID** is generated the system will save it in the configuration file along with the LAG name, therefore the value will stay the same across system reload.

NOTE
The LAG **ID** parmeter is for static and dynamic LAGs only. No explicit configuration of a LAG **ID** is allowed on keepalive LAGs.

The **static** parameter specifies that the LAG with the name specified by the <*lag-name*> variable will be configured as a static LAG.

The **dynamic** option specifies that the LAG with the name specified by the <*lag-name*> variable will be configured as a dynamic LAG.

Configuration considerations

LAG **ID**s are unique for each LAG in the system. The same LAG **ID** cannot be assigned to two or more different LAGs. If a LAG **ID** is already used, the CLI will reject the new LAG configuration and display an error message that suggests the next available LAG **ID** that can be used.

Example

```
NetIron(config)#lag lag3 static id 123
Error: LAG id 123 is already used. The next available LAG id is 2.
```

Example : LAG configured with LAG id 124.

```
!
lag "lag1" static id 124
 ports ethernet 1/2 to 1/3
 primary-port 1/3
 deploy
!
```

Example : show lag command and the output.

```
NetIron(config)# show lag
Total number of LAGs:          1
Total number of deployed LAGs: 1
Total number of s created:1 (127 available)
LACP System Priority / ID:     1 / 0000.0001.c000
LACP Long timeout:             90, default: 90
LACP Short timeout:            3, default: 3
=== LAG "lag1" ID 124 (static Deployed) ===
LAG Configuration:
   Ports:         ethe 1/2 to 1/3
   Port Count:    2
   Primary Port:  1/3
    Type:    hash-based
Deployment:   ID 124, Active Primary 1/2
Port  Link L2 State  Dupl Speed  Tag Priori MAC Name
1/2   Up   Forward   Full 10G   124   No  level0 0000.0001.c002
1/3   Up   Forward   Full 10G   124   No  level0 0000.0001.c002
```

Creating a keepalive LAG

To create a **keep-alive** LAG, enter the following.

```
NetIron(config)# lag lag1 keep-alive
```

Syntax: [no] lag <*name*> **keep-alive**

The **keep-alive** option specifies that the LAG with the name specified by the <*lag-name*> variable will be configured a keep-alive LAG. The keep-alive LAG option allows you to configure a LAG for use in keep alive applications similar to the UDLD feature.

Adding Ports to a LAG or Deleting Ports from a LAG

A static or dynamic LAG can consist of from 2 to 32 ports of the same type and speed that are on any interface module within the PowerConnect chassis. A keep alive LAG consists of only one port.

To configure the static LAG named “blue” with two ports, use the following command:

```
NetIron(config)# lag blue static
NetIron(config-lag-blue)# ports ethernet 3/1 ethernet 7/2
```

Syntax: [no] ports ethernet <*slot/port*> **| pos** <*slot/port*> **[to** <*slot/port*> **] [ethernet** <*slot/port*> **| pos** <*slot/port*> **]**

The ports added to a LAG can be of type **ethernet** or **pos** as specified for the **slot/port** where they reside. The ports can be added to the LAG sequentially as shown in the following example:

```
NetIron(config-lag-blue)# ports ethernet 3/1 ethernet 7/2 ethernet 4/3 ethernet
3/4
```

A range of ports from a single interface module can be specified. In the following example, Ethernet ports 1, 2, 3 and 4 on the interface module in slot 3 are configured in a single LAG:

```
NetIron(config-lag-blue)# ports ethernet 3/1 to 3/4
```

Additionally, you can mix a range of ports from one interface module with individual ports from other interface modules to form a LAG as shown in the following:

```
NetIron(config-lag-blue)# ports ethernet 3/1 to 3/4 ethernet 10/2
```

Using the **no** option allows you to remove ports from a LAG. For example, you can remove port 3/4 from the LAG created above, as shown in the following:

```
NetIron(config-lag-blue)# no ports ethernet 3/4
```

Ports can be added to an undeployed LAG or to currently deployed LAG using the commands described. For special considerations when adding ports to or deleting ports from a currently deployed LAG, refer to the following sections:

- "Adding a Port to Currently Deployed LAG" on page 224
- "Deleting a Port from a Currently Deployed LAG" on page 224

Configuring the primary port for a LAG

The primary port must be explicitly assigned using the **primary port** command.

To designate the primary port for the static LAG "blue", use the following command.

```
NetIron(config)# lag blue static
NetIron(config-lag-blue)# primary port 3/2
```

Syntax: [no] primary port <*slot/port*>

Once a primary port has been configured for a LAG, all configurations that apply to the primary port are applied to the other ports in the LAG.

NOTE
This configuration is only applicable for configuration of a static or dynamic LAGs.

Configuring load sharing type

Individual LAGs can be configured to perform load sharing over the ports in the LAG using either a hash based or per packet method, as shown in the following.

```
NetIron(config)# lag blue static
NetIron(config-lag-blue)# trunk-type hash-based
```

Syntax: [no] trunk-type hash-based | per-packet

NOTE
This configuration is only applicable for configuration of a static or dynamic LAGs.

Specifying the LAG threshold for a LAG group

You can configure the PowerConnect router to disable all of the ports in a LAG group when the number of active member ports drops below a specified threshold value. For example, if a LAG group has 8 ports, and the threshold for the LAG group is 5, then the LAG group is disabled if the number of available ports in the LAG group drops below 5. If the LAG group is disabled, then traffic is forwarded over a different link or LAG group.

NOTE
This configuration is only applicable for configuration of a static or dynamic LAGs.

For example, the following commands establish a LAG group consisting of 4 ports, then establish a threshold for this LAG group of 3 ports.

```
NetIron(config)# lag blue static
NetIron(config-lag-blue)# ports ethernet 3/1 to 3/4
NetIron(config-lag-blue)# trunk-threshold 3
```

In this example, if the number of active ports drops below 3, then all the ports in the LAG group are disabled.

Syntax: [no] trunk-threshold <*number*>

You can specify a threshold from 1 (the default) up to the number of ports in the LAG group.

When a LAG is shut down because the number of ports drops below the configured threshold, the LAG is kept intact and it is re-enabled if enough ports become active to reach the threshold.

NOTE
The **trunk-threshold** command should be configured only at one end of the trunk. If it is set on both sides, link failures will result in race-conditions and the will not function properly.

```
NetIron(config)# lag blue dynamic
NetIron(config-lag-blue)# lacp-port-priority 100000
```

Syntax: [no] lacp-port-priority <*slot/port*> <*number*>

NOTE
This configuration is only applicable for configuration of a dynamic or keep-alive LAGs.

Configuring an LACP timeout

In a dynamic or keep-alive LAG, a port's timeout can be configured as short (3 seconds) or long (90 seconds). After you configure a port timeout, the port remains in that timeout mode whether it is up or down and whether or not it is part of a LAG.

All the ports in a LAG should have the same timeout mode. This requirement is checked when the LAG is enabled on the ports. For example, to configure a port for a short LACP timeout, use the following command.

```
NetIron(config)# lag blue dynamic
NetIron(config-if-e10000-2/1)# lacp-timeout short
```

Syntax: [no] lacp-timeout [long | short]

To delete the configuration, use the **no** form of this command.

The **long** keyword configures the port for the long timeout mode–90 seconds. With the long timeout, an LACPDU is sent every 30 seconds. If no response comes from its partner after 3 LACPDUs are sent, a timeout event occurs, and the LACP state machine transition to the appropriate state based on its current state.

The **short** keyword configures the port for the short timeout mode—3 seconds. In the short timeout configuration, an LACPDU is sent every second. If no response comes from its partner after 3 LACPDUs are sent, a timeout event occurs, and the LACP state machine transitions to the appropriate state based on its current state.

If you specify neither **long** nor **short**, the state machine operates based on the standard IEEE specification as its default behavior. The original IEEE specification says that the state machine starts with short the timeout and moves to the long timeout after the LAG is established. However, sometimes a vendor's implementation always uses either the short timeout or the long timeout without changing the timeout. Dell provides this command so that you can configure Dell devices to interoperate with other vendor's devices.

NOTE
This configuration is applicable to the configuration of dynamic or keep-alive LAGs only.

Deploying a LAG

After configuring a LAG, you must explicitly enable it before it begins aggregating traffic. This task is accomplished by executing the **deploy** command within the LAG configuration. After the **deploy** command runs, the LAG is in the aggregating mode. Only the primary port within the LAG is available at the individual interface level. Any configuration performed on the primary port applies to all ports within the LAG. The running configuration will no longer display deployed LAG ports other than the primary port.

To deploy a LAG, at least one port must be in the LAG and the primary port must be specified for non keep-alive LAGs. After a non keep-alive LAG is deployed, a LAG is formed. If there is only one port in the LAG, a single port LAG is formed. For a dynamic LAG, LACP is stared for each LAG port. For a keep-alive LAG, no LAG is formed and LACP is started on the LAG port.

You can deploy a LAG as shown in the following for the "blue" LAG.

```
NetIron(config)# lag blue static
NetIron(config-lag-blue)# deploy
```

Syntax: [no] deploy [forced | passive]

When the **deploy** command is executed:

For a static and dynamic LAGs, the current LAG veto mechanism is invoked to make sure the LAG can be formed. If the LAG is not vetoed, a LAG is formed with all the ports in the LAG.

For dynamic LAGs, LACP is activated on all LAG ports. When activating LACP, use active mode if **passive** is not specified; otherwise, use **passive** mode.

For a keep-alive LAGs, no LAG is formed, and LACP is started on the LAG port.

Once the **deploy** command is issued, all LAG ports will behave like a single port.

If the **no deploy** command is executed, the LAG is removed. For dynamic LAGs, LACP is de-activated on all of the LAG ports.

If the **no deploy** command is issued and more than 1 LAG port is not disabled the command is aborted and the following error message is displayed: “Error 2 or more ports in the LAG are not disabled, un-deploy this LAG may form a loop - aborted.” Using the **forced** keyword with the **no deploy** command in the previous situation, the un-deployment of the LAG is executed.

Commands available under LAG once it is deployed

Once a LAG has been deployed, the following configurations can be performed on the deployed LAG:

- Configuring ACL-based Mirroring
- Disabling Ports within a LAG
- Enabling Ports within a LAG
- Monitoring and Individual LAG Port
- Assigning a name to a port within a LAG
- Enabling sFlow Forwarding on a port within a LAG
- Setting the sFlow Sampling Rate for a port within a LAG

Configuring ACL-based mirroring

To configure ACL-based mirroring for all ports in a LAG, configure it on the primary port of the LAG at the interface configuration level (see “ACL-based inbound mirroring” on page 148). ACL-based mirroring can be configured for an individual member port within a LAG by using the **acl-mirror-port** command, as shown in the following.

```
NetIron(config)# lag blue static
NetIron(config-lag-blue)# deploy
NetIron(config-lag-blue)# acl-mirror-port ethe-port-monitored 3/1 ethernet 3/2
```

In this example, traffic on Ethernet port 3/1 (a member port of LAG “blue”) will be mirrored to Ethernet port 3/2.

Syntax: [**no**] **acl-mirror-port** { **ethe-port-monitored** <*slot/port*> | **named-port-monitored** <*name*> | **pos-port-monitored** <*slot/port*> } **ethernet** <*slot/port*>

Use the **ethe-port-monitored** option with the appropriate <*slot/port*> variable to specify an Ethernet port for which you want to provide ACL mirroring.

Use the **named-port-monitored** option with the appropriate <*slot/port*> variable to specify a named port for which you want to provide ACL mirroring.

Use the **pos-port-monitored** option with the appropriate <*slot/port*> variable to specify a Packet-over-SONET port for which you want to provide ACL mirroring.

The **ethernet** keyword precedes the <*slot/port*> variable identifying the port which will receive the mirrored packets.

NOTE
A port with ACL-based mirroring already configured on it cannot be added to a LAG, and a LAG cannot be deployed if any of its member ports has ACL-based mirroring. To use ACL-based mirroring on a LAG member port, deploy the LAG, then configure mirroring on the member port. If a port is removed from a LAG, ACL-based mirroring will be removed from that port, and if a LAG is deleted mirroring will be removed from all member ports.

Disabling ports within a LAG

You can disable an individual port within a LAG using the disable command within the LAG configuration as shown in the following.

```
NetIron(config)# lag blue static
NetIron(config-lag-blue)# deploy
NetIron(config-lag-blue)# disable ethernet 3/1
```

Syntax: [no] disable ethernet [slot/port] | named [name] |pos [slot/port]

Use the **ethernet** option with the appropriate **[slot/port]** variable to specify a Ethernet port within the LAG that you want to disable.

Use the **named** option with the appropriate **[slot/port]** variable to specify a named port within the LAG that you want to disable.

Use the **pos** option with the appropriate **[slot/port]** variable to specify a Packet-over-SONET port within the LAG that you to disable.

Enabling ports within a LAG

You can enable an individual port within a LAG using the enable command within the LAG configuration as shown in the following.

```
NetIron(config)# lag blue static
NetIron(config-lag-blue)# deploy
NetIron(config-lag-blue)# enable ethernet 3/1
```

Syntax: [no] enable ethernet [slot/port] | named [name] |pos [slot/port]

Use the **ethernet** option with the appropriate **[slot/port]** variable to specify a Ethernet port within the LAG that you want to enable.

Use the **named** option with the appropriate **[slot/port]** variable to specify a named port within the LAG that you want to enable.

Use the **pos** option with the appropriate **[slot/port]** variable to specify a Packet-over-SONET port within the LAG that you to enable.

Adding a Port to Currently Deployed LAG

Ports can be added to a currently deployed LAG. Adding a port to a deployed LAG uses the same procedures as described in "Adding Ports to a LAG or Deleting Ports from a LAG" on page 219. When you add ports to a deployed LAG, the MAC address of the port being added is changed to that of the primary port of the LAG to which it is being added.

Deleting a Port from a Currently Deployed LAG

Ports can be deleted from a currently deployed LAG. Deleting a port in a currently deployed LAG uses the same procedures as described in "Adding Ports to a LAG or Deleting Ports from a LAG" on page 219. However, when deleting ports from a currently deployed LAG you must consider the following:

- The primary port cannot be removed.

- If removal of a port will result in the trunk threshold value becoming greater than the number of ports in the LAG, the port deletion will be rejected.
- The port being deleted must be in the “disabled” state or you must use the forced option (as described in the following command syntax) when deleting it from a currently deployed LAG. Otherwise, the deletion request will be denied and the following error message will be displayed: “Error: ports to be deleted from the deployed LAG are not disabled, deleting these ports from the LAG may form a loop – aborted.”

To delete port 3/1 which is in the “enabled” state from a currently deployed LAG named “blue”, use the following command:

```
NetIron(config)# lag blue static
NetIron(config-lag-blue)# no ports ethernet 3/1 forced
```

Syntax: **no ports ethernet** <*slot/port*> **|** **pos** <*slot/port*> **[to** <*slot/port*> **] [ethernet** <*slot/port*> **|** **pos** <*slot/port*> **] [forced]**

This command operates as described in “Adding Ports to a LAG or Deleting Ports from a LAG” on page 219 except for the **forced** option which is described in the following:

The **forced** option to the **no ports** command deletes a port from a currently deployed LAG even if it is currently in the “enabled state”. Because deleting an enabled port from a currently deployed LAG can cause a loop to be formed, we recommend that you disable any port being removed from a LAG before removing it. Only use the **forced** option when you are confident that a loop will not be created in your network topology.

NOTE
When a port is deleted from a currently deployed LAG, the MAC address of the port is changed back to its original value.

Monitoring an individual LAG port

By default, when you monitor the primary port in a LAG group, aggregated traffic for all the ports in the LAG is copied to the mirror port. You can configure the device to monitor individual ports in a LAG including Ethernet, POS, or named ports. You can monitor the primary port or another member port individually.

NOTE
You can use only one mirror port for each monitored LAG port. To monitor traffic on an individual port in a LAG group, enter commands such as the following.

This command enables monitoring of an individual port within a LAG.

```
NetIron(config)# lag blue static
NetIron(config-lag-blue)# deploy
NetIron(config-lag-blue)# monitor ethe-port-monitored 3/1 ethernet 10/3 both
```

Syntax: **[no] monitor ethe-port-monitored [slot/port] | named-port-monitored [name] |pos-port-monitored [slot/port] ethernet [slot/port] [input | output | both]**

Use the **ethe-port-monitored** option with the appropriate **[slot/port]** variable to specify a Ethernet port within the LAG that you want to monitor.

Use the **named-port-monitored** option with the appropriate **[slot/port]** variable to specify a named port within the LAG that you want monitor.

Use the **pos-port-monitored** option with the appropriate **[slot/port]** variable to specify a Packet-over-SONET port within the LAG that you want to monitor.

The **ethernet** <*slot/port*> parameter specifies the port to which the traffic analyzer is attached. While a POS port can be monitored, a POS port cannot be configured as a mirror port. Therefore, traffic monitored from a POS port must be mirrored through an Ethernet port.

The **input | output | both** parameters specify the traffic direction to be monitored.

Assigning a name to a port within a LAG

You can assign a name to an individual port within a LAG using the **port-name** command within the LAG configuration as shown in the following.

```
NetIron(config)# lag blue static
NetIron(config-lag-blue)# deploy
NetIron(config-lag-blue)# port-name orange ethernet 3/1
```

Syntax: [no] port-name <*text*> **ethernet [slot/port] | pos [slot/port]**

The <*text*> variable specifies the port name. The name can be up to 50 characters long.

Use the **ethernet** option with the appropriate **[slot/port]** variable to apply the specified name to an Ethernet port within the LAG.

Use the **pos** option with the appropriate **[slot/port]** variable to apply the specified name to a Packet-over-SONET port within the LAG.

Refer to "Allowable characters for LAG names" on page 15 for additional information on on LAG naming conventions.

Enabling sFlow forwarding on a port in a LAG

You can enable sFlow forwarding on an individual port within a LAG using the **sflow-forwarding** command within the LAG configuration as shown in the following.

```
NetIron(config)# lag blue static
NetIron(config-lag-blue)# deploy
NetIron(config-lag-blue)# sflow-forwarding ethernet 3/1
```

Syntax: [no] sflow-forwarding ethernet [slot/port] | port-name [text] |pos [slot/port]

Use the **ethernet** option with the appropriate **[slot/port]** variable to specify a Ethernet port within the LAG that you want to enable sFlow forwarding for.

Use the **port-name** option with the appropriate **[text]** variable to specify a named port within the LAG that you want to enable sFlow forwarding for.

Use the **pos** option with the appropriate **[slot/port]** variable to specify a Packet-over-SONET port within the LAG that you want to enable sFlow forwarding for.

Setting the sFlow sampling rate for a port in a LAG

You can set the sFlow sampling rate for an individual port within a LAG using the **sflow-subsampling** command within the LAG configuration as shown in the following.

```
NetIron(config)# lag blue static
NetIron(config-lag-blue)# deploy
NetIron(config-lag-blue)# sflow-subsampling ethernet 3/1 512
```

Syntax: [no] sflow-subsampling ethernet [slot/port] | port-name [text] |pos [slot/port] <*num*>

Use the **ethernet** option with the appropriate **[slot/port]** variable to specify the Ethernet port within the LAG that you want to configure the sampling rate for.

Use the **port-name** option with the appropriate **[text]** variable to specify the named port within the LAG that you want to configure the sampling rate for.

Use the **pos** option with the appropriate **[slot/port]** variable to specify the Packet-over-SONET port within the LAG that you want to configure the sampling rate for.

The <*num*> variable specifies the average number of packets from which each sample will be taken. The software rounds the value you enter up to the next odd power of 2. This can be a value between 512 - 1048576.

Configuring a dynamic LAG within a VRF

In release 3.8.00, support was added for dynamic LAGs within a VRF. When configuring a dynamic LAG within a VRF, the following must be considered:

- The dynamic LAG must be configured before adding it to a VRF.
- Before the LAG is deployed, all members must be in the default VRF.
- After the LAG is deployed, all LAG ports are in the LACP BLOCK state until the LACP protocol completes negotiation with the other end of the LAG.
- Once the LACP protocol negotiation is completed with the other end of the LAG, all the LAG ports are set to the FORWARD state.
- When a dynamic LAG within a VRF is undeployed, the primary port will stay in the VRF where the LAG was configured and the secondary ports of the LAG will return to the default VRF.

The following example uses the LAG and VRF commands to configure a LAG within a VRF.

```
NetIron(config)# lag red dynamic
NetIron(config-lag-red)# primary port 3/2
NetIron(config-lag-red)# ports ethernet 3/1 ethernet 7/2
NetIron(config-lag-red)# exit
NetIron(config)# interface ethernet 3/2
NetIron(config-if-e10000-3/2)# ip vrf forwarding VPN1
NetIron(config)# lag red dynamic
NetIron(config-lag-red)# deploy
```

Displaying LAG information

You can display LAG information for a PowerConnect router in either a **full** or **brief** mode.

The following example displays the **brief** option of the **show lag** command.

```
NetIron# show lag brief
Total number of LAGs:          4
Total number of deployed LAGs: 3
Total number of s created:3 (125 available)
LACP System Priority / ID:     0001 / 0004.80a0.4000
LACP Long timeout:             90, default: 90
LACP Short timeout:            3, default: 3

LAG           Type    Deploy  Primary  Port List
d1            dynamic  Y    3     32/2     ethe 13/2 to 13/3 ethe 32/2
e             dynamic  Y    1     2/3      ethe 2/1 ethe 2/3 ethe 2/5
p             static   Y    2     3/1      pos 1/2 pos 3/1
s1            static   N    none  32/3     ethe 13/4 ethe 32/3 to 32/4
```

Syntax: show lag brief

Table 40 describes the information displayed by the **show lag brief** command.

The following example displays the full option of the **show lag** command.

```
NetIron# show lag
Total number of LAGs:          4
Total number of deployed LAGs: 3
Total number of s created:3 (125 available)
LACP System Priority / ID:     0001 / 0004.80a0.4000
LACP Long timeout:             90, default: 90
LACP Short timeout:            3, default: 3

=== LAG "d1" (dynamic Deployed) ===
LAG Configuration:
   Ports:         ethe 13/2 to 13/3 ethe 32/2
   Primary Port:  32/2
    Type:    hash-based
   LACP Key:      104

Deployment:   ID 3, Active Primary 3/2

```

Syntax: show lag <*lag-name*> **[deployed] [dynamic] [keep-alive] [static]**

Using command this without options displays information for all LAGs configured on the router.

The <*lag-name*> variable allows you to limit the display to information for a specific LAG.

The **deployed** option limits the display to LAGs that are currently deployed.

The **dynamic** option limits the display to dynamic LAGs.

The **keep-alive** option limits the display to keep alive LAGs.

The **deployed** option limits the display to static LAGs.

Table 40 describes the information displayed by the **show lag** command.

TABLE 40 Show LAG information

This field...	Displays...
Total number of LAGS	The total number of LAGs that have been configured on the router.
Total number of Deployed LAGS	The total number of LAGs on the router that are currently deployed.
Total number of LAGs Created	The total number of LAGs that have been created on the LAG. The total number of LAGs available are shown also. Since keep-alive LAGs do not use a LAG ID, they are not listed and do not subtract for the number of LAGs available.
LACP System Priority /ID	The system priority configured for the router. The ID is the system priority which is the base MAC address of the router.
LACP Long timeout	The number of seconds used for the LACP Long timeout mode. This is only applicable for dynamic or keep-alive LAGs.
LACP Short timeout	The number of seconds used for the LACP Short timeout mode. This is only applicable for dynamic or keep-alive LAGs.
The following information is displayed per-LAG in the show lag brief command.	
LAG	The name of the LAG.
Type	The configured type of the LAG: static, dynamic, or keep-alive
Deploy	Status of LAG deployment: Y – yes, LAG is deployed. N – no, LAG is not deployed.
LAG	The LAG ID number.
Primary	The primary port of the LAG.
Port List	The list of ports that are configured in the LAG.
The following information is displayed per-LAG the show lag command for each LAG configured.	
LAG Configuration	
Ports:	List of ports configured with the LAG.
Primary Port:	The primary port configured on the LAG.
LAG Type:	The load sharing method configured for the LAG: either hash-based or per-packet.
LACP Key	The link aggregation key for the LAG.
Deployment	
LAG ID	The LAG ID number.
Active Primary	The port within the LAG where most protocol packets are transmitted. This is not the same as the configured Primary Port of the LAG.
Port	The chassis slot and port number of the interface.
Link	The status of the link which can be one of the following: • up • down
L2 State	The L2 state for the port.
Dupl	The duplex state of the port, which can be one of the following: • Full • Half • None

TABLE 40 Show LAG information (Continued)

This field...	Displays...
Speed	The bandwidth of the interface.
LAG	The LAG ID of the port.
Tag	Indicates whether the ports have 802.1q VLAN tagging. The value can be Yes or No.
Priori	Indicates the Quality of Service (QoS) priority of the ports. The priority can be a value from 0 – 7.
MAC	The MAC address of the port.
Name	The name (if any) configured for the port.
Sys P	Lists the system priority configured for the device.
Port P	Lists the port's link aggregation priority.
Key	Lists the link aggregation key.
Act	Indicates the link aggregation mode, which can be one of the following: • No – The mode is passive on the port. If link aggregation is enabled (and the mode is passive), the port can send and receive LACPDU messages to participate in negotiation of an aggregate link initiated by another port, but cannot search for a link aggregation port or initiate negotiation of an aggregate link. • Yes – The mode is active. The port can send and receive LACPDU messages.
Tio	Indicates the timeout value of the port. The timeout value can be one of the following: • L – Long. The LAG group has already been formed and the port is therefore using a longer message timeout for the LACPDU messages exchanged with the remote port. Typically, these messages are used as confirmation of the health of the aggregate link. • S – Short. The port has just started the LACPDU message exchange process with the port at the other end of the link. The S timeout value also can mean that the link aggregation information received from the remote port has expired and the ports are starting a new information exchange.
Agg	Indicates the link aggregation state of the port. The state can be one of the following: • Agg – Link aggregation is enabled on the port. • No – Link aggregation is disabled on the port.
Syn	Indicates the synchronization state of the port. The state can be one of the following: • No – The port is out of sync with the remote port. The port does not understand the status of the LACPDU process and is not prepared to enter a LAG link. • Syn – The port is in sync with the remote port. The port understands the status of the LACPDU message exchange process, and therefore knows the LAG group to which it belongs, the link aggregation state of the remote port, and so on.
Col	Indicates the collection state of the port, which determines whether the port is ready to send traffic over the LAG link: • Col – The port is ready to send traffic over the LAG link. • No – The port is not ready to send traffic over the LAG link.
Dis	Indicates the distribution state of the port, which determines whether the port is ready to receive traffic over the LAG link. • Dis – The port is ready to receive traffic over the LAG link. • No – The port is not ready to receive traffic over the LAG link.

TABLE 40 Show LAG information (Continued)

This field...	Displays...
Def	Indicates whether the port is using default link aggregation values. The port uses default values if it has not received link aggregation information through LACP from the port at the remote end of the link. This field can have one of the following values: • Def – The port has not received link aggregation values from the port at the other end of the link and is therefore using its default link aggregation LACP settings. • No – The port has received link aggregation information from the port at the other end of the link and is using the settings negotiated with that port.
Exp	Indicates whether the negotiated link aggregation settings have expired. The settings expire if the port does not receive an LACPDU message from the port at the other end of the link before the message timer expires. This field can have one of the following values: • Exp – The link aggregation settings this port negotiated with the port at the other end of the link have expired. The port is now using its default link aggregation settings. • No – The link aggregation values that this port negotiated with the port at the other end of the link have not expired, so the port is still using the negotiated settings.
Ope	• Ope (operational) - The port is operating normally. • Blo (blocked) - The port is blocked because the adjacent port is not configured with link aggregation or because it is not able to join a LAG group. An LACP port is blocked until it becomes part of a LAG. Also, an LACP is blocked if its state becomes “default”. To unblock the port and bring it to an operational state, enable link aggregation on the adjacent port and ensure that the ports have the same key.

Displaying LAG statistics

You can display LAG statistics for a PowerConnect router in either a **full** or **brief** mode. Full mode is the default and is displayed when the **show statistics lag** command is executed without the **brief** option. The examples below show both options of the **show statistics lag** command.

```
NetIron# show statistics brief lag
LAG                  Packets            Collisions                  Errors
                      [Receive            Transmit]   [Recv  Txmit]      [InErr
OutErr]
        LAG d1          1173              1018        0       0        0       0
         LAG e          1268              1277        0       0        0       0

NetIron# show statistics lag
LAG d1 Counters:
         InOctets             127986          OutOctets             107753
           InPkts               1149            OutPkts                996
  InBroadcastPkts                 0    OutBroadcastPkts                  0
  InMulticastPkts               852    OutMulticastPkts                684
    InUnicastPkts               297      OutUnicastPkts                312
       InDiscards                 0         OutDiscards                  0
         InErrors                 0           OutErrors                  0
     InCollisions                 0       OutCollisions                  0
                                        OutLateCollisions                 0
        Alignment                 0                 FCS                   0
```

```
      GiantPkts                0          ShortPkts                0
    InBitsPerSec               0       OutBitsPerSec               0
    InPktsPerSec               0       OutPktsPerSec               0
   InUtilization            0.0%      OutUtilization            0.0%
```

Syntax: show statistics [brief] lag [<*lag-name*> **]**

VLANs 8

Overview

The following VLAN features are supported by NetIron MLX Series devices.

- VLANs
- VLAN Tagging
- Port-Based VLANs
- Protocol-Based VLANs
- Virtual Routing Interfaces
- Integrated Switch Routing (ISR)
- VLAN Groups
- Super Aggregated VLANs
- 802.1q-in-q Tagging
- 802.1q Tag-type Translation
- Assigning a VLAN Priority
- Allocating Memory for More VLANs or Virtual Routing Interfaces
- Uplink Ports Within a Port-Based VLAN
- Hardware Flooding for Layer 2 Multicast and Broadcast Packets
- Unknown Unicast Flooding on VLAN Ports
- VLAN CPU Protection
- VLAN Byte Counters
- Extended VLAN counters
- multi-port static MAC address
- Transparent VLAN Flooding
- VLAN ID Range - 1-4090

A Virtual Local Area Network (VLAN) lets you segment traffic in a network by placing ports and interfaces into separate broadcast domains. Each broadcast domain is uniquely identified by a VLAN ID. These broadcast domains can span multiple devices.

The PowerConnect router supports two types of VLANs: *port-based VLANs* and *protocol-based VLANs*. A port-based VLAN consists of interfaces that constitute a Layer 2 broadcast domain. (Protocol-based VLANs are described in "Protocol-based VLANs" on page 237.) By default, all interfaces on a PowerConnect router are members of the *default* VLAN, which is VLAN 1. Thus, by default, all interfaces on all devices on a network constitute a single Layer 2 broadcast domain. Once you create a port-based VLAN and assign an interface to that VLAN, that interface is automatically removed from the default VLAN if the interface is assigned to the VLAN as an untagged interface. If the interface is assigned as a tagged interface, then the interface is a member of both the default VLAN, and the VLAN it is assigned to.

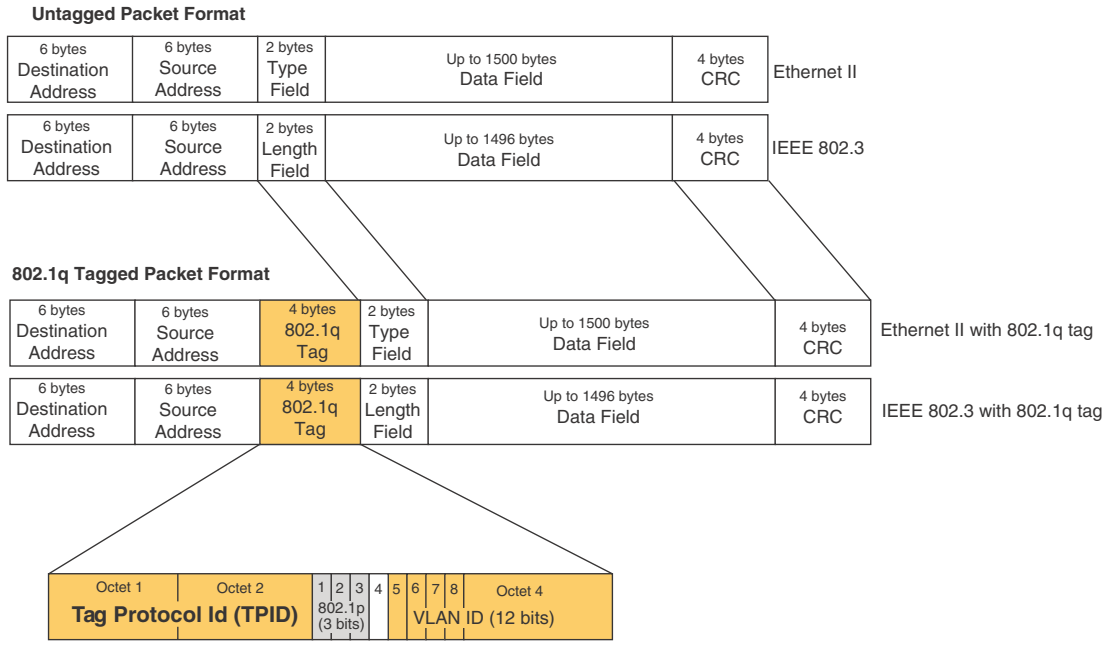
Tagged, untagged, and dual mode ports

Interfaces assigned to port-based VLANs can be defined as untagged, tagged, and dual-mode ports. An untagged port is a member of only one VLAN, while a tagged port can be a member of more than one VLAN. Thus a tagged port can be a member of more than one broadcast domain. Dual-mode ports are configured by adding one or more tagged VLANs and one untagged VLAN to a port.

Tagged ports allow the PowerConnect router to add a four-byte 802.1q tag to the packet. 802.1q tagging is an IEEE standard that allows a networking device to add information to Layer 2 packets. This information identifies the VLAN membership of the packet, as well as the VLAN ID of the VLAN from which the packet is sent. Furthermore, the default tag value of the 802.1q tag is 8100 (hexadecimal). This value comes from the IEEE 802.1q specification. You can change this tag value on a per-port or on a global basis on PowerConnect router if needed to be compatible with other vendors' equipment.

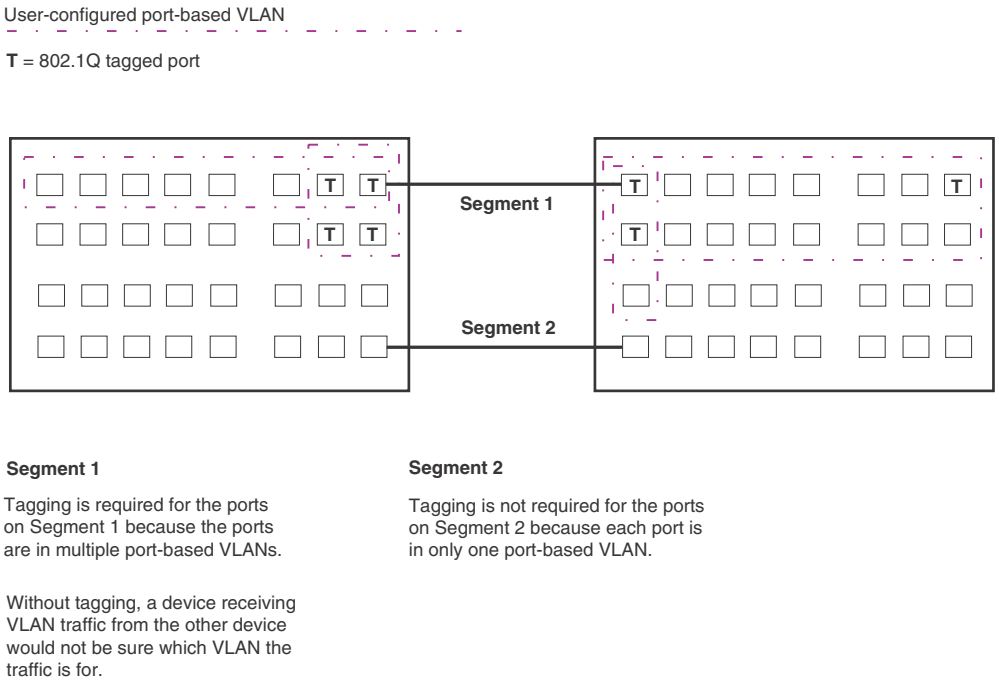
Figure 6 shows the format of packets with and without the 802.1q tag.

FIGURE 6 Packet containing Dell's 802.1QVLAN tag



If you configure a VLAN that spans multiple devices, you need to use tagging only if a port connecting one of the devices to the other is a member of more than one port-based VLAN. If a port connecting one device to the other is a member of only a single port-based VLAN, tagging is not required. Figure 7 shows an example of two devices that have the same Layer 2 port-based VLANs configured across them. Notice that only one of the VLANs requires tagging.

FIGURE 7 VLANs configured across multiple devices



Protocol-based VLANs

Interfaces that belong to a port-based VLAN can further be divided into Layer 3 broadcast domains by using protocol-based VLANs. Protocol-based VLANs accept broadcasts of a specified protocol type. For example, an IP subnet VLAN accepts broadcasts for the specified IP subnets only. This feature enables you to limit the amount of broadcast traffic to end-stations, servers, and routers.

In a PowerConnect router, you can configure the following protocol-based VLANs within a port-based VLAN:

- **AppleTalk** - The device sends AppleTalk broadcasts to all ports within the AppleTalk protocol VLAN.
- **IP** - The device sends IP broadcasts to all ports within the IP protocol VLAN.
- **IPX** - The device sends IPX broadcasts to all ports within the IPX protocol VLAN.
- **IPv6** - The device sends IPv6 broadcasts to all ports within the IPv6 protocol VLAN.

NOTE
You can configure a protocol-based VLAN as a broadcast domain for IPv6 traffic. When the PowerConnect router receives an IPv6 multicast packet (a packet with 06 in the version field and 0xFF as the beginning of the destination address), the PowerConnect router forwards the packet to all other ports in the VLAN except to the port that received the packet.

Protocol-based VLANs can be configured to have *static* or *excluded* port memberships. Static ports are permanent members of a protocol-based VLAN. They remain active members of the protocol-based VLAN regardless of whether they receive traffic for the VLAN's protocol.

NOTE
The dynamic port membership is not supported on PowerConnect devices.

If you want to exclude certain ports in a port-based VLAN from protocol-based VLANs, the protocol-based VLAN can be explicitly configured to exclude those ports.

VLAN configuration rules

To create any type of VLAN on a PowerConnect router, Layer 2 forwarding must be enabled. When Layer 2 forwarding is enabled, the PowerConnect becomes a switch on all ports for all non-routable protocols.

In addition to this rule, the sections below summarize the rules for configuring VLANs.

NOTE
To enable Layer 2 forwarding, do "**no route-only**".

VLAN ID range

The upper range of VLAN IDs available for user VLANs (including the default VLAN) has been reduced to 4090 (formerly 4094). The VLAN ID range above 4090 has been reserved for current and future features for internal control purposes.

Tagged VLANs

When configuring VLANs across multiple devices, you need to use tagging only if a port connecting one of the devices to the other is a member of more than one port-based VLAN. If you are configuring tagged VLANs across multiple devices, make sure all the devices support the same tag format.

VLAN hierarchy

A hierarchy of VLANs exists between the Layer 2 and Layer 3 protocol-based VLANs:

- Port-based VLANs are at the lowest level of the hierarchy.
- Layer 3 protocol-based VLANs are at the highest level of the hierarchy.

As a PowerConnect router receives packets, the VLAN classification starts from the highest level VLAN first. Therefore, if an interface is configured as a member of a port-based VLAN and a protocol-based VLAN, packets coming into the interface are classified as members of the protocol-based VLAN because that VLAN is higher in the VLAN hierarchy.

When a port in a VLAN receives a packet, the device forwards the packet based on the following VLAN hierarchy:

- If it is a Layer 3 packet and the port is a member of a Layer 3 protocol-based VLAN for the packet's protocol, the device forwards the packet on all the Layer 3 protocol-based VLAN ports that have been configured or drops the packet if the port is explicitly excluded from the protocol VLAN.
- If the packet cannot be forwarded based on its VLAN membership types but the packet can be forwarded at Layer 2, the device forwards the packet on all the ports within the receiving port's port-based VLAN.

Multiple VLAN membership rules

The multile VLAN membership rules are listed below:

- A port can belong to multiple, overlapping Layer 2 port-based VLANs only if the port is a tagged port. Packets sent out of a tagged port use an 802.1q-tagged frame.
- A port can belong to multiple, unique, overlapping Layer 3 protocol-based VLANs.
- When both port and protocol-based VLANs are configured on a given device, all protocol-based VLANs must be strictly contained within a port-based VLAN. A protocol-based VLAN cannot include ports from multiple port-based VLANs. This rule is required to ensure that port-based VLANs remain loop-free Layer 2 broadcast domains.
- One of each type of protocol-based VLAN can be configured within each port-based VLAN on the PowerConnect.
- Removing a configured port-based VLAN from a PowerConnect router automatically removes any protocol-based VLAN, or any virtual routing interfaces defined within the port-based VLAN.

Dual-mode default VLAN

As previously described, ports can be defined as dual-mode, which means that they can exist in both tagged and untagged VLANs. As such, they can coexist untagged in the default or a non-default VLAN and be added as a tagged port into non-default VLAN. One way that ports become dual-mode is by adding a port to a non-default, tagged VLAN. The normal behavior is for the port to remain in the default VLAN as an untagged port.

Changing the dual-mode default VLAN behavior

The **no dual-mode-default-vlan** command has been added to change this behavior. This is useful in situations where there is a danger of loops being created if Spanning Tree is not or can not be configured on the default VLAN such as when ports are facing a service provider network and STP BPDUs are not welcome on those ports.

Once the **no dual-mode-default-vlan** command is applied at the global level, a port will not be entered into the dual-mode state by default. If the **no dual-mode-default-vlan** command is configured, when a port is added as tagged to a non-default user-defined VLAN, it is automatically removed from the default VLAN and added to the non-default VLAN as a pure tagged port. Once in this state, a port can only be placed in dual-mode by explicitly configuring it as an untagged port into a non-default VLAN.

When the **no untagged** <*vlan-name*> **command** is applied in dual mode, the port will go into pure tagged mode in contrast to the default operating conditions where the port is automatically placed in the dual mode state in regards to the default VLAN. To change the default condition a a PowerConnect router regarding the dual-mode, default VLAN behavior, enter the **no dual-mode-default-vlan** command as shown in the following.

```
NetIron(config)# no dual-mode-default-vlan
```

Syntax: [no] dual-mode-default-vlan

The default state is for ports added as tagged to a non-default VLAN to remain as untagged ports in the default VLAN and become dual-mode ports.

Using this command with the **no** option, changes the default state and automatically removes a port from the default VLAN when it is added as a tagged port to a non-default VLAN. Using the command without the **no** option, will return the systems behavior to its normal operating condition.

NOTE
When a PowerConnect router is operating in the default state regarding the **no dual-default-vlan** command (which is not configured), syslog messages are generated whenever a port is moved out of the default VLAN. This is normal and expected behavior. Because when the **no dual-default-vlan** command is configured, it is normal operating behavior for a port to be moved out of the default VLAN whenever it enters the dual-mode state syslog messages may be generated when the ports are moved, which is not expected. These messages may be generated in the following situations:

- When a port is added “tagged” into the default VLAN, it is automatically deleted from the default VLAN and a syslog message is generated.
- When a port is in dual-mode, and a user issues the **no untagged** <*port-no*> command within the port VLAN configuration, the port is added back to the default VLAN. However, because the **no dual-default-vlan** command is configured, the port is transitioned out of the default VLAN which generates an additional syslog message.

Restrictions for use of this command

The **no dual-mode-default-vlan** command can only be applied if the router does not currently have any ports configured in dual-mode. If any port is currently in the dual-mode state when the **no dual-mode-default-vlan** command is executed, the command is rejected without it being applied to any ports on the router. Consequently, using the **no dual-mode-default-vlan** command does not cause any action but enables a new behavior for ports that are added to a VLAN.

If there are ports configured into the dual-mode (default VLAN) state, they can be moved from that state by removing untagged ports the default VLAN that also exist as tagged in a non-default VLAN or removing tagged ports from non-default VLANs.

Layer 2 control protocols on VLANs

Layer 2 protocols such as STP, RSTP, Foundry MRP, and VSRP can be enabled on a port-based VLAN.

The Layer 2 state associated with a VLAN and port is determined by the Layer 2 control protocol. Layer 2 broadcasts associated with the VLAN will not be forwarded on this port if the Layer 2 state is not FORWARDING.

It is possible that the control protocol, for example STP, will block one or more ports in a protocol-based VLAN that uses a virtual routing interface to route to other VLANs. For IP protocol and IP subnet VLANs, even though some of the physical ports of the virtual routing interface are blocked, the virtual routing interface can still route as long as at least one port in the virtual routing interface’s protocol-based VLAN is not blocked by STP.

You can also enable Single STP (SSTP) on the device; however, the ports in all VLANs on which SSTP is enabled become members of a single spanning tree. The ports in VLANs on which SSTP is disabled are excluded from the single spanning tree. A VLAN can also be selectively added or removed from the single spanning tree domain.

Virtual interfaces and CPU protection co-existence on VLANs

CPU protection can be configured on VLANs regardless of whether there are virtual-interfaces configured on them (Previously, CPU protection was only configurable if a virtual-interface was not configured on the VLAN).

There is a difference in the behavior of CPU protection in each of the following situations:

- When virtual-interfaces are configured on a VLAN, the CPU-protection is done only on unknown-unicast packets from the VLAN. Multicast and broadcast packets from the VLAN will be sent to the CPU. This allows the CPU to process packets such as ARP and OSPF "hello" packets that may be relevant to the router.
- When virtual-interface is not configured on the VLAN, the CPU-protection is performed for all packets (unknown-unicast, multicast and broadcast) from the CPU.

Configuring port-based VLANs

As explained above, you can place ports into VLANs to segment traffic into broadcast domains. When you create a VLAN, you specify if ports added to that VLAN are tagged or untagged.

NOTE
When adding a port to a VLAN you might get an error message concerning iP routing or IPv6 routing information on the port. If you receive this message, check to see if the port was previously configured for routing protocols such as OSPFv2 or OSPFv3 where the routing protocol was removed globally without first being de-configured on that port. If this is the case, re-enable the routing protocol globally to view the interface configuration and then disable the routing protocol from the port. You can then add the port to the VLAN.

To create a VLAN, perform the tasks listed below.

1. At the global CONFIG level assign an ID to the VLAN.

   ```
   NetIron(config)# vlan 2
   ```

   VLAN IDs can be in the range of 1 – 4090. Use the **no** form of the command to delete the VLAN from the configuration.

   The VLAN ID range above 4090 has been reserved for current and future features for internal control purposes.

   In addition to a VLAN number, you can assign a name to a VLAN by entering name <*vlan-name*>. Enter up to 32 characters for name.

2. Once a VLAN ID is assigned, the CLI directs you to the VLAN configuration level. At this level, you add ports to that VLAN and specify if the ports are tagged or untagged.

   ```
   NetIron(config-vlan-2)# untag e 1/9 to 1/16
   NetIron(config-vlan-2)# tagged e 1/1 to 1/8
   ```

The example above configures a port-based VLAN, VLAN 2. It adds Ethernet ports 1/9 through 1/16 as untagged ports and ports 1/1 through 1/8 as tagged ports. Since ports 1/9 through 1/16 are untagged, they can be members of VLAN 2 only, while ports 1/1 through 1/8 are tagged ports and can be members of other VLANs.

NOTE
In the configuration above, ports 1/9 – 1/16 are automatically removed from the default VLAN since they are configured as untagged ports; while port 1/1 – 1/8 are still members of the default VLAN.

Syntax: [no] untagged | tagged ethernet <*slot-number*>/<*port-number*> **[to** <*slot-number*>/<*port-number*> **| ethernet** <*slot-number*>/<*port-number*>**]**

The **untagged** and **tagged** parameter removes ports from the default VLAN and puts them in the port-based VLAN. The **untag** command also allows the ports to process packets that do not contain 802.1q tagging.

The **tagged** parameter allows the PowerConnect router to add a four-byte tag 802.1q tag to the packets that go through the tagged ports. It also allows the ports to be members of other VLANs.

Enter the port that you want to assign to the VLAN for the **ethernet** <*slot-number*>/<*port-number*> parameter. You can add LAG group ports to the VLAN by entering the LAG group's primary port. A LAG group's primary port is the port with the lowest number in the LAG group. When you add the LAG group's primary port, all the ports on the LAG group become members of the VLAN.

Use the **no** form of the command to remove the ports from a VLAN.

Example

```
NetIron(config)# vlan 4
NetIron(config-vlan-4)# no untag ethernet 1/11
```

Strictly or explicitly tagging a port

If you want a port to be strictly or explicitly tagged, that port has to be removed from the default VLAN. Enter a command such as the following.

```
NetIron(config)# vlan 2
NetIron(config-vlan-2)# tagged e 1/1 to 1/8
NetIron(config-vlan-2)# vlan 1
NetIron(config-vlan-1)# no untagged e 1/1 to 1/8
```

Assigning or changing a VLAN priority

You can prioritize traffic on a VLAN by assigning a priority to a VLAN. All packets associated with the VLAN will be classified to the configured priority.

```
NetIron(config-vlan-2)# priority 2
```

Syntax: [no] priority <*num*>

Possible Values: 0 - 7, "0" assigns the lowest priority and "7", the highest priority. The default is "0".

Assigning a different ID to the default VLAN

As stated above, by default, all ports on a PowerConnect router belong to the default VLAN, which is VLAN 1, until it is assigned to a port-based VLAN. The default VLAN port membership is always untagged; however, if you want to use VLAN ID 1 as a configurable VLANs with tagged port members, you can assign a different VLAN ID as the default VLAN. Enter commands such as the following command.

```
NetIron(config)# default-vlan-id 4000
```

Syntax: [no] default-vlan-id <*vlan-id*>

You must specify a VLAN ID that is not already in use. For example, if VLAN 10 exists, do not use "10" as the new VLAN ID for the default VLAN. VLAN IDs are from 1 – 4090. The VLAN ID range above 4090 has been reserved for current and future features for internal control purposes.

Configuring protocol-based VLANs

Once port-based VLANs are created, you can further segment the broadcast domains by creating protocol-based VLANs, based on Layer 3 protocols. Use the general procedure below for creating protocol-based VLANs.

1. Create the port-based VLAN that contains the interface that you want to segment using Layer 3 protocols.

   ```
   NetIron(config)# vlan 2
   NetIron(config-vlan-2)# untag e 1/9 to 1/16
   NetIron(config-vlan-2)# tagged e 1/1 to 1/8
   ```

2. Under the VLAN configuration level, define the Layer 3 protocol you want to use to segment packets that go through the ports assigned to the port-based VLAN.

   ```
   NetIron(config-vlan-2)# ipv6-proto name Blue
   ```

   Syntax: [no] ip-proto | ipv6-proto | ipx-proto | atalk-proto | other-proto name <*protocol-vlan-name*>

   Enter:

   - **ip-proto** to create a IP protocol VLAN.
   - **ipv6-proto** to create a IPv6 protocol VLAN.
   - **ipx-proto** to create a IPX protocol VLAN.
   - **atalk-proto** to create an Appletalk protocol VLAN.
   - **other-proto** to create a protocol VLAN for protocols other than an IP protocol, IPv6, IPX, or Appletalk protocol.

   Enter **name** <*vlan-name*> if you want to assign a name to the protocol-based VLAN. Enter up to 32 characters for name.

   Use the **no** form of the command to remove the protocol-based VLAN.

3. Assign or exclude specific ports to the protocol-based VLAN.

   ```
   NetIron(config-vlan-group-ipv6-proto)# static e 1/1 e 1/24
   NetIron(config-vlan-group-ipv6-proto)# exclude e 1/2 to 1/4
   ```

   Syntax: [no] static | exclude ethernet <*slot-number*>/<*port-number*> **[to** <*slot-number*>/<*port-number*>]

The **static** ethernet <*slot-number*>/<*port-number*> [to <*slot-number*>/<*port-number*>] parameter adds the specified ports within the port-based VLAN as static ports to the protocol-based VLAN. Packets of the specified protocol will be forwarded on these ports.

The **exclude** ethernet <*slot-number*>/<*port-number*> [to <*slot-number*>/<*port-number*>] parameter excludes the specified ports from the protocol-based VLAN. Packets of the specified protocol will be dropped if received on these ports.

Configuring virtual routing interfaces

The PowerConnect router sends Layer 3 traffic at Layer 2 within a protocol-based VLAN. However, Layer 3 traffic from one protocol-based VLAN to another must be routed. If you want the device to be able to send Layer 3 traffic from one protocol-based VLAN to another on the same router, you must configure a virtual routing interface on each protocol-based VLAN, then configure routing parameters on the virtual routing interfaces.

A *virtual routing interface* is a logical routing interface that the PowerConnect router uses to route Layer 3 protocol traffic between protocol-based VLANs. It is a logical port on which you can configure Layer 3 routing parameters.

For example, to enable a PowerConnect router to route IP traffic from one IP protocol VLAN to another, you must configure a virtual routing interface on each IP protocol VLAN, then configure the appropriate IP routing parameters on each of the virtual routing interfaces.

Example

```
NetIron(config)# vlan 2
NetIron(config-vlan-2)# tagged e 1/1 to 1/2
NetIron(config-vlan-2)# router-interface ve 1
```

The PowerConnect router can locally route IP packets between VLANs that are defined within a single router.

If you do not need to further partition the port-based VLAN into protocol-based VLANs, you can define a single virtual routing interface at the port-based VLAN level and enable routing on a single virtual routing interface.

```
NetIron(config)# vlan 2
NetIron(config-vlan-2)# tagged e 1/1 to 1/2
NetIron(config-vlan-2)# router-interface ve 2
NetIron(config-vlan-2)# exit
NetIron(config)# interface ve 2
NetIron(config-ve-2)# ip address 10.1.1.1/24
```

Syntax: **router-interface ve** <*ve-number*>

Enter 1 to the maximum number of virtual routing interfaces supported on the device for <*ve-number*>.

Integrated Switch Routing (ISR)

Integrated Switch Routing (ISR) feature enables VLANs configured on the PowerConnect router to route Layer 3 traffic from one protocol-based VLAN to another instead of forwarding the traffic to an external router. The VLANs provide Layer 3 broadcast domains for the protocols, but do not in themselves provide routing services. This is true even if the source and destination protocols are on the same device.

ISR eliminates the need for an external router by allowing you to route between VLANs using virtual routing interfaces (ves). You configure a separate virtual routing interface on each VLAN that you want to use to route packets. For example, if you configure two IP protocol VLANs on a PowerConnect router, you can configure a virtual routing interface on each of the IP protocol VLAN, then configure IP routing parameters for the IP protocol VLAN. Thus, the PowerConnect router forwards IP broadcasts within each VLAN at Layer 2 but routes Layer 3 traffic between the VLANs using the virtual routing interfaces.

NOTE
The PowerConnect router uses the lowest MAC address on the device (the MAC address of port 1/1) as the MAC address for all ports within all virtual routing interfaces you configure on the device.

The routing parameters and the syntax for configuring them are the same as when you configure a physical interface for routing (for example, **interface ve 10**). The logical interface allows the PowerConnect router to internally route traffic between the protocol-based VLANs without using physical interfaces.

All the ports within a protocol-based VLAN must be in the same port-based VLAN. The protocol-based VLAN cannot have ports in multiple port-based VLANs, unless the ports in the port-based VLAN to which you add the protocol-based VLAN are 802.1q tagged.

You can configure multiple protocol-based VLANs within the same port-based VLAN. In addition, a port within a port-based VLAN can belong to multiple protocol-based VLANs of the same type or different types. For example, if you have a port-based VLAN that contains ports 1/1 – 1/10, you can configure port 1/5 as a member of an AppleTalk protocol VLAN, an IP protocol VLAN, and an IPX protocol VLAN, and so on.

If the router interface for IP is configured on physical ports, then routing occurs independent of the Spanning Tree Protocol (STP). However, if the router interfaces are defined for IP VLAN, they are virtual routing interfaces and are subject to the rules of STP.

If your backbone consists of virtual routing interfaces all within the same STP domain, it is a bridged backbone, not a routed one. This means that the set of backbone interfaces that are blocked by STP will be blocked for routed protocols as well. The routed protocols will be able to cross these paths only when the STP state of the link is FORWARDING. This problem is easily avoided by proper network design.

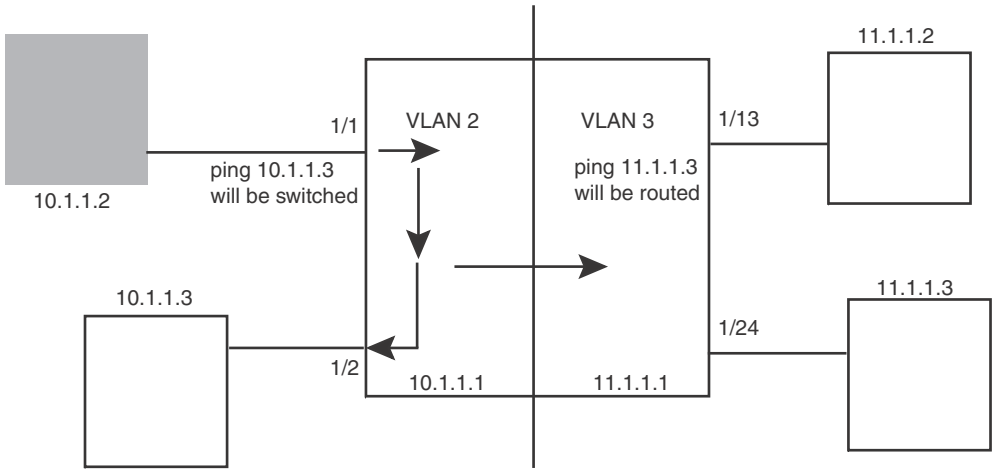
When designing an ISR network, pay attention to your use of virtual routing interfaces and the spanning-tree domain. If Layer 2 switching of your routed protocols (IP, IPX, AppleTalk) is not required across the backbone, then the use of virtual routing interfaces can be limited to edge switch ports within each router. Full backbone routing can be achieved by configuring routing on each physical interface that connects to the backbone. Routing is independent of STP when configured on a physical interface.

If your ISR design requires that you switch IP, IPX, or Appletalk at Layer 2 while simultaneously routing the IP protocol over a single backbone, then create multiple port-based VLANs and use VLAN tagging on the backbone links to separate your Layer 2 switched and Layer 3 routed networks.

There is a separate STP domain for each port-based VLAN. Routing occurs independently across port-based VLANs or STP domains. You can define each end of each backbone link as a separate tagged port-based VLAN. Routing will occur independently across the port-based VLANs. Because each port-based VLAN's STP domain is a single point-to-point backbone connection, you are guaranteed to never have an STP loop. STP will never block the virtual router interfaces within the tagged port-based VLAN, and you will have a fully routed backbone.

A PowerConnect router offers the ability to create a virtual routing interface within a Layer 2 STP port-based VLAN or within each IP protocol VLAN. This combination of multiple Layer 2 or Layer 3 broadcast domains and virtual routing interfaces are the basis for the very powerful Integrated Switch Routing (ISR) technology. ISR is very flexible and can solve many networking problems.

FIGURE 8 Example of two separate backbones for the same protocol



The following is a sample configuration for the illustration above.

```
NetIron(config)# vlan 2
NetIron(config-vlan-2)# tagged e 1/1 to 1/2
NetIron(config-vlan-2)# router-inter ve 2
NetIron(config-vlan-2)# exit
NetIron(config)# vlan 3
NetIron(config-vlan-3)# tagged e 1/13 to 1/24
NetIron(config-vlan-3)# router-int ve 3
NetIron(config-vlan-3)# exit
NetIron(config)# interface ve 2
NetIron(config-ve-2)# ip address 10.1.1.1/24
NetIron(config-if-e1000-2/1)# exit
NetIron(config)# interface ve 3
NetIron(config-ve-3)# ip address 11.1.1.1/24
```

IP packets are bridged (switched) within the same protocol VLAN if they are on the same subnet; they are routed if they are on a different VLAN.

VLAN groups

To simplify VLAN configuration when you have many VLANs with the same configuration, you can configure *VLAN groups*. When you create a VLAN group, the VLAN parameters you configure for the group apply to all the VLANs within the group.

The VLAN group feature allows you to create multiple port-based VLANs with identical port members. Since the member ports are shared by all the VLANs within the group, you must add the ports as tagged ports. This feature not only simplifies VLAN configuration but also allows you to have a large number of identically configured VLANs in a startup configuration file on the device's flash memory module. Normally, a startup configuration file with a large number of VLANs might not fit on the flash memory module. By grouping the identically configured VLANs, you can conserve space in the startup configuration file so that it fits on the flash memory module.

NOTE
Depending on the size of the VLAN ID range you want to use for the VLAN group, you might need to allocate additional memory for VLANs. To allocate additional memory, refer to "Allocating memory for more VLANs or virtual routing interfaces" on page 260.

Configuring a VLAN group

To configure a VLAN group, perform the tasks listed below.

1. Create the VLAN group and assign the VLANs to that group.

```
NetIron(config)# vlan-group 1 vlan 2 to 1000
```

Syntax: **[no] vlan-group** <*num*> **vlan** <*vlan-id*> **to** <*vlan-id*>

The <*num*> parameter specifies the VLAN group ID.

The **vlan** <*vlan-id*> **to** <*vlan-id*> parameters specify a continuous range (with no gaps) of VLAN IDs that have not been configured in the CLI. Specify the low VLAN ID first and the high VLAN ID second. The command adds all the VLANs in the range to the VLAN group.

If a VLAN within the range you specify is already configured, the CLI does not add the group but instead displays an error message. If this happens, create the group by specifying a valid contiguous range that does not include the VLAN. Then add more VLANs to the group after the CLI changes to the configuration level for the group.

NOTE
The device's memory must be configured to contain at least the number of VLANs you specify for the higher end of the range. For example, if you specify 2048 as the VLAN ID at the high end of the range, you first must increase the memory allocation for VLANs to 2048 or higher. Refer to "Allocating memory for more VLANs or virtual routing interfaces" on page 260.

2. The CLI directs you to the VLAN group configuration level. Add tagged ports to the group. Since all the VLANs in the group share the ports, you must add the ports as tagged ports.

```
NetIron(config-vlan-group-1)# tagged e 1/1 to 1/2
```

Syntax: **[no] tagged ethernet [to** <*slot-number*>**/**<*port-number*>**> | ethernet** <*slot-number*>**/**<*port-number*>**]**

Using the **no tagged ethernet** command causes the following error message such as the following to appear.

```
NetIron(config-vlan-10)#no tagged ethernet 4/2
error - ports ether 4/1 to 4/2 are not tagged members of vlan 10
```

This message is normal and indicates that the configuration has take effect. It does not indicate that an error condition has occurred.

3. If required, you can add and remove individual VLANs or VLAN ranges from the VLAN group configuration level. For example, to add VLANs 1001 and 1002 to VLAN group 1 and remove VLANs 900 through 1000, enter the following commands.

```
NetIron(config-vlan-group-1)# add-vlan 1001 to 1002
NetIron(config-vlan-group-1)# remove-vlan 900 to 1000
```

Syntax: **[no] add-vlan** <*vlan-id*> **[to** <*vlan-id*>**]**

Syntax: **[no] remove-vlan** <*vlan-id*> **[to** <*vlan-id*>**]**

Verifying VLAN group configuration

To verify configuration of VLAN groups, display the running configuration file. If you have saved the configuration to the startup configuration file, you also can verify the configuration by displaying the startup configuration file. The following example shows the running configuration information for the VLAN group configured in the previous examples. The information appears in the same way in the startup configuration file.

```
NetIron(config)# show running-config
```

lines not related to the VLAN group omitted...

```
vlan-group 1 vlan 2 to 900
add-vlan 1001 to 1002
tagged ethernet 1/1 to 1/2
```

Displaying information about VLAN groups

To display VLAN group configuration information, enter the following command.

```
NetIron# show vlan-group 10

Configured VLAN-Group entries : 1
Maximum VLAN-Group entries : 32

VLAN-GROUP 10
Number of VLANs: 4
VLANs: 10 to 13
Tagged ports: ethernet 3/1
```

The example shows configuration information for two VLAN groups, group 1 and group 2.

Syntax: show vlan-group [<*group-id*>]

The <*group-id*> specifies a VLAN group. If you do not use this parameter, the configuration information for all the configured VLAN groups is displayed.

Configuring super aggregated VLANs

A super aggregated VLAN allows multiple VLANs to be placed within another VLAN. This feature allows you to construct Layer 2 paths and channels. A path contains multiple channels, each of which is a dedicated circuit between two end points. The two devices at the end points of the channel appear to each other to be directly attached. The network that connects them is transparent to the two devices.

You can aggregate up to 4090 VLANs within another VLAN. This provides a total VLAN capacity on one PowerConnect router of 16,728,100 channels (4090 * 4090).

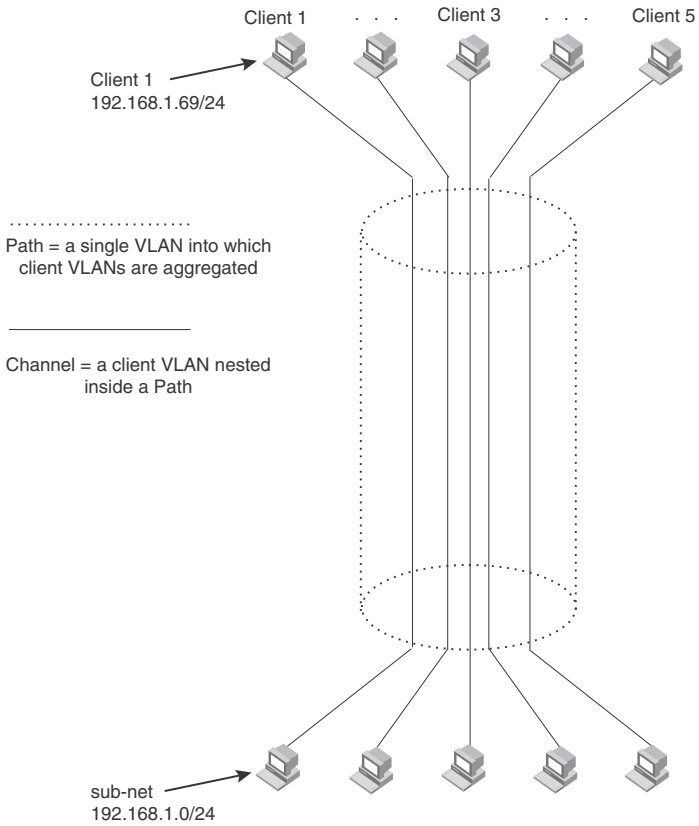
The devices connected through the channel are not visible to devices in other channels. Therefore, each client has a private link to the other side of the channel.

Super aggregated VLANs are useful for applications such as Virtual Private Network (VPN) or Transparent LAN Services (TLS) in which you need to provide a private, dedicated Ethernet connection to individual clients to transparently reach its subnet across multiple networks. The feature allows point-to-point and point-to-multipoint connections.

Figure 9 shows a conceptual picture of the service that aggregated VLANs provide.

In Super Aggregated VLANs, the outer VLAN (i.e. path) and the inner VLAN (i.e. channel) use different tag types. For example, the outer VLAN tag-type can be 9100 and the inner VLAN tag-type can be 8100 as shown in Figure 11.

FIGURE 9 Conceptual model of the super aggregated VLAN application



Each client connected to the edge device is in its own port-based VLAN. All the clients' VLANs are aggregated by the edge device into a single VLAN for connection to the core.

The device that aggregates the VLANs forwards the aggregated VLAN traffic through the core. The core can consist of multiple devices that forward the aggregated VLAN traffic. The edge device at the other end of the core separates the aggregated VLANs into the individual client VLANs before forwarding the traffic. The edge devices forward the individual client traffic to the clients. For the clients' perspective, the channel is a direct point-to-point link.

Figure 10 shows an example application that uses aggregated VLANs. This configuration includes the client connections shown in Figure 9.

FIGURE 10 Example super aggregated VLAN application

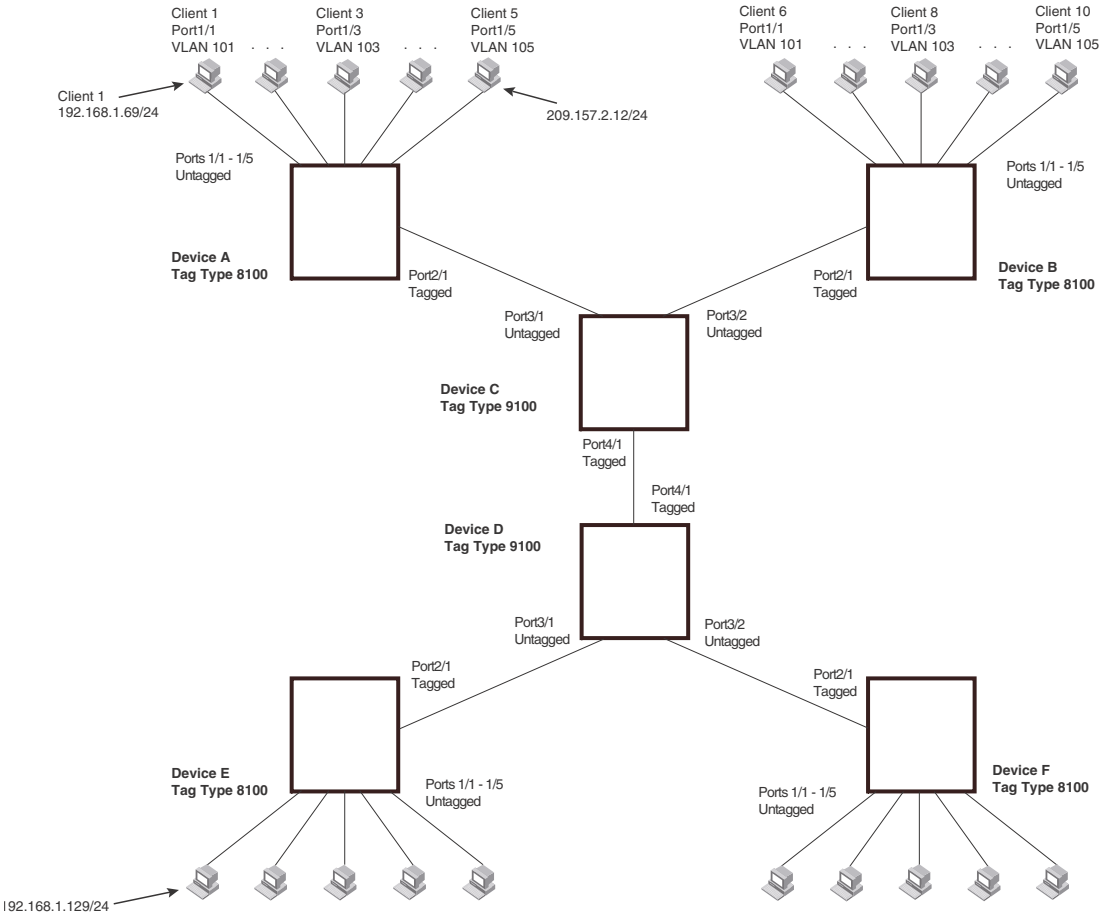


Figure 7 shows a collocation service provides private channels for multiple clients. Although the same devices are used for all the clients, the VLANs ensure that each client receives its own Layer 2 broadcast domain, separate from the broadcast domains of other clients. For example, client 1 cannot ping client 5.

The clients at each end of a channel appear to each other to be directly connected and thus can be on the same subnet and use network services that require connection to the same subnet. In this example, client 1 is in subnet 192.168.1.0/24 and so is the device at the other end of client 1's channel.

Since each VLAN configured on the core devices is an aggregate of multiple client VLANs, the aggregated VLANs greatly increase the number of clients a core device can accommodate.

This example shows a single link between the core devices. However, you can use a LAG group to add link-level redundancy.

Configuring aggregated VLANs

A maximum of 1526 bytes are supported on ports where super-aggregated VLANs are configured. This allows for an additional 8 bytes over the untagged port maximum to allow for support of two VLAN tags.

To configure aggregated VLANs, configure tagged and untagged VLANs on the edge device, then configure the aggregated and other VLANs on the core device. Perform the tasks listed below.

1. On each edge device, configure a separate port-based VLAN for each client connected to the edge device. In each client VLAN:

   - Add the port connected to the client as an untagged port.
   - Add the port connected to the core device (the device that will aggregate the VLANs) as a tagged port. This port must be tagged because all the client VLANs share the port as an uplink to the core device.

   For example, to configure device A in Figure 10 on page 250, enter commands such as the following.

```
NetIron(config)# vlan 101
NetIron(config-vlan-101)# tagged ethernet 2/1
NetIron(config-vlan-101)# untagged ethernet 1/1
NetIron(config-vlan-101)# exit
NetIron(config)# vlan 102
NetIron(config-vlan-102)# tagged ethernet 2/1
NetIron(config-vlan-102)# untagged ethernet 1/2
NetIron(config-vlan-102)# exit
NetIron(config)# vlan 103
NetIron(config-vlan-103)# tagged ethernet 2/1
NetIron(config-vlan-103)# untagged ethernet 1/3
NetIron(config-vlan-103)# exit
NetIron(config)# vlan 104
NetIron(config-vlan-104)# tagged ethernet 2/1
NetIron(config-vlan-104)# untagged ethernet 1/4
NetIron(config-vlan-104)# exit
NetIron(config)# vlan 105
NetIron(config-vlan-105)# tagged ethernet 2/1
NetIron(config-vlan-105)# untagged ethernet 1/5
NetIron(config-vlan-105)# exit
NetIron(config)# write memory
```

   Syntax: [no] **vlan** <*vlan-id*>

   Syntax: [no] **untagged | tagged ethernet** <*slot-number*>/<*port-number*> [**to** <*slot-number*>/<*port-number*> | **ethernet** <*slot-number*>/<*port-number*>]

   The **tagged** command adds the port that the device uses for the uplink to the core device.

   The **untagged** command adds the ports connected to the individual clients.

2. On each core device:

   - Configure a VLAN tag type (tag ID) that is different than the tag type used on the edge devices. If you use the default tag type (8100) on the edge devices, set the tag type on the core devices to another value, such as 9100. The tag type must be the same on all the core devices. The edge devices also must have the same tag type but the type must be different from the tag type on the core devices.

   NOTE
   You can enable the Spanning Tree Protocol (STP) on the edge devices or the core devices, but not both. If you enable STP on the edge devices and the core devices, STP will prevent client traffic from travelling through the core to the other side.

   For example, to configure the aggregated VLANs on device C in Figure 10 on page 250, enter the following commands.

```
NetIron(config)# tag-type 9100
NetIron(config)# vlan 101
NetIron(config-vlan-101)# tagged ethernet 4/1
NetIron(config-vlan-101)# untagged ethernet 3/1
NetIron(config-vlan-101)# exit
NetIron(config)# vlan 102
NetIron(config-vlan-102)# tagged ethernet 4/1
NetIron(config-vlan-102)# untagged ethernet 3/2
NetIron(config-vlan-102)# exit
NetIron(config)# write memory
```

Syntax: [no] **tag-type** <*num*> [**ethernet** <*slot/port*>]

The **num** variable is the hexadecimal ethernet tag type. Default value is 8100.

Complete CLI examples

The following sections show all the Aggregated VLAN configuration commands on the devices in Figure 10 on page 250.

NOTE
In these examples, the configurations of the edge devices (A, B, E, and F) are identical. The configurations of the core devices (C and D) also are identical. The aggregated VLAN configurations of the edge and core devices on one side must be symmetrical (in fact, a mirror image) to the configurations of the devices on the other side. For simplicity, the example in Figure 10 on page 250 is symmetrical in terms of the port numbers. This allows the configurations for both sides of the link to be the same. If your configuration does not use symmetrically arranged port numbers, the configurations should not be identical but must use the correct port numbers.

Commands for device A

```
NetIron-A(config)# vlan 101
NetIron-A(config-vlan-101)# tagged ethernet 2/1
NetIron-A(config-vlan-101)# untagged ethernet 1/1
NetIron-A(config-vlan-101)# exit
NetIron-A(config)# vlan 102
NetIron-A(config-vlan-102)# tagged ethernet 2/1
NetIron-A(config-vlan-102)# untagged ethernet 1/2
NetIron-A(config-vlan-102)# exit
NetIron-A(config)# vlan 103
NetIron-A(config-vlan-103)# tagged ethernet 2/1
NetIron-A(config-vlan-103)# untagged ethernet 1/3
NetIron-A(config-vlan-103)# exit
NetIron-A(config)# vlan 104
NetIron-A(config-vlan-104)# tagged ethernet 2/1
NetIron-A(config-vlan-104)# untagged ethernet 1/4
NetIron-A(config-vlan-104)# exit
NetIron-A(config)# vlan 105
NetIron-A(config-vlan-105)# tagged ethernet 2/1
NetIron-A(config-vlan-105)# untagged ethernet 1/5
NetIron-A(config-vlan-105)# exit
NetIron-A(config)# write memory
```

Commands for device B

The commands for configuring device B are identical to the commands for configuring device A. Notice that you can use the same channel VLAN numbers on each device. The devices that aggregate the VLANs into a path can distinguish between the identically named channel VLANs based on the ID of the path VLAN.

```
NetIron-B(config)# vlan 101
NetIron-B(config-vlan-101)# tagged ethernet 2/1
NetIron-B(config-vlan-101)# untagged ethernet 1/1
NetIron-B(config-vlan-101)# exit
NetIron-B(config)# vlan 102
NetIron-B(config-vlan-102)# tagged ethernet 2/1
NetIron-B(config-vlan-102)# untagged ethernet 1/2
NetIron-B(config-vlan-102)# exit
NetIron-B(config)# vlan 103
NetIron-B(config-vlan-103)# tagged ethernet 2/1
NetIron-B(config-vlan-103)# untagged ethernet 1/3
NetIron-B(config-vlan-103)# exit
NetIron-B(config)# vlan 104
NetIron-B(config-vlan-104)# tagged ethernet 2/1
NetIron-B(config-vlan-104)# untagged ethernet 1/4
NetIron-B(config-vlan-104)# exit
NetIron-B(config)# vlan 105
NetIron-B(config-vlan-105)# tagged ethernet 2/1
NetIron-B(config-vlan-105)# untagged ethernet 1/5
NetIron-B(config-vlan-105)# exit
NetIron-B(config)# write memory
```

Commands for device C

Since device C is aggregating channel VLANs from devices A and B into a single path, you need to change the tag type and enable VLAN aggregation.

```
NetIron-C(config)# tag-type 9100
NetIron-C(config)# vlan 101
NetIron-C(config-vlan-101)# tagged ethernet 4/1
NetIron-C(config-vlan-101)# untagged ethernet 3/1
NetIron-C(config-vlan-101)# exit
NetIron-C(config)# vlan 102
NetIron-C(config-vlan-102)# tagged ethernet 4/1
NetIron-C(config-vlan-102)# untagged ethernet 3/2
NetIron-C(config-vlan-102)# exit
NetIron-C(config)# write memory
```

Commands for device D

Device D is at the other end of path and separates the channels back into individual VLANs. The tag type must be the same as tag type configured on the other core device (Device C). In addition, VLAN aggregation also must be enabled.

```
NetIron-D(config)# tag-type 9100
NetIron-D(config)# vlan 101
NetIron-D(config-vlan-101)# tagged ethernet 4/1
NetIron-D(config-vlan-101)# untagged ethernet 3/1
NetIron-D(config-vlan-101)# exit
NetIron-D(config)# vlan 102
```

```
NetIron-D(config-vlan-102)# tagged ethernet 4/1
NetIron-D(config-vlan-102)# untagged ethernet 3/2
NetIron-D(config-vlan-102)# exit
NetIron-D(config)# write memory
```

Commands for device E

Since the configuration in Figure 10 on page 250 is symmetrical, the commands for configuring device E are identical to the commands for configuring device A.

```
NetIron-E(config)# vlan 101
NetIron-E(config-vlan-101)# tagged ethernet 2/1
NetIron-E(config-vlan-101)# untagged ethernet 1/1
NetIron-E(config-vlan-101)# exit
NetIron-E(config)# vlan 102
NetIron-E(config-vlan-102)# tagged ethernet 2/1
NetIron-E(config-vlan-102)# untagged ethernet 1/2
NetIron-E(config-vlan-102)# exit
NetIron-E(config)# vlan 103
NetIron-E(config-vlan-103)# tagged ethernet 2/1
NetIron-E(config-vlan-103)# untagged ethernet 1/3
NetIron-E(config-vlan-103)# exit
NetIron-E(config)# vlan 104
NetIron-E(config-vlan-104)# tagged ethernet 2/1
NetIron-E(config-vlan-104)# untagged ethernet 1/4
NetIron-E(config-vlan-104)# exit
NetIron-E(config)# vlan 105
NetIron-E(config-vlan-105)# tagged ethernet 2/1
NetIron-E(config-vlan-105)# untagged ethernet 1/5
NetIron-E(config-vlan-105)# exit
NetIron-E(config)# write memory
```

Commands for device F

The commands for configuring device F are identical to the commands for configuring device E. In this example, since the port numbers on each side of the configuration in Figure 10 on page 250 are symmetrical, the configuration of device F is also identical to the configuration of device A and device B.

```
NetIron-F(config)# vlan 101
NetIron-F(config-vlan-101)# tagged ethernet 2/1
NetIron-F(config-vlan-101)# untagged ethernet 1/1
NetIron-F(config-vlan-101)# exit
NetIron-F(config)# vlan 102
NetIron-F(config-vlan-102)# tagged ethernet 2/1
NetIron-F(config-vlan-102)# untagged ethernet 1/2
NetIron-F(config-vlan-102)# exit
NetIron-F(config)# vlan 103
NetIron-F(config-vlan-103)# tagged ethernet 2/1
NetIron-F(config-vlan-103)# untagged ethernet 1/3
NetIron-F(config-vlan-103)# exit
NetIron-F(config)# vlan 104
NetIron-F(config-vlan-104)# tagged ethernet 2/1
NetIron-F(config-vlan-104)# untagged ethernet 1/4
NetIron-F(config-vlan-104)# exit
NetIron-F(config)# vlan 105
```

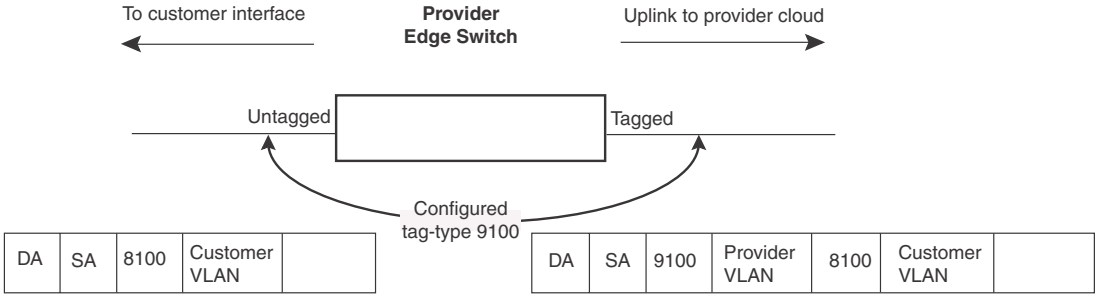
```
NetIron-F(config-vlan-105)# tagged ethernet 2/1
NetIron-F(config-vlan-105)# untagged ethernet 1/5
NetIron-F(config-vlan-105)# exit
NetIron-F(config)# write memory
```

Configuring 802.1q-in-q tagging

802.1Q-in-Q tagging enables you to configure 802.1Q tag-types on a group of ports, such as LAG ports, thereby enabling the creation of two identical 802.1Q tags (802.1Q-in-Q tagging) on a single device. This feature improves SAV interoperablilty between Dell devices and other vendors' devices that support the 802.1Q tag-types, but are not very flexible with the tag-types they accept.

Figure 11 shows an 802.1Q configuration example.

FIGURE 11 SAV configuration example

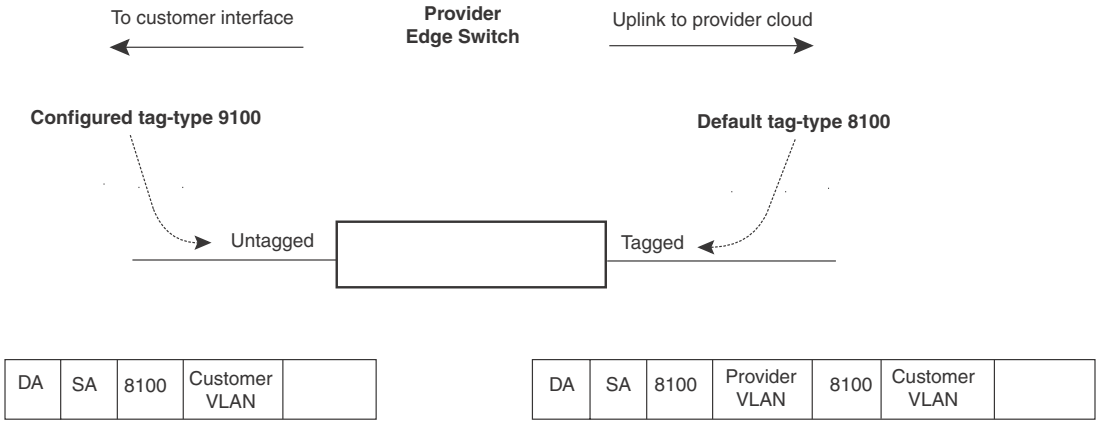


As shown in Figure 11, the ports to customer interfaces are untagged, whereas the uplink ports to the provider cloud are tagged, because multiple client VLANs share the uplink to the provider cloud. In this example, the PowerConnect router treats the customer's private VLAN ID and 8100 tag type as normal payload, and adds the 9100 tag type to the packet when the packet is sent to the uplink and forwarded along the provider cloud.

As long as the switches in the provider's network support the 9100 tag type, the data gets switched along the network. However, devices that do not support the 9100 tag type may not properly handle the packets.

Figure 12 and Figure 13 show an example application of 802.1Q-in-Q.

FIGURE 12 802.1Q-in-Q configuration example



In Figure 14, the untagged ports (to customer interfaces) accept frames that have any 802.1Q tag other than the configured tag-type 9100. These packets are considered untagged on this incoming port and are re-tagged when they are sent out of the uplink towards the provider. The 802.1Q tag-type on the uplink port is 8100, so the PowerConnect router will switch the frames to the uplink device with an additional 8100 tag, thereby supporting devices that only support this method of VLAN tagging.

Configuration rules

Follow the rules below when configuring 802.1q-in-q tagging:

- The PowerConnect router supports per port tag-type configuration. Consequently, each port can have its own tag-type setting.
- The default tag-type for a port is 8100
- The PowerConnect router supports 802.1q-in-q tagging where the inner and outer tag can have different or same tag-type values. This feature maximizes interoperablilty with third-party devices.

Enabling 802.1Q-in-Q tagging

To enable the 802.1Q-in-Q feature, configure an 802.1Q tag type on the untagged edge links (the customer ports) to any value other than the 802.1Q tag for incoming traffic.

For example, in Figure 13, the 802.1Q tag on the untagged edge links (ports 11 and 12) is 9100, whereas, the 802.1Q tag for incoming traffic is 8100.

To configure 802.1 Q-in-Q tagging as shown in Figure 13, enter commands such as the following on the untagged edge links of devices C and D.

```
NetIron(config)# tag-type 9100 e 3/1 to 3/2
```

Syntax: [no] **tag-type** <*num*> [**ethernet** <*slot-number*>/<*port-number*> [**to** <*slot-number*>/<*port-number*>]]

The <*num*> parameter specifies the tag-type number and can be a hexadecimal value from 0 - ffff. The default is 8100.

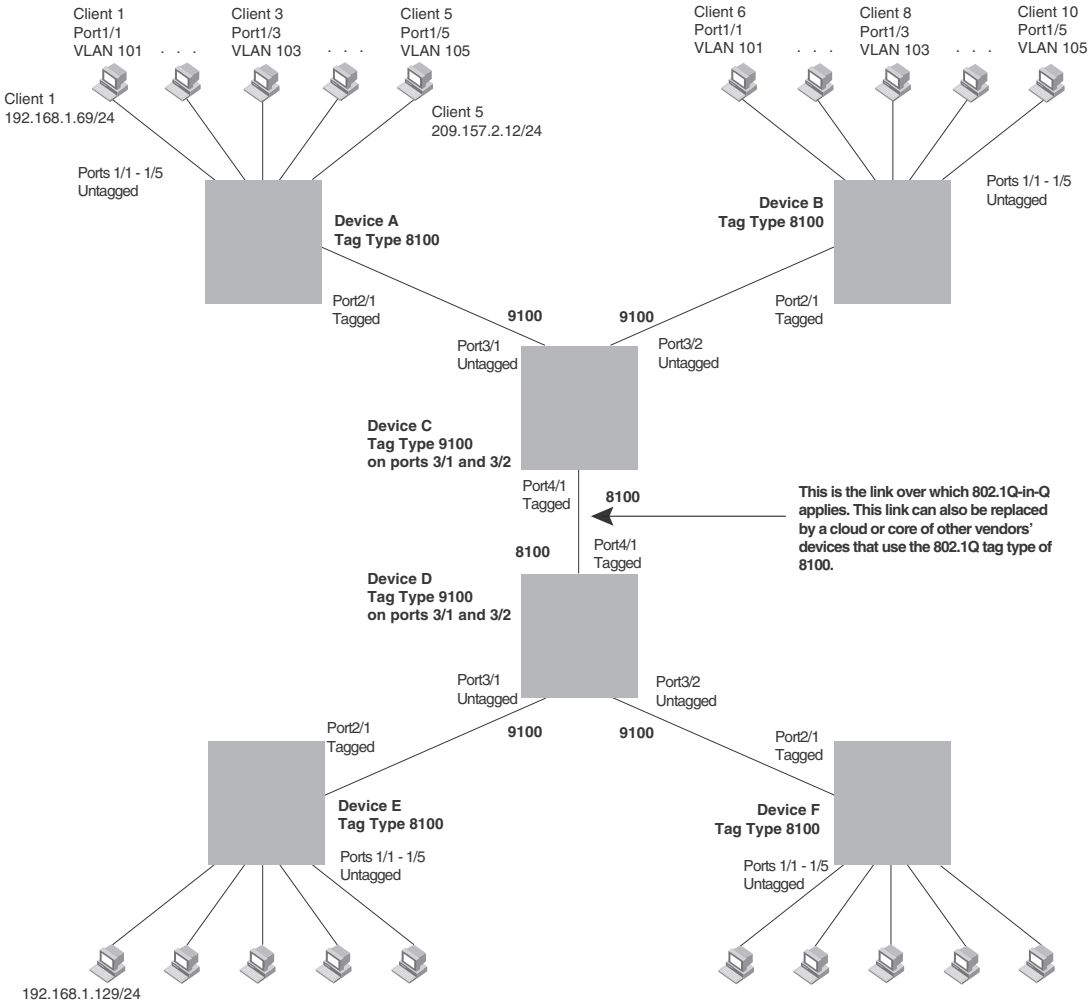
The **ethernet** <*port number*> **to** <*port number*> parameter specifies the ports that will use the defined 802.1Q tag. This parameter operates with the following rules:

- If you do not specify a port or range of ports, the 802.1Q tag applies to all Ethernet ports on the device.

Example configuration

Figure 13 shows an example 802.1Q-in-Q configuration.

FIGURE 13 Example 802.1Q-in-Q configuration



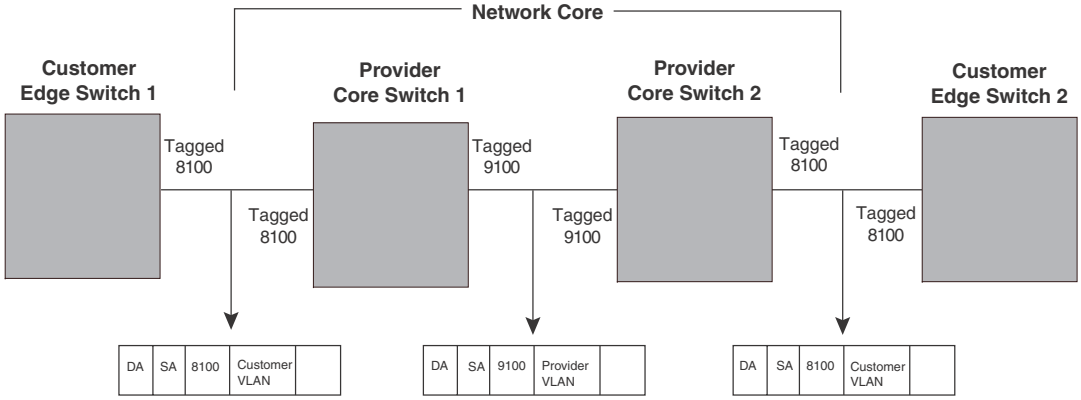
Configuring 802.1q tag-type translation

The introduction of 802.1q tag-type translation provides finer granularity for configuring multiple 802.1q tag-types on a single device, by enabling you to configure 802.1q tag-type per port. This enhancement allows for tag-type translation from one port to the next on tagged interfaces.

802.1Q tag-type translation enables you to configure a separate 802.1q tag-type per port, allowing for tag-type translation from one port to the next on tagged interfaces.

Figure 14 shows a basic example application of the 802.1q tag-type translation feature.

FIGURE 14 802.1q Tag-type translation configuration example 1



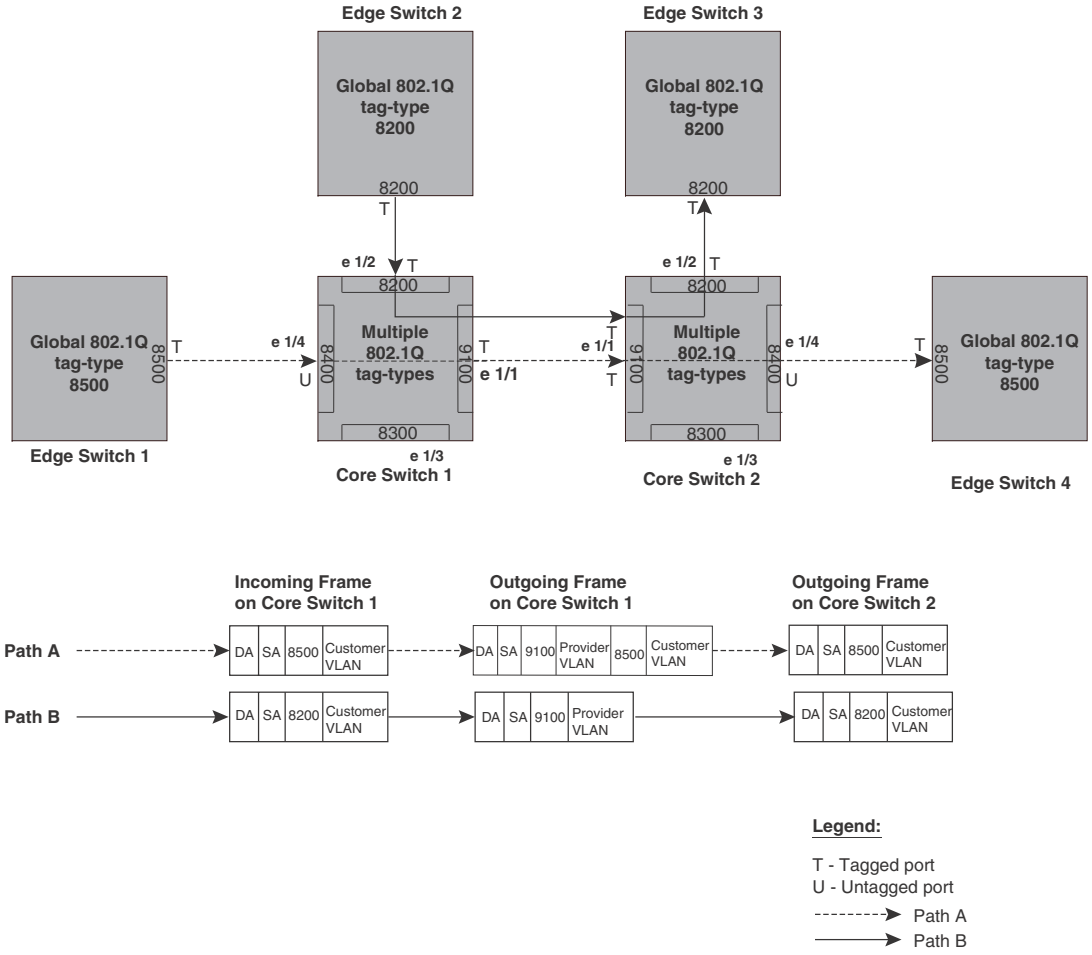
As illustrated in Figure 14, the devices process the packet as follows:

- Customer Edge Switch 1 sends a packet with an 802.1q tag-type of 8100 to Provider Core Switch 1.
- Since the customer-facing interface on Provider Core Switch 1 has the same 802.1q tag-type as the incoming packet, it removes the 8100 tag-type and replaces (translates) it with the 9100 tag-type as it sends the packet to the uplink (Provider Core Switch 2).
- The same process occurs between Provider Core Switch 2 and Customer Edge Switch 2.

Figure 14 shows a simple application of the 802.1q tag-type translation in which all of the ports are tagged and the tag-types between devices match. In this example, each device performs the 802.1q tag-type translation as the packet traverses the network.

Figure 15 shows a more complex example application in which some ports are untagged, not all tag-types between devices match, and the core devices have multiple tag-types. In this example, the tag-type translation feature integrates packets that have single and double tag-types.

FIGURE 15 802.1q Tag-type translation configuration example 2



As illustrated in Figure 15, the devices process the packets as follows:

- Path A: When Core Switch 1 receives the tagged packet from Edge Switch 1, it keeps the 8500 tag-type in the frame header (because the incoming port on Core Switch 1 is untagged) and adds the 9100 tag-type as it sends the packet to the uplink (Core Switch 2). In this case, the packet is double-tagged as it travels between the core devices.
- Path B: When Core Switch 1 receives the tagged packet from Edge Switch 2, it removes the 8200 tag-type and replaces (translates) it with the 9100 tag-type as it sends the packet to the uplink (Core Switch 2).

Configuration rules

Configuration of tag-type ports on the PowerConnect router are on a per-port basis and follow the same rules as described in "Configuration rules" on page 256. Enabling 802.1q Tag-type Translation

To enable 802.1q tag-type translation, configure an 802.1q tag-type on the provider core link, between the provider core switches (refer to Figure 15). Enter commands such as the following.

```
NetIron(config)# tag-type 9100 e 1/1
NetIron(config)# tag-type 8200 e 1/2
NetIron(config)# tag-type 8300 e 1/3
NetIron(config)# tag-type 8400 e 1/4
```

Syntax: [no] tag-type <*num*> **[ethernet** <*slot-number*>/<*port-number*> **[to** <*slot-number*>/<*port-number*>**]]**

The <*num*> parameter specifies the tag-type number and can be a hexadecimal value from 0 - ffff. The default is 8100.

The <*slot-number*>/<*port-number*> [**to** <*slot-number*>/<*port-number*>] parameter specifies the ports that will use the defined 802.1q tag-type. This parameter operates with the following rules:

- If the port that you specify is part of a multi-slot LAG, the device automatically applies the 802.1q tag-type to all of the ports that are part of the multi-slot LAG.
- If you do not specify a port or range of ports, the 802.1q tag-type applies to all Ethernet ports on the device.

Miscellaneous VLAN features

Allocating memory for more VLANs or virtual routing interfaces

By default, you can configure up to 512 VLANs and virtual routing interfaces on the router. Although this is the default maximum, the PowerConnect router can support up to 4090 VLANs and 4090 virtual routing interfaces.

NOTE
If many of your VLANs will have an identical configuration, you might want to configure VLAN groups.

If you need to configure more than 512 VLANs, enter commands such as the following at the global CONFIG level of the CLI.

```
NetIron(config)# system-max vlan 2048
NetIron(config)# write memory
NetIron(config)# end
NetIron# reload
```

Syntax: [no] system-max vlan <*num*>

The <*num*> parameter specifies the maximum number of VLANs that can be configured. The minimum, maximum and default values for this parameter are described in Table 15.

NOTE
You must reload the system for the new parameters to take effect.

Configuring uplink ports within a port-based VLAN

You can configure a subset of the ports in a port-based VLAN as uplink ports. When you configure uplink ports in a port-based VLAN, the device sends all broadcast and unknown-unicast traffic from a port in the VLAN to the uplink ports, but not to other ports within the VLAN. Thus, the uplink ports provide tighter broadcast control within the VLAN.

For example, if two ports within a port-based VLAN are Gigabit ports attached to the network and the other ports in the VLAN are 10/100 ports attached to clients, you can configure the two ports attached to the network as uplink ports. In this configuration, broadcast and unknown-unicast traffic in the VLAN does not go to all ports in the VLAN. The traffic goes only to the uplink ports. The clients on the network do not receive broadcast and unknown-unicast traffic from other ports, including other clients.

To configure a port-based VLAN containing uplink ports, enter commands such as the following.

```
NetIron(config)# vlan 10
NetIron(config-vlan-10)# untag ethernet 1/1 to 1/20
NetIron(config-vlan-10)# untag ethernet 2/1 to 2/2
NetIron(config-vlan-10)# uplink-switch ethernet 2/1 to 2/2
```

Syntax: [no] uplink-switch ethernet <*port-number*> **[to** <*port-number*> **| ethernet** <*port-number*>**]**

In this example, ports 1 - 20 on slot 1 and ports 1 - 2 on slot 2 are added to port-based VLAN 10. The two ports on slot 2 are then configured as uplink ports.

Configuring control protocols in VLANs

You can configure the following protocols on a VLAN:

- Foundry MRP (Refer to 13, “Metro Ring Protocol”.)
- VSRP (Refer to 15, “Virtual Switch Redundancy Protocol (VSRP)”.)
- STP (Refer to 11, “Configuring Spanning Tree Protocol”.)
- RSTP (Refer to 12, “Configuring Rapid Spanning Tree Protocol”.)

Hardware flooding for layer 2 multicast and broadcast packets

Broadcast and multicast packets do not have a specific recipient. In order for these "special" packets to reach their intended recipient, they need to be sent on all ports of the VLAN (or "flooded" across the VLAN).

You must enable hardware flooding for Layer 2 multicast and broadcast packets on the PowerConnect router . (Layer 2 multicast packets have a multicast address in the destination MAC address field.)

You can enable hardware flooding for Layer 2 multicast and broadcast packets on a per-VLAN basis.

Example

```
NetIron(config)#
NetIron(config)# vlan 2
NetIron(config-vlan-2)# multicast-flooding
NetIron(config-vlan-2)# exit
```

Syntax: [no] multicast-flooding

NOTES:

- This feature cannot be enabled on an empty VLAN; the VLAN must already have ports assigned to it prior to enabling this feature.
- This feature is not supported on Layer 3 protocol-based VLANs.
- If you enable this feature on a VLAN that includes a LAG group, hardware flooding for Layer 2 multicast and broadcast packets occurs only on the LAG group's primary port. Multicast and broadcast traffic for the other ports in the LAG group is handled by software.

Unknown unicast flooding on VLAN ports

Unknown unicast packets do not have a specific (or unicast) recipient. In order for these "special" packets to reach their intended recipient, they needed to be sent on all ports of the VLAN (or "flooded" across the VLAN).

You must enable *hardware* flooding for unknown unicast packets on the PowerConnect router. It is disabled by default.

To enable unicast hardware flooding on a VLAN ports and enable software flooding, enter commands such as the following.

```
NetIron(config)# vlan 2
NetIron(config-vlan-2)# unknown-unicast-flooding
NetIron(config-vlan-2)# exit
```

Syntax: [no] unknown-unicast-flooding

Configuring VLAN CPU protection

VLAN CPU protection is recommended for the VLANs which are intended for pure Layer2 use. This feature will protect the CPU from the flooding of unknown-unicast or multicast or broadcast L2 packets on that VLAN. When using routing protocols (like OSPF etc.) on a specific VLAN, you need to disable VLAN CPU protection for it to work. This feature is intended for Layer2 applications and not for Layer3 routing applications.

VLAN CPU protection is enabled per VLAN. To enable VLAN CPU protection on a VLAN, enter the following command.

```
NetIron(config)# vlan 24
NetIron(config-vlan-24)# vlan-cpu-protection
```

Syntax: [no] vlan-cpu-protection

NOTE
The Multi-Service IronWare software has been enhanced to support the dynamic growth of the protocol and flooding sub-partitions in the L2 CAM to grant them a higher priority. Because of this enhancement, the **system-max hw-flooding** command is no longer required and has been retired from the software.

Command changes to support 8x10G modules

The following commands changed to support NI-MLX-10x8G modules.

Deprecated commands:

- The **vlan-counter exclude-overhead** command has been deprecated. The new command is the **statistics -> exclude-ethernet-overhead** command.
- The **byte-accounting** command under a VLAN has been has been deprecated on the NetIron MLX platforms and replaced by the **vlan-accounting on | off** command. In addition, a new global **vlan-policy -> vlan-accounting** command has been introduced to enable/disable accounting for all VLANs.
- The **clear vlan byte-accounting all-vlans** command has been deprecated. The new command is the **clear vlan all-vlan statistics** command.
- The **clear vlan byte-accounting** command has been has been deprecated. The new command is the **clear vlan statistics** command.

Existing display command:

- New options have been added to the **show vlan** command to display VLAN counters for the 8x10G module.

Deprecated commands

vlan-counter exclude-overhead

The **vlan-counter exclude-overhead** command has been deprecated. The new command is the **exclude-ethernet-overhead** command.

NOTE
The **statistics -> exclude-ethernet-overhead** command will replace the **vlan-counter exclude-overhead** command when upgrading to the new image.

By default, the VLAN byte counters include the 20-byte Ethernet overhead. You can use the **exclude-ethernet-overhead** command to direct the PowerConnect router to exclude this overhead when it counts the bytes, as shown in the example below.

```
PowerConnect(config-statistics)#exclude-ethernet-overhead
```

Syntax: [no] exclude-ethernet-overhead

To disable the configuration, use the **no exclude-ethernet-overhead** command.

byte-accounting

NOTE
The **byte-accounting** command has been replaced by the **vlan-accounting on|off** command at the VLAN configuration level for the NetIron MLX platform.

The **byte-accounting** command under a VLAN has been has been deprecated for the NetIron MLX. The new command for those platforms is the **vlan-accounting on l off** command. In addition a new global **vlan-policy -> vlan-accounting** command has also been introduced to enable/disable accounting for all VLANs.

NOTE
The **vlan-accounting on** command will replace the **byte-accounting** command under a VLAN when upgrading to the new image on the NetIron MLX platform.

The **vlan-accounting on | off** command at the VLAN level takes precedence over global configuration. For example, if VLAN accounting is globally enabled, and the user disables VLAN accounting on VLAN 10, then VLAN accounting for VLAN 10 is disabled.

By default, L2 VLAN accounting is globally enabled for all VLANs. The VLAN counters are polled every 50 seconds.

To disable VLAN accounting globally for all VLANs, enter the following command at the config-vlan-policy level of the CLI.

```
NetIron(config-vlan-policy)#no vlan-accounting
```

Syntax: [**no**] **vlan-accounting**

To disable VLAN accounting globally, enter the **no vlan-accounting** command.

To configure VLAN accounting for specific VLAN, enter the following command.

```
PowerConnect(config-vlan-10)# vlan-accounting on.
```

Syntax: **[no] vlan-accounting <**on **|** off**>**

The **vlan-accounting on** command enables counters for a specific VLAN. The **vlan-accounting off** command disables counters for a specific VLAN.

clear vlan all-vlans statistics

The **clear vlan byte-accounting all-vlans** command has been deprecated. The new command is the **clear vlan all-vlans statistics** command.

To clear VLAN counters for all VLANs, enter the following command.

```
NetIron# clear vlan all-vlans statistics
```

Syntax: **clear vlan all-vlans statistics**

clear vlan byte-accounting

The **clear vlan byte-accounting** command has been has been deprecated. The new command is the **clear vlan statistics** command.

To clear the VLAN counters on a specific VLAN, say VLAN 10, enter the following command.

```
NetIron# clear vlan 10 statistics
```

Syntax: **clear vlan** <vlan-id> **statistics**

Use the <vlan-id> parameter to specify the name of the VLAN to clear statistic counter on.

Existing display command:

The byte counter displayed by the output of **show vlan** command is the number of received bytes across all ports (both G2 and non-G2 ports) in the specified VLAN.

```
PowerConnect# show vlan
Configured PORT-VLAN entries: 3
Maximum PORT-VLAN entries: 4090
Default PORT-VLAN id: 1
PORT-VLAN 1, Name DEFAULT-VLAN, Priority Level0
L2 protocols : NONE
Untagged Ports : ethernet 2/1 to 2/20 ethernet 3/1 to 3/20 ethernet
PORT-VLAN 2, Name [None], Priority Level0
L2 protocols : NONE
ip-protocol VLAN, Dynamic port disabled
Name: basic
PORT-VLAN 1001, Name [None], Priority Level0
L2 protocols : MRP
Tagged Ports : ethernet 3/1 ethernet 3/12 to 3/13 ethernet 3/20
Bytes received : 6000
```

TABLE 41 show vlan output details

Configured PORT-VLAN entries	Number of port-based VLANs in the configuration.
Maximum PORT-VLAN entries: 4090	Maximum number of port-based VLANs that you can configure.
Default PORT-VLAN id	ID of the default VLAN.
PORT-VLAN	ID of the port-based VLAN.
Name	Name of the port-based VLAN. [None] appears if a name has not been assigned.
Priority Level	Priority level assigned to the port-based VLAN.
L2 protocols	Layer 2 control protocol configured on the VLAN.
Untagged or Tagged Ports	ID of the untagged or tagged ports that are members of the VLAN.
(protocol-based VLANs)	If protocol based VLANs are configured, their type and name appear after the list of ports.
Bytes received	Displays the number of received bytes across all ports in the specified VLAN.

Extended VLAN counters for 8x10G modules

The NI-MLX-10x8G module supports VLAN counters on the ingress and egress ports. The NI-MLX-10x8G module supports packet and byte accounting for 32K counters on both inbound and outbound traffic on a per-VLAN, per-port, per-priority basis. The 8x10G module supports 64 bit VLAN counters for both packet and byte accounting.

To support extended VLAN accounting, the following modes allow you to configure packet and byte accounting on a 8x10G module.

Priority mode - This mode allows accounting to be performed on a per VLAN, per port, per-priority basis. Priority mode is configured on per-module basis. By default, the per-priority accounting mode is disabled **i.e. accounting is done per VLAN, per port**..

Switched or routed separate mode - This mode allows you to specify whether the switched packet and routed packets should be counted separately or not. This mode is configured globally, and by default, switched packets and routed packets are counted together.

Refer to Table 42 on the number of unique port, VLAN's supported per PPCR based on the configuration of "Priority mode" and "Switched or routed separate mode"...

TABLE 42 Internal priority of switched and routed packets

Switched and routed packets	Account based on the internal priority of the packet- Yes or No	Number of unique port-VLANs that have counters (per-PPCR).
Switch or Route separately	Yes	2047 on ingress and 2047 on egress; each set having 16 counters
Switch or Route separately	No	16383 in ingress and 16383 on egress; each set having 2 counters
Switch or route combined	Yes	4095 on ingress and 4095 on egress; each set having 8 counters
Switch or route combined	No	32767 on ingress and 32767 on egress; each set having 1 counter

Configuring extended VLAN counters

The 8x10g modules supports the following global configuration commands.

Enabling accounting on per-slot basis

You can enable or disable per-VLAN/port,/priority accounting mode on all or a per-slot basis on the ingress and egress counters. Layer 2 VLAN accounting is enabled by default. and counters are polled once every 50 seconds. To enable accounting on per-slot basis, enter the following command.

Layer 2 VLAN accounting is enabled by default. Counters are polled once every 50 seconds

```
PowerConnect(config)#statistics
PowerConnect(config-statistics)#extended-counters priority all
```

Syntax: [no] extended-counters priority <all> **|** <*slot-number*>

The <*slot-number*> variable specifies the ID of 8x10 module on which you can perform accounting on per-slot basis.

If the <all> option is specified, the configuration command is remembered in the system when the 8x10 module is removed.

If you dynamically enable or disable the **extended-counters priority** configuration, the sum of counters displayed on a per-priority basis will not be same as the aggregate count displayed on a per-port or per-VLAN basis.

Enabling accounting on switched or routed packets

To enable or disable accounting on switched packets and routed packets separately, enter the following example:

```
PowerConnect(config)#statistics
PowerConnect(config-statistics)#extended-counters routed-switched
```

Syntax: [no] extended-counters routed-switched

If you dynamically enable or disable the **extended-counters routed-switched** configuration, the current counters are saved and added to the count of aggregate packet and byte counters on a per-port or per-VLAN basis and displayed in the output of combined counters.

Displaying VLAN counters

The **show vlan** commands changed to display port-vlan counters for 8x10G modules.

To display VLAN counters information for specific VLAN, enter the following command.

```
NetIron# show vlan 10 statistics
VLAN 10: Extended Routed/Switched Counters (only applicable for G2 modules):

Slot 12: < -- module with per-VLAN/port/priority based accounting
Interface RxPkts           TxPkts           RxBytes          TxBytes
eth 12/1  0                0                0                0
     p0   0                0                0                0
     p1   0                0                0                0
                           <snip>
     p6   0                0                0                0
     p7   0                0                0                0
eth 12/2  0                0                0                0
     p0   0                0                0                0
     p1   0                0                0                0
                           <snip>
     p6   0                0                0                0
     p7   0                0                0                0
eth 12/3         -- Extended-counter resource allocation failed –   < -- On
encountering Stats ID allocation failure
eth 12/4  0                0                0                0
     p0   0                0                0                0
     p1   0                0                0                0
<snip>
     p6   0                0                0                0
     p7   0                0                0                0

Slot 14: < -- module with per-VLAN/port based accounting
```

Syntax: show vlan <vlan id> **statistics** [detail |routed|switched]

The <vlan-id> parameter specifies the VLAN ID of the port.

The <slot/port> parameter specifies the interface module location of a 8x10g module.

Use the **routed** option to view the counters of routed packets.This option is only accepted if the accounting mode is to count routed and switched packets separately.

Use the **switched** option to view the counters of switched packets.This option is only accepted if the accounting mode is to count routed and switched packets separately.

Use the **detail** option to view the counters of routed packets, counters of switched packets, and counters of both routed and switched packets. This option is only accepted if the accounting mode is to count routed and switched packets separately.

If the “routed” or “switched” option is specified, counters for only routed and switched packets are displayed respectively, otherwise the output displays combined statistics for both routed and switched packets.

TABLE 43 Output descriptions of the **show vlan** command

Field	Description
Interface	The interface the counter statistics are displayed.
RxPkts	The number of packets received at the specified port.
TxPkts	The number of packets transmitted from the specified port.
RxBytes	The number of bytes received at the specified port.
TxBytes	The number of bytes transmitted from the specified port.

Displaying VLAN counters for a specific port

To display VLAN counters information for specific port on a VLAN, enter the following command.

```
PowerConnect# show vlan 10 statistics ethernet 14/1
VLAN 10: Extended Routed/Switched Counters (only applicable for G2 modules):
Interface RxPkts           TxPkts           RxBytes          TxBytes
eth 14/1  0                0                0                0
```

To display VLAN counters information for routed packets on a specific port on a VLAN, enter the following command.

```
PowerConnect# show vlan 10 statistics ethernet 14/1 routed
VLAN 10: Extended Routed Counters (only applicable for G2 modules):
Interface RxPkts           TxPkts           RxBytes          TxBytes
eth 14/1  0                0                0                0
```

To display VLAN counters information for switched packets on a specific port on a VLAN, enter the following command.

```
PowerConnect# show vlan 10 statistics ethernet 14/1 switched
VLAN 10: Extended Switched Counters (only applicable for G2 modules):
Interface RxPkts           TxPkts           RxBytes          TxBytes
eth 14/1  0                0                0                0
```

To display detailed VLAN counters information on a specific port on a VLAN, enter the following command.

```
PowerConnect# show vlan 10 statistics ethernet 14/1 detail
VLAN 10: Extended Counters (only applicable for G2 modules):
Interface RxPkts           TxPkts           RxBytes          TxBytes
eth 14/1
 Routed   0                0                0                0
 Switched 0                0                0                0
 Combined 0                0                0                0
```

Syntax: show vlan <vlan id**> statistics ethernet** <port-id> **[detail |routed |switched]**

The <vlan-id> parameter specifics the VLAN ID of the port.

The <slot/port> parameter specifies the interface module location of a 8x10g module.

Use the **routed** option to view the counters of routed packets.This option is only accepted if the accounting mode is to count routed and switched packets separately.

Use the **switched** option to view the counters of switched packets. This option is only accepted if the accounting mode is to count routed and switched packets separately.

Use the **detail** option to view the counters of routed packets, counters of switched packets, and counters of both routed and switched packets. This option is only accepted if the accounting mode is to count routed and switched packets separately.

If the “routed” or “switched” option is specified, counters for only routed and switched packets are displayed respectively, otherwise the output displays combined statistics for both routed and switched packets.

TABLE 44 Output description for the **show vlan** command

Field	Description
Interface	The interface the counter statistics are displayed.
RxPkts	The number of packets received at the specified port.
TxPkts	The number of packets transmitted from the specified port.
RxBytes	The number of bytes received at the specified port.
TxBytes	The number of bytes transmitted from the specified port.

Clearing extended VLAN counters

You use the following commands to clear the VLAN counters.

Clearing counters for all VLANs

To clear the ingress and egress packet and byte counters for routed packets and switched packets on all VLANs, enter the following command.

```
PowerConnect# clear vlan all-vlans statistics
```

Syntax: clear vlan all-vlans statistics [switched]

Enter the **switched** keyword to clear only the counters of switched packets. If you do not specify the **switched** keyword, the counters for both routed packets and switched packets are cleared. The **switched** keyword is accepted only if the routed packets and switched packets are counted separately.

Clearing counters for a specific VLAN

To clear the VLAN counters for a specific VLAN, enter the following command.

```
PowerConnect# clear vlan 10 statistics
```

Syntax: clear vlan <*vlan-id*> **statistics [switched]**

Use the <*vlan-id*> option to specify the VLAN ID of the port for which you want to clear the counters.

Enter the **switched** keyword to clear only the counters of switched packets. If you do not specify the **switched** keyword, the counters for both routed packets and switched packets are cleared. The **switched** keyword is accepted only if the routed packets and switched packets are counted separately.

Clearing VLAN and port counters

To clear VLAN, port, and priority counters for specific VLAN and port combinations, enter the following command.

```
PowerConnect# clear vlan 10 statistics ethernet 1/2 switched
```

Syntax: clear vlan <*vlan-id*> **statistics ethernet** <*port-id*> **[switched]**

Use the <*vlan-id*> option to specify the VLAN ID of the port for which you want to clear the counters.

Use the <*port-id*> option to specify the port for with you want to clear the counters.

Specify the **switched** keyword to clear counters for the switched packets. If the **switched** keyword is not specified the counters for both routed packets and switched packets will be cleared. The **switched** keyword is accepted only if the routed packets and switched packets are counted separately.

Clearing VLAN counters on a port with a specific priority

To clear counters for a specific port in a VLAN with specific priority, enter the following command.

```
PowerConnect# clear vlan 10 statistics ethernet 1/2 priority 3 switched
```

Syntax: clear vlan <*vlan-id*> **statistics ethernet** <*port-id*> **priority** <*0-7*> **[switched]**

Use the <*vlan-id*> option to specify the VLAN ID of the port for which you want to clear the counters.

Use the <*port-id*> option to specify the port for with you want to clear the counters.

Specify the **switched** keyword to clear counters for the switched packets. If the **switched** keyword is not specified the counters for both the routed packets and switched packets will be cleared. The **switched** keyword is accepted only if the routed packets and switched packets are counted separately.

Clearing extended counters statistics on a port

To clear all extended counters statistics simultaneously for a single port, enter the following command.

```
PowerConnect# clear statistics ethernet 1/2 extended counters
```

Syntax: clear statistics ethernet <*port_id or range* > **extended counters**

Use the <*port_id or range*> option to specify the port or range for which you want to clear the extended counters.

Clearing extended counters statistics on specific slot

To clear all extended counter statistics simultaneously for a slot, enter the following command.

```
PowerConnect# clear statistics slot 2 extended counters
```

Syntax: clear statistics slot <slot -id> extended counters

Use the <*slot-id*> option to specify the slot number for which you want to clear the extended counters.

IP interface commands

You can display and clear the counter details of the physical and virtual IP interfaces.

Displaying IP interface counters

You can display aggregate count of the routed packets and switched packets of an IP interface using the following command.

```
<< If Routed/Switched separate mode >>
NetIron# show ip interface ve 10 statistics
Extended Routed Counters (only applicable for G2 modules):
Total     RxPkts           TxPkts           RxBytes          TxBytes
          0                0                0                0

<< If Routed/Switched combined mode>>
NetIron# show ip interface ve 10 statistics
Extended Routed/Switched Counters (only applicable for G2 modules):
Total     RxPkts           TxPkts           RxBytes          TxBytes
                    0                0                0                0
```

Syntax: show ip interface ethernet <*port-id*> **statistics**

Specify the< *port id*> of the interface for which you want to display the routed and switched packets aggregate count.

TABLE 45 show ip interface command output details

Field	Description
Interface	The interface the counter statistics are displayed.
RxPkts	The number of packets received at the specified port.
TxPkts	The number of packets transmitted from the specified port.
RxBytes	The number of bytes received at the specified port.
TxBytes	The number of bytes transmitted from the specified port.

Displaying IP virtual interface counters

To display the counters for each physical port of a virtual IP interface, use the following command.

```
NetIron#show ip interface ve 10 statistics ethernet 12/1

Extended Routed Counters (applicable for G2 modules only):

Interface RxPkts           TxPkts           RxBytes          TxBytes
eth 12/1  0                0                0                0
     p0   0                0                0                0
     p1   0                0                0                0
                                  <snip>
     p6   0                0                0                0
     p7   0                0                0                0
```

Syntax: show ip interface ve <*vid*> **statistics [ethernet** <*port-id*>**]**

Specify the< *port id*> of the virtual interface for which you want to display.

TABLE 46 show ip interface ve statistics command output details

Field	Description
Interface	The interface the counter statistics are displayed.
RxPkts	The number of packets received at the specified port.
TxPkts	The number of packets transmitted from the specified port.
RxBytes	The number of bytes received at the specified port.
TxBytes	The number of bytes transmitted from the specified port.

Displaying detailed IP virtual interface counters

To display the detailed aggregate count of the routed packets and switched packets of a virtual IP interface are configured separate mode, use the following command.

```
NetIron# show ip interface ve 10 statistics detail

Extended Routed Counters (applicable for G2 modules only):

Interface RxPkts           TxPkts           RxBytes          TxBytes
eth 12/1  0                0                0                0
     p0   0                0                0                0
     p1   0                0                0                0
                                  <snip>
     p6   0                0                0                0
     p7   0                0                0                0

eth 12/2  0                0                0                0
     p0   0                0                0                0
                              <snip>
     p7   0                0                0                0
```

To display the detailed aggregate count of the routed packets and switched packets of a virtual IP interface are configured combined mode, use the following command.

```
NetIron# show ip interface ve 10 statistics detail

Extended Routed/Switched  Counters (applicable for G2 modules only):

Interface RxPkts           TxPkts           RxBytes          TxBytes
eth 12/1  0                0                0                0
     p0   0                0                0                0
```

```
p1   0                0                0                0
                                <snip>
p6   0                0                0                0
p7   0                0                0                0
```

Syntax: show ip interface ve <*vid*> **statistics [detail]**

Use the <*vid*> *option* to specify the interface name of the virtual IP interface for which you want to display the routed and switched packets aggregate count.

TABLE 47 show ip interface ve output details

Field	Description
Interface	The interface the counter statistics are displayed.
RxPkts	The number of packets received at the specified port.
TxPkts	The number of packets transmitted from the specified port.
RxBytes	The number of bytes received at the specified port.
TxBytes	The number of bytes transmitted from the specified port.

Clearing IP interface counters

When clearing IP interface counters, the counters that are cleared are dependent on the accounting mode configuration. If you have configured accounting mode to count routed and switched packets separately, only the routed counters will be cleared. If you have configured accounting mode to count routed and switched packets together, the combined counter will be cleared.

To clear the routed packet and switched packet counters of a specific IP interface, enter the following command.

```
PowerConnect# clear ip interface ethernet 1/2 statistics
```

Syntax: clear ip interface ethernet <*port-id*> **statistics**

Use the <*port-id*> option to specify the interface name to clear.

Clearing IP virtual interface counters

When clearing IP virtual interface counters, the counters that are cleared are dependent on the accounting mode configuration. If you have configured accounting mode to count routed and switched packets separately, only the routed counters will be cleared. If you have configured accounting mode to count routed and switched packets together, the combined counter will be cleared.

To clear the routed packet and switched packet counters of a specific virtual IP interface, enter the following command

```
PowerConnect# clear ip interface ve 2 statistics
```

Syntax: clear ip interface ve <*vid*> **statistics**

Use the <*vid*> option to specify the virtual interface name to clear.

Transparent VLAN flooding

You can configure your PowerConnect router for transparent VLAN flooding. This feature allows packets to be forwarded without any form of CPU intervention including MAC learning and MAC destination lookups.

NOTE
Because this feature floods all VLAN packets in hardware, it is not expected to work in conjunction with routing functions such as establishing routing protocol neighborship and L3 forwarding even when the VLAN has a VE configured.

This implementation of Transparent VLAN Flooding has the following attributes:

- The ability to always distribute traffic to all members of a VLAN in hardware
- It requires no CPU intervention and consequently can handle line-rate traffic forwarding
- Because this feature does not use any MAC address entries in the CAM it is useful when MAC address entries need to be conserved.
- VLAN members can be tagged or untagged ports including a mix of tagged and untagged ports.
- The maximum number of Transparent VLAN Flooded instances is 4k (default: 8)
- You can mix and match ports with different speeds
- Other Layer 2 capabilities such as spanning tree are unaffected
- Output Layer 3 ACLs may be associated with each port that is part of the VLAN instance being transparently flooded
- You cannot configure a VE interface on a VLAN when Transparent VLAN Flooding is used

This feature is particularly useful in situations where MAC learning is not required for traffic forwarding. Examples of where this feature is useful include:

- A configuration where there are only 2 ports in a VLAN
- Where traffic is looped back to a device through another VLAN for firewall or mirroring purposes
- Where the number of MAC addresses will significantly overwhelm the memory and compute resources of a system.

NOTE
Packets that arrive on an interface with the same destination MAC address as the interface are forwarded in hardware just like packets with other destination addresses.

To enable VLAN transparent forwarding on VLAN 10, use the following command.

```
NetIron(config)# vlan 10
NetIron(config-vlan-10)# transparent-hw-flooding
```

Syntax: [no] transparent-hw-flooding

- Layer 2 inbound ACLs may be applied to any port in a VLAN that has TVF enabled.
- Layer 2 or Layer 3 outbound ACLs may be applied to any port in a VLAN that has TVF enabled.
- Input Layer 3 ACLs need to be applied to a virutal routing interface on the VLAN and should not be attached to a port directly. Note that the ACL would apply to all ports in the VLAN by default. If this is not desired, a subset of ports in the VLAN may be specified, as in the following configuration.

```
NetIron(config)# interface ve 1
NetIron(config-vif-1)# ip access-group 101 in ethernet 1/1
NetIron(config-vif-1)# ip access-group ve-traffic
```

NOTE
The above example binds the ACL 101 to the virtual routing interface and configures the virtual routing interface to apply the input ACL 101 for switched and routed traffic received on port 1/1.

Displaying VLAN information

After you configure the VLANs, you can view and verify the configuration.

Displaying VLAN information

Enter the **show vlan** command under the vlan-policy configuration.

NOTE
VLAN byte counters are displayed in the output of the **show vlan** command on an MPLS enabled VE interface.

```
NetIron(config-vlan-policy)#show vlan

Configured PORT-VLAN entries: 7
Maximum PORT-VLAN entries: 512
Default PORT-VLAN id: 1

PORT-VLAN 1, Name DEFAULT-VLAN, Priority Level 0, Priority Force 0
Topo HW idx    : 65535    Topo SW idx: 257    Topo next vlan: 0
L2 protocols   : NONE
Untagged Ports : ethe 1/2 to 1/10 ethe 1/12 to 1/20 ethe 3/3
Bytes received : 112329

PORT-VLAN 13, Name [None], Priority Level 0, Priority Force 0
Topo HW idx    : 65535    Topo SW idx: 257    Topo next vlan: 0
L2 protocols   : NONE
Tagged Ports   : ethe 3/2
Bytes received : 112330

PORT-VLAN 23, Name [None], Priority Level 0, Priority Force 0
Topo HW idx    : 65535    Topo SW idx: 257    Topo next vlan: 0
L2 protocols   : NONE
Tagged Ports   : ethe 3/4
Bytes received : 112338
```

Syntax: **show vlan** [<*vlan-id*>] [**|** [**begin** <*expression*> **|** **exclude** <*expression*> **|** **include** <*expression*>]

The output shows the following information.

TABLE 48 Output of show vlan

This field...	Displays...
Configured PORT-VLAN entries	Number of port-based VLANs in the configuration.
Maximum PORT-VLAN entries: 4090	Maximum number of port-based VLANs that you can configure.
Default PORT-VLAN id	ID of the default VLAN.
PORT-VLAN	ID of the port-based VLAN
Name	Name of the port-based VLAN. [None] appears if a name has not been assigned.
Priority Level	Priority level assigned to the port-based VLAN
Priority Force	The priority force is configured on the ingress port with a priority value between 0 and 7. The default is 0. The priority force option allows you to force the priority on the ingress pram, or choose not to enforce the priority.
Topo HW idx	A topology hardware index is a unique hardware ID that is assigned to a VLAN when a Layer 2 protocol is configured on the VLAN. The VLAN that runs the Layer 2 protocol could be a standalone Layer 2 VLAN or a master VLAN under a topology group. The range for <*hw-index*> is 0 – 511.
Topo SW idx	The topology group id associated with the VLAN.
Topo next vlan	Next VLAN id in the topology group.
L2 protocols	Layer 2 control protocol configured on the VLAN
Untagged or Tagged Ports	ID of the untagged or tagged ports that are members of the VLAN
Bytes received	Displays the number of received bytes across all ports for a specified VLAN. By default, the vlan-accounting command is turned on and hence the Bytes received field is also displayed by default. However, if VLAN accounting for a VLAN is turned off, then the Bytes received field is not displayed in the output. For more information on enabling VLAN byte counters, refer to "Extended VLAN counters for 8x10G modules" on page 265.

To display information for a specific VLAN, enter a VLAN id as shown in the example below.

```
NetIron(config-vlan-13)#show vlan 13

PORT-VLAN 13, Name [None], Priority Level 0, Priority Force 0
Topo HW idx    : 65535    Topo SW idx: 257    Topo next vlan: 0
L2 protocols   : NONE
Tagged Ports   : ethe 3/2
----------------------------------------------------------
Port  Type      Tag-Mode  Protocol  State
3/2   PHYSICAL  TAGGED    NONE      FORWARDING
Arp Inspection: 0
DHCP Snooping: 0
Multicast Snooping: Disabled
```

Displaying VLAN information for specific ports

To determine which VLANs a port is a member of, enter the following command.

```
NetIron# show vlan e 4/1
Port 4/1 is a member of 2 VLANs
VLANs 1 100
```

Syntax: **show vlan ethernet** <*slot-number*>/<*port-number*> **[| [begin** <*expression*> **| exclude** <*expression*> **| include** <*expression*>]

The **ethernet** <*slot-number*>/<*port-number*> parameter specifies a port. The command lists all the VLAN memberships for the port.

The output shows the following information.

TABLE 49 Output of show vlan Ethernet

This field...	Displays...
Port <*slot-number*>/<*port-number*> is a member of # VLANs	The number of VLANs a port is a member of.
VLANs	The IDs of the VLANs that the port is a member of.

Displaying VLAN status and port types

To display detailed information about the state, port types, port modes, of a VLAN, as well as control protocols configured on the VLAN, enter the following command.

```
NetIron# show vlan detail
Untagged Ports  : ethernet 2/1 to 2/20 ethernet 4/4
Tagged Ports    : None
Dual-mode Ports : ethernet 3/1 to 3/20jjj ethernet 4/1 to 4/3
Default VLAN    : 1
Control VLAN    : 4095
VLAN Tag-type   : 0x8100
PORT-VLAN 1, Name DEFAULT-VLAN, Priority Level0
----------------------------------------------------------
Port  Type      Tag-Mode  Protocol  State
2/1   PHYSICAL  UNTAGGED  NONE      DISABLED
2/2   PHYSICAL  UNTAGGED  NONE      DISABLED
2/3   PHYSICAL  UNTAGGED  NONE      DISABLED
2/4   PHYSICAL  UNTAGGED  NONE      DISABLED
2/5   PHYSICAL  UNTAGGED  NONE      DISABLED
.
. (output edited for brevity)
.
4/1   PHYSICAL  UNTAGGED  NONE      FORWARDING
4/2   PHYSICAL  UNTAGGED  NONE      FORWARDING
4/3   PHYSICAL  UNTAGGED  NONE      FORWARDING
4/4   PHYSICAL  UNTAGGED  NONE      DISABLED
PORT-VLAN 100, Name [None], Priority Level0
----------------------------------------------------------
Port  Type      Tag-Mode  Protocol  State
4/1   PHYSICAL  TAGGED    STP       FORWARDING
4/2   PHYSICAL  TAGGED    STP       BLOCKING
```

Syntax: **show vlan detail** <*vlan-id*> **[| [begin** <*expression*> **| exclude** <*expression*> **| include** <*expression*>]

Enter the ID of a VLAN if you want information for a specific VLAN.

The output shows the following information.

TABLE 50 Output of show vlan detail

This field...	Displays...
Untagged Ports	This line appears if you do not specify a VLAN. It lists all the ports that are configured as untagged ports in all the VLANs on the device.
Tagged Ports	This line appears if you do not specify a VLAN. It lists all the ports that are configured as tagged ports in all the VLANs on the device.
Dual-mode ports	This line appears if you do not specify a VLAN. It lists all the ports that are configured as dual-mode ports in all the VLANs on the device.
Default VLAN	ID of the default VLAN
Control VLAN	ID of the control VLAN
PORT-VLAN #, Name, Priority Level	Information for each VLAN in the output begins with the VLAN type and its ID, name and priority level. Then ports that are members of the VLAN are listed, with the following information:
Port	Port <slot-number/port-number >
Type	Port type: physical or LAG
Tag-Mode	Tag mode of the port: untagged, tagged, or dual-mode
Protocol	Protocol configured on the VLAN.
State	Current state of the port such as disabled, blocking, forwarding, etc.

Displaying VLAN group information

To display information about VLAN groups, enter the following command.

```
NetIron# show vlan-group 10

Configured VLAN-Group entries : 1
Maximum VLAN-Group entries : 32

VLAN-GROUP 10
Number of VLANs: 4
VLANs: 10 to 13
Tagged ports: ethernet 3/1
```

Syntax: **show vlan-group** [*vlan-group-id*] [**|** [**begin** <*expression*> **|** **exclude** <*expression*> **|** **include** <*expression*>]

The output shows the following information.

TABLE 51 Output of show vlan Ethernet

This field...	Displays...
Configured VLAN-Group entries	Number of VLAN groups that have been configured on the device.
Maximum VLAN-Group entries	Maximum number of VLAN groups that can be configured on the device.
VLAN-Group #	ID of the VLAN group
VLANs	VLANs that belong to the VLAN group.
Tagged ports:	Type and ID of the tagged ports that are members of the VLAN group

Configuring multi-port static MAC address

To configure multi-port static MAC address, enter the following command at the VLAN configuration node level of the CLI. You must configure at least one port.

```
NetIron# vlan 10
static-mac-address 0100.5e42.7f40 multi-ports ethe 1/1 to 1/3
ethe 2/1 to 2/5 priority 5
```

Syntax: [no] static-mac-address <*mac-address*> multi-ports ethernet [<*slot1/port1*>|[<*slot1/port1*> to <*slot1/port#k*>] .. ethernet [<*slot#n/port#n*> to <*slot#n/port#m*>] [priority <*0-7*>]

Limitations

The configuration of multi-port static MAC address has the following limitations:

- A maximum number of 400 multi-port MAC addresses and static MAC addresses can be configured in a system; however, the number of configured entries is limited by the number of multicast FIDs available in the system.
- FIDs with the same port mask are shared among multiple multi-port MAC addresses and multi-port ARP entries to conserve the number of multicast FIDs created in the system.
- Multi-port static MAC address is not supported on POS ports.
- Multi-port static MAC address cannot be configured on VLAN groups.
- You cannot add any of the interface MAC address as multi-port static MAC address.
- Multi-port static MAC address can be configured for either unicast or multicast addresses.
- Unicast MAC addresses configured as multi-port static MAC addresses will not be learned dynamically in the system or allowed to be dynamically moved to a different port.
- If the multi-port static MAC address being added already exists in the dynamic MAC table, then the dynamic MAC will be deleted and replaced with the configured multi-port static MAC.
- Trunk load-balancing is not supported. The multi-port static MAC address traffic will always be forwarded on the active primary port of the trunk port.

Error messages

Error messages are displayed in the following cases:

- You can configure multi-port static MAC addresses only if all the ports in the port list are members of the VLAN.

  ```
  NetIron(config-vlan-100)#static-mac 0001.0001.0003 multi-port eth 2/11
  Error - Multiport mac cannot be configured, Port 2/11 is not member of vlan 100
  ```

- You must provide the complete port mask for deleting the multi-port static MAC address configuration.

  ```
  NetIron(config-vlan-100)#no static-mac 0001.0001.0002 multi-ports eth 2/19 to
  2/20
  Error - the port list does not match with the configured multiport mac port
  list
  ```

- On a trunk port, multi-port static MAC address configuration is allowed only on the primary port of the trunk.

```
NetIron(config-vlan-100)#static-mac-address 0001.0001.0003 multi-ports ethe
2/19 to 2/20 ethe 4/3
Error - Multiport mac cannot be configured with non-primary trunk port  4/3
```

- A port with multi-port static MAC address configuration cannot be a secondary member of the trunk group.

```
NetIron(config-lag-LAG1)#ports eth 4/11
Error: port 4/11 is part of multiport-mac and cannot be added as secondary
port of a trunk
```

- When a LAG primary port is part of a multi-port static MAC address, the LAG cannot be undeployed or deleted. Also, when a non-LAG port is part of a multi-port static MAC address, you cannot deploy a LAG with that port. These configurations will be rejected. The following are the sample error messages for each of these cases:
  - Veto check for deploying LAG.

```
NetIron(config-lag-LAG1)#deploy
Error: LAG LAG1 primary port 4/11 is configured as part of a multi-port mac
entry, cannot deploy the LAG
```

  - Veto check for undeploying LAG.

```
NetIron(config-lag-LAG2)#no deploy
Error: The primary port 4/15 is configured as part of a multi-port mac
entry, cannot undeploy the LAG
```

  - Veto check for deleting LAG.

```
NetIron(config)#no lag LAG2
Error: The primary port 4/15 is configured as part of a multi-port mac
address, cannot remove the LAG
```

- A port belonging to a multi-port static MAC address is not allowed to be removed from a VLAN unless it is removed from all the multi-port static MAC addresses.

```
NetIron(config-vlan-100)#no tag e 2/19
Error - port 2/19 is configured as part of a multi-port mac address, cannot
remove port from vlan
```

- Module configuration deletion (no module) will be rejected if any of the ports in that module are configured as part of any multi-port static MAC addresses.

```
NetIron(config)#no mod 4 ni-mlx-20-port-1g-100fx
Error - module 4 has ports that are member of the multi-port mac addresses,
Cannot remove the module
```

Displaying multi-port static MAC address information

You can display the following information about multi-port static MAC addresses on the device:

- Running configuration
- Changes in the MAC table
- M-port debug information
- LP information

Displaying running configuration

To display the running configuration information of multi-port static MAC addresses, enter the following command.

```
NetIron# show run
vlan 10
tagged ethe 1/1 to 1/20 ethe 2/1 to 2/48
static-mac-address 0100.5e42.7f40 multi-ports ethe 1/1 to 1/3
ethe 2/1 to 2/5 prority 5
```

Displaying changes in the MAC table

You can display the complete MAC table, a specific entry in the MAC table, or a specific MAC entry with M-port details.

To display the complete MAC table, enter the following command.

```
NetIron# show mac
MAC Address     Port      Age      VLAN    Type
0100.5e42.7f40  1/1...    Static   10
Ports  : e 1/1 to 1/3 e 2/1 to 2/5
0000.999d.9996  2/20     Static    10
```

To display a specific MAC address from the MAC table, enter the following command.

```
NetIron# show mac 0100.5e42.7f40
MAC Address     Port      Age      VLAN    Type
0100.5e42.7f40  1/1...   Static   10
Ports: e 1/1 to 1/3 e 2/1 to 2/5
```

To display a specific MAC address with M-port details, enter the following command.

```
NetIron#show mac 0100.5e42.7f40 debug
MAC Address     Port      Age      VLAN    Type
0100.5e42.7f40  1/1…   Static   10
Mport: 30324 FID: 0x00008006 Ports: e 1/1 to 1/3 e 2/1 to 2/5
```

SA and DA learning and aging

Static MAC addresses and multi-port MAC addresses can always be programmed in the CAM of all LP modules with valid VLAN membership. Multi-port static MAC addresses are added or removed from the CAM when a port is added to or deleted from a VLAN. These addresses cannot be dynamically learned or moved to a different port. These addresses will not be removed from the hardware unless the user deletes the multi-port static MAC addresses.

MP switchover and hitless upgrade

The Multi-port static MAC Address feature supports MP switchover and hitless upgrade.

The static MAC table is maintained on both active and standby MPs. The static MAC table is synched to standby MP by CLI configuration commands. The M-port table and FID are also synched from the active MP to the standby MP. After MP switchover, M-port MAC addresses are associated with the FID and, in the case of a missing FID, a new FID will be created and programmed for the multi-port static MAC address.

The static MAC table and FID table will be reprogrammed after LP reload.

Flooding features

User-configured multi-port static MAC addresses will always be programmed on DA CAMs in all PPCR CAMs. So, traffic with this DA MAC address will never be flooded in the VLAN, even when flooding features like transparent VLAN, unknown unicast flooding, multicast flooding, and CPU protection are configured on the system.

Configuring Quality of Service for the NetIron MLX 9

This chapter describes how QoS is implemented and configured in the PowerConnect. The chapter contains the following sections:

- **Ingress Traffic Processing through a Router** – This section describes the QoS operation on Ingress Traffic of a PowerConnect router. Refer to "Ingress Traffic processing through a router" on page 284.
- **Creating an Ingress Decode Policy Map** – This section describes the policy maps used to determine the priority and drop precedence values that will be assigned to the packet within the router. Refer to "Creating an Ingress decode policy map" on page 286.
- **Forcing or Merging Priority of a Packet** – This section describes how once a packet's Ingress priority has been mapped, the values used for processing on the router are determined by either forcing or merging. Refer to "Forcing or merging the priority of a packet" on page 286
- **Forcing or Merging the Drop Precedence of a Packet** – This section describes how once a packet's Ingress drop precedence has been mapped, the values used for processing on the router are determined by either forcing or merging. Refer to "Forcing or merging the drop precedence of a packet" on page 287.
- **Egress Traffic Processing Exiting a Router** – This section describes the QoS operation on Egress Traffic of a PowerConnect router. This process involves marking packets as they leave a router on the Egress port. Refer to "Egress Traffic processing exiting a router" on page 288.
- **Creating an Egress Decode Policy Map** – This section describes the policy maps used to determine the priority and drop precedence values that a packet will carry when it exits the router. Refer to "Creating an egress encode policy map" on page 288.
- **Default QoS Mappings** – This section describes the default mappings for the following PCP Encode, PCP Decode, DSCP Encode, DSCP Decode, EXP Encode and EXP Decode. Refer to "Default QoS mappings" on page 288.
- **Configuring QoS** – This section describes all of the procedures required for both Ingress and Egress QoS Configuration. Refer to "Configuring QoS" on page 294.
- **Displaying QoS Information** – This section describes how to enable and display the following QoS information: QoS Configuration Information and QoS Packet and Byte Statistics. Refer to "Displaying QoS information" on page 321.
- **Configuring Port-level QoS Commands on LAG Ports** – When applying port-level QoS commands to ports in a LAG, the rules can be different according the configuration as described in "Configuring port-level QoS commands on LAG ports" on page 320.
- **Determining Packet Drop Priority using WRED** – Weighted Random Early Detection (WRED) provides a mechanism for determining which packets to drop in a congested network. This section describes how WRED works. Refer to "Weighted Random Early Discard (WRED)" on page 326.
- **Configuring Packet Drop Priority using WRED** – This section describes how to configure Weighted Random Early Detection (WRED). Refer to "Configuring packet drop priority using WRED" on page 328.

- **Scheduling Traffic for Forwarding** – The NetIron supports six different schemes for prioritizing traffic for forwarding in a congested network. This section describes each of these schemes and how to configure them. Refer to "Scheduling traffic for forwarding" on page 334.

Ingress Traffic processing through a router

The QoS operation on Ingress Traffic of a PowerConnect router involves reception and processing of packets based upon priority information contained within the packet. As the packets are processed through the router, there are several opportunities to influence the processing by configuration as described in the steps below.

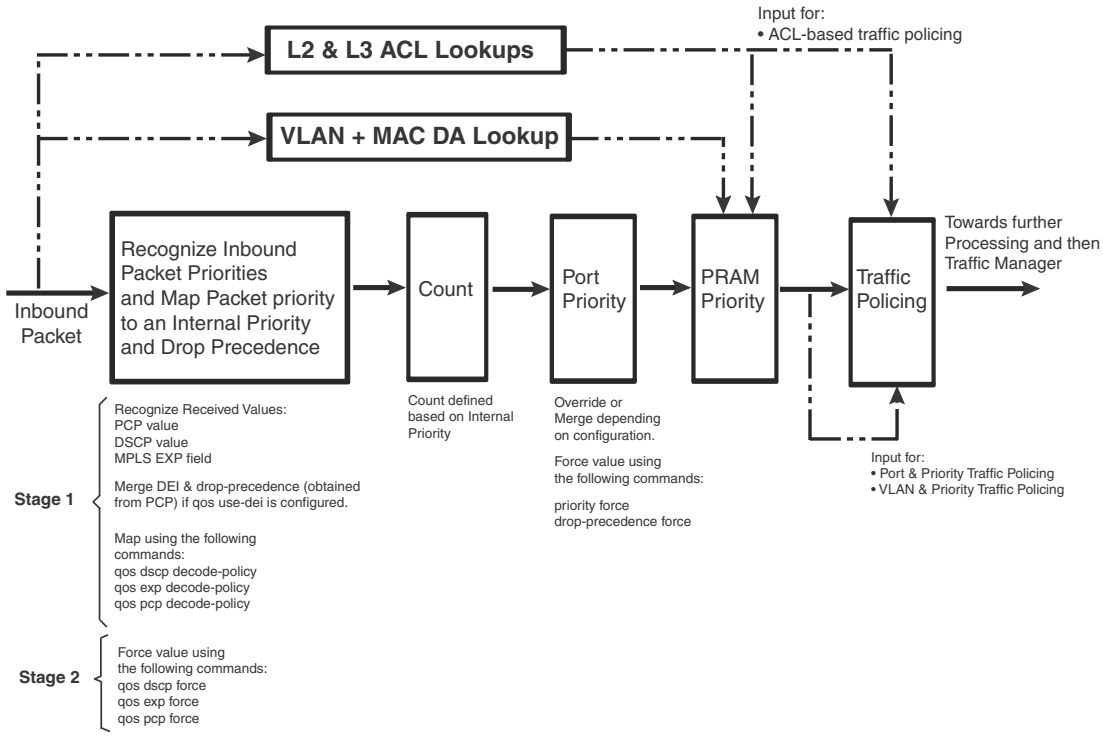
1. Derive priority and drop precedence from the packets PCP (IEEE 802.1p) value. The Priority Code Point (PCP) is a 3-bit field within an IEEE 802.1Q tagged frame that is used to convey the priority of the frame. By using a mapping table, the 3-bit PCP field can be decoded to derive priority and drop precedence information.

NOTE
The PCP field was formerly called IEEE 802.1p.

2. Derive priority and drop precedence from the packets EXP value.
3. Derive priority and drop precedence from the packets DSCP value.
4. Merge or force the priorities described is steps 1 through 3.
5. Merge or force the priority and drop precedence value based on the value configured for the physical port.
6. Merge or force the priority value based on the value configured for the VLAN.
7. Merge or force the priority value based on an ACL look-up. This is used for setting a a specific priority for and L2, L3 or L4 traffic flow.

This process is described in Figure 16.

FIGURE 16 Logic flow of Ingress QoS processing



Recognizing inbound packet priorities and mapping to internal priority

The processes performed in the first block of Figure 16 can be described in two stages as described in the following:

Stage 1

Collect priority and drop precedence information from various portions of the packet header

- If a packet's EtherType matches 8100 or the port's EtherType, derive a priority value and drop precedence by decoding the PCP value.
- If the **qos use-dei** command is configured, the bit between the VLAN ID and PCP in the VLAN tag will be interpreted as a drop precedence and priority value.
- For MPLS packets, derive a priority value and drop precedence by decoding the EXP bits.
- For IPv4 or v6 packets, derive a priority value and drop precedence by decoding the DSCP bits.
- The derived values for PCP, EXP and DSCP are mapped to either a default map or a configured Ingress Decode Policy Map.
- To assist the router in the decoding process described in "stage 1" decode-map tables are defined.

Stage 2
Determine if a priority value should be forced or merged

- If a packet's EtherType matches 8100 or the port's EtherType, derive a priority value and drop precedence by decoding the PCP value
- If the **qos pcp force** command is configured on the port, the priority and drop precedence values are set to the value read from the PCP bits.
- If the **qos exp force** command is configured on the port, the priority and drop precedence values are set to the value read from the MPLS EXP bits.
- If the **qos dscp force** command is configured on the port, the priority and drop precedence values are set to the value read from the DSCP bits.
- If none of the qos force commands are configured, the priority and drop precedence values are set for IPv4 or v6 packets and MPLS packets as described in the following:

  For IPv4 or v6 Packets: Priority and drop precedence values obtained as a merge of the decoded PCP and decoded DSCP values.

  For MPLS Packets: Priority and drop precedence values obtained as a merge of the decoded PCP and decoded EXP values.

Creating an Ingress decode policy map

Once a packet's Ingress priority has been recognized for the PCP, DSCP and EXP values, those values are matched against a policy map to determine the priority and drop precedence values that will be assigned to the packet within the router. The maps used can be either:

- Default policy maps described in "Default QoS mappings" on page 288, or
- User-configured policy maps that are defined as described:

  dscp decode-map <*decode-map-name*> – This command allows you to map a recognized DSCP value to a value that you define.

  pcp decode-map <*decode-map-name*> – This command allows you to map a recognized PCP value to a value that you define.

  exp decode-map <*decode-map-name*> – This command allows you to map a recognized MPLS EXP value to a value that you define.

Forcing or merging the priority of a packet

Once a packet's Ingress priority has been mapped, the values that will be used for processing on the router are determined by either forcing or merging.

There are a variety of commands to "force" the priority of a packet based on the following criteria:

- Forced to a priority configured for a specific Ingress port. The **priority force** command is configured at the interface where you want it to be applied.
- Forced to a priority configured for a specific VLAN. The **priority force** command is configured at the VLAN where you want is to be applied.
- Forced to a priority that is obtained from the DSCP priority bits. The **qos- dscp force** command is configured at the interface where you want it to be applied.

- Forced to a priority that is obtained from the EXP priority bits. The **qos- exp force** command is configured at the interface where you want it to be applied.
- Forced to a priority that is obtained from the PCP priority bits. The **qos- pcp force** command is configured at the interface where you want it to be applied.
- Forced to a priority that is based on an ACL match. The **priority-force** keyword can be used within an ACL to apply a priority to specified traffic.

If multiple commands containing the **priority force** keyword are specified, the command with the highest precedence will take effect as determined by the following order.

1. ACL match (if the **qos-tos mark cos** command is configured, it has the same #1 priority precedence as ACL match). Refer to "Specifying the trust level and enabling marking" on page 316 for details.
2. VLAN priority
3. Physical port priority value
4. DSCP value in an incoming IPv4 or v6 packet
5. EXP value in an incoming MPLS packet
6. PCP value in a tagged frame or PCP field or .1ad DE

Details of how to configure the force commands are provided in "Configuring a force priority" on page 305. For information about configuring a force priority with ACLs refer to the following:

- "Filtering and priority manipulation based on 802.1p priority" on page 817 (for Layer-2 ACLs)
- "QoS for IPv6 traffic" on page 1746

Forcing or merging the drop precedence of a packet

Once a packet's Ingress drop precedence has been mapped, the values that will be used for processing on the router are determined by either forcing or merging.

There are a variety of commands to "force" the drop precedence of a packet based on the following criteria:

- Forced to a drop precedence configured for a specific Ingress port. The **drop-precedence force** command is configured at the interface where you want it to be applied.
- Forced to a drop precedence that is obtained from the DSCP priority bits. The **qos dscp force** command is configured at the interface where you want it to be applied.
- Forced to a drop precedence that is obtained from the EXP priority bits. The **qos exp force** command is configured at the interface where you want it to be applied.
- Forced to a drop precedence that is obtained from the PCP priority bits. The **qos pcp force** command is configured at the interface where you want it to be applied.
- Forced to a drop precedence that is based on an ACL match. The **drop-precedence-force** keyword can be used within an ACL to apply a priority to specified traffic.

If multiple commands containing the **force** keyword are specified, the command with the highest precedence will take effect as determined by the following order.

1. ACL match
2. Physical port's drop precedence value

3. DSCP value in an incoming IPv4v6 packet
4. EXP value in an incoming MPLS packet
5. PCP value in a tagged frame or PCP field or .1ad DE

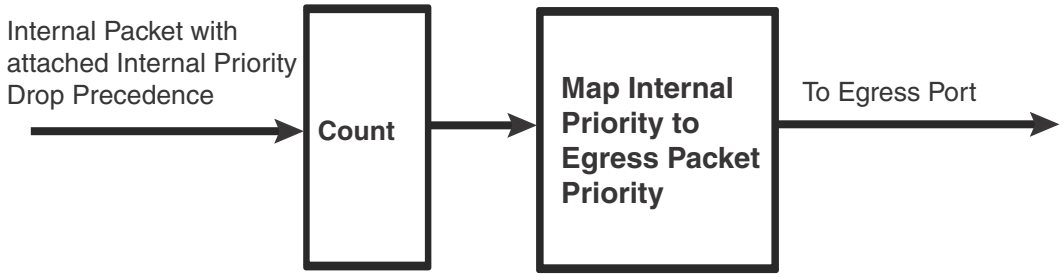
Details of how to configure the force commands are provided in "Configuring a force priority" on page 305. For information about configuring a force priority with ACLs refer to the following:

- "Filtering and priority manipulation based on 802.1p priority" on page 817 (for Layer-2 ACLs)
- "QoS for IPv6 traffic" on page 1746

Egress Traffic processing exiting a router

The QoS operation on Egress Traffic of a PowerConnect router involves marking packets as they leave a router on the egress port. As the packets are prepared to exit the router you can set the PCP, DSCP, and EXP values in the packet headers. This process is described in Figure 17.

FIGURE 17 Logic flow of Egress QoS processing



Creating an egress encode policy map

The QoS value that a packet carries in its header when it exits a PowerConnect router on an egress interface is determined by a specified mapping. Unless configured, this value once determined is placed in an internal queue by using one of the default maps described in "Default QoS mappings" on page 288. Alternately, the following commands can be used to define an alternate mapping:

- **pcp encode-map** <*encode-map-name*> – This command allows you to map the internal priority and drop precedence values of a packet into the PCP code point.
- **dscp encode-map** <*encode-map-name*> – This command allows you to map the internal priority and drop precedence values of a packet into the DSCP code point.
- **exp encode-map** <*encode-map-name*> – This command allows you to map the internal priority and drop precedence values of a packet into the EXP code point.

Default QoS mappings

If a user defined map is not created or applied to Ingress or Egress traffic, the PowerConnect router uses a default map to assign PCP, DSCP and EXP priority and drop precedence values. The following tables describe the default QoS mapping values:

- PCP Encode Table

- PCP Decode Table
- DSCP Encode Table
- DSCP Decode Table
- EXP Encode Table
- EXP Decode Table

Table 52 lists the default PCP Encode mappings.

NOTE
The encode commands for QOS mapping such as **qos pcp encode** <on | off>, **qos dscp encode** <on | off> and **qos exp encode** <on | off> are available only at the physical port level. There are no direct commands at global level to enable or disable QOS encode mapping.

Configuring QoS

The QoS configuration process involves separate procedures for Ingress and Egress QoS Processing as described in the following major sections.

Configuring Ingress QoS procedures

The following procedures are required to configure a PowerConnect router for Ingress QoS processing:

- **Creating Ingress Decode Policy Maps** – If you want the priority and drop precedence values used within the router to be mapped to a specified value, you must create a Decode Priority map as described in "Configuring Ingress decode policy maps" on page 295.
- **Binding Ingress Decode Policy Maps** – If you want to apply an Ingress Policy Map other than the default, you must bind the Ingress Policy Map either globally or to a specified interface as described in "Binding Ingress decode policy maps" on page 301.

- **Configuring a Force priority** – Where there are multiple QoS values that can be used to determine the QoS level used on the router, the default policy is to determine the value used by performing a merge as described in "Stage 2 Determine if a priority value should be forced or merged" on page 286. Otherwise, you can specify a value that you want used from either the port or VLAN configured value or the DSCP, EXP or PCP values in the packets as described in "Configuring a force priority" on page 305.

Configuring Egress QoS procedures

The following procedures are required to configure a PowerConnect router for Egress QoS processing:

- **Creating Egress Encode Policy Maps** – If you want the priority and drop precedence values of packets leaving the router to be marked with a specified value, you must create an Encode Priority map as described in "Configuring Egress encode policy maps" on page 307.
- **Binding Egress Encode Policy Maps** – If you want to apply an Egress Policy Map other than the default, you must bind the Egress Policy Map either globally or to a specified interface as described in "Binding an Egress encode EXP policy map" on page 311.

Configuring QoS procedures applicable to Ingress and Egress

The following procedures are required to configure procedures applicable to both Ingress and Egress QoS Processing on a PowerConnect router:

- **Enabling a Port to Use the DEI bit** – You can configure the router to use the DEI bit when computing the drop precedence value for an incoming packet or encoding the DEI bit for transmitted frame as described in "Enabling a port to use the DEI bit for Ingress and Egress processing" on page 316.
- **Specifying the Trust Level and Enabling Marking** – Refer to "Specifying the trust level and enabling marking" on page 316
- **Support for Super Aggregate VLANS** – If you want to use the enhanced QoS feature with Super Aggregate VLANs, refer to "Configuring support for super aggregate VLANs" on page 320
- **Support for QoS Configurations on LAG Ports** – If you are configuring the enhanced QoS feature on ports within a LAG, refer to "Configuring port-level QoS commands on LAG ports" on page 320

Configuring Ingress decode policy maps

Ingress Decode Policy Maps are created globally and are applied later either globally for all ports on a router or locally to specific port. To create an Ingress Decode Policy Map, you must first enter the QoS mapping configuration level of the command interface using the **qos-mapping** command, as shown in the following.

```
NetIron(config)# qos-mapping
```

Configuration of each of the decode and encode mappings is described in the following sections:

- Configuring Ingress Decode DSCP Policy Maps
- Configuring Ingress Decode PCP Policy Maps

- Configuring Ingress Decode EXP Policy Maps

Configuring Ingress decode DSCP policy maps

The following procedures are used when configuring an Ingress Decode DSCP Policy Map:

- Naming an Ingress Decode DSCP Policy Map
- Configuring an Ingress Decode DSCP Policy Map

Naming an Ingress decode DSCP policy map

Once you are in the QoS configuration level, can define the name of a Ingress Decode DSCP Policy Map using the **pcp decode-map** command, as shown in the following.

```
NetIron(config)# qos-mapping
NetIron(config-qos-mapping)# dscp decode-map Customer1
```

Syntax: [no] dscp decode-map <*map-name*>

The **no** option is used to delete a currently configured Ingress Decode DSCP Policy Map. If the Ingress Decode DSCP Policy Map is currently in use the **no** command will be rejected and an error message will be displayed.

The <*map-name*> variable specifies the name of the Ingress Decode DSCP Policy Map that you are defining. It can be up to 64 characters in length. You can specify the same <*map-name*> for different types of policy maps. For example, you can use the same name for an Ingress Decode DSCP Policy Map and a Ingress Decode EXP Policy Map.

NOTE
The name "default-map" cannot be used because it is reserved for standard mappings as described in "Default QoS mappings" on page 288.

Configuring an Ingress decode DSCP policy map

Once you have named an Ingress Decode DSCP Policy Map using the **dscp decode-map** command, you can set the values of the named Ingress Decode DSCP Policy Map. Setting the values in an Ingress Decode DSCP Policy Map involves specifying the value of the DSCP bits of an incoming packet and setting them to correspond to a value of 0 to 7 of the router's internal priority. Optionally, you can set a drop precedence value of 0 to 3 in addition to the internal priority value.

To set the values of an Ingress Decode DSCP Policy Map, first specify name of the policy map and then populate the values in the policy map using the **dscp-value** command as shown in the following.

```
NetIron(config)# qos-mapping
NetIron(config-qos-mapping)# dscp decode-map Customer1
NetIron(config-qos-mapping-dscp-decode)# dscp-value 32 to priority 5
drop-precedence 2
```

Syntax: [no] dscp-value <*dscp-value*> [<*dscp-value*>] **to priority** <*priority-value*> **[drop-precedence** <*dp-value*>]

The <*dscp-value*> variable specifies the value of the DSCP bits within the packet header of the incoming packets. You can optionally specify multiple <*dscp-value*> variables if you want to specify more than one value to map to the same internal priority and drop precedence. Where DSCP values within a policy map are unspecified, the default mapping will be used.

The **priority** keyword together with the <*priority-value*> variable specifies the internal priority that the packets with the previously specified <*dscp-value*> value will be mapped to. The <*priority-value*> variable can be a value between 0 and 7. Please note, when generating the configuration file, a configured priority value that is the same as the value in the default priority map will not be shown.

The **drop-precedence** keyword is an optional parameter that allows you to specify a <*dp-number*> variable that represents the drop precedence value that you want to assign to incoming packets with the previously specified <*dp-value*> value. This value is specified in addition to a **priority** <*priority-value*> value. The <*dp-number*> variable can be a value between 0 and 3. The default value is the value described in the default DSCP table. Please note, when generating the configuration file, a value for drop precedence will only be shown for non-default values.

When using the **[no]** option to negate a previously configured value of this command, observe the considerations described below.

1. You can negate both the **priority** and **drop-precedence** values (returning them to their default values) by using the **[no]** option with the original command only up to the **priority** value.

   For example: the following command has been used to set the map to assign an internal priority of "4" and a drop precedence of "2" to Ingress packets that have a DSCP value of "40".

   ```
   NetIron(config-qos-mapping-dscp-decode)# dscp-value 40 to priority 4
   drop-precedence 2
   ```

   To set the priority and and **drop-precedence** values back to the default values, use the **[no]** option with the previous command up to where the **priority** value is configured, as shown in the following.

   ```
   NetIron(config-qos-mapping-dscp-decode)# no dscp-value 40 to priority 4
   ```

   After this command is executed, the **priority** and **drop-precedence** values for **dscp-value 40** will be returned to their default values as described in the default map tables that are defined in "Default QoS mappings" on page 288.

2. You can negate the **drop-precedence** value (returning it to its default value) without changing the currently configured **priority** value. This is done by using the **[no]** option with the original command that includes both the **priority** and **drop-precedence** values.

   For example: the following command has been used to set the priority map to assign an internal priority of "5" and a drop precedence of "1" to Ingress packets that have a DSCP value of "60".

   ```
   NetIron(config-qos-mapping-dscp-decode)# dscp-value 60 to priority 5
   drop-precedence 1
   ```

   To set the **drop-precedence** value back to the default value, use the **[no]** option with the previous command, as shown in the following.

   ```
   NetIron(config-qos-mapping-dscp-decode)# no dscp-value 60 to priority 5
   drop-precedence 1
   ```

   After this command is executed, the **priority** value will remain at 5 and the **drop-precedence** value will be returned to the default **drop-precedence** value for **dscp-value 60**, as described in the default map tables that are defined in "Default QoS mappings" on page 288.

Configuring Ingress decode PCP policy maps

The following procedures are used when configuring an Ingress Decode PCP Policy Map:

- Naming an Ingress Decode PCP Policy Map
- Configuring an Ingress Decode PCP Policy Map

Naming an Ingress decode PCP policy map

Once you are in the QoS configuration level, can define the name of an Ingress Decode PCP Policy Map using the **dscp decode-map** command, as shown in the following.

```
NetIron(config)# qos-mapping
NetIron(config-qos-mapping)# pcp decode-map Customer1
```

Syntax: [no] pcp decode-map <*map-name*>

The **no** option is used to delete a currently configured Ingress decode PCP policy map. If the policy map is currently in use, the **no** command will be rejected and an error message will be displayed.

The <*map-name*> variable specifies the name of the Ingress decode PCP policy map that you are defining. It can be up to 64 characters in length. You can specify the same map name for different types of maps. For example, you can use the same name for an Ingress decode PCP policy map and an Ingress decode DSCP policy map.

NOTE
The name "default-map" cannot be used because it is reserved for standard mappings as described in "Default QoS mappings" on page 288.

Configuring an Ingress decode PCP policy map

Once you have named an Ingress PCP Decode Policy Map using the **pcp decode-map** command, you can set the values of the named policy map. Setting the values in a policy map involves specifying the value of the PCP bits of an incoming packet and setting them to correspond to a value of 0 to 7 of the router's internal priority. Optionally, you can set a drop precedence value of 0 to 3 in addition to the internal priority value.

To set the values of an Ingress Decode PCP Policy Map, first specify name of the policy map and then populate the values in the Ingress Decode PCP Policy Map using the **pcp-value** command as shown in the following.

```
NetIron(config)# qos-mapping
NetIron(config-qos-mapping)# pcp decode-map Customer1
NetIron(config-qos-mapping-pcp-decode)# pcp-value 7 to priority 3 drop-precedence
2
```

Syntax: [no] pcp-value <*pcp-value*> [<*pcp-value*>] **to priority** <*priority-value*> **[drop-precedence** <*dp-value*>]

The <*pcp-value*> variable specifies the value of the PCP bits within the packet header of the incoming packets. You can optionally specify multiple <*pcp-value*> variables if you want to specify more than one value to map to the same internal priority and drop precedence. Where PCP values within a policy map are unspecified, the default mapping will be used.

The **priority** keyword together with the <*priority-value*> variable specifies the internal priority that the packets with the previously specified <*pcp-value*> value will be mapped to. The <*priority-value*> variable can be a value between 0 and 7. Please note, when generating the configuration file a configured priority value that is the same as the value in the default map will not be shown.

The **drop-precedence** keyword is an optional parameter that allows you to specify a <*dp-number*> variable that represents the drop precedence value that you want to assign to incoming packets with the previously specified <*dp-value*> value. This value is specified in addition to a **priority** <*priority-value*> value. The <*dp-number*> variable can be a value between 0 and 3. The default value is 0. Please note, when generating the configuration file a value for drop precedence will only be shown for non-zero values.

When using the **[no]** option to negate a previously configured value of this command, observe the considerations described below.

1. You can negate both the **priority** and **drop-precedence** values (returning them to their default values) by using the **[no]** option with the original command only up to the **priority** value.

   For example: the following command has been used to set the map to assign an internal priority of "3" and a drop precedence of "2" to Ingress packets that have a PCP value of "7".

   ```
   NetIron(config-qos-mapping-pcp-decode)# pcp-value 7 to priority 3
   drop-precedence 2
   ```

   To set the **priority** and and **drop-precedence** values back to the default values, use the **[no]** option with the previous command up to where the **priority** value is configured, as shown in the following.

   ```
   NetIron(config-qos-mapping-pcp-decode)# no pcp-value 7 to priority 3
   ```

   After this command is executed, the **priority** and **drop-precedence** values for **pcp-value 7** will be returned to their default values as described in the default map tables that are defined in "Default QoS mappings" on page 288.

2. You can negate the **drop-precedence** value (returning it to its default value) without changing the currently configured **priority** value. This is done by using the **[no]** option with the original command that includes both the **priority** and **drop-precedence** values.

   For example: the following command has been used to set the priority map to assign an internal priority of "4" and a drop precedence of "2" to Ingress packets that have a PCP value of "6".

   ```
   NetIron(config-qos-mapping-pcp-decode)# pcp-value 6 to priority 4
   drop-precedence 2
   ```

   To set the **drop-precedence** value back to the default value, use the **[no]** option with the previous command, as shown in the following.

   ```
   NetIron(config-qos-mapping-pcp-decode)# no pcp-value 6 to priority 4
   drop-precedence 2
   ```

   After this command is executed, the **priority** value will remain at 4 and the **drop-precedence** value will be returned to the default **drop-precedence** value for **pcp-value 6**, as described in the default map tables that are defined in "Default QoS mappings" on page 288.

Configuring Ingress decode EXP Ppolicy maps

The following procedures are used when configuring an Ingress Decode EXP Policy Map:

- Naming an Ingress Decode EXP Policy Map
- Configuring an Ingress Decode EXP Policy Map

Naming an Ingress decode EXP policy mMap

Once you are in the QoS configuration level, can define the name of a Ingress Decode EXP Policy Map using the **exp decode-map** command, as shown in the following.

```
NetIron(config)# qos-mapping
NetIron(config-qos-mapping)# exp decode-map Customer1
```

Syntax: [no] exp decode-map <*map-name*>

The **no** option is used to delete a currently configured Ingress Decode EXP Policy Map. If the Ingress Decode EXP Policy Map is currently in use, the **no** command will be rejected and an error message will be displayed.

The <*map-name*> variable specifies the name of the Ingress Decode EXP Policy Map that you are defining. It can be up to 64 characters in length. You can specify the same Ingress Decode EXP Policy Map for different types of policy maps. For example, you can use the same name for an Ingress Decode DSCP Policy Map and an Ingress Decode EXP Policy Map.

NOTE
The name "default-map" cannot be used because it is reserved for standard mappings as described in "Default QoS mappings" on page 288.

Configuring an Ingress decode EXP policy map

Once you have named an Ingress Decode EXP Policy Map using the **exp decode-map** command, you can set the values of the named policy map. Setting the values in a policy map involves specifying the value of the EXP bits of an incoming packet and setting them to correspond to a value of 0 to 7 of the router's internal priority value. Optionally, you can set a drop precedence value of 0 to 3 in addition to the internal priority value.

To set the values of an Ingress Decode EXP Policy Map, first specify name of the policy map and then populate the values in the policy map using the **exp-value** command as shown in the following.

```
NetIron(config)# qos-mapping
NetIron(config-qos-mapping)# exp decode-map Customer1
NetIron(config-qos-mapping-exp-decode)# exp-value 7 to priority 5 drop-precedence
2
```

Syntax: [no] exp-value <*exp-value*> **[<***exp-value***>] to priority <***priority-value***> [drop-precedence <***dp-value***>]**

The <*exp-value*> variable specifies the value of the EXP bits within the packet header of the incoming packets. You can optionally specify multiple <*exp-value*> variables if you want to specify more than one value to map to the same internal priority and drop precedence values. Where EXP values within a policy map are unspecified, the default mapping will be used.

The **priority** keyword together with the <*priority-value*> variable specifies the internal priority value that the packets with the previously specified <*exp-value*> value will be mapped to. The <*priority-value*> variable can be a value between 0 and 7. Please note, when generating the configuration file a configured priority value that is the same as the value in the default priority map will not be shown.

The **drop-precedence** keyword is an optional parameter that allows you to specify a <*dp-number*> variable that represents the drop precedence value that you want to assign to incoming packets with the previously specified <*dp-value*> value. This value is specified in addition to a **priority** <*priority-value*> value. The <*dp-number*> variable can be a value between 0 and 3. The default value is the value described in the default EXP table. Please note, when generating the configuration file a value for drop precedence will only be shown for non-default values.

When using the **[no]** option to negate a previously configured value of this command, observe the considerations described below.

1. You can negate both the **priority** and **drop-precedence** values (returning them to their default values) by using the **[no]** option with the original command only up to the **priority** value.

   For example: the following command has been used to set the map to assign an internal priority of "5" and a drop precedence of "2" to Ingress packets that have an EXP value of "7".

   ```
   NetIron(config-qos-mapping-exp-decode)# exp-value 7 to priority 5
   drop-precedence 2
   ```

   To set the **priority** and and **drop-precedence** values back to the default values, use the **[no]** option with the previous command up to where the **priority** value is configured, as shown in the following.

   ```
   NetIron(config-qos-mapping-exp-decode)# no exp-value 7 to priority 5
   ```

   After this command is executed, the **priority** and **drop-precedence** values for **exp-value 7** will be returned to their default values as described in the default map tables that are defined in "Default QoS mappings" on page 288.

2. You can negate the **drop-precedence** value (returning it to its default value) without changing the currently configured **priority** value. This is done by using the **[no]** option with the original command that includes both the **priority** and **drop-precedence** values.

   For example: the following command has been used to set the priority map to assign an internal priority of "5" and a drop precedence of "2" to Ingress packets that have a EXP value of "7".

   ```
   NetIron(config-qos-mapping-exp-decode)# exp-value 7 to priority 5
   drop-precedence 2
   ```

   To set the **drop-precedence** value back to the default value, use the **[no]** option with the previous command, as shown in the following.

   ```
   NetIron(config-qos-mapping-exp-decode)# no exp-value 7 to priority 5
   drop-precedence 2
   ```

   After this command is executed, the **priority** value will remain at 5 and the **drop-precedence** value will be returned to the default **drop-precedence** value for **exp-value 7**, as described in the default map tables that are defined in "Default QoS mappings" on page 288.

Binding Ingress decode policy maps

You can bind an Ingress decode policy map globally or per-port using either the default policy map, an all zero policy map, or a user defined policy map. Additionally, for PCP, you can bind the following pre-defined policy maps: 7P1D, 6P2D, and 5P3D. The following procedures describe how to bind Ingress decode policy maps:

- Binding Ingress Decode DSCP Policy Maps
- Binding Ingress Decode PCP Policy Maps
- Binding Ingress Decode EXP Policy Maps

Binding Ingress decode DSCP policy maps

The following procedures describe how to configure the binding of Ingress Decode DSCP Policy Maps:

- Globally Binding an Ingress Decode DSCP Policy Map
- Binding an Ingress Decode DSCP Policy Map to a Port

Globally Binding an Ingress decode DSCP policy map

You can bind an Ingress Decode DSCP Policy Map globally for a PowerConnect router using the **qos dscp decode-policy** command as shown in the following.

```
NetIron(config)# qos dscp decode-policy Customer1
```

Syntax: [no] qos dscp decode-policy <*decode-map-name*> **| default-map | all-zero-map**

The <*decode-map-name*> variable is the name assigned to the Ingress Decode DSCP Policy Map that you want applied globally on the router. If you try to apply an <*decode-map-name*> value that has not been defined, the configuration will be rejected. If the <*decode-map-name*> value that has been defined but the policy has not been configured, the configuration will be accepted and the **default-map** will be applied.

The **default-map** option assigns the default Ingress Decode DSCP Policy Map globally on the router. Since the default Ingress Decode DSCP Policy Map is the default setting, this option is only required when the router has been previously set to a different Ingress Decode DSCP Policy Map.

The **all-zero-map** option assigns a Ingress Decode DSCP Policy Map where all DSCP values are mapped to priority 0 and drop precedence 0. This is useful if you do not want to process any DSCP information in the incoming packet.

Binding an Ingress decode DSCP policy map to a port

You can bind an Ingress Decode DSCP Policy Map to a specified port on a PowerConnect router using the **qos dscp decode-policy** command within an interface configuration, as shown in the following.

```
NetIron(config)# interface ethernet 10/1
NetIron(config-if-e10000-10/1)qos dscp decode-policy Customer1
```

Syntax: [no] qos dscp decode-policy <*decode-map-name*> **| default-map | all-zero-map**

The <*decode-map-name*> variable is the name assigned to the Ingress Decode DSCP Policy Map that you want applied to the port whose configuration this is under.

The **default-map** option assigns the default Ingress Decode DSCP Policy Map to the port whose configuration this is under. Since the default Ingress Decode DSCP Policy Map is the global default setting, this option is only required when the router's global map has been set to a Ingress Decode DSCP Policy Map other than the default.

The **all-zero-map** option assigns an Ingress Decode DSCP Policy Map where all DSCP values are mapped to priority 0 and drop precedence 0. This is useful if you do not want to process any DSCP information in the incoming packet

Binding an Ingress decode PCP policy map

The following procedures describe how to configure the binding of an Ingress Decode PCP Policy Map:

- Globally Binding an Ingress Decode PCP Policy Map
- Binding an Ingress Decode PCP Policy Map to a Port

Globally binding an Ingress decode PCP policy map

You can bind an Ingress Decode PCP Policy Map globally for a PowerConnect router using the **qos pcp decode-policy** command as shown in the following.

```
NetIron(config)# qos pcp decode-policy Customer1
```

Syntax: [no] qos pcp decode-policy *<decode-map-name>* **| default-map | all-zero-map | 7P1D |6P2D | 5P3D**

The *<decode-map-name>* variable is the name assigned to the Ingress Decode PCP Policy Map that you want applied globally on the router. If you try to apply an *<decode-map-name>* value that has not been defined, the configuration will be rejected. If the *<decode-map-name>* value that has been defined but the policy has not been configured, the configuration will be accepted and the **default-map** will be applied.

The **default-map** option assigns the default Ingress Decode PCP Policy Map globally on the router. The default policy map for PCP is the 8P0D decode map. Since the default Ingress Decode PCP Policy Map is the default setting, this option is only required when the router has been previously set to a different Ingress Decode PCP Policy Map.

The **all-zero-map** option assigns an Ingress Decode PCP Policy Map where all PCP values are mapped to priority 0 and drop precedence 0. This is useful if you do not want to process any PCP information in the incoming packet.

The **7P1D** option assigns the 7P1D Ingress Decode PCP Policy Map globally on the router.

The **6P2D** option assigns the 6P2D Ingress Decode PCP Policy Map globally on the router.

The **5P3D** option assigns the 5P3D Ingress Decode PCP Policy Map globally on the router.

NOTE
7P1D, 6P2D, and **5P3D** are as defined in the IEEE 802.1ad specification and described in Table 53.

Binding an Ingress decode PCP policy map to a port

You can bind an Ingress Decode PCP Policy Map to a specified port on a PowerConnect router using the **qos pcp decode-policy** command as shown in the following.

```
NetIron(config)# qos pcp decode-policy Customer1
NetIron(config)# interface ethernet 10/1
NetIron(config-if-e10000-10/1)qos pcp decode-policy Customer1
```

Syntax: [no] qos pcp decode-policy <*decode-map-name***> | default-map | all-zero-map | 7P1D |6P2D | 5P3D**

The *<decode-map-name>* variable is the name assigned to the Ingress Decode PCP Policy Map that you want applied to the port whose configuration this is under.

The **default-map** option assigns the default Ingress Decode PCP Policy Map to the port whose configuration this is under. Since the default Ingress Decode PCP Policy Map is the default setting, this option is only required when the router's global map has been set to an Ingress Decode PCP Policy Map other than the default.

The **all-zero-map** option assigns an Ingress Decode PCP Policy Map where all PCP values are mapped to priority 0 and drop precedence 0. This is useful if you do not want to process any PCP information in the incoming packet.

The **7P1D** option assigns the 7P1D Ingress Decode PCP Policy Map to the port whose configuration this is under.

The **6P2D** option assigns the 6P2D Ingress Decode PCP Policy Map to the port whose configuration this is under.

The **5P3D** option assigns the 5P3D Ingress Decode PCP Policy Map to the port whose configuration this is under.

NOTE
7P1D, 6P2D, and **5P3D** are as defined in the IEEE 802.1ad specification and described in Table 53.

Binding an Ingress decode EXP policy map

The following procedures describe how to configure the binding of an Ingress Decode EXP Policy Map:

- Globally Binding an Ingress Decode EXP Policy Map
- Binding an Ingress Decode EXP Policy Map to a Port

Globally binding an Ingress decode EXP policy map

You can bind an Ingress Decode EXP Policy Map globally for a PowerConnect router using the **qos exp decode-policy** command as shown in the following.

```
NetIron(config)# qos exp decode-policy Customer1
```

Syntax: [no] qos exp decode-policy <*decode-map-name*> | default-map | all-zero-map

The <*decode-map-name*> variable is the name assigned to the Ingress Decode EXP Policy Map that you want applied globally on the router. If you try to apply a <*decode-map-name*> value that has not been defined, the configuration will be rejected. If the <*decode-map-name*> value that has been defined but the policy has not been configured, the configuration will be accepted and the **default-map** will be applied.

The **default-map** option assigns the default Ingress Decode EXP Policy Map globally on the router. Since the default Ingress Decode EXP Policy Map is the default setting, this option is only required when the router has been previously set to a different Ingress Decode EXP Policy Map.

The **all-zero-map** option assigns an Ingress Decode EXP Policy Map where all EXP values are mapped to priority 0 and drop precedence 0.

Binding an Ingress decode EXP policy map to a port

You can bind an Ingress Decode EXP Policy Map to a specified port on a PowerConnect router using the **qos exp decode-policy** command as shown in the following.

```
NetIron(config)# interface ethernet 10/1
NetIron(config-if-e10000-10/1)qos exp decode-policy Customer1
```

Syntax: [no] qos exp decode-policy <*decode-map-name*> | default-map | all-zero-map

The <*decode-map-name*> variable is the name assigned to the Ingress Decode EXP Policy Map that you want applied to the port whose configuration this is under,

The **default-map** option assigns the default Ingress Decode EXP Policy Map to the port whose configuration this is under. Since the default Ingress Decode EXP Policy Map is the default setting, this option is only required when the router's global map has been set to an Ingress Decode EXP Policy Map other than the default.

The **all-zero-map** option assigns an Ingress Decode EXP Policy Map where all EXP values are mapped to priority 0 and drop precedence 0. This is useful if you do not want to process any EXP information in the incoming packet

Configuring a force priority

In situations where there are conflicting priority values for packets on an Ingress port, that conflict can be resolved by performing a priority merge or by using a **force** command to direct the router to use a particular value above other values. A **force** command can be configured for each of the following:

- Force to the values configured on a port
- Force to the value configured for a VLAN
- Force to the value in the DSCP bits
- Force to the value in the EXP bits
- Force to the value in the PCP bits
- Force to a value specified within an ACL

Configuring a force priority for a port

You can configure an Ingress port with a priority to apply to packets that arrive on it using the **priority** command.

To configure an Ingress port with a priority, use the **priority** command as shown in the following.

```
NetIron(config)# interface ethernet 10/1
NetIron(config-if-e10000-10/1)priority 6
```

Syntax: [no] priority < *priority-value*>

The <*priority-value*> variable is a value between 0 and 7. The default value is 0.

Once a port has been configured with a priority using the **priority** command, you can then configure the port (using the **priority force** command) to force the configured priority when determining the priority relative to other priority values of incoming packets.

To configure an Ingress port to force the port-configured priority, use the **priority force** command as shown in the following:

```
NetIron(config)# interface ethernet 10/1
NetIron(config-if-e10000-10/1)priority force
```

Syntax: [no] priority force

Configuring a force drop precedence for a port

You can configure an Ingress port with a drop precedence to apply to packets that arrive on it using the **drop-precedence** command.

To configure an Ingress port with a drop precedence, use the **drop-precedence** command as shown in the following.

```
NetIron(config)# interface ethernet 10/1
NetIron(config-if-e10000-10/1)drop-precedence 3
```

Syntax: [no] drop-precedence <*dp-value*>

The <*dp-value*> variable is a value between 0 and 3.

Once a port has been configured with a drop precedence using the **drop-precedence** command, you can then configure the port (using the **drop-precedence force** command) to force the configured drop precedence when determining the priority relative to other priority values of incoming packets.

To configure an Ingress port to force the port-configured drop precedence, use the **drop-precedence force** command as shown in the following.

```
NetIron(config)# interface ethernet 10/1
NetIron(config-if-e10000-10/1)drop-precedence force
```

Syntax: [no] drop-precedence force

Configuring a force priority for a VLAN

By default, VLANs have priority 3. To change a port-based VLAN's QoS priority, use the following method. The priority applies to outbound traffic on ports in the VLAN.

To change the QoS priority of port-based VLAN 20 on a Chassis device to priority queue 7, enter the following commands.

```
NetIron(config)# vlan 20
NetIron(config-vlan-20)# priority 7
```

Syntax: [no] priority <*num*>

The <*num*> parameter can be from 3 – 7 and specifies one of the eight QoS queues.

Once a VLAN has been configured with a priority using the **priority** command, you can then configure the VLAN (using the **priority force** command) to force the configured priority when determining the priority relative to other priority values of incoming packets.

To configure an Ingress port to force the VLAN-configured priority, use the **priority force** command as shown in the following.

```
NetIron(config)# vlan 20
NetIron(config-vlan-20) priority force
```

Syntax: [no] priority force

Configuring force priority to the DSCP value

You can configure an Ingress port (using the **qos dscp force** command) to force the configured DSCP value when determining the priority relative to other priority values of incoming packets.

To configure an Ingress port to force the DSCP value, use the **qos dscp force** command as shown in the following.

```
NetIron(config)# interface ethernet 10/1
NetIron(config-if-e10000-10/1)qos dscp force
```

Syntax: [no] qos dscp force

Configuring force priority to the EXP value

You can configure an Ingress port (using the **qos exp force** command) to force the configured EXP value when determining the priority relative to other priority values of incoming packets.

To configure an Ingress port to force the EXP value, use the **qos exp force** command as shown in the following.

```
NetIron(config)# interface ethernet 10/1
NetIron(config-if-e10000-10/1)qos exp force
```

Syntax: qos exp force

Configuring force priority to the PCP value

You can configure an Ingress port (using the **qos pcp force** command) to force the configured PCP value when determining the priority relative to other priority values of incoming packets.

To configure an Ingress port to force the PCP value, use the **qos pcp force** command as shown in the following.

```
NetIron(config)# interface ethernet 10/1
NetIron(config-if-e10000-10/1)qos pcp force
```

Syntax: qos pcp force

This command is not supported on POS interfaces.

Configuring force priority to a value specified by an ACL

You can use the **priority-force** keyword within an ACL to apply a priority to specified traffic as described in "Filtering and priority manipulation based on 802.1p priority" on page 778.

Configuring Egress encode policy maps

Egress Encode Policy Maps are created globally and are applied later either globally for all ports on a router or locally to specific port. To create an Egress Encode Policy Map, you must first enter the QoS mapping configuration level of the command interface using the **qos-mapping** command, as shown in the following.

```
NetIron(config)# qos-mapping
```

Configuration of each of the Egress Encode Policy Maps is described in the following sections:

- Configuring Egress Encode DSCP Policy Maps
- Configuring Egress Encode PCP Policy Maps
- Configuring Egress Encode EXP Policy Maps

Configuring Egress encode DSCP policy maps

The following procedures are used when configuring an Egress Encode DSCP Policy Map:

- Naming an Egress Encode DSCP Policy Map
- Configuring an Egress Encode DSCP Policy Map

Naming an Egress encode DSCP policy map

Once you are in the QoS configuration level, can define the name of an Egress Encode DSCP Policy Map using the **dscp encode-map** command, as shown in the following.

```
NetIron(config)# qos-mapping
NetIron(config-qos-mapping)# dscp encode-map Customer1
```

Syntax: [no] dscp encode-map <*map-name*>

The **no** option is used to delete a currently configured Egress Encode DSCP Policy Map. If the policy map is currently in use, the **no** command will be rejected and an error message will be displayed.

The <*map-name*> variable specifies the name of the Egress Encode DSCP Policy Map that you are defining. It can be up to 64 characters in length. You can specify the same policy map name for different types of maps. For example, you can use the same policy pam name for an Egress Encode DSCP Policy Map and an Egress Encode EXP Policy map.

NOTE
The name "default-map" cannot be used because it is reserved for standard mappings as described in "Default QoS mappings" on page 288.

Configuring an Egress encode DSCP policy map

Once you have named an Egress Encode DSCP Policy Map using the **dscp encode-map** command, you can set the values of the named encode policy map. Setting the values in an Egress Encode DSCP Policy Map involves specifying a DSCP value to be marked in outgoing packets for a specified priority value (0 - 7) and optionally a drop precedence value (0 - 3).

To set the values of an Egress Encode DSCP Policy Map, first specify name of the policy map and then populate the values in the Egress Encode DSCP Policy Map using the **priority** command as shown in the following.

```
NetIron(config)# qos-mapping
NetIron(config-qos-mapping)# dscp encode-map Customer1
NetIron(config-qos-mapping-dscp-encode)# priority 7 drop-precedence 2 to
dscp-value 3
```

Syntax: [no] **priority** <*priority-value*> [**drop-precedence** <*dp-value*>] [<*dp-value*>] **to dscp-value** <*dscp-value*>

The **priority** keyword together with the <*priority-value*> variable specifies the internal priority value that egress packets will be marked from. The <*priority-value*> variable can be a value between 0 and 7. For unspecified priority values, the default mapping values are used.

The **drop-precedence** keyword is an optional parameter that allows you to specify a <*dp-number*> variable that represents the drop precedence value that you specify in addition to a **priority** <*priority-value*> value. The <*dp-number*> variable can be a value between 0 and 3. Multiple <*dp-number*> variables can be configured in a single command. The default value is "any" which means that drop priorities 0 - 3 are assigned. If a drop precedence value is specified only for a subset of values, the entries with unspecified values will be initialized as specified in the default mapping.

The <*dscp-value*> variable specifies the value that will be marked onto the DSCP bits within the packet header of the outgoing packets. This applies to packets that match the **priority** and **drop precedence** values specified in this command.

The **[no]** option allows you to negate a previously configured value and return to the default mapping for the specified **priority** and **drop precedence** values.

Configuring an Egress encode PCP policy map

The following procedures are used when configuring an Egress Encode PCP Policy Maps:

- Naming an Egress Encode PCP Policy Map

- Configuring an Egress Encode PCP Policy Map

Naming an Egress encode PCP policy map

Once you are in the QoS configuration level, can define the name of an Egress Encode PCP Policy Map using the **pcp encode-map** command, as shown in the following.

```
NetIron(config)# qos-mapping
NetIron(config-qos-mapping)# pcp encode-map Customer1
```

Syntax: [no] pcp encode-map <*map-name*>

The **no** option is used to delete a currently configured Egress Encode PCP Policy Map. If the policy map is currently in use, the **no** command will be rejected and an error message will be displayed.

The <*map-name*> variable specifies the name of the Egress Encode PCP Policy Map that you are defining. It can be up to 64 characters in length. You can specify the same policy map name for different types of policy maps. For example, you can use the same name for an Egress Encode PCP Policy Map and an Egress Encode EXP Policy Map.

NOTE
The name "default-map" cannot be used because it is reserved for standard mappings as described in "Default QoS mappings" on page 288.

Configuring an Egress encode PCP policy map

Once you have named an Egress Encode PCP Policy Map using the **pcp encode-map** command, you can set the values of the named policy map. Setting the values in an Egress Encode PCP Policy Map involves specifying a PCP value to be marked in outgoing packets for a specified internal priority value (0 - 7) and optionally a drop precedence value (0 - 3).

To set the values of an Egress Encode PCP Policy Map, first specify name of the policy map and then populate the values in the policy map using the **priority** command as shown in the following.

```
NetIron(config)# qos-mapping
NetIron(config-qos-mapping)# pcp encode-map Customer1
NetIron(config-qos-mapping-pcp-encode)# priority 7 drop-precedence 2 to pcp-value
3
```

Syntax: [no] priority <*priority-value*> **[drop-precedence** <*dp-value*>**] [**<*dp-value*>**] to pcp-value** <*pcp-value*>

The **priority** keyword together with the <*priority-value*> variable specifies the priority value that the egress packets will be marked with. The <*priority-value*> variable can be a value between 0 and 7. For unspecified priority values, the default mapping values are used.

The **drop-precedence** keyword is an optional parameter that allows you to specify a <*dp-number*> variable that represents the drop precedence value that you specify in addition to a **priority** <*priority-value*> value. The <*dp-number*> variable can be a value between 0 and 3. Multiple <*dp-number*> variables can be configured in a single command. The default value is "any" which means that drop priorities 0 - 3 are assigned. If a drop precedence value is specified only for a subset of values, the entries with unspecified values will be initialized as specified in the default mapping.

The <*pcp-value*> variable specifies the value that will be marked onto the PCP bits within the packet header of the outgoing packets. This applies to packets that match the **priority** and **drop precedence** values specified in this command.

The **[no]** option allows you to negate a previously configured value and return to the default mapping for the specified **priority** and **drop precedence** values.

Configuring an Egress Eencode EXP policy map

The following procedures are used when configuring an Egress Encode EXP Policy Map:

- Naming an Egress Encode EXP Policy Map
- Configuring an Egress Encode EXP Policy Map

Naming an Egress encode EXP policy map

Once you are in the QoS configuration level, can define the name of an Egress Encode EXP Policy Map using the **exp encode-map** command, as shown in the following.

```
NetIron(config)# qos-mapping
NetIron(config-qos-mapping)# exp encode-map Customer1
```

Syntax: [no] exp encode-map <*map-name*>

The <*map-name*> variable specifies the name of the Egress Encode EXP Policy Map that you are defining. It can be up to 64 characters in length. You can specify the same policy map name for different types of policy maps. For example, you can use the same name for an Egress Encode EXP Policy and an Egress Encode DSCP Policy Map.

The **no** option is used to delete a currently configure Egress Encode EXP Policy Map. If the policy map is currently in use, the **no** command will be rejected and an error message will be displayed.

NOTE
The name "default-map" cannot be used because it is reserved for standard mappings as described in "Default QoS mappings" on page 288.

Configuring an Egress encode EXP policy map

Once you have named an Egress Encode EXP Policy Map using the **exp encode-map** command, you can set the values of the named encode policy map. Setting the values in an Egress Encode EXP Policy Map involves specifying an EXP value to be marked in outgoing packets for a specified priority value (0 - 7) and optionally a drop precedence value (0 - 3).

To set the values of an Egress Encode EXP Policy Map, first specify name of the policy map and then populate the values in the policy map using the **priority** command as shown in the following.

```
NetIron(config)# qos-mapping
NetIron(config-qos-mapping)# exp encode-map Customer1
NetIron(config-qos-mapping-exp-encode)# priority 7 drop-precedence 2 to exp-value
3
```

Syntax: [no] priority <*priority-value*> **[drop-precedence** <*dp-value*>**] [**<*dp-value*>**] to exp-value** <*exp-value*>

The **priority** keyword together with the <*priority-value*> variable specifies the internal forwarding value of the egress packets. The <*priority-value*> variable can be a value between 0 and 7. For unspecified priority values, the default mapping values are used.

The **drop-precedence** keyword is an optional parameter that allows you to specify a <*dp-number*> variable that represents the drop precedence value that you specify in addition to a **priority** <*priority-value*> value. The <*dp-number*> variable can be a value between 0 and 3. Multiple <*dp-number*> variables can be configured in a single command. The default value is "any" which means that drop priorities 0 - 3 are assigned. If a drop precedence value is specified only for a subset of values, the entries with unspecified values will be initialized as specified in the default mapping.

The <*exp-value*> variable specifies the value that will be marked onto the EXP bits within the packet header of the outgoing packets. This applies to packets that match the **priority** and **drop precedence** values specified in this command.

The **[no]** option allows you to negate a previously configured value and return to the default mapping for the specified **priority** and **drop precedence** values.

Binding an Egress encode EXP policy map

You can bind an Egress Encode Policy map globally or per-port using either the default policy map, an all zero policy map, or a user defined policy map. Additionally, for PCP, you can bind the following pre-defined policy maps: 7P1D, 6P2D, and 5P3D. The following procedures describe how to bind Egress Encode Policy Maps:

- Binding an Egress Encode DSCP Policy Map
- Binding an Egress Encode PCP Policy Map
- Binding an Engress Encode EXP Policy Map

Binding an Egress encode DSCP policy map

The following procedures describe how to configure the binding of an Egress Encode DSCP Policy Map:

- Globally Binding an Egress Encode DSCP Policy Map
- Binding an Egress Encode DSCP Policy Map to a Port

Globally binding an Egress encode DSCP policy map

You can bind an Egress Encode DSCP Policy Map globally for a PowerConnect router using the **qos dscp decode-policy** command as shown in the following.

```
NetIron(config)# qos dscp encode-policy Customer1
```

Syntax: [no] qos dscp encode-policy <*encode-map-name*> | default-map | all-zero-map

The <*encode-map-name*> variable is the name assigned to the Egress Encode DSCP Policy Map that you want applied globally on the router. If you try to apply a <*encode-map-name*> value that has not been defined, the configuration will be rejected. If the <*encode-map-name*> value that has been defined but the policy has not been configured, the configuration will be accepted and the **default-map** will be applied.

The **default-map** option assigns the default Egress Encode DSCP Policy Map globally on the router. Since the default Egress Encode DSCP Policy Map is the default setting, this option is only required when the router has been previously set to a different Egress Encode DSCP Policy Map. When configured globally, the **qos dscp encode-policy default-map** command will not be displayed within the configuration even if it is explicitly configured.

The **all-zero-map** option assigns an Egress Encode DSCP Policy Map where all 32 combinations of priority and drop precedence are mapped to 0.

The **no** option allows you to withdraw a previously configured encode policy. If the **qos dscp encode-policy** command is not configured, then the **no qos pcp encode-policy** command will generate an error message.

The **no** option allows you to withdraw a previously configured encode policy. If the **qos dscp encode-policy default-map** command is not configured, then the **no qos dscp encode-policy default-map** command will still be allowed because the **qos dscp encode-policy default-map** is the default configuration.

Binding an Egress encode DSCP policy map to a port

You can bind an Egress Encode DSCP Policy Map to a specified port on a PowerConnect router using the **qos dscp encode-policy** command within an interface configuration, as shown in the following.

```
NetIron(config)# interface ethernet 10/1
NetIron(config-if-e10000-10/1)qos dscp encode-policy Customer1
NetIron(config-if-e10000-10/1)qos dscp encode-policy on
```

Syntax: [no] qos dscp encode-policy <*encode-map-name*> **| default-map | all-zero-map**

NOTE
The **qos dscp encode-policy on** command is shown in this example because unlike PCP or EXP, the DSCP encode policy is off by default.

The <*encode-map-name*> variable is the name assigned to the Egress Encode DSCP Policy Map that you want applied to the port whose configuration this is under.

The **default-map** option assigns the default Egress Encode DSCP Policy Map to the port whose configuration this is under. Since the default Egress Encode DSCP Policy Map is the global default setting, this option is only required when the router's global map has been set to an Egress Encode DSCP Policy Map other than the default. The **qos dscp encode-policy** command will not be displayed within the configuration unless it is explicitly configured.

The **all-zero-map** option assigns an Egress Encode DSCP Policy Map where all 32 combinations of priority and drop precedence are mapped to 0.

The **no** option allows you to withdraw a previously configured encode policy. If the **qos pcp encode-policy** command is not configured, then the **no qos pcp encode-policy** command will generate an error message.

The **no** option allows you to withdraw a previously configured Egress Encode DSCP Policy Map. If the **qos dscp encode-policy default-map** command is not configured, then the **no qos dscp encode-policy default-map** command will generate an error message because the **qos dscp encode-policy default-map** command was never configured on the port.

Enabling and disabling an Egress Encode DSCP Policy Map on a port

To enable or disable an Egress Encode DSCP Policy Map on a port, use the **qos dscp encode-policy** command as shown in the following.

```
NetIron(config)# interface ethernet 10/1
NetIron(config-if-e10000-10/1)qos dscp encode-policy on
```

Syntax: [no] qos dscp encode-policy on | off

The **on** option enables DSCP encode on the port. The **qos dscp encode-policy on** command will not be displayed within the configuration unless it is explicitly configured.

The **off** option disables DSCP encode on the port. This is the default setting.

Binding Egress encode PCP policy map

The following procedures describe how to configure the binding of an Egress Encode PCP Policy Map:

- Globally Binding an Egress Encode PCP Policy Map Policy
- Binding an Egress Encode PCP Policy Map to a Port

Globally binding an Egress Encode PCP Policy Map

You can bind an Egress Encode PCP Policy Map globally for a PowerConnect router using the **qos pcp encode-policy** command as shown in the following.

```
NetIron(config)# qos pcp encode-policy Customer1
```

Syntax: [no] qos pcp encode-policy <*encode-map-name*> **| default-map | all-zero-map | 7P1D |6P2D | 5P3D**

The <*encode-map-name*> variable is the name assigned to the Egress Encode PCP Policy Map that you want applied globally on the router. If you try to apply a <*encode-map-name*> value that has not been defined, the configuration will be rejected. If the <*encode-map-name*> value has been defined but the policy has not been configured, the configuration will be accepted and the **default-map** will be applied.

The **default-map** option assigns the default Egress Encode PCP Policy Map globally on the router. Since the default Egress Encode PCP Policy Map is the default setting, this option is only required when the router has been previously set to a different Egress Encode PCP Policy Map. When configured globally, the **qos pcp encode-policy default-map** command will not be displayed within the configuration even if it is explicitly configured.

The **all-zero-map** option assigns an Egress Encode PCP Policy Map where all 32 combinations of priority and drop precedence are mapped to 0.

The **7P1D** option assigns the 7P1D Egress Encode PCP Policy Map globally on the router.

The **6P2D** option assigns the 6P2D Egress Encode PCP Policy Map globally on the router.

The **5P3D** option assigns the 5P3D Egress Encode PCP Policy Map globally on the router.

NOTE
7P1D, 6P2D, and **5P3D** are as defined in the IEEE 802.1ad specification and described in Table 52.

The **no** option allows you to withdraw a previously configured encode policy. If the **qos pcp encode-policy default-map** command is not configured, then the **no qos pcp encode-policy default-map** command will still be allowed because the **qos pcp encode-policy default-map** is the default configuration.

Binding an Egress encode PCP policy map to a port

You can bind an Egress Encode PCP Policy Map to a specified port on a PowerConnect router using the **qos pcp encode-policy** command as shown in the following.

```
NetIron(config)# interface ethernet 10/1
NetIron(config-if-e10000-10/1)qos pcp encode-policy Customer1
```

Syntax: [no] qos pcp encode-policy <*encode-map-name*> **| default-map | all-zero-map | 7P1D |6P2D | 5P3D**

The <*encode-map-name*> variable is the name assigned to the Egress Encode PCP Policy Map that you want applied to the port whose configuration this is under.

The **default-map** option assigns the default Egress Encode PCP Policy Map to the port whose configuration this is under. Since the default Egress Encode PCP Policy Map is the default setting, this option is only required when the router's global map has been set to an Egress Encode PCP Policy Map other than the default. The **qos pcp encode-policy default-map** command will not be displayed within the configuration unless it is explicitly configured.

The **all-zero-map** option assigns an Egress Encode PCP Policy Map where all 32 combinations of priority and drop precedence are mapped to 0.

The **7P1D** option assigns the 7P1D Egress Encode PCP Policy Map to the port whose configuration this is under.

The **6P2D** option assigns the 6P2D Egress Encode PCP Policy Map to the port whose configuration this is under.

The **5P3D** option assigns the 5P3D Egress Encode PCP Policy Map to the port whose configuration this is under.

NOTE
7P1D, 6P2D, and **5P3D** are as defined in the IEEE 802.1ad specification and described in Table 52.

The **no** option allows you to withdraw a previously configured Egress Encode PCP Policy Map. If the **qos pcp encode-policy** command is not configured, then the **no qos pcp encode-policy** command will generate an error message.

The **no** option allows you to withdraw a previously configured Egress Encode PCP Policy Map. If the **qos pcp encode-policy default-map** command is not configured, then the **no qos pcp encode-policy default-map** command will generate an error message because the **qos pcp encode-policy default-map** command was never configured on the port.

Enabling and disabling an Egress Encode PCP Policy Map on a port

To enable or disable an Egress Encode DSCP Policy Map on a port, use the **qos pcp encode-policy** command as shown in the following.

```
NetIron(config)# interface ethernet 10/1
NetIron(config-if-e10000-10/1)qos pcp encode-policy on
```

Syntax: qos pcp encode-policy on | off

The **on** option enables PCP encode-policy on the port. This is the default setting. The **qos pcp encode-policy on** command will not be displayed within the configuration unless it is explicitly configured.

The **off** option disables PCP encode-policy on the port.

This command is not supported on POS interfaces.

Binding Egress encode EXP policy maps

The following procedures describe how to configure the binding of an Egress Encode EXP Policy Map:

- Globally Binding an Egress Encode EXP Policy Map
- Binding an Egress Encode EXP Policy Map to a Port

Globally binding an Egress Encode EXP Policy Map

You can bind an Egress Encode EXP Policy Map globally for a PowerConnect router using the **qos exp encode-policy** command as shown in the following.

```
NetIron(config)# qos exp encode-policy Customer1
```

Syntax: [no] qos exp encode-policy *<encode-map-name>* **| default-map | all-zero-map**

The *<encode-map-name>* variable is the name assigned to the Egress Encode EXP Policy Map that you want applied globally on the router. If you try to apply an *<encode-map-name>* value that has not been defined, the configuration will be rejected. If the *<encode-map-name>* value that has been defined but the policy has not been configured, the configuration will be accepted and the **default-map** will be applied.

The **default-map** option assigns the default Egress Encode EXP Policy Map globally on the router. Since the default Egress Encode EXP Policy Map is the default setting, this option is only required when the router has been previously set to a different Egress Encode EXP Policy Map. When configured globally, the **qos exp encode-policy default-map** command will not be displayed within the configuration even if it is explicitly configured.

The **all-zero-map** option assigns an Egress Encode EXP Policy Map where all 32 combinations of priority and drop precedence are mapped to 0.

The **no** option allows you to withdraw a previously configured Egress Encode EXP Policy Map. If the **qos exp encode-policy** command is not configured, then the **no qos exp encode-policy** command will generate an error message.

The **no** option allows you to withdraw a previously configured Egress Encode EXP Policy Map. If the **qos exp encode-policy default-map** command is not configured, the **no qos exp encode-policy default-map** command will still be allowed because **qos exp encode-policy default-map** is the default configuration.

Binding an Egress Encode EXP Policy Map to a port

You can bind an Egress Encode EXP Policy Map to a specified port on a PowerConnect router using the **qos exp encode-policy** command as shown in the following.

```
NetIron(config)# interface ethernet 10/1
NetIron(config-if-e10000-10/1)qos exp encode-policy Customer1
```

Syntax: [no] qos exp encode-policy *<encode-map-name>* **| default-map | all-zero-map**

The *<encode-map-name>* variable is the name assigned to the Egress Encode EXP Policy Map that you want applied to the port whose configuration this is under,

The **default-map** option assigns the default Egress Encode EXP Policy Map to the port whose configuration this is under. Since the default Egress Encode EXP Policy Map is the default setting, this option is only required when the router's global policy map has been set to an Egress Encode EXP Policy Map other than the default. The **qos exp encode-policy default-map** command will not be displayed within the configuration unless it is explicitly configured.

The **all-zero-map** option assigns an Egress Encode EXP Policy Map where all 32 combinations of priority and drop precedence are mapped to 0.

The **no** option allows you to withdraw a previously configured encode policy. If the **qos exp encode-policy default-map** command is not configured, then the **no qos exp encode-policy default-map** command will generate an error message because the **qos exp encode-policy default-map** command was never configured on the port.

Enabling and disabling an Egress Encode EXP Policy Map on a port

To enable or disable an Egress Encode EXP Policy Map on a port, use the **qos exp encode-policy** command as shown in the following.

```
NetIron(config)# interface ethernet 10/1
NetIron(config-if-e10000-10/1)qos exp encode-policy on
```

Syntax: [no] qos exp encode-policy on | off

The **on** option enables EXP encode on the port. This is the default setting. The **qos exp encode-policy on** command will not be displayed within the configuration unless it is explicitly configured.

The **off** option disables EXP encode on the port.

Enabling a port to use the DEI bit for Ingress and Egress processing

In the IEEE 802.1ad specification, two types of tag are defined:

- Customer VLAN tag (C-TAG)
- Service VLAN tag (S-TAG)

The semantics and structure of the S-TAG is identical to that of the C-TAG, with the exception that bit 5 in octet 1, the Drop Eligible Indicator (DEI) bit, dis used to indicate if the packet is drop eligible. This allows all 3 bits in the PCP ID to be used for indicating priority of the packet with the drop precedence indicated by the DEI bit. The IEEE 802.1ad requires that if this capability is provided, it must be independently manageable for each port.

On the PowerConnect router the **qos use-dei** command can be configured at the port level to allow a drop-precedence value for incoming packet to be computed based on the DEI bit. Additionally, if this command is configured, then a drop-eligible parameter will be encoded in the DEI bit of transmitted frames. If the internal drop precedence of the packet is 2 or 3, the DEI will be transmitted as 1; otherwise it will be transmitted as 0.

This command is configured as described in the following.

```
NetIron(config)# interface ethernet 10/1
NetIron(config-if-e10000-10/1)qos use-dei
```

Syntax: [no] qos use-dei

NOTE
This command applies for both Ingress and Egress processing.

Specifying the trust level and enabling marking

The commands are as follows:

- qos-tos trust
- qos-tos mark

These commands operate on the QoS values within the packets as they arrive on the router. The **qos-tos trust** command specifes which value among the following to use to classify the packet for marking: **cos, ip-prec,** and **dscp**. The **qos-tos mark** command specifies a CoS or DSCP value to mark on outgoing packets as specified by the mappings described in "Packet mapping commands" on page 318.

NOTES: You cannot use these commands and other L4 features such as:

- IPv4 ACLs and IPv4 ACL-based rate-limiting
- L2 ACLs and L2 ACL-based rate-limiting
- PBR
- VLAN ID and Inner VLAN ID translation on the same interface

NOTE
The design of this feature requires that the **qos-tos trust** and **qos-tos mark** commands be used together.

NOTE
You can now directly configure the **qos-tos trust** and **qos-tos mark** commands at the interface-level.

Specifying the trust level

The trust level specifies where you want the device to get the QoS value for a packet received on the interface.

To set the trust level for an interface to IP Precedence, enter the following command at the configuration level for the interface.

```
NetIron(config-if-1/1)# qos-tos trust ip-prec
```

Syntax: [no] qos-tos trust < cos | ip-prec | dscp >

The **cos | ip-prec | dscp** parameter specifies the trust level:

- **cos** – The device uses the IEEE 802.1p (CoS) priority value in the packet's Ethernet frame header. Use this trust option when you plan to mark the packet's DSCP value based on the incoming IEEE 802.1p value.
- **ip-prec** – The device uses the three most-significant bits in the packet's ToS field and interprets them as an IP precedence value. Use this trust option when the incoming packet is from a device that does not support DSCP and you need to mark the packet for QoS on DSCP devices.
- **dscp** – The device uses the six most-significant bits in the packet's ToS field and interprets them as a DSCP value.

Enabling marking

Marking changes the value of an outbound packet's IEEE 802.1p priority field, DSCP field, or both to match the results of the QoS mappings performed by the device. When you enable marking on an interface, the marking applies to packets that enter the device through that interface.

The following example enables marking for traffic that arrives on port 1/1 and enables the **qos pcp encode-policy on** command on egress port 1/14, as shown.

```
NetIron(config-if-e10000-1/1)# qos-tos mark cos
NetIron(config-if-e10000-1/1)# interface ethernet 1/14
NetIron(config-if-e10000-1/1)# qos pcp encode-policy on
```

This command enables marking of the IEEE 802.1p field in the Ethernet frame.

Syntax: [no] qos-tos mark cos | dscp

The **cos | dscp** parameter specifies the type of marking:

- **cos** – The device changes the outbound packet's IEEE 802.1p priority value to match the results of the device's QoS mapping from the specified trust level.
- **dscp** – The device changes the outbound packet's IEEE 802.1p priority value to match the results of the device's QoS mapping from the specified trust level.

NOTE
The **qos pcp encode-policy on** command must be configured when the **qos-tos mark cos** command is configured. The **qos pcp encode-policy** command is on by default and does not require explicit configuration unless it has been configured to be **off**.

NOTE
You can't apply an ACL to an interface in the outbound direction to change the priority of certain types of traffic.

Packet mapping commands

The **qos-tos trust** command specifies that a COS, IP-Precedence, or DSCP value received on an Ingress port will be used to determine the QoS value that is marked on an outgoing packet on an egress port. The **qos-tos mark** command directs the router to mark outgoing packets with a COS or DSCP value as specified in the command. The value to be marked is determined by a mapping between the value received on the Ingress port and another value that you set using one of the following procedures:

- Changing the CoS -> DSCP Mappings
- Changing the IP Precedence –> DSCP Mappings
- Changing the DSCP –> DSCP Mappings

Changing the CoS –> DSCP mappings

The CoS –> DSCP mappings are used if the trust level is CoS as set by the **qos-tos trust** command.

To change the CoS –> DSCP mappings, enter commands such as the following at the global CONFIG level of the CLI.

```
NetIron(config)# qos-tos map cos-dscp 0 33 25 49 17 7 55 41
NetIron(config)# ip rebind-acl all
```

This command configures the mappings displayed in the COS-DSCP map portion of the QoS information display.

```
NetIron(config-if-1/1)# show qos-tos
```

...portions of table omitted for simplicity...

```
COS-DSCP map:

     COS: 0 1 2 3 4 5 6 7
  ---------------------------------------------------------
     dscp: 0 33 25 49 17 7 55 41
```

Syntax: **[no] qos-tos cos-dscp** *<dscp1> <dscp2> <dscp3> <dscp4> <dscp5> <dscp6> <dscp7> <dscp8>*

The *<dscp1> ... <dscp8>* parameters specify the DSCP values you are mapping to the eight CoS values. You must enter DSCP values for all eight CoS values, in order from CoS value 0 – 7.

NOTE
To place a qos-tos mapping change into effect, you must enter the **ip rebind-acl all** command at the global CONFIG level of the CLI after making the mapping change. This applies to mappings that are configured using the **qos-tos map** command.

Changing the IP precedence –> DSCP mappings

The IP precedence –> DSCP mappings are used if the trust level is IP Precedence as set by the **qos-tos trust** command.

To change the IP precedence –> DSCP mappings, enter commands such as the following at the global CONFIG level of the CLI.

```
NetIron(config)# qos-tos map ip-prec-dscp 0 32 24 48 16 8 56 40
NetIron(config)# ip rebind-acl all
```

This command configures the mappings displayed in the IP Precedence-DSCP map portion of the QoS information display.

```
NetIron(config-if-1/1)# show qos-tos
```

...portions of table omitted for simplicity...

```
IP Precedence-DSCP map:

  ip-prec:     0     1     2     3     4     5     6     7
  ---------------------------------------------------------
     dscp:     0    32    24    48    16     8    56    40
```

For information about the rest of this display, refer to "Displaying QoS configuration information".

Syntax: **[no] qos-tos map ip-prec-dscp** *<dscp1> <dscp2> <dscp3> <dscp4> <dscp5> <dscp6> <dscp7> <dscp8>*

The *<dscp1> ... <dscp8>* parameters specify the DSCP values you are mapping to the IP precedence values. You must enter DSCP values for all eight IP precedence values, in order from IP precedence value 0 – 7.

NOTE
To place a qos-tos mapping change into effect, you must enter the **ip rebind-acl all** command at the global CONFIG level of the CLI after making the mapping change. This applies to mappings that are configured using the **qos-tos map** command.

Changing the DSCP –> DSCP mappings

To change a DSCP –> DSCP mapping, enter a command such as the following at the global CONFIG CLI level.

```
NetIron(config)# qos-tos map dscp-dscp 0 10
NetIron(config)# ip rebind-acl all
```

This command changes the mapping of DSCP value 0 from 0 to 10.

Syntax: [no] qos-tos map dscp-dscp <*old-dscp-value*> [<*old-dscp-value*>...]
to <*new-dscp-value*> [<*new-dscp-value*>...]

You can change up to eight DSCP values in the same commend. Make sure you enter the old values and their new values in the same order.

NOTE
To place a qos-tos mapping change into effect, you must enter the **ip rebind-acl all** command at the global CONFIG level of the CLI after making the mapping change. This applies to mappings that are configured using the **qos-tos map** command.

Configuring support for super aggregate VLANs

In a super-aggregate VLAN application, you can optionally configure an untagged interface to copy the QOS bits from the tag value set by the edge device to the tag value set by the core device. This is only supported if the incoming packet has ETYPE 0x8100. This can be configured using the **qos decode-cvlan-pcp** command as shown in the following.

```
NetIron(config)# interface ethernet 10/1
NetIron(config-if-e10000-10/1)qos decode-cvlan-pcp
```

Syntax: [no] qos decode-cvlan-pcp

NOTE
The command **aggregated-vlan-copy-cos** is available at the physical interface level to copy the COS value from the internal to the external VLAN tag (for SAV). This command will be automatically migrated to the new command **qos decode-cvlan-pcp**.

Configuring port-level QoS commands on LAG ports

When applying port-level QoS commands to ports in a LAG, the rules can differ according the following:

- For port-level QoS Configurations where QoS Values are Applied Directly to the Port. These commands include the followings: **priority**, **priority force**, **drop-precedence**, **drop-precedence force**.
- For Port-level QoS configurations using commands that begin with the **qos** keyword. These commands include: **qos use-dei, qos dscp decode-policy**, **qos pcp decode-policy**, **qos exp decode-policy**, **qos dscp force**, **qos pcp force**, **qos exp force**, **qos dscp encode-policy**, **qos pcp encode-policy**, and **qos exp encode-policy**.

LAG configuration rules where QoS values are applied directly to the port

In port-level QoS Configurations where QoS values are applied directly to the port, the considerations listed below must be followed.

1. Each port that is configured into the LAG, must have the same **priority**, **priority force**, **drop-precedence**, and **drop-precedence force** configuration.

   If you try to configure a LAG with ports that have a different configuration for these commands, the LAG deployment will fail and you will get an error message as shown in the following.

```
NetIron(config)# lag mylag static
NetIron(config-lag-mylag)# ports eth 10/1 to 10/2
NetIron(config-lag-mylag)# primary 10/1
NetIron(config-lag-mylag)# deploy
port 10/1 priority is 5, but port 10/2 priority is 0
Error: port 10/1 and port 10/2 have different configurations
LAG mylag deployment failed!
NetIron(config-lag-mylag)#
```

2. If you have already formed a LAG with the same configuration, you can change the configuration by making changes to the LAG's primary port.
3. If the LAG configuration is deleted, each of the port in the LAG (primary and secondary) will inherit the QoS configuration of the primary port.

LAG configuration rules for QoS configurations using commands that begin with the qos keyword

In port-level QoS Configurations where QoS Configurations Using Commands that begin with the **qos** keyword are used, the considerations listed below must be followed.

1. The secondary ports configured in the LAG must not have any QoS values configured on them.
2. The **qos** commands that are configured on the primary port are applied to all ports in the LAG.
3. After the LAG is formed, you can change the QoS configuration for all ports in the LAG by making changes to the LAG's primary port, but you cannot change the QoS configurations directly on any of the secondary ports.
4. If the LAG is deleted, the QoS configuration will only be retained on the primary port.

Displaying QoS information

You can display the following QoS information as described:

- **QoS Configuration Information** – Using the **show qos-map decode-map** and **show qos-map encode-map** commands, you can display the priority and drop-precedence values mapped between values internal to the router and values that are received at the router or marked on packets leaving the router. This is described in "Displaying QoS configuration information" on page 321.
- **QoS Packet and Byte Statistics** – Using the **show qos-map decode-map** and **show qos-map encode-map** commands, you can enable and display the contents of the QoS Packet and Byte Counters as described in "Displaying QoS packet and byte counters" on page 324.

Displaying QoS configuration information

You can display the following QoS Configuration information:

- QoS Decode Policy Map Configurations
- QoS Policy Map Binding Configurations

Displaying QoS Decode Policy Map configurations

To display QoS Decode Policy Map configuration information, enter the following command at any level of the CLI.

```
NetIron(config)# Show qos-map dscp decode-map test1
DSCP decode map test1
  DSCP  0 to priority  0 drop-precedence  0
  DSCP  1 to priority  0 drop-precedence  0
  DSCP  2 to priority  0 drop-precedence  1
  DSCP  3 to priority  0 drop-precedence  1
  DSCP  4 to priority  0 drop-precedence  2
  DSCP  5 to priority  0 drop-precedence  2
  DSCP  6 to priority  0 drop-precedence  3
  DSCP  7 to priority  0 drop-precedence  3
  DSCP  8 to priority  7 drop-precedence  0
  DSCP  9 to priority  1 drop-precedence  0
  DSCP 10 to priority  6 drop-precedence  1
  DSCP 11 to priority  1 drop-precedence  1
  DSCP 12 to priority  1 drop-precedence  2
  DSCP 13 to priority  1 drop-precedence  2
  DSCP 14 to priority  1 drop-precedence  3
  DSCP 15 to priority  1 drop-precedence  3
  DSCP 16 to priority  2 drop-precedence  0
  DSCP 17 to priority  2 drop-precedence  0
  DSCP 18 to priority  2 drop-precedence  1
  DSCP 19 to priority  2 drop-precedence  1
  DSCP 20 to priority  2 drop-precedence  2
  DSCP 21 to priority  7 drop-precedence  2
  DSCP 22 to priority  2 drop-precedence  3
  DSCP 23 to priority  2 drop-precedence  3
  DSCP 24 to priority  3 drop-precedence  0
  DSCP 25 to priority  3 drop-precedence  0
  DSCP 26 to priority  3 drop-precedence  1
  DSCP 27 to priority  3 drop-precedence  1
  DSCP 28 to priority  3 drop-precedence  2
  DSCP 29 to priority  3 drop-precedence  2
  DSCP 30 to priority  2 drop-precedence  1
  DSCP 31 to priority  3 drop-precedence  3
   ....
```

Syntax: show qos-map dscp | exp | pcp decode-map <*map-name*> **| all-zero-map | default-map**

The **dscp** option is used to display an Ingress DSCP Policy Map configuration.

The **exp** option is used to display an Ingress EXP Policy Map configuration.

The **pcp** option is used to display an Ingress PCP Policy Map configuration.

The <*map-name*> variable is the name of the Ingress Policy Map whose configuration you want to display.

The **all-zero-map** option is used to display the specified Ingress Policy Map's all-zero-map configuration.

The **default-map** option is used to display the specified Ingress Policy Map's default configuration.

Displaying QoS Egress Encode Policy Map configurations

To display QoS Egress Encode Policy Map configuration information, enter the following command at any level of the CLI.

```
NetIron(config)# show qos-map dscp encode-map test2
DSCP encode map test2
  Priority  0 drop-precedence  0 to DSCP  0
  Priority  0 drop-precedence  1 to DSCP  2
  Priority  0 drop-precedence  2 to DSCP  4
  Priority  0 drop-precedence  3 to DSCP  6
  Priority  1 drop-precedence  0 to DSCP 44
  Priority  1 drop-precedence  1 to DSCP 44
  Priority  1 drop-precedence  2 to DSCP 44
  Priority  1 drop-precedence  3 to DSCP 44
  Priority  2 drop-precedence  0 to DSCP 20
  Priority  2 drop-precedence  1 to DSCP 25
  Priority  2 drop-precedence  2 to DSCP 20
  Priority  2 drop-precedence  3 to DSCP 20
  Priority  3 drop-precedence  0 to DSCP 55
  Priority  3 drop-precedence  1 to DSCP 55
  Priority  3 drop-precedence  2 to DSCP 55
  Priority  3 drop-precedence  3 to DSCP 55
  Priority  4 drop-precedence  0 to DSCP 32
  Priority  4 drop-precedence  1 to DSCP 34
  Priority  4 drop-precedence  2 to DSCP 36
  Priority  4 drop-precedence  3 to DSCP 38
  Priority  5 drop-precedence  0 to DSCP 54
  Priority  5 drop-precedence  1 to DSCP 54
  Priority  5 drop-precedence  2 to DSCP 54
  Priority  5 drop-precedence  3 to DSCP 54
  Priority  6 drop-precedence  0 to DSCP 48
  Priority  6 drop-precedence  1 to DSCP 50
  Priority  6 drop-precedence  2 to DSCP 52
  Priority  6 drop-precedence  3 to DSCP 54
  Priority  7 drop-precedence  0 to DSCP 27
  Priority  7 drop-precedence  1 to DSCP 27
  Priority  7 drop-precedence  2 to DSCP 27
  Priority  7 drop-precedence  3 to DSCP 27
```

Syntax: show qos-map dscp | exp | pcp encode-map <*map-name*> **| all-zero-map | default-map**

The **dscp** option is used to display an Egress DSCP Policy Map configuration.

The **exp** option is used to display an Egress EXP Policy Map configuration.

The **pcp** option is used to display an Egress PCP Policy Map configuration.

The <*map-name*> variable is the name of the Egress Policy Map whose configuration you want to display.

The **all-zero-map** option is used to display the specified Egress Policy Map's all-zero-map configuration.

The **default-map** option is used to display the specified Egress Policy Map's default configuration.

Displaying QoS Binding configurations

To display QoS Binding configuration information, enter the following command at any level of the CLI.

```
NetIron(config)# show qos-map binding global
 qos pcp decode-policy pcp-t2
 qos exp decode-policy exp-t1
 qos dscp decode-policy dscp-t3
 qos dscp encode-policy dscp-d3
```

Syntax: show qos-map binding global | *<slot/port>*

The **global** option is used to display all QoS Policy Map bindings configured on the router.

The *<slot/port>* variable is used to display all QoS Policy Map bindings configured on the router.

Displaying QoS packet and byte counters

You can enable and display the collection of statistics for Ingress and Egress packet priorities as described in the following sections:

- Enabling QoS Packet and Byte Counters
- Displaying QoS Packet and Byte Counters
- Clearing QoS Packet and Byte Counters

Enabling QoS packet and byte counters

You can enable the collection of statistics for Ingress and Egress packet priorities using the **enable-qos-statistics** command as shown in the following.

```
NetIron# enable-qos-statistics
NetIron#
```

Syntax: [no] enable-qos-statistics

The default for this command is disabled.

Using the **no** option returns a previous enabled configuration to the default disabled state.

Displaying QoS packet and byte counters

You can enable the collection of statistics for Ingress and Egress packet priorities using the **enable-qos-statistics** command. Once the collection of statistics is enabled, the **show np qos statistics** command can be used to display a count of the packet priorities of Ingress and Egress packets as shown in the following.

```
NetIron# show np qos statistics eth 1/1
Port 1/1
  Ingress counters:
    COS 0: packets 0                    bytes 0
    COS 1: packets 0                    bytes 0
    COS 2: packets 0                    bytes 0
    COS 3: packets 0                    bytes 0
    COS 4: packets 0                    bytes 0
    COS 5: packets 0                    bytes 0
    COS 6: packets 0                    bytes 0
    COS 7: packets 1122084909           bytes 134650189080
  Egress counters:
    COS 0: packets 0                    bytes 0
    COS 1: packets 0                    bytes 0
    COS 2: packets 0                    bytes 0
    COS 3: packets 0                    bytes 0
    COS 4: packets 4056756685           bytes 486810801752
    COS 5: packets 0                    bytes 0
    COS 6: packets 0                    bytes 0
    COS 7: packets 453                  bytes 49490
```

Syntax: show np qos statistics ethernet <*slot/port*> **| pos** <*slot/port*> **| slot** <*slot-number*>

The **ethernet** option is used to display all QoS counters for the ethernet interface specified by the <*slot/port*> variable.

The **pos** option is used to display all QoS counters for the packet-over-sonet interface specified by the <*slot/port*> variable.

The **slot** option is used to display all QoS counters for the interface module whose location is specified by the <*slot-number*> variable.

Table 61 describes the parameters displayed for the show np qos statistics command.

TABLE 61 QoS counter information

This field...	Displays...
Ingress Counters	Statistics displayed below this heading are for packets arriving on the Ingress port (or ports) before any overrides or merging of packet priorities have been performed.
COS <*num*>: packets	The number of packets that have arrived on the specified port or module with a DSCP, EXP, or PCP value equal to the value of the <*num*> variable.
COS <*num*>: bytes	The number of bytes contained in the packets that have arrived on the specified port or module with a DSCP, EXP, or PCP value equal to the value of the <*num*> variable.
Egress Counters	Statistics displayed below this heading are for packets leaving the router on the Egress port (or ports) accounting for all priority modifications that have been performed on them. These statistics accurately reflect the values for packets that are forwarded out of the router.

TABLE 61 QoS counter information (Continued)

This field...	Displays...
COS <*num*>: packets	The number of packets leaving the router on the specified port or module with a DSCP, EXP, or PCP value equal to the value of the <*num*> variable.
COS <*num*>: bytes	The number of bytes contained in the packets leaving the router on the specified port or module with a DSCP, EXP, or PCP value equal to the value of the <*num*> variable.

Clearing the QoS packet and byte counters

You can clear the QoS counters whose display is generated using the **show np qos statistics** command as shown in the following.

Syntax: clear np qos statistics ethernet <*slot/port*> **| pos** <*slot/port*>

The **ethernet** option is used to clear all QoS counters for the ethernet interface specified by the <*slot/port*> variable.

The **pos** option is used to clear all QoS counters for the packet-over-sonet interface specified by the <*slot/port*> variable.

Weighted Random Early Discard (WRED)

On the PowerConnect Router, queues are provided to buffer traffic levels that exceed the bandwidth of individual ports. For each output port, a set of eight priority queues is allocated on each inbound traffic manager. When traffic exceeds the bandwidth of a port, packets are dropped randomly as long as the congestion persists. Under these conditions, traffic of greater priority can be dropped instead of traffic with a lesser priority.

Instead of being subject to this random process, you can configure a PowerConnect Router to monitor traffic congestion and drop packets according to a WRED (Weighted Random Early Discard) algorithm. This algorithm enables the system to detect the onset of congestion and take corrective action. In practice, WRED causes a router to start dropping packets as traffic in the router starts to back up. WRED provides various control points that can be configured to change a system's reaction to congestion. The following variables are used when calculating whether to drop or forward packets:

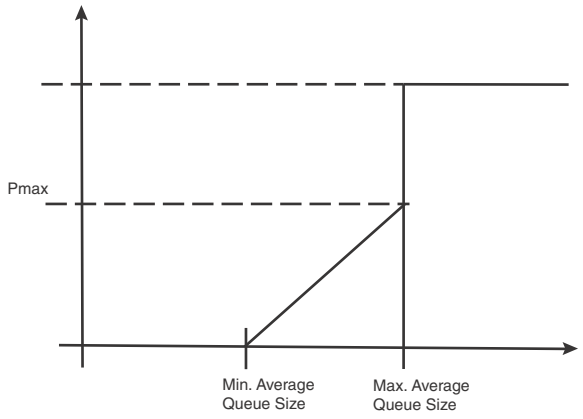
- **Statistical Average-Q-Size** – The statistical average size of the queue calculated over time on the router.
- **Current-Q-Size** – The current size of the queue as calculated on the router.
- **Wq** – This variable specifies the weights that should be given to the current queue size and the statistical average-q-size when calculating the size for WRED calculations.
- **Max-Instantaneous-Q-Size** – The maximum size up to which a queue is allowed to grow. Packets that cause the queue to grow beyond this point are unconditionally dropped. This variable is user configured.
- **Min-Average-Q-Size** – The average queue size below which all packets are accepted. This variable is user configured.
- **Max-Average-Q-Size** – The average queue size above which all packets are dropped. This variable is user configured.

- **Pmax** – The maximum drop probability when queue-size is at Max-Average-Q-Size. This variable is user configured.
- **Pkt-Size-Max** – The packet size to which the current packet's size is compared as shown in the algorithm below. This variable is user configured.

How the WRED algorithm operates

The graph in Figure 18 describes the interaction of the previously described variables in the operation of WRED. When a packet arrives at a router, the average queue size (**q-size**) is calculated (note that this is not the statistical average queue size - refer to "Calculating avg-q-size" on page 327). If **q-size** as calculated is below the configured Min. Average Queue Size, then the packet is accepted. If the average queue size is above the Max. configured Average Queue Size threshold, the packet is dropped. If the instantaneous queue size exceeds the value configured for the Max-Instantaneous-Q-Size, the packet is dropped. If the Average Queue size falls between the Min. Average Queue Size and the Max. Average Queue Size, packets are dropped according to the calculated probability described in "Calculating packets that are dropped" on page 328.

FIGURE 18 WRED operation graph



Calculating avg-q-size

The algorithm first calculates the **avg-q-size** through the following equation.

avg-q-size = ((1 - Wq) * Statistical Average-Q-Size) + (Wq * Current-Q-Size)

The user-configured **Wq** value is instrumental to the calculation and can be:

- equal to the statistical average queue size (**Wq** == 0), or
- equal to the current queue size (**Wq** == 1) or
- be between 0 and 1 (0 < **Wq** < 1).

Lower Wq values cause the **avg-q-size** to lean towards the statistical average queue size, reducing WRED's sensitivity to the current state of the queue and thus reducing WRED's effectiveness. On the other hand, higher **Wq** values cause the **avg-q-size** to lean towards the instantaneous queue size, which exposes WRED to any change in the instantaneous queue size and thus may cause WRED to overreact in cases of bursts. Thus, the value of **Wq** should be carefully chosen according to the application at hand.

Calculating packets that are dropped

The **Pdrop** value, as calculated in the following equation, is the probability that a packet will be dropped in a congested router.

$$Pdrop = \frac{\text{pkt-size}}{\text{pkt-size-max}} * Pmax * \frac{\text{(avg-q-size - min-avg-q size)}}{\text{(max-avg-q-size - min-avg-q size)}}$$

Applying the WRED algorithm to router traffic

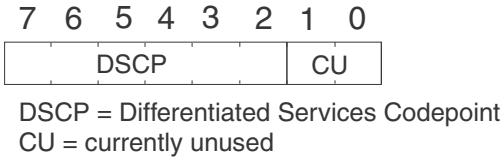
Packets are assigned to an Ingress queue type based on their individual destination port and one of the 8 (0 - 7) internal priorities. Each of these priorities is assigned a queue type from 0 - 7 according to the internal priority it belongs to as shown in Table 62.

TABLE 62 Internal priority to queue type mapping

Internal priority	0	1	2	3	4	5	6	7
Queue type	0	1	2	3	4	5	6	7

The WRED algorithm is applied to traffic on these individual queues based upon parameters configured for its assigned queue type. When traffic arrives at a queue, it is passed or dropped as determined by the WRED algorithm. Packets in an individual queue are further differentiated by one of four drop precedence values which are determined by the value of bits 3:2 of the TOS or DSCP bits in the IPv4 or IPv6 packet header as shown in Figure 19.

FIGURE 19 TOS or DSCP bits in packet header



The user configurable values applied per queue type and per drop precedence value are:

- Maximum Drop Probability
- Minimum and Maximum Average Queue Size
- Maximum Packet Size

Configuring packet drop priority using WRED

For a description of WRED, refer to "Weighted Random Early Discard (WRED)" on page 326. This section describes how to configure the parameters described in that section to enable the use of WRED on a PowerConnect router. In addition, there is a default configuration that can be enabled that sets the parameters to the values shown in Table 64. If you use the default configuration, you do not need to set the parameters individually.

To configure WRED, you must configure the following parameters:

- "Enabling WRED"
- "Setting the averaging-weight (Wq) parameter" (optional)

- "Configuring the maximum instantaneous queue size" (optional)
- "Configuring the drop precedence parameters" (optional)
- "Restoring default WRED parameters"

Enabling WRED

WRED must be enabled for the queue type of any forwarding queue that you want it to operate on. To enable WRED for the forwarding queues with a queue type of 3, enter the following command.

```
NetIron(config)#qos queue-type 3 wred enable
```

Syntax: [no] qos queue-type <*queue-number*> **wred enable**

The <*queue-type*> variable is the number of the forwarding queue that you want to enable WRED for. There are eight forwarding queues on PowerConnect Routers. They are numbered 0 to 7. Default values are as described in Table 64. You can optionally adjust any of the pre-configured parameters described there.

Setting the averaging-weight (Wq) parameter

The Wq parameter described in "Weighted Random Early Discard (WRED)" on page 326 is configured as the **averaging-weight** parameter. In this implementation, you can set one of 13 (1 - 13) possible values. These values represent a Wq value as described in Table 63

TABLE 63 Possible Wq values

Averaging weight setting	Wq value as a percentage
1	50%
2	25%
3	12.5%
4	6.2%
5	3.12%
6	1.56%
7	0.78%
8	0.4%
9	0.2%
10	0.09%
11	0.05%
12	0.02%
13	0.01%

To set the wq parameter for queues with a queue type of 1 to 25%, use the following command.

```
NetIron(config)#qos queue-type 1 wred averaging-weight 2
```

This gives the current queue size a weight of 25% over the statistical average queue size.

Syntax: [no] qos queue-type <*queue-type*> **wred averaging-weight** <*avg-weight-value*>

The <*queue-type*> variable is the number of the forwarding queue type that you want to configure the **averaging-weight** (Wq) parameter for. There are eight forwarding queue types on PowerConnect Routers. They are numbered 0 to 7.

The <*avg-weight-value*> variable is the weight-ratio between instantaneous and average queue sizes. It is described as the Wq parameter in "Weighted Random Early Discard (WRED)" on page 326. It can be one of the 13 values expressed as 1 to 13 described in Table 63. The default value is 9 which maps to a Wq value of .19%.

Configuring the maximum instantaneous queue size

You can set the maximum size to which a queue is allowed to grow. Packets that cause the queue to grow beyond this setting are unconditionally dropped. To set the maximum instantaneous queue size for queues with a queue type of 1 to 32000, use the following command.

```
NetIron(config)#qos queue-type 1 max-queue-size 32
```

Syntax: [no] qos queue-type <*queue-number*> **max-queue-size** <*max-queue*>

The <*queue-type*> variable is the number of the forwarding queue type that you want to configure the **instantaneous-queue-size** parameter for. There are eight forwarding queue types on PowerConnect Routers. They are numbered 0 to 7.

The <*max-queue*> variable is the maximum size to which a queue is allowed to grow. It is defined in Kbytes. The default values are shown in Table 64.

Configuring the drop precedence parameters

The DSCP or TOS bits in packets are used to prioritize packet delivery for specified queue types. These values are from 0 to 4. Packets with a DSCP or TOS value of 0 are least likely to be dropped and packets with a DSCP or TOS of 3 are most likely to be dropped.

NOTE
In addition to bits in the DSCP, the DP option can use other fields (in the PCP header or the EXP bit header) to control WRED in the priority queues.

In addition, the maximum drop probability, the minimum and maximum average queue size, and the maximum packet size can be configured to apply selectively to packets with a specified queue type and DSCP or TOS value. The following sections describe how to set the following drop precedence parameters for each of the four DSCP or TOS values for each of the four queue types:

- "Setting the maximum drop probability"
- "Setting the minimum and maximum average queue size"
- "Setting the maximum packet size"

NOTE
Packets that do not have the DSCP or TOS value set are assigned a drop precedence equal to the DSCP or TOS level of 0.

Setting the maximum drop probability

To set the maximum drop probability for queue type 1 and drop precedence 0 when the queue size reaches the Max-average-q-size value to 20% use the following command.

```
NetIron(config)#qos queue-type 1 wred drop-precedence 0 drop-probability-max 20
```

Syntax: **[no] qos queue-type** <*queue-type*> **wred drop-precedence** <*drop-precedence-value*> **drop-probability-max** <*p-max*>

The <*queue-type*> variable is the number of the forwarding queue type that you want to configure drop-precedence for. There are eight forwarding queue types on PowerConnect Routers. They are numbered 0 to 7.

The <*drop-precedence-value*> variable for the drop-precedence parameter is the TOS or DSCP value in the IPv4 or IPv6 packet header. It determines drop precedence on a scale from **0 - 3**. Packets than contain a DSCP value of **0** are least likely to be dropped and packets with a value of **3** are most likely to be dropped. The default value is **0**.

The <*p-max*> variable defines the maximum drop probability when the queue size is at the value configured for **max-avg-q-size**. This value is expressed as a percentage. The default values are shown in Table 64.

Setting the minimum and maximum average queue size

Configuration Considerations

When setting the minimum and maximum average queue size, consider the following:

- If a user enters a min-avg-queue-size value that is equal to what is currently configured for the max-avg-queue-size, then the min-avg-queue-size is decremented by 64. The min-avg-queue-size is decremented by 64 because the value must be different from the max-avg-queue-size that is currently configured. The following example is a warning message that is displayed on the console:

```
Warning: The min-avg-queue-size is decreased to(min-avq-queue-size-64)as min and
max should be different to be effective.
```

- If a user enters a max-avg-queue-size value that is equal to what is currently configured for the min-avg-queue-size, then the max-avg-queue-size is incremented by 64. The max-avg-queue-size is incremented by 64 because the value must be different from the min-avg-queue-size that is currently configured. The following example is a warning message that is displayed on the console:

```
Warning: The max-avg-queue-size is increased to(max-avq-queue-size+64)as min and
max should be different to be effective.
```

- If a user enters a min-avg-queue-size value equal to the max-avg-queue-size, then the max-avg-queue-size is incremented by 64. The max-avg-queue-size is incremented by 64 because the value must be different from the min-avg-queue-size. The following example is a warning message that is displayed on the console:

```
Warning: The max-avg-queue-size is increased to(max-avq-queue-size+64)as min and
max should be different to be effective.
```

However if a user enters a max-avg-queue-size and min-avg-queue-size equal to 32768, then the min-avg-queue-size is decremented.

To set the maximum average queue size for queue type 1 and drop precedence 0 to the maximum size of 32768 Kbytes, use the following command.

```
NetIron(config)#qos queue-type 1 wred drop-precedence 0 max-avg-queue-size 32768
```

Syntax: **[no] qos queue-type** <*queue-type*> **wred drop-precedence** <*drop-precedence-value*> **max-avg-queue-size** <*max-size*>

To set the minimum average queue size to the maximum size of 16 Kbytes, use the following command.

```
NetIron(config)#qos queue-type 1 wred drop-precedence 0 min-avg-queue-size 16
```

Syntax: **[no] qos queue-type** <*queue-type*> **wred drop-precedence** <*drop-precedence-value*> **min-avg-queue-size** <*min-size*>

The <*queue-type*> variable is the number of the forwarding queue type that you want to configure drop-precedence for. There are eight forwarding queue types on PowerConnect Routers. They are numbered **0** to **7**.

The <*drop-precedence-value*> variable for the drop-precedence parameter is the TOS or DSCP value in the IPv4 or IPv6 packet header. It determines drop precedence on a scale from **0 - 3**. Packets than contain a DSCP value of **0** are least likely to be dropped and packets with a value of **3** are most likely to be dropped. The default value is **0**.

The <*min-size*> variable is the average queue size below which all packets are accepted. Possible values are 1 - 32768 KBytes. It must be set in multiples of 64K. The default values are shown in Table 64.

The <*max-size*> variable is the average queue size above which all packets are dropped. (1 - 32768) (KBytes) in multiples of 64K. The default values are shown in Table 64.

Setting the maximum packet size

To set the maximum packet size to 16 bytes for queue type 1 and drop precedence 0, use the following command.

```
NetIron(config)#qos queue-type 1 wred drop-precedence 0 packet-size-max 16
```

Syntax: **[no] qos queue-type** <*queue-type*> **wred drop-precedence** <*drop-precedence-value*> **packet-size-max** <*pkt-size*>

The <*queue-type*> variable is the number of the forwarding queue type that you want to configure drop-precedence for. There are eight forwarding queue types on PowerConnect Routers. They are numbered 0 to 7.

The <*drop-precedence-value*> variable for the drop-precedence parameter is the TOS or DSCP value in the IPv4 or IPv6 packet header. It determines drop precedence on a scale from 0 - 3. Packets than contain a DSCP value of 0 are least likely to be dropped and packets with a value of 3 are most likely to be dropped. The default value is 0.

The <*pkt-size*> variable is the pkt-size-max variable used in the equation described in "Calculating packets that are dropped" on page 328. Permissible values are an even number of bytes between 16 and 32768. The default values are shown for each queue type and drop precedence value in Table 64.

Restoring default WRED parameters

Table 64 describes all of the default values for each of the WRED parameters. If you change any of the values from the default values, you can restore the defaults per queue type. To reset the queue type 1 with default values for the WRED parameters, use the following command.

```
NetIron(config)#qos queue-type 1 wred default-params
```

Syntax: **[no] qos queue-type** <*queue-number*> **default-params**

The <*queue-number*> variable is the number of the forwarding queue that you want to configure drop-precedence for. There are eight forwarding queues on PowerConnect Routers. They are numbered 0 to 7

TABLE 64 WRED default settings

Queue type	Drop precedence	Minimum average queue size (KByte)	Maximum average queue size (KByte)	Maximum packet size (Byte)	Maximum drop probability	Maximum instantaneous queue size (Kbyte)	Average weight
0	0	320	1024	16384	2%	1024	6.25%

	3	320	832	16384	6%		

NOTES:

- If you enter the **min-avg-queue-size** equal to what is already configured as the **max-avg-queue-size**, then the **min-avg-queue-size** will be decremented by 64 to make it different from the **max-avg-queue-size**, the following warning is displayed: "Warning - **min-avg-queue-size** is decreased to (**min-avg-queue-size** - 64) as min and max should be different to be effective."
- If you enter the **max-avg-queue-size** equal to what is already configured as the min-avg-queue-size, then the **max-avg-queue-size** will be incremented by 64 to make it different from the **min-avg-queue-size**, the following warning is displayed: "Warning - max-avg-queue-size is increased to (max-avg-queue-size + 64) as the min & max should be different to be effective."
- If you enter the min-average-queue-size equal to the **max-avg-queue-size**, the **max-avg-queue-size** will be incremented by 64 to make it different from **min-avg-queue-size**, the following warning is displayed: "Warning - **max-avg-queue-size** incresed to (**max-avg-queue-size + 64**) as min & max should be different to be effective." Unless you enter the **max-avg-queue-size** and **min-avg-queue-size** equal to 32768, the **min-avg-queue-size** will be decremented.

Displaying the WRED configuration

To view a WRED configuration, use the following command.

```
NetIron# show qos wred
QType Enable AverWt    MaxQSz DropPrec MinAvgQSz MaxAvgQSz MaxDropProb MaxPktSz
0     Yes    9(0.19%)  16384  0             5696     16384          2%      16384
                               1             4864     16384          4%      16384
                               2             4096     16384          9%      16384
                               3             3264     16384         10%      16384

```

Scheduling traffic for forwarding

If the traffic being processed by a PowerConnect is within the capacity of the router, all traffic is forwarded as received. Once we reach the point where the router is bandwidth constrained, it becomes subject to drop priority if configured as described in "Configuring packet drop priority using WRED" on page 328 or traffic scheduling as described in this section.

The PowerConnect routers classify packets into one of eight internal priorities. Traffic scheduling allows you to selectively forward traffic according to the forwarding queue that is mapped to according to one of the following schemes:

- **Strict priority-based scheduling** – This scheme guarantees that higher-priority traffic is always serviced before lower priority traffic. The disadvantage of strict priority-based scheduling is that lower-priority traffic can be starved of any access.

- **WFQ weight-based traffic scheduling** – With WFQ destination-based scheduling enabled, some weight-based bandwidth is allocated to all queues. With this scheme, the configured weight distribution is guaranteed across all traffic leaving an egress port and an input port is guaranteed allocation in relationship to the configured weight distribution.
- **Mixed strict priority and weight-based scheduling** – This scheme provides a mixture of strict priority for the three highest priority queues and WFQ for the remaining priority queues.

Configuring traffic scheduling

Traffic scheduling can be configured on a per-port basis. It affects the outgoing traffic on the configured port when bandwidth congestion occurs on that port. The following sections describe how to configure each of the traffic scheduling schemes:

- "Configuring strict priority-based traffic scheduling" This option is the default traffic scheduling method if traffic scheduling is not configured on a port.
- "Calculating the values for WFQ Weight-based traffic scheduling"
- "Configuring WFQ weight-based traffic scheduling"
- "Configuring mixed strict priority and weight-based scheduling"

Configuring strict priority-based traffic scheduling

To configure strict priority-based scheduling use a command such as the following.

```
NetIron(config)# interface ethernet 1/1
NetIron(config-if-e1000-1/1)# qos scheduler strict
```

Syntax: qos scheduler strict

This is the default when traffic scheduling is not configured.

Calculating the values for WFQ Weight-based traffic scheduling

Weighted Fair Queueing (WFQ) scheduling is configured to be a percentage of available bandwidth using the following formula.

$$\text{Weight of } q(x) = \frac{q(x)}{q0 + q1 + q2 + q3 + q4 + q5 + q6 + q7}$$

Where

q (x) = The value of the queue that you want to determine the weight for. It can be the value of any queue (0 - 7).

q0 - q7 = the assigned values of the eight queues.

Weight of q (x) = the calculated weight as a percentage of the port's total bandwidth.

For example if you assign the following values to queues 0 to 7:

- Queue 0 =10, Queue 1 = 15, Queue 2 = 20, Queue 3 = 25, Queue 4 = 30, Queue 5 = 35, Queue 6 = 40, and Queue 7 = 45,

To determine the weight of **q3**, use the following formula.

$$\text{Weight of q3} = \frac{25}{10 + 15 + 20 + 25 + 30 + 35 + 40 + 45}$$

The weight of q3 is 11.4%. Consequently, q3 will get 11.4% of the port's total bandwidth.

The values of the remaining queues are calculated to be the following: q7 = 20.5%, q6 = 18.2%, q5 = 15.9%, q4 = 13.6%, q3 = 11.4%, q2 = 9.1%, q1 = 6.8%, and q0 = 4.5%

Configuring WFQ weight-based traffic scheduling

To configure WFQ weight-based scheduling use a command such as the following.

```
NetIron(config)# interface ethernet 1/1
PowerConnect(config-if-e1000-1/1)# qos scheduler weighted 5 10 15 20 30 15 5 10
```

Syntax: **qos scheduler weighted** <*queue7-weight*> <*queue6-weight*> <*queue5-weight*> <*queue4-weight*> <*queue3-weight*> <*queue2-weight*> <*queue1-weight*> <*queue0-weight*>

The <*queue7-weight*> variable defines the relative value for queue7 in calculating queue7's allocated bandwidth.

The <*queue6-weight*> variable defines the relative value for queue6 in calculating queue6's allocated bandwidth.

The <*queue5-weight*> variable defines the relative value for queue5 in calculating queue5's allocated bandwidth.

The <*queue4-weight*> variable defines the relative value for queue4 in calculating queue4's allocated bandwidth.

The <*queue3-weight*> variable defines the relative value for queue3 in calculating queue3's allocated bandwidth.

The <*queue2-weight*> variable defines the relative value for queue2 in calculating queue2's allocated bandwidth.

The <*queue1-weight*> variable defines the relative value for queue1 in calculating queue1's allocated bandwidth.

The <*queue0-weight*> variable defines the relative value for queue0 in calculating queue0's allocated bandwidth

The acceptable range for <*queuex-weight*> variables is 1-128.

Refer to "Calculating the values for WFQ Weight-based traffic scheduling" for information on assigning queue0-weight to queue7-weight values.

Configuring mixed strict priority and weight-based scheduling

When configuring the mixed strict priority and weight-based scheduling option, queues 5 - 7 are allocated to strict priority-based scheduling and queues 0 - 4 are allocated to weight-based scheduling.

To configure mixed priority and weight-based scheduling use a command such as the following.

```
NetIron(config)# interface ethernet 1/1
NetIron(config-if-e1000-1/1)# qos scheduler mixed 100 80 60 40 20
```

Syntax: **qos scheduler mixed** *<Queue4-weight> <Queue3-weight> <Queue2-weight> <Queue1-weight> <Queue0-weight>*

The *<queue4-weight>* variable defines the relative value for queue4 in calculating queue4's allocated bandwidth.

The *<queue3-weight>* variable defines the relative value for queue3 in calculating queue3's allocated bandwidth.

The *<queue2-weight>* variable defines the relative value for queue2 in calculating queue2's allocated bandwidth.

The *<queue1-weight>* variable defines the relative value for queue1 in calculating queue1's allocated bandwidth.

The *<queue0-weight>* variable defines the relative value for queue0 in calculating queue0's allocated bandwidth

The acceptable range for *<queuex-weight>* variables is 1-128.

Refer to "Calculating the values for WFQ Weight-based traffic scheduling" for information on assigning queue0-weight to queue4-weight values.

Egress port and priority based rate shaping

Rate shaping is a mechanism to smooth out the variations in traffic above a certain rate. The primary difference between rate shaping and rate limiting is that in rate limiting, traffic exceeding a certain threshold is dropped. In rate shaping, the traffic that exceeds a threshold is buffered so that the output from the buffer follows a more uniform pattern. Rate shaping is useful when burstiness in the source stream needs to be smoothed out and a more uniform traffic flow is expected at the destination.

NOTE
Because excess traffic is buffered, rate shaping must be used with caution. In general, it is not advisable to rate shape delay-sensitive traffic.

PowerConnect support Egress rate shaping. Egress rate shaping is supported per port or for each priority queue on a specified port.

Configuring port-based rate shaping

When setting rate shaping for a port, you can limit the amount of bandwidth available on a port within the limits of the port's rated capacity. Within that capacity, you can set the bandwidth at increments within the ranges described in Table 65.

TABLE 65 Port-based rate shaping interval table

Range	Increment supported within the range
0 - 10M	8,333
10M - < 100M	20,833
100 M - < 1G	208,333
1G - 10G	2,083,333

NOTE
The egress rate shaping burst size for a port-based shaper is 10000 bytes.

These limits provide a minimum and maximum rate that the port can be set to. They also provide the increments at which the port capacity can be set. In operation, you can set any number between the minimum and maximum values. The router will automatically round-up the value to the next higher increment.

For example, if you set the rate of a 10G port to 2,000,000,000, the actual rate would be 2,002,083,173. This is because it is the next highest increment above 2,000,000,000.

To set a 10 Gbps port to the incremental port capacity over 2 Gbps, use the following command.

```
NetIron(config)# interface ethernet 2/2
NetIron(config-if-e10000-2/2)# qos shaper 2000000
```

Syntax: [no] qos shaper <*rate*>

The <*rate*> variable sets the rate you want to set for the port within the limits available as described in Table 65.

Configuring port and priority-based rate shaping

When setting rate shaping for a priority queue, you can limit the amount of bandwidth available for a specified priority within the limits of the capacity of the port that the priority is configured on. You can set the limit for the priority to any value from one to the port's maximum rating and the router will automatically round-up the value to the next increment supported. This will be a slightly higher value than what you specify with the command. For example, if you set the rate for priority 2 on a 10G port to 2,000,000,100, the actual rate would be slightly higher.

NOTE
The egress rate shaping burst size for a port and priority-based shaper is 3072 bytes.

To set the capacity for priority 2 traffic on a 10 Gbps port to the incremental capacity over 2 Gbps, use the following command.

```
NetIron(config)# interface ethernet 2/2
NetIron(config-if-e10000-2/2)# qos shaper priority 2 2000000
```

Syntax: [no] qos shaper priority <*priority-level*> <*rate*>

The <*priority-level*> variable specifies the priority that you want to set rate shaping for on the port being configured.

The <*rate*> variable sets the rate you want to set for the priority.

Multicast queue size, flow control and rate shaping

There are four internal priorities for multicast or broadcast traffic. These four priorities are mapped from the router's eight internal priorities as described inTable 66

TABLE 66 Mapping between multicast or broadcast and internal forwarding priorities

Internal Forwarding Priority	0,1	2,3	4,5	6,7
Multicast Internal Priority	0	1	2	3

The internal forwarding priority of a multicast or broadcast packet is determined from the packet's IEEE 802.1p priority, incoming port priority or IP ToS or DSCP as described in the "Default QoS mappings" on page 288. Four multicast queue types (0 to 3) are used for multicast internal priorities 0 to 3 respectively.

Configuring multicast queue size

The following example configures a 2 MByte queue size for queue 0.

```
NetIron(config)# qos multicast-queue-type 0 max-queue-size 2048
```

Syntax: [no] qos multicast-queue-type <*queue-number*> **max-queue-size <queue-size.>**

The <*queue-number*> variable specifies the queue that you want to configure a maximum size for. Possible values are 0 - 3.

The <*queue-size*> variable specifies size in KBytes that you want to set as the maximum value for the specified multicast queue. Possible values are 1 - 32768 KBytes. The default queue size is 1 Mbyte.

This command is applied per router and takes effect on all Traffic Managers within the configured router.

Configuring multicast flow control

Flow controls are available from egress to Ingress, and from fabric to Ingress. At the egress of each Traffic Manager, there are pre-determined thresholds for consumed resources and available resources and separate thresholds for guaranteed multicast or broadcast traffic and best-effort multicast or broadcast traffic. When a threshold is crossed, flow control can be triggered and multicast or broadcast traffic of the corresponding class is stopped at Ingress until resources are below the threshold again. Flow control is disabled by default and can be enabled on an interface using the command shown in the following.

```
NetIron(config)# interface ethernet 2/2
NetIron(config-if-e10000-2/2)# qos multicast flow-control
```

Syntax: [no] qos multicast flow-control

This command changes the flow control setting on the Traffic Manager where the interface resides.

Configuring multicast rate shaping

You can specify either guaranteed or best effort multicast rate shaping for a port in Kilobits per second. Multicast rate shaping is configured per-port to the Ingress port.

The following example changes the best-effort multicast traffic rate to 10 Mbps.

```
NetIron(config)# interface ethernet 2/2
NetIron(config-if-e10000-2/2)# qos multicast shaper best-effort rate 10000
```

Syntax: [no] qos multicast shaper [guaranteed | best-effort] rate <*bandwidth*>

The **guaranteed** option specifies that the multicast or broadcast shaper applies only to internal multicast priority 3 (the highest multicast priority) traffic.

The **best-effort** option specifies that the multicast or broadcast shaper applies to internal multicast priority 0, 1 and 2 traffic only.

The <*bandwidth*> variable specifies the maximum bandwidth in Kbps for best effort or guaranteed multicast traffic scheduled by the Traffic Manager across the switch fabric.

Configuration considerations

When applied to a port, the **qos multicast shaper** configuration is applied to all ports on the Interface module that use the same Traffic Manager as the configured port. This is unlike the behaviour of rate shaping applied for unicast traffic. The relationship between ports and Traffic Managers is defined in the following tables: "Ethernet ports per traffic manager" on page 344.

Example 1

In the following example, multicast rate shaping is applied to port 1/18 on a 20-port, 10/100/1000 Copper Ethernet Interface module.

```
NetIron(config)# interface ethernet 1/18
NetIron(config-if-e1000-1/18)# qos multicast shaper best-effort rate 10000
```

In this example, the configuration will apply to Ingress traffic that arrives on any port of the Interface module.

Example 2

In the following example, multicast rate shaping is applied to port 1/1 of a 4-port, 10 GbE Ethernet Interface module.

```
NetIron(config)# interface ethernet 1/1
NetIron(config-if-e10000-1/1)# qos multicast shaper best-effort rate 10000
```

In this example, the configuration will apply to Ingress traffic that arrives on either port 1/1 or port 1/2 of the Interface module.

NOTE
When a **qos multicast shaper** command is configured for a port, the configuration command is placed in the running config for all ports that belong to the same Traffic Manager. In Example 1, that would mean that the **qos multicast shaper best-effort rate 10000** command would appear in the interface configuration section for all ports (1 to 20) on the Interface Module. In Example 2, that would mean that the **qos multicast shaper best-effort rate 10000** command would appear in the interface configuration section for ports 1 and 2 on the Interface Module.

Traffic manager statistics display

Counters have been introduced to track the packets and bytes that enter the Ingress traffic manager and exit the egress traffic manager. Data from these counters can be displayed as described in the following sections.

Displaying all traffic manager statistics for a router

The following command displays all traffic manager statistics for a router by port groups that belong to each traffic manager.

```
NetIron# show tm statistics
--------- Ports 2/1 - 2/20 ---------
Ingress Counters:
   Total Ingress Pkt Count:                 464418
   EnQue Pkt Count:                         464418
   EnQue Byte Count:                        51904240
   DeQue Pkt Count:                         464418
   DeQue Byte Count:                        51904240
   TotalQue Discard Pkt Count:              0
   TotalQue Discard Byte Count:             0
   Oldest Discard Pkt Count:                0
   Oldest Discard Byte Count:               0
Egress Counters:
   EnQue Pkt Count:                         701812
   EnQue Byte Count:                        78785888
   Discard Pkt Count:                       0
   Discard Byte Count:                      0
--------- Ports 4/1 - 4/20 ---------
Ingress Counters:
   Total Ingress Pkt Count:                 0
   EnQue Pkt Count:                         0
   EnQue Byte Count:                        0
   DeQue Pkt Count:                         0
   DeQue Byte Count:                        0
   TotalQue Discard Pkt Count:              0
   TotalQue Discard Byte Count:             0
   Oldest Discard Pkt Count:                0
   Oldest Discard Byte Count:               0
Egress Counters:
   EnQue Pkt Count:                         0
   EnQue Byte Count:                        0
   Discard Pkt Count:                       0
   Discard Byte Count:                      0
```

Syntax: show tm statistics

Displaying traffic manager statistics for a port group

The following command displays all traffic manager statistics for a specified port group as identified by a slot and port within the group.

```
NetIron#show tm statistics ethernet 2/1
--------- Ports 2/1 - 2/20 ---------
Ingress Counters:
   Total Ingress Pkt Count:                 464454
   EnQue Pkt Count:                         464454
   EnQue Byte Count:                        51907696
   DeQue Pkt Count:                         464454
   DeQue Byte Count:                        51907696
   TotalQue Discard Pkt Count:              0
   TotalQue Discard Byte Count:             0
   Oldest Discard Pkt Count:                0
   Oldest Discard Byte Count:               0
Egress Counters:
```

```
   EnQue Pkt Count:                          701866
   EnQue Byte Count:                         78791072
   Discard Pkt Count:                        0
   Discard Byte Count:                       0
```

Syntax: show tm statistics ethernet <*slot/port*>

The <*slot/port*> variable specifies the slot and port number of the port group that you want to display traffic manager statistics for.

NOTE
A traffic manager contains a specific number of ports depending on the Interface module as described in Table 68. Specifying a particular port and slot gathers statistics for all ports that belong to the same port group.

Displaying traffic manager statistics for an interface module

The following command displays all traffic manager statistics for an interface module identified by its slot number.

```
NetIron#show tm statistics slot 4
--------- Ports 4/1 - 4/20 ---------
Ingress Counters:
   Total Ingress Pkt Count:                  0
   EnQue Pkt Count:                          0
   EnQue Byte Count:                         0
   DeQue Pkt Count:                          0
   DeQue Byte Count:                         0
   TotalQue Discard Pkt Count:               0
   TotalQue Discard Byte Count:              0
   Oldest Discard Pkt Count:                 0
   Oldest Discard Byte Count:                0
Egress Counters:
   EnQue Pkt Count:                          0
   EnQue Byte Count:                         0
   Discard Pkt Count:                        0
   Discard Byte Count:                       0
```

Syntax: show tm statistics ethernet <*slot/port*>

The **slot** <*slot-number*> option specifies an interface module that you want to display traffic manager statistics from.

TABLE 67 Traffic manager statistics

This field...	Displays...
Ingress Statistics	
Total Ingress Pkt Count	A count of all packets entering into this traffic manager. A traffic manager contains a specific number of ports depending on the Interface module as described in Table 68.
EnQue Pkt Count	A count of all packets entering Ingress queues on this traffic manager. A traffic manager contains a specific number of ports depending on the Interface module as described in Table 68.

TABLE 67 Traffic manager statistics (Continued)

This field...	Displays...
EnQue Byte Count	A count of all bytes entering Ingress queues on this traffic manager. A traffic manager contains a specific number of ports depending on the Interface module as described in Table 68.
DeQue Pkt Count	A count of all packets dequeued from Ingress queues and forwarded on this traffic manager. A traffic manager contains a specific number of ports depending on the Interface module as described in Table 68.
DeQue Byte Count	A count of all bytes dequeued from Ingress queues and forwarded on this traffic manager.
TotalQue Discard Pkt Count	A count of all packets failing to enter Ingress queues on this traffic manager. This may be due to: • the queue reaching its maximum depth, WRED, or other reasons. • the network processor deciding to drop packets for reasons including: an unknown Layer-3 route, RPF, or segment filtering. A traffic manager contains a specific number of ports depending on the Interface module as described in Table 68.
TotalQue Discard Byte Count	A count of all bytes failing to enter Ingress queues on this traffic manager. This may be due to: • the queue reaching its maximum depth, WRED, or other reasons. • the network processor deciding to drop packets for reasons including: an unknown Layer-3 route, RPF, or segment filtering. A traffic manager contains a specific number of ports depending on the Interface module as described in Table 68.
Oldest Discard Pkt Count	A count of all packets entering Ingress queues on this traffic manager, but deleted afterwards due to buffer full. A traffic manager contains a specific number of ports depending on the Interface module as described in Table 68.
Oldest Discard Byte Count	A count of all bytes entering Ingress queues on this traffic manager, but deleted afterwards due to buffer full. A traffic manager contains a specific number of ports depending on the Interface module as described in Table 68.
Egress statistics	
EnQue Pkt Count	A count of all packets entering egress queues and forwarded out on this traffic manager. A traffic manager contains a specific number of ports depending on the Interface module as described in Table 68.
EnQue Byte Count	A count of all bytes entering egress queues and forwarded out on this traffic manager. A traffic manager contains a specific number of ports depending on the Interface module as described in Table 68.
Discard Pkt Count	A count of all packets failing to enter egress queues on this traffic manager. A traffic manager contains a specific number of ports depending on the Interface module as described in Table 68.
Discard Byte Count	A count of all bytes failing to enter egress queues on this traffic manager. A traffic manager contains a specific number of ports depending on the Interface module as described in Table 68.

NOTE
The byte counts displayed from the **show tm statistics** command incorporate proprietary internal headers of various lengths.

TABLE 68 Ethernet ports per traffic manager

Interface module	Ports per Traffic Manager (TM)	
	TM 1	TM 2
4 X 10 Gbps (Ethernet)	1 - 2	3 - 4
2 X 10 Gbps (Ethernet)	1 - 2	
20 X 1 Gbps (Ethernet)	1 - 20	

Displaying traffic manager statistics for NI-MLX-10Gx8-M and NI-MLX-10Gx8-D modules

The following command displays traffic manager statistics for the NI-MLX-10Gx8-M module, and the NI-MLX-10Gx8-D module identified by its slot number.

```
PowerConnect#show tm statistics slot 4
--------- Ports 4/1 - 4/4 ---------
Ingress Counters:
   Total Ingress Pkt Count:                  61402830423
   EnQue Pkt Count:                          61402825288
   DeQue Pkt Count:                          61402692118

   Discard Byte Count:                       0
```

Syntax: show tm statistics [slot <*slot-number*>**]**

The **slot** <*slot-number*> option specifies the slot number of the port group that you want to display traffic manager statistics for.

Displaying traffic manager statistics for the 24x1G module

The following command displays traffic manager statistics for the 24x1G module.

```
NetIron#show tm statistics all-counters 0
Ingress Counters:
   LBP Pkt Count:                          0
   QDP EnQue Pkt Count:                    0
   QDP EnQue Byte Count:                   0
   QDP DeQue Pkt Count:                    0
   QDP DeQue Byte Count:                   0
   QDP Head Delete Pkt Count:              0
   QDP Head Delete Byte Count:             0
   QDP Tail Delete Pkt Count:              0
   QDP Tail Delete Byte Count:             0
   Flow Status Message Count:              0
   Transmit Data Cell Count:               0
   TDM_A Pkt Count:                        0
   TDM_B Pkt Count:                        0

Programmable Ingress Counters:
[Queue Select: 8000, Queue Mask 0x0007]
   QDP EnQue Pkt Count:                    0
   QDP EnQue Byte Count:                   0
   QDP DeQue Pkt Count:                    0
   QDP DeQue Byte Count:                   0
   QDP Head Delete Pkt Count:              0
   QDP Head Delete Byte Count:             0
   QDP Tail Delete Pkt Count:              0
   QDP Tail Delete Byte Count:             0
   Flow Status Message Count:              0

Egress Counters:
   EGQ EnQue Pkt Count:                    0
   EGQ EnQue Byte Count:                   0
   EGQ Discard Pkt Count:                  0
   EGQ Discard Byte Count:                 0
   EGQ Segment Error Count:                0
   EGQ Fragment Error Count:               0
   Port63 Error Pkt Count:                 0
   Pkt Header Error Pkt Count:             0
   Pkt Lost Due to Buffer Full Pkt Count:  0
   Reassem Err Discard Pkt Count:          0
   Reassem Err Discard Fragment(32B) Count:  0
   TDM_A Lost Pkt Count:                   0
   TDM_B Lost Pkt Count:                   0

Programmable Egress Counters:
[Port Id for Enque: 0 (Disable), Port Id for Discard: 0 (Disable)]
   EGQ EnQue Pkt Count:                    0
   EGQ EnQue Byte Count:                   0
   EGQ Discard Pkt Count:                  0
   EGQ Discard Byte Count:                 0
```

Syntax: show tm statistics all-counters <*dev_id*>

The <*dev_id*> variable specifies the device id that you want to display traffic manager statistics for.

Clearing traffic manager statistics

You can clear traffic manager statistics selectively for a specified port group, selectively for an interface module, or for an entire PowerConnect router as shown in the following.

```
NetIron# clear tm statistics ethernet slot 4
```

Syntax: clear tm statistics [ethernet <*slot/port*> **| slot** <*slot-number*> **]**

Executing the **clear tm statistics** command without any options clears all traffic manager statistics on the router.

The **ethernet** <*slot/port*> option specifies a port group that you want to clear traffic manager statistics from.

The **slot** <*slot-number*> option specifies an interface module that you want to clear traffic manager statistics from.

New network processor counters displayed for packets to and from traffic manager

Output from the **show interface** command has been enhanced to provide the following traffic manager related information:

- Number of packets received at the network processor (NP)
- Number of packets sent from the NP to the traffic manager (TM)
- Number of Ingress packets dropped at the NP
- Number of packets transmitted from the NP
- Number of packets received by the NP from the TM

The following is an example of the new output from the show interface command with the changed output highlighted in **bold**.

```
NetIron(config)# show interface ethernet 3/3
GigabitEthernet3/3 is up, line protocol is up
Hardware is GigabitEthernet, address is 0004.80a0.4052 (bia 0004.80a0.4052)
Configured speed auto, actual 1Gbit, configured duplex fdx, actual fdx
Member of L2 VLAN ID 1, port is untagged, port state is Forwarding
STP configured to ON, Priority is level0, flow control enabled
mirror disabled, monitor disabled
Not member of any active trunks
Not member of any configured trunks
No port name
MTU 1544 bytes, encapsulation ethernet
300 second input rate: 754303848 bits/sec, 1473249 packets/sec, 89.57% utilization
300 second output rate: 754304283 bits/sec, 1473250 packets/sec, 89.57%
utilization
1015230949 packets input, 64974783168 bytes, 0 no buffer
Received 0 broadcasts, 0 multicasts, 1015230949 unicasts
0 input errors, 0 CRC, 0 frame, 0 ignored
0 runts, 0 giants
NP received 1039220106 packets, Sent to TM 1039220442 packets
NP Ingress dropped 0 packets
1015231660 packets output, 64974824768 bytes, 0 underruns
Transmitted 0 broadcasts, 0 multicasts, 1015231660 unicasts
0 output errors, 0 collisions
NP transmitted 1039221393 packets, Received from TM 1039221562 packets
```

QoS for NI-MLX-1Gx48-T modules

The NI-MLX-1Gx48-T module supports 48 1G port. In a fully loaded 32 slot chassis, there are only 8 queues supported on the TM port. The PowerConnect chassis supports 1008 ports with 8 queues per port. Beginning with this release, the PowerConnect configuration allows you configure more ports in the system by changing the TM port to use 4 queues instead of 8. The PowerConnect chassis supports 2016 ports using 4 queues per port.

Limitations on TM ports

The TM Port limitations are reached under the following situations.

1. When a new module type is configured.

2. When a new line card is inserted (no configured type).

3. When the user tries to configure the **max-tm-queue** parameter from 4 to 8.

The relationship between max TM queues and max TM ports are supported in the system as follows:

TABLE 69 Maximum TM queues and TM ports

Max TM queue per port	Max TM port
8	1008
4	2016

Configuring priority queues from 8 to 4

The **system-init max-tm-queues** command allows you to configure the maximum number of queues in TM to 4. To configure priority queues from 8 to 4, enter the following command.

```
NetIron(config)# system-init max-tm-queues 4
```

Syntax: [no] system-init max-tm-queues <*num*>

The <*num*> value specifies changing the number of queues to 4.

NOTE
When configuring priority queues from 8 to 4, or vice versa, the system displays the following message: **Reload required. Please write memory and then reload or power cycle. Failure to reload could cause system instability or failure.**

The NP continues to map all inbound packets to 8 internal priorities. If the **system-init max-tm-queues** command is configured, the NP will right shift this priority number by one bit before sending the packet to TM. The TM will en-queue the packets based on the following table:

TABLE 70 Queue type

NP priority	TM queue
7,6	3
5,4	2

TABLE 70 Queue type (Continued)

NP priority	TM queue
3,2	1
1,0	0

QoS commands affected by priority queues

- Priority-based Rate Shaping
- Weighted Random Early Discard (WRED)
- Weighted-based Scheduling and Mixed Strict Priority
- CPU Copy Queue
- Traffic Manager Statistics

Priority-based rate shaping

If the user specifies a priority of 4-7 when the max-tm-queues parameter is configured using 4 queues, the **qos shaper priority** command is accepted, but a warning message is displayed.

The following example displays the **qos shaper priority** command configured with a priority 4 shaper.

```
NetIron(config-if-eth-16/1)# qos shaper priority 4 1000000
Warn: current max TM queues is 4-configuration of priority 4-7 will not have any
effect.
```

NOTE
If a priority 5 shaper is already configured, and the max-tm-queues parameter changes from 8 to 4 queues and is reloaded, then the priority 5 shaper configuration line is still displayed. The priority shaper 5 will not take effect.

Weighted Random Early Discard (WRED)

When WRED is enabled for a queue type of any forwarding queue, it will receive a warning message that is similar to when the **priority-based rate shaping** command is configured. Refer to "Priority-based rate shaping" on page 349 for more information.

The following example displays enabling WRED for the forwarding queues with a queue type of 6.

```
NetIron(config)#qos queue-type 6 wred enable
Warn: current max TM queues is 4-configuration of queue-type 4-7 will not have any
effect.
```

NOTE
If the **system-init max-tm-queues 4** command is configured, the user is able to configure similar WRED parameters, such as Average weight, Max Instantaneous queue size, Drop Precedence, etc. for all priorities. The default values of all WRED parameters (refer to Table 70 on page 348) is only effective when queue-type 0-3 is used.

Weighted-based scheduling and mixed strict priority

When the **max-tm-queues** parameter is configured with 8 or 4 queues, the **qos scheduler weighted** command and **qos scheduler mixed** command will still take the same number of weight values, but the unnecessary priority values are ignored.

The following example displays when the **qos scheduler weighted** command is configured using 4 queues.

```
NetIron(config-ethe-1/1)#qos scheduler weighted 7 6 5 4 3 2 11
Current max TM queues is 4 - weights “7”, “6”, “5”, “4” for priority 7-4 will not
have any effect.
```

The following example displays when the **qos scheduler mixed** command is configured using 4 queues.

```
NetIron(config-ethe-1/1)#qos scheduler mixed 4 3 2 1 1
Current max TM queues is 4 - weights “4”, “3”, “2” for queues 4-2 will not have
any effect.
```

The following table displays how traffic scheduling for Strict Priority-based Scheduling and Weighted-based Scheduling is configured differently between 8 and 4 queues:

TABLE 71 Strict v.s. weighted queues

	8 queues (current)	4 queues (new)
Strict	7,6,5	3,2
Weighted	4,3,2,1,0	1,0

Error messages for CPU copy queue and traffic manager statistics

The following error messages are displayed for CPU copy queue and traffic manager statistics when the incorrect queues are configured.

CPU copy queue

When **system-init max-tm-queues 4** command is configured, the **rl-cpu-copy** command displays a warning message when the user specifies a priority 4-7.

Example

```
NetIron(config)# rl-cpu-copy priority 4 1000000
Warn: current max TM queues is 4-configuration of priority 4-7 will not have any
effect.
```

Traffic manager statistics

When **system-init max-tm-queues 4** command is configured, the **show tm-voq-stat** command will only take a priority 0-3. An error message is displayed when an invalid priority range is enabled.

Example

```
NetIron#show tm-voq-stat src_port e 9/1 dst_port e 2/3 5
Error: priority range 0 to 3.
```

NOTE

The **show tm-voq-stat** command will print statistics for 4 queues, instead of 8. The output from the TM Q statistics is available only if the src card type is a 48x1GC module, or a POS module.

Configuring Traffic Policing for the NetIron MLX 10

Traffic policing on the PowerConnect

The PowerConnect Router provides line-rate traffic policing in hardware on inbound ports and outbound ports.

You can configure a PowerConnect Router to use one of the following modes of traffic policing policies:

- **Port-based** – Limits the rate on an individual physical port to a specified rate. Only one inbound and one outbound port-based traffic policing policy can be applied to a port. (Refer to "Configuring port-based traffic policing For inbound and outbound ports" on page 357.) These policies can be applied to inbound and outbound traffic.
- **Port-and-priority-based** – Limits the rate on an individual hardware forwarding queue on an individual physical port. Only one port-and-priority-based traffic policing policy can be specified per priority queue for a port. (Refer to "Configuring a port and priority-based traffic policing policy for inbound and outbound ports" on page 358.) These policies can be applied to inbound and outbound traffic.
- **VLAN-based** – Untagged packets as well as tagged packets can be rate-limited. Only one rate can be specified for each VLAN. (Refer to "Configuring a VLAN-based traffic policing policy" on page 359.) Up to 990 VLAN-based policies can be configured for a port under normal conditions or 3960 policies if priority-based traffic policing is disabled as described in "Configuring for no priority-based traffic policing" on page 362. These policies can be applied to inbound and outbound traffic.
- **VLAN group based** – Limits the traffic for a group of VLANs. Members of a VLAN group share the specified bandwidth defined in the traffic policing policy that has been applied to that group. (Refer to "Configuring a VLAN group-based traffic policing policy" on page 359.) Up to 990 VLAN Group-based policies can be configured for a port under normal conditions or 3960 policies if priority-based traffic policing is disabled as described in "Configuring for no priority-based traffic policing" on page 362. These policies can only be applied to inbound traffic.

  NOTE
  If a VLAN based policing is configured on a port for a particular VLAN, the policing will be applicable to all ports on that Network Processor that belong to that VLAN".

- **Port-and-ACL-based** – Limits the rate of IP traffic on an individual physical port that matches the permit conditions in IP Access Control Lists (ACLs). Layer 2 ACL-based traffic policing is supported. You can use standard or extended IP ACLs. Standard IP ACLs match traffic based on source IP address information. Extended ACLs match traffic based on source and destination IP address and IP protocol information. Extended ACLs for TCP and UDP also match on source and destination TCP or UDP addresses. and protocol information. These policies can be applied to inbound and outbound traffic. Up to 990 Port-and-ACL-based policies can be configured for a port under normal conditions or 3960 policies if priority-based traffic policing is disabled as described in "Configuring for no priority-based traffic policing" on page 362.

- **Rate Limiting for Copied-CPU-bound Traffic** – You can limit the rate of Copied-CPU-bound packets from applications such as sFlow, ACL logging, RPF logging, and source MAC address learning (with known destination address). Copied-CPU-bound packets are handled and queued separately from packets destined to the CPU such as protocol packets and using this feature they can be assigned to one of eight priority queues which has a rate limit assigned to it. The queue and rate are assigned by port and apply to all of the ports that are supported by the same packet processor. Table 72 describes the ports that are associated a packet processor.

Multi-Service IronWare supports applying traffic policing parameters directly to a port or creating a policy map to define a set of traffic policing parameters and then applying that policy map to one or more ports. In addition, the traffic policing parameters available from each of these options are different. The parameters used when applying traffic policing parameters directly to a port reflect the Multi-Service IronWare features that were available before this release. These parameters and the information required to use them are described in "Applying traffic policing parameters directly to a port" on page 354.

The parameters used when applying traffic policing through use of a policy map reflect the traffic policing features that have been added with this release. These parameters and the information required to use them are described in "Applying traffic policing parameters using a policy map" on page 355.

Applying traffic policing parameters directly to a port

When applying a traffic policing policy directly to a port, there are specific parameters that are applied to implement the policy that are different than those used when using a policy map. Using this method, a traffic policing policy specifies two parameters: average rate and maximum burst. These parameters are used to configure credits and credit totals.

Average rate

The *Average Rate* is the maximum number of bits a port is allowed to receive during a one-second interval. The rate of the traffic that matches the traffic policing policy will not exceed the average rate.

The Average Rate represents a percentage of an interface's line rate (bandwidth), expressed in bits per second (bps). It cannot be smaller than 8,144 bits per second (bps) and it cannot be larger than the port's line rate.

Average Rate must be entered in multiples of 8,144 bps. If you enter a number that is not a multiple of 8,144, the software adjusts the rate down to the lowest multiple of the number so that the calculation of credits does not result in a remainder of a partial Credit. For example, if you enter 10,000 bps, the value will be adjusted to 8,144 bps. The adjusted rate is sometimes called the *adjusted average rate*.

Maximum burst

Maximum burst provides a higher than average rate to traffic that meet the rate limiting criteria. Traffic will be allowed to pass through the port for a short period of time. The unused bandwidth can be accumulated up to a maximum of "maximum burst" value.

Credits and credit total

Each rate limiting policy is assigned a class. A *class* uses the average rate and maximum burst in the rate limit policy to calculate credits and credit totals.

Credit size is measured in bytes. A credit is a forwarding allowance for a traffic policed port, and is the smallest number of bytes that can be allowed during a rate limiting interval. Minimum credit size can be 1 byte.

During a rate limiting interval, a port can send or receive only as many bytes as the port has Credits for. For example, if an inbound rate limiting policy results in a port receiving two credits per rate limiting interval, the port can send or receive a maximum of 2 bytes of data during that interval.

In each interval, the number of bytes equal to the credit size is added to the running total of the class. The running total of a class represents the number of bytes that can be allowed to pass through without being subject to rate limiting.

The second parameter is the maximum *credit total*, which is also measured in bytes. The maximum credit total is based on the maximum burst value and is also measured in bytes.

The running total can never exceed the maximum credit total. When packets arrive at the port, a class is assigned to the packet based on the traffic policing policies. If the running total of the class is less than the size of the packet, then the packet is dropped. Otherwise, the size of the packet is subtracted from the running total and the packet is forwarded. If there is no traffic that matches traffic policing criteria, then the running total can grow up to the maximum credit total.

Applying traffic policing parameters using a policy map

When using the traffic policing policies available from previous versions, the policy parameters are provided explicitly for each port during port configuration. In this version, the policies must be defined using a policy map. The policy map configuration ties a policy name to a set of traffic policing policies. The policy name is then applied to the port or ports that you want to rate limit using the defined policy. This allows you to set a policy in a single location the affects multiple ports and to make changes to that policy. Configuration of a policy map is described in "Configuring a policy map" on page 356.

Within the policy map configuration, the parameters used to define traffic policing have been changed. When configuring traffic policing within a policy map, these new parameters apply. With this release, traffic policing policy determines the rate of inbound or outbound traffic (in bits per second or bps) that is allowed per port. This traffic is initially traffic policed by a Committed Information Rate (CIR) bucket. Traffic that is not accommodated in the CIR bucket is then subject to the Excess Information Rate (EIR) bucket.

The CIR bucket

The CIR rate limiting bucket is defined by two separate parameters: the CIR rate, and the Committed Burst Size (CBS) rate. The CIR rate is the maximum number of bits a port is allowed to receive or send during a one-second interval. The rate of the traffic that matches the traffic policing policy can not exceed the CIR rate. The CIR rate represents a portion of an interface's line rate (bandwidth), expressed in bits per second (bps) and it cannot be larger than the port's line rate. CIR-defined traffic that does not use the CIR rate available to it accumulates credits that it can use later in circumstances where it temporarily exceeds the CIR rate.

When traffic exceeds the bandwidth that has been reserved for it by the CIR rate defined in its policy, it becomes subject to the CBS rate. The CBS rate provides a rate higher than the CIR rate to traffic that exceeded its CIR rate. The bandwidth in the CBS rate is accumulated during periods of time when traffic that has been defined by a policy does not use the full CIR rate available to it. Traffic is allowed to pass through the port for a short period of time at the CBS rate.

When inbound or outbound traffic exceeds the bandwidth available for the defined CIR and CBS rates, it is either dropped, or made subject to the conditions set in it EIR bucket.

The EIR bucket

The EIR bucket provides an option for traffic that has exceeded the conditions set by policy for the CIR bucket. In the EIR bucket, there are two parameters that define the traffic that is available: the Excess Information Rate (EIR) and the Excess Burst Size (EBS) rate. The EIR and EBS operate exactly like the CIR and CBS except that they only act upon traffic that has been passed to the EIR bucket because it could not be accommodated by the CIR bucket. Like the CIR, the EIR provides an initial bandwidth allocation to accommodate inbound and outbound traffic. If the bandwidth provided by the EIR is insufficient to accommodate the excess traffic, the defined EBS rate provides for burst traffic. Like the CBS, the bandwidth available for burst traffic from the EBS is subject to the amount of bandwidth that is accumulated during periods of time when traffic that has been allocated by the EIR policy is not used.

In addition, to providing additional bandwidth for traffic that exceeds that available for the CIR bucket, traffic rate limited by the EIR bucket can have its excess priority and excess dscp values changed. Using this option, priority parameters are set following the EBS value that change the priority of traffic that is being rate limited using the EIR bucket.

Configuration considerations

- Only one type of traffic policing policy can be applied on a physical port. For example, you cannot apply port-and-ACL-based and port-based traffic policing policies on the same port.
- When a VLAN-based traffic policing policy is applied to a port, all the ports controlled by the same packet processor are rate limited for that VLAN. You cannot apply a VLAN-based traffic policing policy on another port of the same packet processor for the same VLAN ID.
- The Multi-Service IronWare software supports VLAN-based traffic policing that can limit tagged and untagged packets that match the VLAN ID specified in the policy. Untagged packets are not subject to traffic policing.
- The maximum burst in a traffic policing policy cannot be less than the average rate and cannot be more than the port's line rate.
- Control packets are not subject to traffic policing.
- Source MAC address with Virtual Leased Line (VLL) endpoints are not subject to traffic policing.

Configuring traffic policing on PowerConnect devices

The following sections show examples of how to configure each traffic policing policy type.

Configuring a policy map

To configure a policy map, enter a command such as the following.

```
NetIron(config)# policy-map map1 cir 1000000 cbs 2000000 eir 1000000 ebs 2000000
excess-dp 2 excess-dscp 37
```

The command configures the traffic policing policy map map1 to limit CIR rate to 1000000 the CBS rate to 2000000, the EIR rate to 1000000 and the EBS to 2000000. In addition, traffic that exceeds the bandwidth available in the CIR bucket will have its packets drop precedence set to 2 and its DSCP set to 37. This command only creates a policy, it must be applied to one or more ports to be operational.

Syntax: **[no] policy-map** <*map-name*> **cir** <*cir-rate*> **cbs** <*cbs-rate*> **[eir** <*eir-rate*> **ebs** <*ebs-rate*> **excess-priority** <*priority-num*> **[excess-dscp** <*dscp-num*>**]] | [eir** <*eir-rate*> **ebs** <*ebs-rate*> **excess-dp** <*dp-val*> **[excess-dscp** <*dscp-num*>**]]**

The map-name variable is the name you will use to reference the policy map in traffic policing command. It can be a character string up to 64 characters long.

The cir parameter defines the value of the Committed Information Rate (CIR) as the rate defined in the <*cir-rate*> variable. Acceptable values are: 0 - 10000000000 bps in increments of 8,144 bps.

The cbs parameter defines the value of the Committed Burst Size (CBS) as the rate defined in the <*cbs-rate*> variable. Acceptable values are: 1250 - 1250000000 bytes in increments of 1 byte.

The eir parameter defines the value of the Excess Information Rate (EIR) as the rate defined in the <*eir-rate*> variable. Acceptable values are: 0 - 10000000000 bps in increments of 8,144 bps.

The **ebs** parameter defines the value of the Excess Burst Size (EBS) as the rate defined in the <*ebs-rate*> variable. Acceptable values are: 1250 - 1250000000 bytes in increments of 1 byte.

The **excess-priority** parameter specifies that traffic whose bandwidth requirements exceeds what is available in the CIR bucket and is sent to the EIR bucket will have its packets priority queue set to the value set in the <*priority-num*> variable. Acceptable values for the <*priority-num*> are 0-7.

The **excess-dp** parameter specifies the WRED drop precedence for traffic whose bandwidth requirements exceed what is available in the CIR bucket and is sent to the EIR bucket. Acceptable values for the <*dp-value*> are 0-3. Packets with a value of 0 are least likely to be dropped and packets with a value of 3 are most likely to be dropped.

The **excess-dscp** parameter specifies that traffic whose bandwidth requirements exceeds what is available in the CIR bucket and is sent to the EIR bucket will have its packets DSCP priority set to the value set in the <*dscp-num*> variable. Acceptable values for the <*dscp-num*> are 0-63. When this parameter is used together with the **excess-dp** parameter, the value set for bits 2:1 (zero-based) in the **excess-dscp** parameter must be equal to the value set for **excess-dp**.

Configuring port-based traffic policing For inbound and outbound ports

Port-based traffic policing limits the rate on an individual inbound or outbound physical port to a specified rate.

To configure port-based traffic policing policy for outbound ports, enter commands such as the following at the interface level.

```
NetIron(config)# interface ethernet 1/1
NetIron(config-if-1/1)# rate-limit out 500000000 750000000
```

The commands configure a traffic policing policy for outbound traffic on port 1/1. The policy limits the average rate of all outbound traffic to 500 Mbps with a maximum burst size of 750 Mbps.

To configure port based traffic policing policy through a policy map, enter a command such as the following.

```
NetIron(config)# interface ethernet 1/1
NetIron(config-if-1/1)# rate-limit input policy-map map1
```

The commands configure a traffic policing policy for inbound traffic on port 1/1. The policy references the policy map map1 for rate limiting policy parameters.

The complete syntax for configuring a port-based traffic policing policy is:

Syntax: [no] rate-limit [in | out] [<*average-rate*> <*maximum-burst*> **| policy-map** <*map-name*>**]**

The **input** parameter applies the policy to traffic on inbound ports.

The **output** parameter applies the policy to traffic on outbound ports.

Only one inbound and one outbound port-based traffic policing policy can be applied to a port.

The <*average-rate*> parameter specifies the maximum rate allowed on a port during a one-second interval. The software automatically adjusts the number you enter to the lower multiple of 8,144 bps. Refer to the section "Average rate" on page 354 for more details. This command is only used when configuring traffic policing directly to a port as described in "Applying traffic policing parameters directly to a port" on page 354.

The <*maximum-burst*> parameter specifies the extra bits above the average-rate that traffic can have. Refer to the section "Maximum burst" on page 354 for more details. This command is only used when configuring traffic policing directly to a port as described in "Applying traffic policing parameters directly to a port" on page 354.

The **policy-map** parameter specifies the policy map named in the <*policy-map*> variable to be used to provide parameters for rate limiting the port and VLAN specified. This command is only used when configuring traffic policing to a port using a policy map as described in "Applying traffic policing parameters using a policy map" on page 355.

Configuring a port and priority-based traffic policing policy for inbound and outbound ports

To configure port based traffic policing policy directly, enter a command such as the following.

```
NetIron(config)# interface ethernet 1/1
NetIron(config-if-1/1)# rate-limit input priority 2 500000000 750000000
```

The commands configure a traffic policing policy for inbound traffic on port 1/1. The policy limits the average rate of all inbound traffic to 500 Mbps with a maximum burst size of 750 Mbps for packets with their priority queue set to 2.

Syntax: **[no] rate-limit [input | output] priority** <*queue-num*> [<*average-rate*> <*maximum-burst*> | **policy-map** <*map-name*>]

The **input** parameter applies the policy to traffic on inbound ports.

The **output** parameter applies the policy to traffic on outbound ports.

Only one port-based traffic policing policy can be applied to a port.

The **priority** parameter specifies an 802.1p value in the <*queue-num*> variable that is used to identify packets that will be rate limited by this command.

The <*average-rate*> parameter specifies the maximum rate allowed on a port during a one-second interval. The software automatically adjusts the number you enter to the nearest multiple of 8,144 bps. Refer to the section "Average rate" on page 354 for more details. This command is only used when configuring rate limiting directly to a port as described in "Applying traffic policing parameters directly to a port" on page 354.

The <*maximum-burst*> parameter specifies the extra Mbits above the average-rate that traffic can have. Refer to the section "Maximum burst" on page 354 for more details. This command is only used when configuring rate limiting directly to a port as described in "Applying traffic policing parameters directly to a port" on page 354.

The **policy-map** parameter specifies the policy map named in the <*policy-map*> variable to be used to provide parameters for rate limiting the port. This command is only used when configuring rate limiting to a port using a policy map as described in "Applying traffic policing parameters using a policy map" on page 355.

Configuring a VLAN-based traffic policing policy

To configure a port-and-VLAN based traffic policing policy, enter commands such as the following.

```
NetIron(config)# interface ethernet 1/1
NetIron(config-if-1/1)# rate-limit input vlan 10 500000000 750000000

NetIron(config)# interface ethernet 1/2
NetIron(config-if-1/2)# rate-limit output vlan 20 policy-map map1
```

These commands configure two traffic policing policies that limit the average rate of all inbound traffic on port 1/1 with VLAN tag 10 and all outbound traffic on port 1/2 VLAN tag 20. The first policy limits packets with VLAN tag 10 to an average rate of 500 Mbps with a maximum burst size of 750 Mbits on port 1/1. The second policy limits packets with VLAN tag 20 to values defined in policy map map1. Tagged packets belonging to VLANs other than 10 and 20 and untagged packets are not subject to traffic policing on these ports.

Syntax: **[no] rate-limit [input | output] [priority** <*queue-num*>**] vlan-id** <*vlan-num*> **[**<*average-rate*> <*maximum-burst*> **| policy-map** <*map-name*> **]**

The **input** parameter applies the policy to traffic on inbound ports.

The **output** parameter applies the policy to traffic on outbound ports.

The **priority** parameter specifies an 802.1p value in the <*queue-num*> variable that is used to identify packets that will be rate limited by this command. This parameter is optional.

The vlan-id <*vlan-number*> parameter species the VLAN ID to which the policy applies. You can specify up to 990 priority or 3960 non-priority VLAN-based traffic policing policies on a port.

The <*average-rate*> parameter specifies the maximum rate allowed on a port during a one-second interval. The software automatically adjusts the number you enter to the nearest multiple of 8,144 bps. Refer to the section "Average rate" on page 354 for more details. This command is only used when configuring traffic policing directly to a port as described in "Applying traffic policing parameters directly to a port" on page 354.

The <*maximum-burst*> parameter specifies the extra Mbits above the average-rate that traffic can have. Refer to the section "Maximum burst" on page 354 for more details. This command is only used when configuring traffic policing directly to a port as described in "Applying traffic policing parameters directly to a port" on page 354.

The **policy-map** parameter specifies the policy map named in the <*policy-map*> variable to be used to provide parameters for traffic policing the port and VLAN specified. This command is only used when configuring traffic policing to a port using a policy map as described in "Applying traffic policing parameters using a policy map" on page 355.

Configuring a VLAN group-based traffic policing policy

A traffic policing policy can be applied to a VLAN group. VLANs that are members of a VLAN group share the specified bandwidth defined in the traffic policing policy applied to that group.

To configure a traffic policing policy for a VLAN group, perform the following tasks.

1. Define the VLANs that you want to place in a traffic policing VLAN group.
2. Define a rate limiting VLAN group. This VLAN group is specific to the traffic policing feature. Enter commands such as the following.

   ```
   NetIron(config)# rl-vlan-group 10
   NetIron(config-vlan-rate-group)# vlan 3 5 to 7 10
   ```

The commands assign VLANs 3, 5,6, 7, and 10 to traffic policing VLAN group 10.

Syntax: [no] rl-vlan-group <*vlan-group-number*>

Syntax: [no] vlan <*vlan-number*> **[to <vlan-number]**

The **rl-vlan-group** command takes you to the VLAN group traffic policing level. Enter the ID of the VLAN group that you want to create or update by entering a value for <*vlan-group-number*>.

Use the vlan command to assign or remove VLANs to the rate limiting VLAN group. You can enter the individual VLAN IDs or a range of VLAN IDs.

3. Create a policy for the VLAN group and apply it to the interface you want. Enter commands such as the following.

```
NetIron(config)# interface ethernet 1/1
NetIron(config-if-1/1)# rate-limit input group 10 500000000 750000000
```

These commands configure a traffic policing policy that limits the average rate of all inbound traffic on port 1/1 from vlan group VlanGroupA. This policy limits packets from VlanGroupA to an average rate of 500 Mbps with a maximum burst size of 750 Mbits on port 1/1. VLAN Group based traffic policing is only available for inbound ports.

Syntax: [no] rate-limit input group <*vlan-group-id*> **[priority** <*queue-num*>**]** **[**<*average-rate*> <*maximum-burst*> **| policy-map** <*map-name*> **]**

The **input** parameter applies the policy to traffic on inbound ports.

The **priority** parameter specifies an 802.1p value in the <*queue-num*> variable that is used to identify packets that will be traffic policed by this command. This parameter is optional.

The <*vlan-group-id*> parameter species the VLAN GroupID to which the policy applies.

The <*average-rate*> parameter specifies the maximum rate allowed on a port during a one-second interval. The software automatically adjusts the number you enter to the nearest multiple of 8,144 bps. Refer to the section "Average rate" on page 354 for more details. This command is only used when configuring rate limiting directly to a port as described in "Applying traffic policing parameters directly to a port" on page 354.

The <*maximum-burst*> parameter specifies the extra Mbits above the average-rate that traffic can have. Refer to the section "Maximum burst" on page 354 for more details. This command is only used when configuring rate limiting directly to a port as described in "Applying traffic policing parameters directly to a port" on page 354.

The **policy-map** parameter specifies the policy map named in the <*policy-map*> variable to be used to provide parameters for rate limiting the VLAN specified. This command is only used when configuring traffic policing to a port using a policy map as described in "Applying traffic policing parameters using a policy map" on page 355.

Configuring a port and ACL-based rate limiting

You can use standard or extended IP ACLs for port-and-ACL-based rate limiting:

- Standard IP ACLs match traffic based on source IP address information.
- Extended ACLs match traffic based on source and destination IP addresses and IP protocol information. Extended ACLs for TCP and UDP protocol must also match on source and destination IP addresses and TCP or UDP protocol information.
- You can bind multiple rate limiting policies to a single port. However, once a matching ACL clause is found for a packet, the device does not evaluate subsequent clauses in that rate limiting ACL and subsequent rate limiting ACLs.

- You can apply an ACL ID to a port-and-ACL-based traffic policing policy even before you define the ACL. The traffic policing policy does not take effect until the ACL is defined.
- It is not necessary to remove an ACL from a port-and-ACL-based rate limiting policy before deleting the ACL.
- Layer 2 ACL rate limiting is supported.

Port-and-ACL-based traffic policing is supported for traffic on inbound and outbound ports. To configure port-and-ACL-based traffic policing policies, enter commands such as the following.

```
NetIron(config)#access-list 50 permit host 1.1.1.2
NetIron(config)#access-list 50 deny host 1.1.1.3
NetIron(config)#access-list 60 permit host 2.2.2.3
NetIron(config-if-1/1)# rate-limit input access-group 50 priority q1 500000000
750000000
NetIron(config-if-1/1)# rate-limit input access-group 60 100000000 200000000
```

These commands first configure access-list groups that contain the ACLs that will be used in the traffic policing policy. Use the **permit** condition for traffic that will be traffic policed. Traffic that match the **deny** condition are not subject to traffic policing.

Next, the commands configure two traffic policing policies on port 1/1. The policies limit the average rate of all inbound IP traffic that match the permit rules of ACLs 50 and 60. The first policy limits the rate of all permitted IP traffic with a priority queue value of q1 from host 1.1.1.2 to an average rate of 500 Mbps with a maximum burst size of 750 Mbits. Rate of all traffic from host 1.1.1.3 is not subject to rate limiting since it is denied by ACL 50; it is merely forwarded on the port.

The second policy limits the rate of all IP traffic from host 2.2.2.3 to an average rate of 100 Mbps with a maximum burst size of 200 Mbits.

All IP traffic that does not match ACLs 50 and 60 are not subject to traffic policing.

Syntax: [no] **rate-limit** [**input** | **output**] [**vrf** <*vrf-name*>] **access-group** <*group-number*> [**priority** <*queue-num*>] [<*average-rate*> <*maximum-burst*> | **policy-map** <*map-name*>]

The **input** parameter applies the policy to traffic on inbound ports.

The **output** parameter applies the policy to traffic on outbound ports.

The **VRF** parameter specifies that the access-group will only apply to traffic within the VRF whose name is specified in the <*vrf-name*> variable. This feature is only supported on inbound traffic with Layer-3 ACLs.

The **access-group**, group-number> parameter specifies the group number to which the ACLs used in the policy belong.

NOTE
An ACL must exist in the configuration before it can take effect in a traffic policing policy.

The **priority** parameter specifies a priority queue value in the <*queue-num*> variable that is used to identify packets that will be traffic policed by this command. The possible values for this parameter are: q0, q1, q2, or q3. Multiple queues can be specified. This parameter is optional.

The <*average-rate*> parameter specifies the maximum rate allowed on a port during a one-second interval. The software automatically adjusts the number you enter to the nearest multiple of 8,144 bps. Refer to the section "Average rate" on page 354 for more details. This command is only used when configuring rate limiting directly to a port as described in "Applying traffic policing parameters directly to a port" on page 354

The <*maximum-burst*> parameter specifies the extra Mbits above the average-rate that traffic can have. Refer to the section "Maximum burst" on page 354 for more details. This command is only used when configuring traffic policing directly to a port as described in "Applying traffic policing parameters directly to a port" on page 354

The **policy-map** parameter specifies the policy map named in the <*policy-map*> variable to be used to provide parameters for traffic policing the VLAN specified. This command is only used when configuring traffic policing to a port using a policy map as described in "Applying traffic policing parameters using a policy map" on page 355.

Using ACLs for filtering in addition to rate limiting

When you use the ACL-based mode, the permit and deny conditions in an ACL you use in a rate limiting policy work as follows:

- **Permit** – The traffic is rate limited according to the other parameters in the rate limiting policy.
- **Deny** – The traffic is forwarded instead of dropped, by default.

You can configure the device to drop traffic that is denied by the ACL instead of forwarding the traffic, on an individual port basis.

NOTE
Once you configure an ACL-based rate limiting policy on a port, you cannot configure a regular (traffic filtering) ACL on the same port. To filter traffic, you must enable the strict ACL option.

To configure the device to drop traffic that is denied by a rate limiting ACL, enter the following command at the configuration level for the port.

```
NetIron(config-if-1/1)# rate-limit strict-acl
```

Syntax: [no] rate-limit strict-acl

Configuring for no priority-based traffic policing

By default, up to 990 different traffic policing policies can be applied to a single 10 GB Ethernet port. This combined with the 4 priorities utilizes 3960 rate limiting classes. You can configure a system-wide policy so that up to 3960 individual traffic policing policies can be applied to a single 10 GB Ethernet port.

To configure a PowerConnect Router to not allow priority-based traffic policing, enter commands such as the following at the interface level.

```
NetIron(config)# qos-policy
NetIron(qos-policy)# no rate-limit internal-priority-based
```

Syntax: [no] rate-limit internal-priority-based

If this command is implemented, the number of different rate limiting policies that can be applied to a single port is increased from 990 to 3960.

Configuring rate limiting for Copied-CPU-bound traffic

A new feature was added that allows you to limit the rate of Copied-CPU-bound packets from applications such as sFlow, ACL logging, RPF logging, and source MAC address learning (with known destination address). This feature can be configured as described in this section

The following command assigns a rate limit of 200,000,000 bps and a priority queue of 0 to copied-CPU-bound incoming traffic on PPCR 1 though its assignment on port 3/2.

```
NetIron(config)# rl-cpu-copy 0 200000000 ethernet 3/2
```

Syntax: rl-cpu-copy <*priority-number*> <*limit-rate*> **ethernet** <*slot/port*> **[to ethernet** <*slot/port*> **]**

The <*priority-number*> variable specifies the CPU-bound traffic priority queue to apply the rate limiting. This can be a value from 0 to 7.

The <*limit-rate*> variable specifies the limiting rate for the specified CPU-bound traffic priority queue. Acceptable values are from 1 to 300000000 bps. The default rate for all is 300,000,000 bps.

The <*slot/port*> variable specifies the port that you want to apply copied-CPU-bound rate limiting to. You can apply the command to a range of ports using the **to ethernet** <*slot/port*> option. When you assign a port, the command applies to all ports that are associated with the same packet processor (PPCR). Table 72 describes the ports that are associated a packet processor.

TABLE 72 Ports per packet processor

Interface module	Ports Per Packet Processor (PPCR)	
	PPCR1	PPCR2
4 X 10 Gbps	1 - 2	3 - 4
20 X 1 Gbps	1 - 20	

You can display the **rl-cpu-copy** configuration displayed previously using the following command.

```
NetIron# show rl-cpu-copy
Rate shaping configuration on CPU Copy priority queues
priority 0 200000000 ethernet 3/1 to 3/20
```

Notice that although the command was only executed for port 3/2, it applies to all the ports attached to the same PPCR. In this case ports 3/1 to 3/20.

Syntax: show rl-cpu-copy

Displaying rate limiting policies

Use one of the following commands to view the rate limiting policies that have been configured:

- **show rate limit counters** – Displays accounting information for rate limit usage.
- **show rate limit group** – Displays the VLANs that are in the specified group.
- **show rate limit** – Displays rate limiting policies implemented per interface.
- **show policy map** – Displays rate limiting policies implemented in the configured policy maps.

You can configure an PowerConnect router to exclude the 20-byte per-packet Ethernet overhead from Traffic Policing byte accounting. This can be done by configuring the **vlan-counter exclude-overhead** command.

Displaying accounting information for rate limit usage

To display accounting information for rate limit usage, enter the following command.

```
NetIron# show rate-limit counters
```

Syntax: show rate-limit counters [interface slot/port]

The **interface slot/port** option allows you to get accounting information for a specified interface only.

Output such as the following will display.

```
NetIron# show rate-limit counters
interface e 2/1
 rate-limit input access-group 400 999993616 1000000000
  Fwd:        0                       Drop:  0 bytes
  Re-mark:    0                       Total: 0 bytes
```

This display shows the following information.

TABLE 73 Rate limit counters parameters

This field...	Displays...
Interface	The interface that rate limit accounting information is being displayed for.
rate-limit input	A rate limit configuration that defines rate limit policy for inbound traffic on the defined interface.
Fwd	The traffic in bytes that has been forwarded from this interface as a result of this rate limit policy since the router was started up or the counter has been reset.
Drop	The traffic in bytes that has been dropped from this interface as a result of the defined rate limit policy since the router was started up or the counter has been reset.
Re-mark	The number of packets whose priority have been remarked as a result of exceeding the bandwidth available in the CIR bucket for this rate limit policy.
Total	The total traffic in bytes that has been carried on this interface for the defined rate limit policy since the router was started up or the counter has been reset.

Monitoring rate limit usage by SNMP

Accounting information for rate limit usage can also be monitored by SNMP. The agAclAccntTable supports the following objects, which map to the rate limit usage counters.

agAclAccntRaclDropCnt: drop counters

agAclAccntRaclFwdCnt: fwd counters

agAclAccntRaclRemarkCnt: re-mark counters

agAclAccntRaclTotalCnt: total counters

For detailed information, please refer to the “Filtering Traffic” chapter of the *Fabric OS MIB Reference*.

Among other applications, this accounting feature allows per-port VLAN statistics in the inbound or outbound direction to be extracted by means of SNMP. This can be achieved by adding ACL filters for the monitored VLAN on the appropriate port. This accounting feature works for all modules of the NetIron MLX platform. For modules that do not support extended VLAN statistics, this feature provides a means of extracting per-port VLAN statistics.

Resetting the rate limit counters

You can reset all of the rate limit counters using the following command.

```
NetIron# clear rate-limit counters
```

Syntax: clear rate-limit counters [interface]

The **interface** variable specifies an interface that you want to clear the rate limit counters for. If you do not specify an interface, all rate limit counters on the router will be reset.

Displaying information about rate limit VLAN groups

To display information about rate limit VLAN groups, enter the following command.

```
NetIron# show rate-limit group
```

Syntax: show rate-limit group

Output such as the following will display

```
rl-vlan-group 1
 vlan 10 to 15
```

This display shows the following information.

TABLE 74 Rate limit VLAN group parameters

This field...	Displays...
rl-vlan-group	The VLAN group whose contents are displayed.
vlan	VLANs contained in the VLAN group specified.

Displaying rate limit policies per interface

To display information about rate limit policies that are configured per interface, enter the following command.

```
NetIron# show rate-limit
```

Syntax: show rate-limit

Output such as the following will display.

```
NetIron(config-if-e10000-1/1)#show rate-limit

interface e 1/1
 rate-limit input 959904 2000000
 rate-limit output 2986368 2000000
```

This display shows the following information.

TABLE 75 Rate limit interface parameters

This field...	Displays...
rate-limit input	The average-rate and maximum burst rate configured for inbound traffic on the specified interface.
rate-limit output	The average-rate and maximum burst rate configured for outbound traffic on the specified interface.

Displaying rate limit policies configured in policy maps

To display information about rate limit policy maps, enter the following command.

```
NetIron# show policy-map
```

Syntax: show policy-map [map-name]

The <*map-name*> variable limits the display of policy map configuration information to the map specified. If this variable is not used, configuration information will be displayed for all policy maps configured on the router.

Output such as the following will display.

```
NetIron(config-policymap pmap1)#show policy-map

policy-map pmap1
  cir 106656       bps cbs 24000        bytes
  eir 53328        bps ebs 20000        bytes
  excess-priority 2 excess-dscp 43

policy-map pmap2
  cir 106656       bps cbs 24000        bytes
  eir 53328        bps ebs 30000        bytes
  excess-priority 1 excess-dscp 30
```

This display shows the following information.

TABLE 76 Rate limit policy map parameters

This field...	Displays...
policy-map	The name of the policy map whose configuration is being displayed
cir	The value of the Committed Information Rate (CIR) configured for this policy map. Possible values are: 1 - 10000000000 bps.
cbs	The value of the Committed Burst Size (CBS) configured for this policy map. Possible values are: 1250 - 1250000000 bytes.
eir	The value of the Excess Information Rate (EIR) configured for this policy map. Possible values are: 1 - 10000000000 bps.
ebs	The value of the Excess Burst Size (EBS) configured for this policy map. Possible values are: 1250 - 1250000000 bytes.
excess-priority	The priority queue that traffic whose bandwidth requirements exceeds what is available in the CIR bucket and is sent to the EIR bucket is set to. Possible values are 0-3.
excess-dscp	The priority queue that traffic whose bandwidth requirements exceeds what is available in the CIR bucket and is sent to the EIR bucket is set to. Possible values are 0-63.

Layer 2 ACL-based rate limiting

Layer 2 ACL-based rate limiting enables devices to limit the rate of incoming traffic in hardware, without CPU intervention. Rate limiting in hardware enables the device to manage bandwidth at line-rate speed.

In general, Layer 2 ACL-based rate limiting works along the same lines as hardware-based rate limiting feature. All the rules and regulations that apply to hardware-based rate limiting also apply to this feature.

Configuration rules and notes

- You can apply Layer 2 ACL-based rate limiting on a physical port. You cannot apply it to a virtual interface or a LAG port.
- You cannot use IPv4 ACL-based filtering and IPv4 Layer 2 ACL-based rate limiting on the same port. You can, however, configure one port on the device to use IP ACLs and another port on the same device to use Layer 2 ACL-based rate limiting.
- You cannot use IPv4 ACL-based rate limiting and IPv4 Layer 2 ACL-based rate limiting on the same port. You can, however, configure one port on the device to use IPv4 ACL-base rate limitng and another port on the same device to use Layer 2 ACL-based rate limiting.
- You can bind multiple rate limiting policies to a single port. However, once a matching ACL clause is found for a packet, the device does not evaluate subsequent clauses in that rate limiting ACL and subsequent rate limiting ACLs.
- Only number ACLs support rate limiting
- Layer 2 rate limiting ACLs will function with vlan-cpu-protection, broadcast and multicast limiting features. If incoming traffic matches an inbound Layer 2 rate limiting ACL, it is first rate-limited based on the policy. If packets are not dropped due to rate limiting, they are forwarded either to the CPU or flooded in the VLAN according to the vlan-cpu-protection feature.
- The broadcast and multicast packet limiting feature limits packets in the CPU, while the Layer 2 ACL RL is a network processing (NP) RL feature. Packets are first subjected to the Layer 2 ACL RL at the NP. Once packets are forwarded to CPU, the broadcast and multicast limiting feature begins functioning and packets may be dropped in the CPU if the rate exceeds the limit.

Editing a Layer 2 ACL Table

You can make changes to the Layer 2 ACL table definitions without unbinding and rebinding the rate limit policy. For example, you can add a new clause to the ACL table, delete a clause from the table, or delete the ACL table that is used by a rate limit policy.

Define rate limiting parameters

To define rate limiting parameters, enter commands such as the following:

```
NetIron(config)#policy-map map1
NetIron(config-policymap map1)#cir 1000000 cbs 2000000 eir 1000000 ebs 2000000
excess-dp 2
```

Binding Layer 2 ACL-based rate limiting policy to a port

To bind an Layer 2 ACL based rate-limiting policy on a specific port, enter commands such as the following:

```
NetIron(config-policymap map1)#int eth 14/1
NetIron(config-if-e10000-14/1)# rate-limit input access-group 400 policy-map map1
```

Syntax: [no}rate-limit [input|output] access-group <num> policy-map <map-name>

Specifying rate limiting parameters without a policy map

To specify rate-limiting without using a policy map, enter a command such as the following:

```
NetIron(config-if-e10000-14/1)# rate-limit input access-group 400 49999998416
75000000000
```

Syntax: [no] rate-limit [input|output] access-group <acl-id> <average-rate> <maximum-burst>

The <acl-id> for Layer 2 ACLs can range from 400 to 499.

The <average-rate> is the maximum number of bits the policy allows during one second.

The <maximum-burst> parameter specifies the extra bits above the average-rate that traffic can have. Refer to the section "Maximum burst" on page 354 for more details. This command is only used when configuring traffic policing directly to a port as described in "Applying traffic policing parameters directly to a port" on page 354.

Display accounting

To display access list accounting, enter a command such as the following.

```
PowerConnect#show access-list accounting eth 14/1 in rate-limit
Collecting L2 ACL accounting for 400 on port 14/1  ...  Completed successfully.
RL ACL Accounting Information:
Inbound: ACL 400
    0:   permit 0000.0000.0021 ffff.ffff.ffff any any etype any
       Hit count: (1 sec)                  0   (1 min)                  0
                  (5 min)                  0   (accum)                  0
```

Rate limiting protocol traffic using Layer 2 inbound ACLs

Using interface level Layer 2 inbound ACLs, you can rate limit the following types of protocol traffic by explicitly configuring a filter to match the traffic:

- STP/RSTP/BPDU
- MRP
- VSRP
- LACP
- GARP
- UDLP

To rate-limit all such control traffic enter commands such as the following:

```
PowerConnect(config)#access-list 402 permit any 0180.c200.0000 ffff.ffff.ffff any
etype any
PowerConnect(config)#access-list 402 permit any 0304.8000.0000 ffff.ffff.ffff any
etype any
PowerConnect(config)#access-list 402 permit any 0304.8000.0100 ffff.ffff.ff00 any
etype any
PowerConnect(config)#access-list 402 permit any 0180.c200.0002 ffff.ffff.ffff any
etype any
PowerConnect(config)#access-list 402 permit any 0180.c200.0020 ffff.ffff.fff0 any
etype any
```

```
PowerConnect(config)#access-list 402 permit any 00e0.5200.0000 ffff.ffff.ffff any
etype any
PowerConnect(config)#access-list 402 deny any any any etype any
```

Table 77 lists the protocols and their corresponding filters.

TABLE 77 Filters for protocols

Protocol	Filter
STP/RSTP/BPDU	access-list 402 permit any 0180.c200.0000 ffff.ffff.ffff any etype any
MRP	access-list 402 permit any 0304.8000.0000 ffff.ffff.ffff any etype any
VSRP	access-list 402 permit any 0304.8000.0100 ffff.ffff.ff00 any etype any
LACP	access-list 402 permit any 0180.c200.0002 ffff.ffff.ffff any etype any
GARP	access-list 402 permit any 0180.c200.0020 ffff.ffff.fff0 any etype any
UDLP	access-list 402 permit any 00e0.5200.0000 ffff.ffff.ffff any etype any

NOTE
The filters must have the specific destination MAC address as shown above in the configuration. You can filter all protocols as shown in the previous configuration example above, or only specific protocols.

Example of Layer 2 ACL to rate limit broadcast traffic

To define an ACL that rate limits broadcast traffic and forwards all other traffic without rate limiting, enter commands such the following:

```
NetIron(config)#access-list 411 permit any ffff.ffff.ffff ffff.ffff.ffff
NetIron(config)#access-list 411 deny any any
```

To bind an ACL that rate limits broadcast traffic and forwards all other traffic without rate limiting, enter commands such the following

```
NetIron(config)#int eth 14/1
NetIron(config-if-e10000-14/1)#rate-limit in access-gr 411 8144 100
```

Rate limiting ARP packets

You can limit the rate of ARP traffic that requires CPU processing on PowerConnect devices, such as ARP request traffic, and ARP response addressed to the router. The feature is set globally and applies to all ARP traffic received at the device. With this feature you can apply a defined policy map to all ARP traffic bound for the CPU.

When the **vlan-cpu-protection** command is configured, ARP request packets are switched within a VLAN by the hardware and thus cannot be rate-limited by the **ip rate limit arp policy-map** command. To limit the rate of ARP packets that are forwarded by hardware, use interface-level, layer-2 inbound ACLs with the "etype arp" option.

Configuring rate limiting of ARP packets

To rate limit ARP packets bound for the CPU using a policy map named “limitarp”, enter the following command.

```
NetIron(config)# ip rate-limit arp policy-map limitarp
```

Syntax: [no] ip rate-limit arp policy-map <map-name>

The <map-name> variable is the name of the policy map to be used to provide parameters for rate limiting CPU-bound ARP packets. If the policy map specified has not been defined, the rate limit values are initialized to the line rate values.

Displaying statistics for ARP rate limiting

You can display ARP Rate Limiting Statistics using the following command.

```
NetIron# show rate-limit arp
 Fwd:        1865392                Drop:  867731400 bytes
 Re-mark:    1864800                Total: 871461592 bytes
```

Syntax: show rate-limit arp

This display shows the following information.

TABLE 78 Rate limit ARP display parameters

Parameter	Description
Fwd	The ARP traffic in bytes that has been sent to the CPU as a result of the ARP rate limit policy since the router was started up or the counter was reset.
Drop	The ARP traffic in bytes that has been dropped as a result of the ARP rate limit policy since the router was started up or the counter was reset.
Re-mark	The ARP traffic in bytes whose priority have been remarked as a result of exceed the bandwidth available in the CIR bucket for the ARP rate limit policy since the router was started up or the counter was reset.
Total	The total ARP traffic in bytes that has been subjected to the ARP rate limit policy since the router was started up or the counter was reset.

Clearing Statistics for ARP Rate Limiting

You can clear ARP Rate Limiting Statistics using the following command:

```
NetIron# clear rate-limit arp
```

Syntax: clear rate-limit arp

Configuring Spanning Tree Protocol 11

Overview

The following STP features are supported by NetIron MLX Series devices.

- IEEE 802.1D Spanning Tree Protocol (STP)
- STP per VLAN
- STP Fast Forwarding
- STP Enable or Disable per Port or VLAN
- Root Guard
- BPDU Guard
- IEEE Single Spanning Tree (SSTP)
- SuperSpan
- PVST or PVST+ Compatibility
- 802.1s Multiple Spanning Tree Protocol
- STP support under an ESI with support for B-VLANs, S-VLANs and C-VLANs

A user can configure ESIs in the process of configuring Provider Bridging and Provider Backbone Bridging. By default, a device has a "default ESI" configured in which VLANs 1- 4090 exist. This chapter refers to configuration and use of Spanning Tree Protocols under the default ESI.

IEEE 802.1D Spanning Tree Protocol (STP)

The PowerConnect router supports Spanning Tree Protocol (STP) as described in the IEEE 802.10-1998 specification. STP eliminates Layer 2 loops in networks, by selectively blocking some ports and allowing other ports to forward traffic, based on configurable bridge and port parameters. STP also ensures that the least cost path is taken when multiple paths exist between ports or VLANs. If the selected path fails, STP searches for and then establishes an alternate path to prevent or limit retransmission of data.

Enabling or disabling STP

STP is disabled by default on the PowerConnect. Thus, new VLANs you configure on the PowerConnect have STP disabled by default. Table 79 lists the default STP states for the PowerConnect

TABLE 79 Default STP states

Device type	Default STP type	Default STP state	Default STP state of new VLANs
PowerConnect	Dell's multiple instances of spanning tree	Disabled	Disabled

By default, each VLAN on a PowerConnect runs a separate spanning tree instance. Each PowerConnect has one VLAN (VLAN 1) by default that contains all of its ports. However, if you configure additional port-based VLANs on a PowerConnect, then each of those VLANs on which STP is enabled and VLAN 1 all run separate spanning trees.

You can enable or disable STP on the following levels:

- **Globally** – Affects all VLANs on the PowerConnect.
- **Individual VLAN** – Affects all ports within the specified VLAN. When you enable or disable STP within a VLAN, the setting overrides the global setting. Thus, you can enable STP for the ports within a VLAN even when STP is globally disabled, or disable the ports within a port-based VLAN when STP is globally enabled.
- **Individual port** – Affects only the individual port. However, if you change the STP state of the primary port in a LAG group, the change affects all ports in the LAG group.

Enabling or disabling STP globally

Use the following methods to enable or disable STP on the PowerConnect on which you have not configured VLANs.

NOTE
When you configure a VLAN, the VLAN inherits the global STP settings. However, once you begin to define a VLAN, you can no longer configure standard STP parameters globally using the CLI. From that point on, you can configure STP only within individual VLANs.

NOTE
Reloading the PowerConnect switch with global STP enabled can display error on boot-up (error - no more stp instances available) if the number of vlans in the configuration are more than configured **system-max** for STP instances. The error message has no effect on the functionality.

When configuring spanning- tree at the global CLI level, the following message will prompt you to enter "y" for yes or "n" for no to change the spanning-tree behavior at the global level:

```
NetIron(config)#spanning-tree
This will change the spanning-tree behavior at the global level.
Are you sure? (enter 'y' or 'n'): y
```

Enter 'y' to change the spanning-tree behavior. Enter 'n' to make no change to the spanning-tree configuration at the global level.

This command enables a separate spanning tree in each VLAN, including the default VLAN.

Syntax: [no] **spanning-tree**

Enabling or disabling STP on a VLAN

Use the following procedure to disable or enable STP on a PowerConnect on which you have configured a VLAN. Changing the STP state in a VLAN affects only that VLAN.

To enable STP for all ports in a port-based VLAN, enter commands such as the following.

```
NetIron(config)# vlan 10
NetIron(config-vlan-10)# spanning-tree

that there is no effect on the functionality due to this error message
```

Syntax: [no] spanning-tree

Enabling or disabling STP on a port

Use the following procedure to disable or enable STP on an individual port.

NOTE
If you change the STP state of the primary port in a LAG group, the change affects all ports in the LAG group.

To enable STP on an individual port, enter commands such as the following.

```
NetIron(config)# interface 1/1
NetIron(config-if-e1000-1/1)# spanning-tree
```

Syntax: [no] spanning-tree

Default STP bridge and port parameters

Table 80 lists the default STP bridge parameters. The bridge parameters affect the entire spanning tree. If you are using MSTP, the parameters affect the VLAN. If you are using SSTP, the parameters affect all VLANs that are members of the single spanning tree.

NOTE
STP information is specific to a VLAN, and the MultiService IronWare software uses the CONTROL VLAN to get the STP information for the all MIBs under dot1dStp and dot1DStpPortTable. Due to the limitation of the MIBs, information of per STP implementation of every specific VLAN is not displayed.

TABLE 80 Default STP bridge parameters

Parameter	Description	Default and valid values
Forward Delay	The period of time a bridge will wait (the listen and learn period) before beginning to forward data packets.	15 seconds Possible values: 4 – 30 seconds
Maximum Age	The interval a bridge will wait for a hello packet from the root bridge before initiating a topology change.	20 seconds Possible values: 6 – 40 seconds
Hello Time	The interval of time between each configuration BPDU sent by the root bridge.	2 seconds Possible values: 1 – 10 seconds
Priority	A parameter used to identify the root bridge in a spanning tree (instance of STP). The bridge with the lowest value has the highest priority and is the root. A higher numerical value means a lower priority; thus, the highest priority is 0.	32768 Possible values: 0 – 65535

NOTE
If you plan to change STP bridge timers, it is recommended that you stay within the following ranges, from section 8.10.2 of the IEEE specification:

– 2 * (forward_delay -1) >= max_age
– max_age >= 2 * (hello_time +1)

Table 81 lists the default STP port parameters. The port parameters affect individual ports and are separately configurable on each port.

TABLE 81 Default STP port parameters

Parameter	Description	Default and valid values
Priority	The preference that STP gives this port relative to other ports for forwarding traffic out of the spanning tree. A higher numerical value means a lower priority; thus, the highest priority is 8.	128 Possible values: 8 – 252, configurable in increments of 4
Path Cost	The cost of using the port to reach the root bridge. When selecting among multiple links to the root bridge, STP chooses the link with the lowest path cost and blocks the other paths. Each port type has its own default STP path cost.	10 Mbps – 100 100 Mbps – 19 Gigabit – 4 10 Gigabit – 2 Possible values are 1– 65535

Changing STP bridge parameters

To change a PowerConnect's STP bridge priority to the highest value, so as to make the PowerConnect the root bridge, enter the following command.

```
NetIron(config)# vlan 20
NetIron(config-vlan-20)# spanning-tree priority 0
```

To make this change in the default VLAN, enter the following commands.

```
NetIron(config)# vlan 1
NetIron(config-vlan-1)# spanning-tree priority 0
```

Syntax: **[no] spanning-tree [forward-delay** <*value*>**] | [hello-time** <*value*>**] | [max-age** <*value*>**] | [priority** <*value*>**]**

You can specify some or all of the parameters on the same command line. For information on parameters, possible values and defaults, refer to Table 80 on page 373.

NOTE
The **hello-time** <*value*> parameter applies only when the device or VLAN is the root bridge for its spanning tree.

Changing STP port parameters

To change the path and priority costs for a port, enter commands such as the following.

```
NetIron(config)# vlan 10
NetIron(config-vlan-10)# spanning-tree ethernet 1/5 path-cost 15 priority 64
```

Syntax: **[no] spanning-tree ethernet** <*slot*>/<*portnum*> **path-cost** <*value*> **| priority** <*value*> **| disable | enable**

The **ethernet** <*slot*>/<*portnum*> parameter specifies the interface.

For descriptions of path cost and priority, their default and possible values, refer to Table 81 on page 374. If you enter a priority value that is not divisible by four, the software rounds it to the nearest value.

The **disable | enable** parameter disables or re-enables STP on the port. The STP state change affects only this VLAN. The port's STP state in other VLANs is not changed.

Root Guard

In this release, a new security feature has been added that allows a port to run STP but not allow the connected device to become the Root. The Root Guard feature provides a way to enforce the root bridge placement in the network and allows STP to interoperate with user network bridges while still maintaining the bridged network topology that the administrator requires. Errors are triggered if any change from the root bridge placement is detected.

NOTE
The feature is also available for MSTP and RSTP.

When Root Guard is enabled on a port, it keeps the port in designated FORWARDING state. If the port receives a superior BPDU, which is a Root Guard violation, it sets the port into BLOCKING state and triggers a Syslog message and an SNMP trap. No further traffic will be forwarded on this port. This allows the bridge to prevent traffic from being forwarded on ports connected to rogue or misconfigured STP or RSTP bridges.

Root Guard should be configured on all ports where the root bridge should not appear. In this way, the core bridged network can be cut off from the user network by establishing a protective perimeter around it.

Once the port stops receiving superior BPDUs, Root Guard will automatically set the port back to a FORWARDING state after the timeout period has expired.

NOTE
Root Guard may prevent network connectivity if improperly configured. It needs to be configured on the perimeter of the network rather than the core. Also, Root Guard should be configured only on the primary port of a LAG. If a port configured with Root Guard is made a secondary port, the LAG deployment will be vetoed.

Enabling Root Guard

Root Guard is configured on a per interfaces basis. To enable Root Guard, enter a command such as the following.

```
NetIron(config)# interface ethernet 5/5
NetIron(config-if-e10000-5/5) spanning-tree root-protect
```

Syntax: [no] spanning-tree root-protect

Enter the **no** form of the command to disable Root Guard on the port.

Setting the Root Guard timeout period

To configure the Root Guard timeout period globally, enter a command such as the following.

```
NetIron(config)# spanning-tree root-protect timeout 120
```

Syntax: [no] spanning-tree root-protect timeout <*timeout in seconds*>

The **timeout in seconds** parameter allows you to set the timeout period. The timeout period may be configured to anything between 5 and 600 seconds. Default is 30 seconds.

Checking if Root Guard is configured

To determine if Root Guard is configured, enter the following command.

```
NetIron#show interface ethernet 1/4
10GigabitEthernet1/4 is up, line protocol is up
  STP Root Guard is enabled, STP BPDU Guard is disabled
```

Syntax: show interface ethernet <*slot*>/<*port*>

Displaying the Root Guard state

To display the Root Guard state, enter the **show spanning-tree root-protect** command.

```
NetIron#show spanning-tree root-protect
Port VLAN Current State

13/6 3 Consistent state
13/9 2 Inconsistent state (29 seconds left on timer)
```

Syntax: show spanning-tree root-protect

Reconfiguring the timeout period

The timeout period timer is activated whenever a port encounters a superior BPDU, which then results in a Root Guard violation. If the timeout period is reconfigured while a timer is in use, the timer on that port is set to the new timeout period, minus the time elapsed since the superior BPDU was received.

For example, the original timeout period on a device was configured for 60 seconds. The port encounters a superior BPDU and the timer starts. Issuing a **show span root-protect** CLI command displays the following information.

```
NetIron(config)#show span root-protect

Port    VLAN  Current State

1/4     1     Inconsistent state (56 seconds left on timer)
```

While the timer is in use, the timeout period is changed to 30 seconds through the issue of the following command.

```
NetIron(config)# spanning-tree root-protect timeout 30
```

The timer continues the countdown and minus the time that have already elapsed (about 10 seconds) since the superior BPDU was detected. Issuing a **show span root-protect** CLI command displays the following information.

```
NetIron(config)# show span root-protect

Port    VLAN  Current State

1/4     1     Inconsistent state (20 seconds left on timer)
```

Next, the timeout period is increased to 120 seconds.

```
NetIron(config)# spanning-tree root-protect timeout 120
```

Since the timer has not expired, it continues the countdown. The remaining time left is adjusted by the time that has already elapsed (about 18 seconds) since the superior BPDU was detected. Issuing a **show span root-protect** CLI command displays the following information.

```
NetIron(config)# show span root-protect

Port    VLAN  Current State

1/4     1     Inconsistent state (102 seconds left on timer)
```

Checking for Syslog messages

A Syslog message such as the following is generated after the Root Guard blocks a port.

```
Sep 9 18::39:27:I:STP: Root Guard Port 12/21, VLAN 10 inconsistent (Received
superior BPDU)
```

A Syslog message such as the following is generated after the Root Guard unblocks a port.

```
Sep 9 18::39:27:I:STP: Root Guard Port 12/21, VLAN 10 consistent (Timeout)
```

Checking for traps

The following SNMP traps are generated for Root Guard:

- snTrapStpRootGuardDetect is generated after the Root Guard blocks a port.
- snTrapStpRootGuardExpire is generated after a blocked port (due to Root Guard) goes back to a Forwarding state

Refer to the *IronWare MIB Reference* manual for details.

BPDU Guard

STP protection provides the ability to prohibit an end station from initiating or participating in an STP topology. The Bridge Protocol Data Units (BPDU) Guard is used to keep all active network topologies predictable.

NOTE
The feature is also available for MSTP and RSTP.

STP detects and eliminates logical loops in a redundant network by selectively blocking some data paths and allowing only some data paths to forward traffic.

In an STP environment, switches, end stations, and other Layer 2 devices use BPDUs to exchange information that STP will use to determine the best path for data flow. When a Layer 2 device is powered ON and connected to the network, or when a Layer 2 device goes down, it sends out an BPDU, triggering a topology change.

In some instances, it is unnecessary for a connected device, such as an end station, to initiate or participate in a topology change. In this case, you can enable the BPDU Guard feature on the Dell port to which the end station is connected. The BPDU Guard feature disables the connected device's ability to initiate or participate in an topology change, by dropping all BPDUs received from the connected device.

As an extended security measure, the administrator can disable a port if a BPDU is received on a port where BPDU Guard is configured. A Syslog message and SNMP trap are triggered when the port is disabled.

You can re-enable the disabled port from the CLI; however, make sure the offending BPDUs have stopped before re-enabling the port. Otherwise, the port will be disabled again the moment a new BPDU is received.

NOTE
BPDU Guard should be configured only on the primary port of a LAG. If a port configured with BPDU guard is made a secondary port, the LAG deployment will be vetoed.

Enabling BPDU Guard

You can enable BPDU Guard on a per-port basis.

To prevent an end station from initiating or participating in topology changes, enter the following command at the interface level of the CLI.

```
NetIron(config) interface ethe 2/1
NetIron(config-if-e1000-2/1)# spanning-tree protect
```

Syntax: [no] spanning-tree protect

This command causes the port to drop BPDUs sent from the device on the other end of the link.

Enter the **no** form of the command to disable BPDU Guard on the port and remove the **spanning-tree protect do-disable** feature if they are configured.

Enabling BPDU Guard and disabling a port that receives BPDUs

You can enable BPDU Guard on a port and at the same time configure a port to be disabled when it receives a BPDU. Enter the following commands.

```
NetIron(config) interface ethe 2/1
NetIron(config-if-e1000-2/1)#spanning-tree protect do-disable
```

Syntax: [no] spanning-tree protect do-disable

If both **spanning-tree protect** and **spanning-tree protect do-disable** are configured on an interface, **spanning-tree protect do-disable** takes precedence. This means that when the port receives a BPDU, the port will drop the BPDU and disable the port.

If you issue a **no spanning-tree protect do-disable** command, the port will be re-enabled and will no longer be disabled when it receives a BPDU. The following message is displayed when you enter the **no spanning-tree protect do-disable** command.

```
This command removes only "spanning-tree protect do-disable". To remove
"spanning-tree protect", please issue a separate command "no spanning-tree
protect".
```

Re-Enabling a port disabled due to BPDU guard

A port disabled by the **spanning-tree protect do-disable** command can be enabled by the following commands:

- Entering the **no spanning-tree protect do-disable** command.

- Entering the **spanning-tree protect re-enable** command. Make sure the offending BPDUs have stopped before issuing this command; otherwise, the port will be disabled again once it receives a new BPDU.

```
NetIron(config)# interface ethernet 1/4
NetIron(config-if-e10000-1/4)#spanning-tree protect re-enable
```

Syntax: [no] spanning-tree protect re-enable

Issuing the **spanning-tree protect re-enable** command does not remove the **spanning-tree protect do-disable** configuration on the port. If a new BPDU is received on the port, the port will be disabled again. To prevent this from happening, you can do one of the following:

- Remove the **spanning-tree protect do-disable** configuration by issuing the **no spanning-tree protect do-disable** command, followed by the **spanning-tree protect re-enable** command to re-enable the port.
- Remove the source of the offending BPDUs from the network.

There is no **no** form of this command.

Displaying BPDU Guard configuration

To determine if BPDU Guard is configured on the device, enter the following command.

```
NetIron#show spanning-tree protect

  protect   Show STP BPDU Guard information
NetIronr# show span protect
Port    Disable Port on BPDU Rx       Current Port State
1/1     No                            down
1/2     Yes                           down
1/3     No                            up
1/4     Yes                           up
```

Syntax: show spanning-tree protect

The command shows the following information.

TABLE 82 CLI display of show spanning-tree bp

This field...	Displays...
Port	The port on which BPDU Guard is configured
Disable Port on BPDU Rx	Indicates if **spanning-tree protect do-disable** is configured on the port: • Yes - **spanning-tree protect do-disable** is configured on the port. The BPDU will be dropped and the port will be disabled when it receives a BPDU. • No - **spanning-tree protect do-disable** is not configured. The BPDU will be dropped but the port will not be disabled.
Current Port State	Indicates if the port is currently UP or DOWN.

Determining if BPDU Guard is enabled

The **show interface** command displays the state of a port.

If BPDU Guard is disabled or has not been configured, the output shows the following information.

```
NetIron#show interface ethernet 1/4
10GigabitEthernet1/4 is up, line protocol is up
  STP Root Guard is disabled, STP BPDU Guard is disabled
```

If BPDU Guard has been enabled using the **spanning-tree protect** command, the output shows the following.

```
NetIron#show interface ethernet 1/4
10GigabitEthernet1/4 is up, line protocol is up
  STP Root Guard is disabled, STP BPDU Guard is enabled
```

If BPDU Guard is enabled using the **spanning-tree protect do-disable** command, the output shows.

```
NetIron#show interface ethernet 1/4
10GigabitEthernet1/4 is up, line protocol is up
  STP Root Guard is disabled, STP BPDU Guard is enabled with port to be disabled
on BPDU receive
```

Syntax: show interface ethernet <*slot*>/<*port*>

Checking for Syslog messages

When the **spanning-tree protect do-disable** command is issued, the port becomes disabled and the following Syslog messages are generated.

```
Sep 9 18::39:27:I:STP: BPDU Guard port 1/4 disable
Sep 9 18::39:27:I:System: Interface ethernet 1/4, state down - disabled
```

When the **spanning-tree protect re-enable** is issued to re-enable a port, the following Syslog messages are generated.

```
Sep 9 18:43:21:I:STP: BPDU Guard re-enabled on ports ethe 1/4
Sep 9 18:43:23:I:System: Interface ethernet 1/4, state up
```

Checking for traps

The following SNMP traps are generated for BPDU Guard:

- snTrapStpBPDUGuardDetect is generated when a port is disabled because **spanning-tree protect do-disable** on a port and that port received a BPDU and disabled the port.
- snTrapSTPBPDUGuardExpire is generated when a port that has been disabled due to a BPDU Guard violation is re-enabled using the **spanning-tree protect re-enable** command.

Refer to the *IronWare MIB Reference* manual for details.

Displaying STP information

You can display the following STP information:

- All the global and interface STP settings
- Detailed STP information for each interface
- STP state information for a VLAN
- STP state information for an individual interface

Displaying STP information for an entire device

To display STP information, enter the following command at any level of the CLI.

```
NetIron# show spanning-tree vlan 10

VLAN 10 - STP instance 1
------------------------------------------------------------------
STP Bridge Parameters:

Bridge           Bridge Bridge Bridge Hold  LastTopology Topology
Identifier       MaxAge Hello  FwdDly Time  Change       Change
hex              sec    sec    sec    sec   sec          cnt
8000000480a04000 20     2      15     1     0            0

RootBridge       RootPath  DesignatedBridge Root  Max Hel Fwd
Identifier       Cost      Identifier       Port  Age lo  Dly
hex                        hex                    sec sec sec
8000000480a04000 0         8000000480a04000 Root  20  2   15

STP Port Parameters:

Port  Prio Path      State      Designat- Designated       Designated
Num   rity Cost                ed Cost   Root             Bridge
1/3   128  4         DISABLED   0         0000000000000000 0000000000000000
1/13  128  4         DISABLED   0         0000000000000000 0000000000000000
```

Syntax: **show spanning-tree** [**vlan** <*vlan-id*>] | [**pvst-mode**] | [<*num*>] | [**detail** [**vlan** <*vlan-id*> [**ethernet** <*slot/port*>] [| **begin**<*expression*> | **exclude**<*expression*> | **include**<*expression*>]

The **vlan** <*vlan-id*> parameter displays STP information for the specified port-based VLAN.

The **pvst-mode** parameter displays STP information for the PowerConnect's Per VLAN Spanning Tree (PVST+) compatibility configuration. Refer to "PVST or PVST+ compatibility" on page 396.

The <*num*> parameter displays only the entries after the number you specify. For example, on a PowerConnect with three port-based VLANs, if you enter 1, then information for the second and third VLANs is displayed, but information for the first VLAN is not displayed. Information is displayed according to VLAN number, in ascending order. The entry number is not the same as the VLAN number. For example, if you have port-based VLANs 1, 10, and 2024, then the command output has three STP entries. To display information for VLANs 10 and 2024 only, enter **show spanning-tree 1**.

The **detail** parameter and its additional optional parameters display detailed information for individual ports. Refer to "Displaying detailed STP information for each interface" on page 384.

The **show spanning-tree** command shows the following information.

TABLE 83 CLI display of STP information

This field...	Displays...
Global STP Parameters	
VLAN ID	The port-based VLAN that contains this spanning tree and the number of STP instance on the VLAN. VLAN 1 is the default VLAN. If you have not configured port-based VLANs on this device, all STP information is for VLAN 1.
Bridge Parameters	

TABLE 83 CLI display of STP information (Continued)

This field...	Displays...
Bridge Identifier	The ID assigned by STP to this bridge for this spanning tree in hexadecimal. **NOTE:** If this address is the same as the Root ID, then this device or VLAN is the root bridge for its spanning tree.
Bridge MaxAge sec	The number of seconds this bridge waits for a hello message from the root bridge before deciding the root has become unavailable and performing a reconvergence.
Bridge Hello sec	The interval between each configuration BPDU sent by the bridge.
Bridge FwdDly sec	The number of seconds this bridge waits following a topology change and consequent reconvergence.
Hold Time sec	The minimum number of seconds that must elapse between transmissions of consecutive Configuration BPDUs on a port.
Last Topology Chang sec	The number of seconds since the last time a topology change occurred.
Topology Change cnt	The number of times the topology has changed since this device was reloaded.
Root Bridge Parameters	
Root Identifier	The ID assigned by STP to the root bridge for this spanning tree in hexadecimal.
Root Cost	The cumulative cost from this bridge to the root bridge. If this device is the root bridge, then the root cost is 0.
DesignatedBridge Identifier	The designated bridge to which the root port is connected. The designated bridge is the device that connects the network segment on the port to the root bridge.
Root Port	The port on this device that connects to the root bridge. If this device is the root bridge, then the value is “Root” instead of a port number.
Max Age sec	The number of seconds this root bridge waits for a hello message from the bridges before deciding a bridges has become unavailable and performing a reconvergence.
Hello sec	The interval between each configuration BPDU sent by the root bridge.
FwdDly sec	The number of seconds this root bridge waits following a topology change and consequent reconvergence.
Port STP Parameters	
Port Num	The port number.
Priority	The port’s STP priority. **NOTE:** If you configure this value, specify it in decimal format. Refer to “Changing STP port parameters” on page 374.
Path Cost	The port’s STP path cost.

TABLE 83 CLI display of STP information (Continued)

This field...	Displays...
State	The port's STP state. The state can be one of the following: • BLOCKING – STP has blocked Layer 2 traffic on this port to prevent a loop. The device or VLAN can reach the root bridge using another port, whose state is FORWARDING. When a port is in this state, the port does not transmit or receive user frames, but the port does continue to receive STP BPDUs. • DISABLED – The port is not participating in STP. This can occur when the port is disconnected or STP is disabled on the port. • FORWARDING – STP is allowing the port to send and receive frames. • LISTENING – STP is responding to a topology change and this port is listening for a BPDU from neighboring bridges in order to determine the new topology. No user frames are transmitted or received during this state. • LEARNING – The port has passed through the LISTENING state and will change to the BLOCKING or FORWARDING state, depending on the results of STP's reconvergence. The port does not transmit or receive user frames during this state. However, the device can learn the MAC addresses of frames that the port receives during this state and make corresponding entries in the MAC table.
Design Cost	The cost to the root bridge as advertised by the designated bridge that is connected to this port. If the designated bridge is the root bridge itself, then the cost is 0. The identity of the designated bridge is shown in the Design Bridge field.
Designated Root	The root bridge as recognized on this port. The value is the same as the root bridge ID listed in the Root ID field.
Designated Bridge	The bridge as recognized on this port.

Displaying detailed STP information for each interface

To display the detailed STP information, enter the following command at any level of the CLI.

```
NetIron# show spanning-tree detail vlan 10
VLAN 10 - STP instance 1
------------------------------------------------------------------------
STP Bridge Parameters:

Bridge identifier - 0x8000000480a04000
Root bridge - 0x8000000480a04000
Control ports - ethernet 1/3 ethernet 1/13
Active global timers - None

STP Port Parameters:

Port 1/3 - DISABLED
Port 1/13 - DISABLED

VLAN 20 - STP instance 2
------------------------------------------------------------------------
STP Bridge Parameters:

Bridge identifier - 0x8000000480a04000
Root bridge - 0x8000000480a04000
Control ports - ethernet 1/3 ethernet 1/13
Active global timers - None

STP Port Parameters:

Port 1/3 - DISABLED
Port 1/13 - DISABLED
```

If a port is disabled, the only information shown by this command is “DISABLED”. If a port is enabled, this display shows the following information.

Syntax: show spanning-tree detail [vlan <*vlan-id*> **[ethernet** <*slot/port*>**]]**

The **vlan** <*vlan-id*> parameter specifies a VLAN.

The **ethernet** <*slot*>/<*portnum*> parameter specifies an individual port within the VLAN (if specified).

The <*num*> parameter specifies the number of VLANs you want the CLI to skip before displaying detailed STP information. For example, if the PowerConnect has six VLANs configured (VLAN IDs 1, 2, 3, 99, 128, and 256) and you enter the command **show span detail 4**, detailed STP information is displayed for VLANs 128 and 256 only.

NOTE
If the configuration includes VLAN groups, the **show span detail** command displays the master VLANs of each group but not the member VLANs within the groups. However, the command does indicate that the VLAN is a master VLAN. The **show span detail vlan** <*vlan-id*> command displays the information for the VLAN even if it is a member VLAN. To list all the member VLANs within a VLAN group, enter the **show vlan-group** [<*group-id*>] command.

The **show spanning-tree detail** command shows the following information for each VLAN participating in the spanning tree.

TABLE 84 CLI display of detailed STP information for ports

This field...	Displays...
VLAN ID	The VLAN that contains the listed ports and the number of STP instances on this VLAN. The STP type can be one of the following: • Proprietary multiple Spanning Tree • IEEE 802.1Q Single Spanning Tree (SSTP) **NOTE:** If STP is disabled on a VLAN, the command displays the following message instead: "Spanning-tree of port-vlan <*vlan-id*> is disabled."
STP Bridge Parameters:	
Bridge identifier	The STP identity of this device.
Root	The ID assigned by STP to the root bridge for this spanning tree.
Control ports	The ports in the VLAN.
Active global timers	The global STP timers that are currently active, and their current values. The following timers can be listed: • Hello – The interval between Hello packets. This timer applies only to the root bridge. • Topology Change (TC) – The amount of time during which the topology change flag in Hello packets will be marked, indicating a topology change. This timer applies only to the root bridge. • Topology Change Notification (TCN) – The interval between Topology Change Notification packets sent by a non-root bridge toward the root bridge. This timer applies only to non-root bridges.
STP Port Parameters:	
Port number and STP state	The internal port number and the port's STP state. The internal port number is one of the following: • The port's interface number, if the port is the designated port for the LAN. • The interface number of the designated port from the received BPDU, if the interface is not the designated port for the LAN. The state can be one of the following: • BLOCKING – STP has blocked Layer 2 traffic on this port to prevent a loop. The device or VLAN can reach the root bridge using another port, whose state is FORWARDING. When a port is in this state, the port does not transmit or receive user frames, but the port does continue to receive STP BPDUs. • DISABLED – The port is not participating in STP. This can occur when the port is disconnected or STP is administratively disabled on the port. • FORWARDING – STP is allowing the port to send and receive frames. • LISTENING – STP is responding to a topology change and this port is listening for a BPDU from neighboring bridges in order to determine the new topology. No user frames are transmitted or received during this state. • LEARNING – The port has passed through the LISTENING state and will change to the BLOCKING or FORWARDING state, depending on the results of STP's reconvergence. The port does not transmit or receive user frames during this state. However, the device can learn the MAC addresses of frames that the port receives during this state and make corresponding entries in the MAC table. **NOTE:** If the state is DISABLED, no further STP information is displayed for the port.

IEEE Single Spanning Tree (SSTP)

By default, each port-based VLAN on the PowerConnect runs a separate spanning tree, which you can enable or disable on an individual VLAN basis.

Alternatively, you can configure the PowerConnect to run a single spanning tree across all of its ports and VLANs. The SSTP feature is especially useful for connecting a PowerConnect to third-party devices that run a single spanning tree in accordance with the 802.1q specification.

SSTP uses the same parameters, with the same value ranges and defaults, as the default STP supported on the PowerConnect. Refer to "Default STP bridge and port parameters" on page 373.

SSTP defaults

SSTP is disabled by default. When you enable the feature, all VLANs on which STP is enabled become members of a single spanning tree. All VLANs on which STP is disabled are excluded from the single spanning tree:

- To add a VLAN to the single spanning tree, enable STP on that VLAN.
- To remove a VLAN from the single spanning tree, disable STP on that VLAN.

When you enable SSTP, all the ports that are in port-based VLANs with STP enabled become members of a single spanning tree domain. Thus, the ports share a single BPDU broadcast domain. The PowerConnect places all the ports in a non-configurable VLAN, 4095, to implement the SSTP domain. However, this VLAN does not affect port membership in the port-based VLANs you have configured. Other broadcast traffic is still contained within the individual port-based VLANs. Therefore, you can use SSTP while still using your existing VLAN configurations without changing your network. In addition, SSTP does not affect 802.1q tagging. Tagged and untagged ports alike can be members of the single spanning tree domain.

NOTE
When SSTP is enabled, the BPDUs on tagged ports go out untagged.

If you disable SSTP, all VLANs that were members of the single spanning tree now do not run any form of spanning tree. Per VLAN STP can be enabled again using either global STP enable or the spanning-tree enable command under individual VLANs.

NOTE
If the PowerConnect has only one port-based VLAN (the default VLAN), then it is already running a single instance of STP. In this case, you do not need to enable SSTP. You need to enable SSTP only if the PowerConnect contains more than one port-based VLAN and you want all the ports to be in the same STP broadcast domain.

To configure the PowerConnect to run a single spanning tree, enter the following command at the global CONFIG level.

```
NetIron(config)# spanning-tree single
```

To change a global STP parameter, enter a command such as the following at the global CONFIG level.

```
NetIron(config) spanning-tree single priority 2
```

This command changes the STP priority for all ports to 2.

To change an STP parameter for a specific port, enter commands such as the following.

```
NetIron(config) spanning-tree single ethernet 1/1 priority 10
```

The commands shown above override the global setting for STP priority and set the priority to 10 for port 1/1.

Here is the syntax for the global STP parameters:

Syntax: **[no] spanning-tree single [forward-delay** <*value*>**]**
[hello-time <*value*>**] | [maximum-age** <*time*>**] | [priority** <*value*>**]**

Here is the syntax for the STP port parameters:

Syntax: **[no] spanning-tree single [ethernet** <*slot*>**/**<*portnum*> **path-cost** <*value*> **| priority** <*value*>**]**

For the parameter definitions and possible values, refer to "Default STP port parameters" on page 374.

NOTE
Both commands listed above are entered at the global CONFIG level.

Also, you can use the **rstp single** command to control the topology for VLANs. Refer to "Enabling or disabling RSTP on a single spanning tree" on page 443.

Displaying SSTP information

To verify that SSTP is in effect, enter the following commands at any level of the CLI.

```
NetIron(config)# show spanning-tree
VLAN 4095 - STP instance 0
------------------------------------------------------------------
STP Bridge Parameters:

Bridge           Bridge Bridge Bridge Hold  LastTopology Topology
Identifier       MaxAge Hello  FwdDly Time  Change       Change
hex              sec    sec    sec    sec   sec          cnt

For information on the command syntax, refer to "Displaying STP information" on page 380.

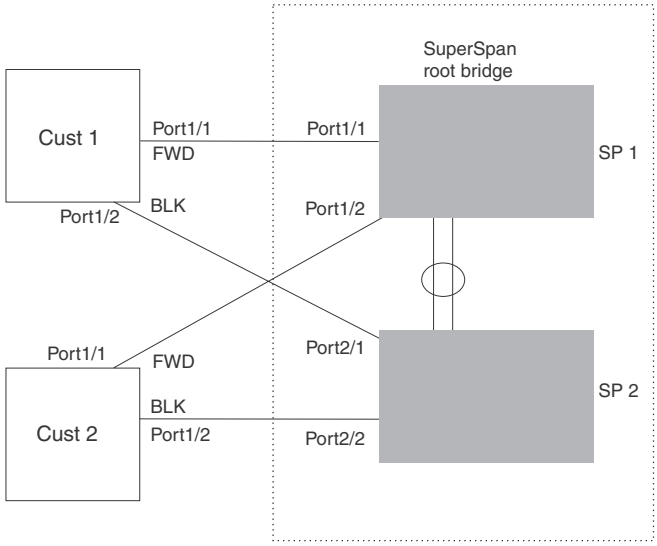
SuperSpan™

SuperSpan is a Dell STP enhancement that allows Service Providers (SPs) to use STP in both SP networks and customer networks. The SP devices are PowerConnect devices and are configured to tunnel each customers' STP BPDUs through the SP. From the customer's perspective, the SP network is a loop-free non-blocking device or network. The SP network behaves like a hub in the sense that the necessary blocking occurs in the customer network, not in the SP.

The interfaces that connect the SP to a customer's network are configured as SuperSpan boundary interfaces. Each SuperSpan boundary interface is configured with a customer ID, to uniquely identify the customer's network within SuperSpan.

Figure 20 shows an example SuperSpan implementation. In this example, an SP's network is connected to multiple customers. Each customer network is running its own instance of standard STP. The PowerConnect devices in the SP are running SuperSpan.

FIGURE 20 SuperSpan example



In this example, the SP network contains two devices that are running SuperSpan. The SP is connected to two customer networks. Each customer network is running its own instance of STP. SuperSpan prevents Layer 2 loops in the traffic flow with each customer while at the same time isolating each customer's traffic and spanning tree from the traffic and spanning trees of other customers. For example, the SP devices provide loop prevention for Customer 1 while ensuring that Customer 1's traffic is never forwarded to Customer 2. In this example, customer 1 has two interfaces to the SP network, ports 1/1 and 1/2 connected to SP 1. The SP network behaves like a non-blocking hub. BPDUs are tunneled through the network. To prevent a Layer 2 loop, customer 1's port 1/2 enters the blocking state.

Customer ID

SuperSpan uses a SuperSpan customer ID to uniquely identify and forward traffic for each customer. You assign the customer ID as part of the SuperSpan configuration of the PowerConnect devices in the SP. In Figure 20, the spanning trees of customer 1 and customer 2 do not interfere with one another because the SP network isolates each customer's spanning tree based on the SuperSpan customer IDs in the traffic.

BPDU forwarding

When the PowerConnect receives a customer's BPDU on a boundary interface, the PowerConnect changes the destination MAC address of the BPDU from the bridge group address (01-80-c2-00-00-00) as follows:

- The first byte (locally administered bit) is changed from 01 to 03, to indicate that the BPDU needs to be tunneled.
- The fourth and fifth bytes are changed to the customer STP ID specified on the boundary interface.

For example, if the customer's STP ID is 1, the destination MAC address of the customer's BPDUs is changed to the following: 03-80-c2-00-01-00.

Each PowerConnect that is configured for SuperSpan forwards the BPDU using the changed destination MAC address. At the other end of the tunnel, the PowerConnect connected to the customer's network changes the destination MAC address back to the bridge group address (01-80-c2-00-00-00).

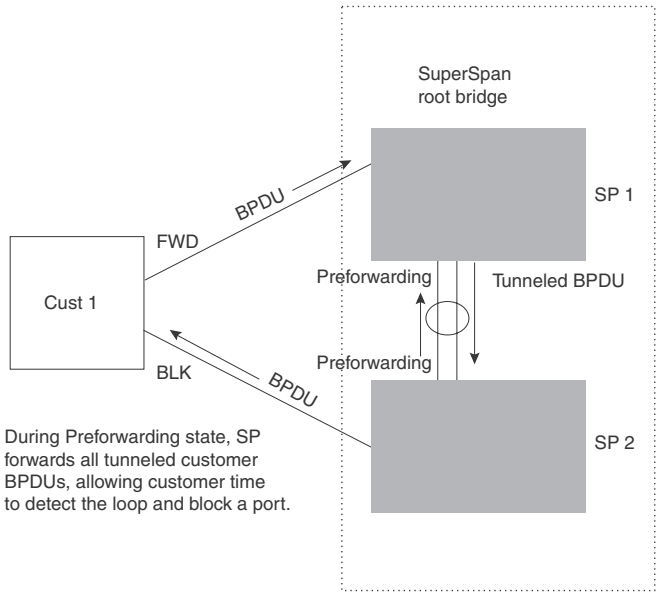
Preforwarding state

To ensure that the customer's network has time to converge at Layer 2 and prevent loops, the PowerConnect devices configured for SuperSpan use a special forwarding state, Preforwarding. The Preforwarding state occurs between the Learning and Forwarding states and by default lasts for five seconds. During the Preforwarding state, the PowerConnect forwards tunneled BPDUs from customers only and does not forward data traffic. This ensures that the customer's network will detect the Layer 2 loop and block a port. The SP network remains unblocked. After the Preforwarding state, the ports change to the Forwarding state and forward data traffic as well as BPDUs.

The default length of the Preforwarding state is five seconds. You can change the length of the Preforwarding state to a value from 3 – 30 seconds.

Figure 21 shows an example of how the Preforwarding state is used.

FIGURE 21 SuperSpan Preforwarding state



In this example, a customer has two links to the SP. Since the SP is running SuperSpan, the SP ports enter the Preforwarding state briefly to allow the customer ports connected to the SP to detect the Layer 2 loop and block one of the ports.

NOTE
If you add a new PowerConnect to a network that is already running SuperSpan, you must enable SuperSpan on the PowerConnect, at least on the VLANs that will be tunneling the customer traffic. Otherwise, the new PowerConnect does not use the Preforwarding state. This can cause the wrong ports to be blocked.

Combining single STP and multiple spanning trees

You can use SuperSpan in any of the following combinations:

- Customer and SP networks both use multiple spanning trees (a separate spanning tree in each VLAN).
- Customer uses multiple spanning trees but SP uses Single STP (all STP-enabled VLANs are in the same spanning tree).
- Customer uses Single STP but SP uses multiple spanning trees.
- Customer and SP networks both use Single STP.

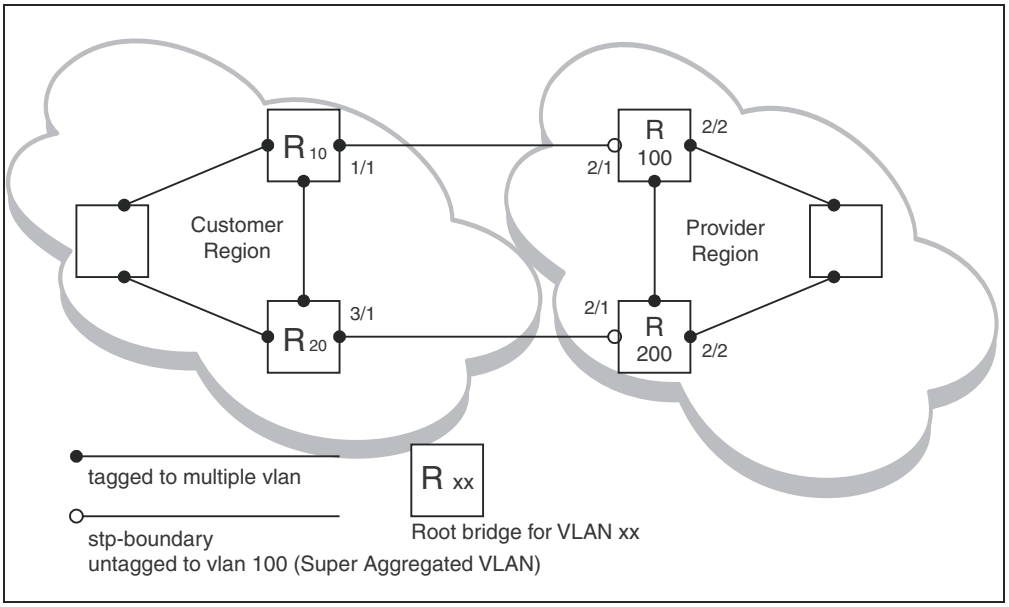
The following sections provide an example of each combination.

NOTE
All the combinations listed above are supported when the boundary ports joining the SP SuperSpan domain to the client spanning trees are untagged. For example, all these combinations are valid in super aggregated VLAN configurations. If the boundary ports are tagged, you cannot use Single STP in the client network in combination with multiple spanning trees in the SP SuperSpan domain.

Customer and SP use multiple spanning trees

Figure 22 shows an example of SuperSpan where both the customer network and the SP network use multiple spanning trees (a separate spanning tree in each port-based VLAN).

FIGURE 22 Customer and SP using multiple spanning trees



Both the customer and SP regions are running multiple spanning trees (one per port-based VLAN) in the Layer 2 switched network. The customer network contains VLANs 10 and 20 while the SP network contains VLANs 100 and 200. Customer traffic from VLAN 10 and VLAN 20 is aggregated by VLAN 100 in the SP since the boundary ports, 2/1 on R100 and R200, are untagged members of VLAN 100. By adjusting the bridge priority on VLANs 10 and 20, the customer can select a different root bridge for each spanning tree running in the customer network.

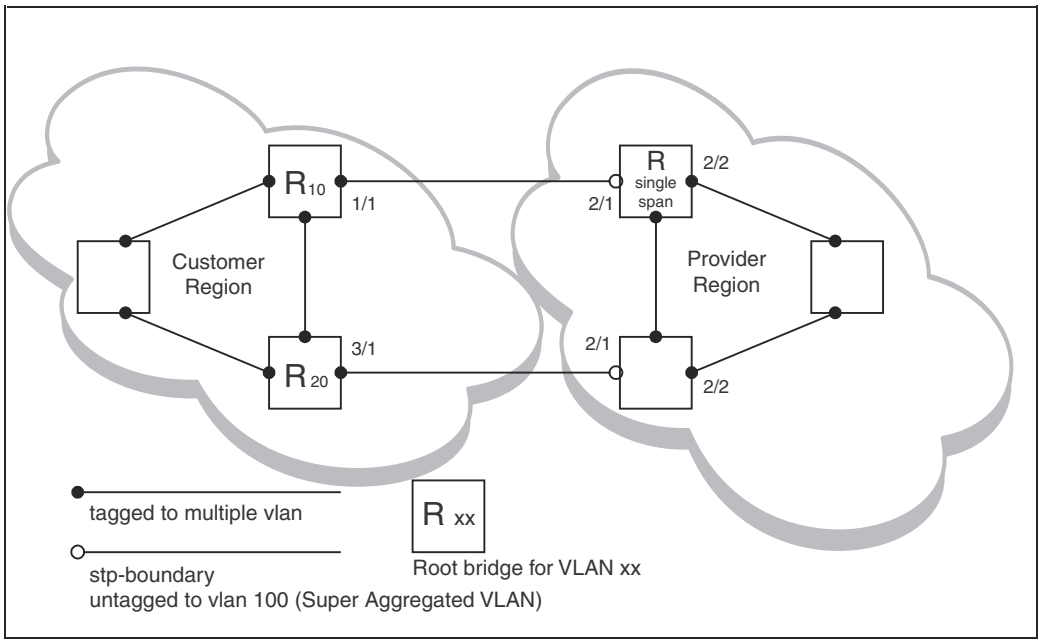
In the above example, STP in VLAN 10 will select R10 as the root bridge and make 1/1 on R10 forwarding while blocking port 3/1 on R20. The opposite occurs for STP in VLAN 20. As a result, both links connecting the customer and SP regions are fully utilized and serve as backup links at the same time, providing loop-free, non-blocking connectivity. In the SP network, multiple STP instances are running (one for VLAN 100 and one for VLAN 200) to ensure loop-free, non-blocking connectivity in each VLAN.

SuperSPAN boundaries are configured at port 2/1 of R100 and R200. Since the customer's traffic will be aggregated into VLAN 100 at the SP, the SP network appears to the customer to be a loop-free non-blocking hub to the customer network when port 2/2 on R200 is blocked by STP in VLAN 100.

Customer uses multiple spanning trees but SP uses single STP

Figure 23 shows an example of SuperSpan where the customer network uses multiple spanning trees while the SP network uses Single STP.

FIGURE 23 Customer using multiple spanning trees and SP using Single STP



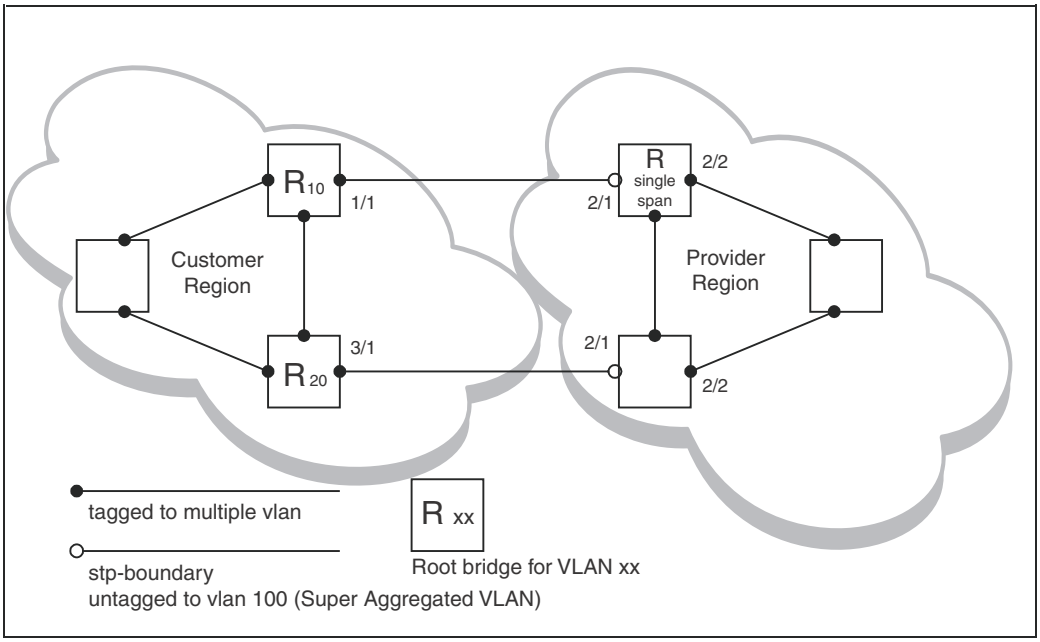
Customer traffic from different VLANs is maintained by different spanning trees, while the SP network is maintained by a single spanning tree. The SP can still use multiple VLANs at the core to separate traffic from different customers. However, all VLANs will have the same network topology because they are all calculated by the single spanning tree. The loop-free, non-blocking network acts like a hub for the customer network, with boundary ports 2/1 on each device being untagged members of VLAN 100.

Traffic from all VLANs in the customer network will be aggregated through VLAN 100 at the SP. This setup leaves the customer network's switching pattern virtually unchanged from the scenario in "Customer and SP use multiple spanning trees" on page 391, since the SP network still is perceived as a virtual hub, and maintenance of the hub's loop-free topology is transparent to the customer network.

Customer uses single STP but SP uses multiple spanning trees

Figure 24 shows an example of SuperSpan where the customer network uses Single STP while the SP uses multiple spanning trees.

FIGURE 24 Customer using Single STP and SP using multiple spanning trees

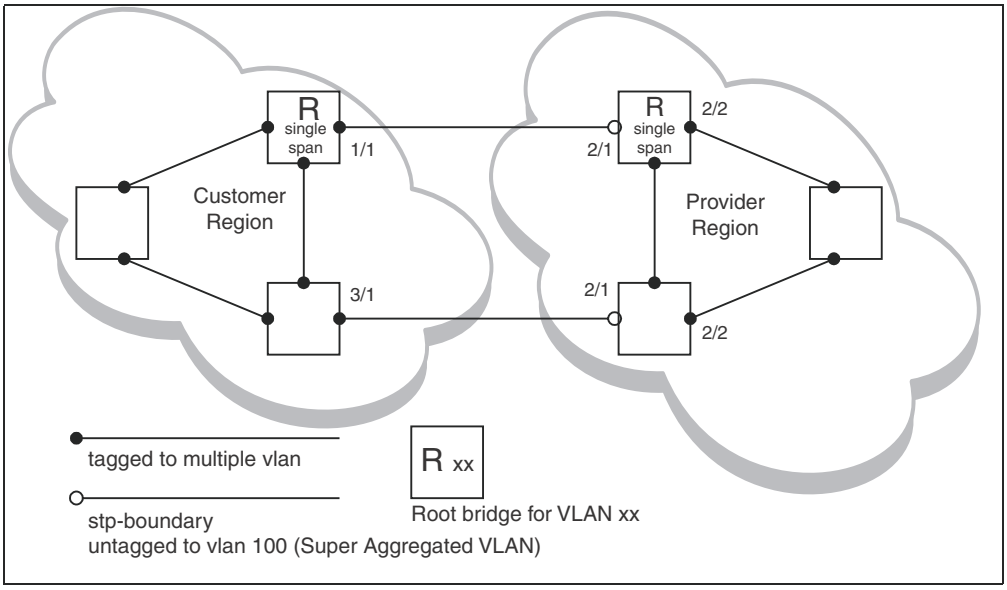


In this setup, the customer network is running a single spanning tree for VLANs 10 and 20. The traffic from VLAN 10 and 20 will be carried, or aggregated by VLAN 100 at the SP's network. The main difference between this scenario and the previous tow scenarios is that all traffic at the customer's network now follows the same path, having the same STP root bridge in all VLANs. Therefore, the customer network will not have the ability to maximize network utilization on all its links. On the other hand, loop-free, non-blocking topology is still separately maintained by the customer network's single spanning tree and the SP's per-VLAN spanning tree on VLAN 100.

Customer and SP use single STP

Figure 25 shows an example of SuperSpan where the customer network and SP both use Single STP.

FIGURE 25 Customer and SP using Single STP



In this setup, both the customer and SP networks are running a single spanning tree at Layer 2. The traffic from VLAN 10 and 20 will be carried, or aggregated by VLAN 100 at the SP network as in the previous scenario. Loop-free, non-blocking topology is still separately maintained by the customer's single spanning tree and the SP's single spanning tree.

Configuring SuperSpan

To configure the PowerConnect for SuperSpan:

- Configure each interface on the PowerConnect that is connected to customer equipment as a boundary interface. This step enables the interface to convert the destination MAC address in the customer's BPDUs.

  The software requires you to specify a SuperSpan customer ID when configuring the boundary interface. Use an ID from 1 – 65535. The customer ID uniquely identifies the customer. Use the same customer ID for each SP interface with the same customer. When tunneling BPDUs through the network, the PowerConnect devices use the customer ID to ensure that BPDUs are forwarded only to the customer's devices, and not to other customers' devices.

- Globally enable SuperSpan. This step enables the Preforwarding state.

Configuring a boundary interface

To configure the boundary interfaces on SP 1 in Figure 20 on page 388, enter the following commands.

```
NetIron(config)# interface 1/1
NetIron(config-if-e1000-1/1)# stp-boundary 1
NetIron(config)# interface 1/2
NetIron(config-if-e1000-1/2)# stp-boundary 2
```

These commands configure two interfaces on the PowerConnect as SuperSpan boundary interfaces. Interface
1/1 is a boundary interface with customer 1. Interface 1/2 is a boundary interface with customer 2. Each boundary interface is associated with a number, which is the SuperSpan ID. The SuperSpan ID identifies the instance of SuperSpan you are associating with the interface. Use the same SuperSpan ID for each boundary interface with the same customer. Use a different SuperSpan ID for each customer. For example, use SuperSpan ID 1 for all the boundary interfaces with customer 1 and use SuperSpan ID 2 for all boundary interfaces with customer 2.

Syntax: [no] stp-boundary <*num*>

The <*num*> parameter specifies the SuperSpan ID. Possible values: 1 – 65535.

To configure the boundary interfaces on SP 2 in Figure 20 on page 388, enter the following commands.

```
NetIron(config)# interface 2/1
NetIron(config-if-e1000-2/1)# stp-boundary 1
NetIron(config)# interface 2/2
NetIron(config-if-e1000-2/2)# stp-boundary 2
```

Enabling SuperSpan

After you configure the SuperSpan boundary interfaces, enable SuperSpan. You can enable SuperSpan globally or on an individual VLAN level. If you enable the feature globally, the feature is enabled on all VLANs.

NOTE
If you enable the feature globally, then create a new VLAN, the new VLAN inherits the global SuperSpan state. For example, if SuperSpan is globally enabled when you create a VLAN, SuperSpan also is enabled in the new VLAN.

You also can change the length of the preforwarding state.

To globally enable SuperSpan, enter the following command.

```
NetIron(config)# super-span
```

Syntax: [no] super-span [preforward-delay <*secs*>**]**

The <*secs*> parameter specifies the length of the preforwarding state. You can specify from 3 – 15 seconds. The default is 5 seconds.

SuperSpan is enabled in all VLANs on the PowerConnect. To disable SuperSpan in an individual VLAN, enter commands such as the following.

```
NetIron(config)# vlan 10
NetIron(config-vlan-10)# no super-span
```

Syntax: [no] super-span

Displaying SuperSpan information

To display the boundary interface configuration and BPDU statistics, enter the following command.

```
NetIron(config)# show super-span
CID 1 Boundary Ports:
     Port  Customer    Tunnel
           BPDU Rx     BPDU Rx
     1/1   1            1
     1/2   0            0
     Total 1            1

CID 2 Boundary Ports:
     Port  Customer    Tunnel
           BPDU Rx     BPDU Rx
     2/1   0            3
     2/2   0            0
     Total 0            3
```

In this example, the PowerConnect has two SuperSpan customer IDs.

Syntax: show superspan [cid <*num*>**]**

The **cid** <*num*> parameter specifies a SuperSpan customer ID. If you do not specify a customer ID, information for all the customer IDs configured on the PowerConnect is shown.

This command shows the following information.

TABLE 85 CLI display of SuperSpan customer ID information

This field...	Displays...
CID	The SuperSpan customer ID number.
Port	The boundary port number.
Customer BPDU Rx	The number of BPDUs received from the client spanning tree.
Tunnel BPDU Rx	The number of BPDUs received from the SuperSpan tunnel.

To display general STP information, refer to "Displaying STP information" on page 380.

PVST or PVST+ compatibility

Dell's support for Cisco's Per VLAN Spanning Tree plus (PVST+) allows the PowerConnect to run multiple spanning trees (MSTP) while also interoperating with IEEE 802.1Q devices[1]. Ports automatically detect PVST+ BPDUs and enable support for the BPDUs once detected.

When it is configured for MSTP, the PowerConnect can interoperate with PVST.

1. Cisco user documentation for PVST or PVST+ refers to the IEEE 802.1Q spanning tree as the ***Common Spanning Tree (CST)***.

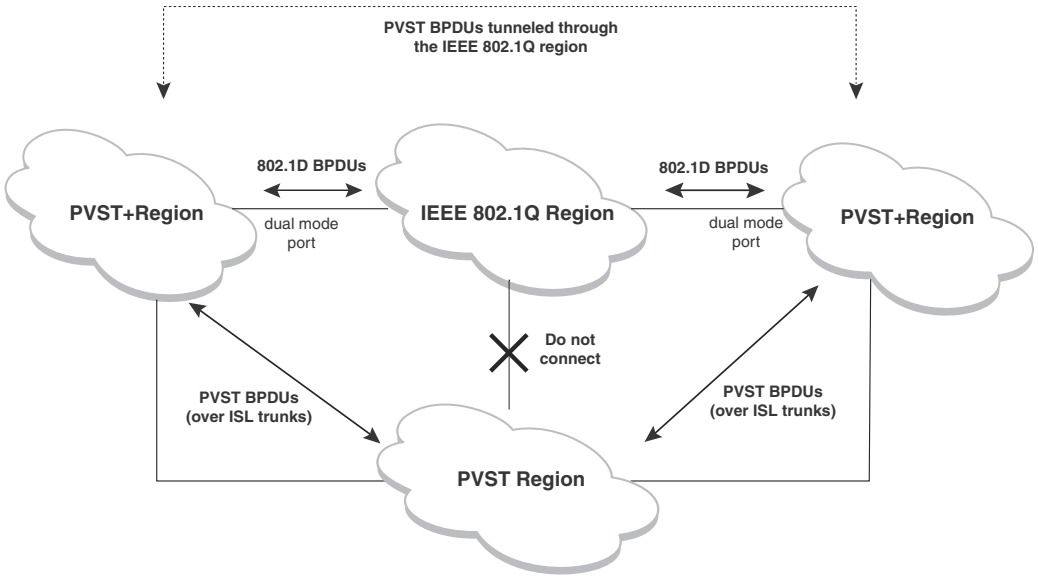
Overview of PVST and PVST+

Per VLAN Spanning Tree (PVST) is a Cisco proprietary protocol that allows a Cisco device to have multiple spanning trees. The Cisco device can interoperate with spanning trees on other PVST devices but cannot interoperate with IEEE 802.1Q devices. An IEEE 802.1Q device has all its ports running a single spanning tree. ***PVST+*** is an extension of PVST that allows a Cisco device to also interoperate with devices that are running a single spanning tree (IEEE 802.1Q).

The PVST+ support allows the PowerConnect to interoperate with PVST spanning trees and the IEEE 802.1Q spanning tree at the same time.

IEEE 802.1Q and PVST regions cannot interoperate directly but can interoperate indirectly through PVST+ regions. PVST BPDUs are tunneled through 802.1Q regions, while PVST BPDUs for VLAN 1 (the IEEE 802.1Q VLAN) are processed by PVST+ regions. Figure 26 shows the interaction of IEEE 802.1Q, PVST, and PVST+ regions.

FIGURE 26 Interaction of IEEE 802.1Q, PVST, and PVST+ regions



VLAN Tags and dual mode

The **dual-mode** feature enables the port to send and receive both tagged and untagged frames on a port. When the dual-mode feature is enabled, the port is an untagged member of one of its VLANs and is at the same time a tagged member of all its other VLANs. The untagged frames are supported on the port's **Port Native VLAN**.

To interoperate with other vendors, the dual-mode feature must be enabled on the port. Some vendors use VLAN 1 by default to support the IEEE 802.1Q based standard spanning tree protocols such as 802.1d and 802.1w for sending the untagged frames on VLAN 1. On Dell FastIron switches by default, the Port Native VLAN is the same as the device's **Default VLAN1**, which by default is VLAN 1. Thus, to support IEEE 802.1Q in a typical configuration, the port must be able to send and receive untagged frames for VLAN 1 and tagged frames for the other VLANs and interoperate with the vendors also using VLAN 1. If you want to use tagged frames on VLAN 1, you can change the

default VLAN ID to an ID other than 1. You also can specify the VLAN on which you want the port to send and receive untagged frames (the Port Native VLAN). The Port Native VLAN ID does not need to be the same as the Default VLAN. Make sure that untagged (Native) VLAN is also changed on the interoperating vendor side to match with that on the Dell side.

To support the IEEE 802.1Q with non-standard proprietary protocols such as PVST and PVST+, a port must always send and receive untagged frames on VLAN 1 on both sides. In that case, enable the dual-mode 1 feature to allow untagged BPDUs on VLAN 1and use Native VLAN 1 on the interoperating vendor side. You should not use VLAN 1 for tagged frames in this case.

NOTE
Support for the IEEE 802.1Q spanning tree always uses VLAN 1, regardless of whether the PowerConnect devices are configured to use tagged or untagged frames on the VLAN.

Enabling PVST+ support

PVST+ support is automatically enabled when the port receives a PVST BPDU. You can manually enable the support at any time or disable the support if desired.

If you want a tagged port to also support IEEE 802.1Q BPDUs, you need to enable the dual-mode feature on the port. The dual-mode feature is disabled by default and must be enabled manually.

A port that is in PVST+ compatibility mode due to auto-detection reverts to the default MSTP mode when one of the following events occurs:

- The link is disconnected or broken
- The link is administratively disabled
- The link is disabled by interaction with the link-keepalive protocol

This allows a port that was originally interoperating with PVST+ to revert to multiple spanning tree when connected to a PowerConnect.

Enabling PVST+ support manually

To immediately enable PVST+ support on a port, enter commands such as the following.

```
NetIron(config)# interface ethernet 1/1
NetIron(config-if-e1000-1/1)# pvst-mode
```

Syntax: [no] pvst-mode

NOTE
If you disable PVST+ support, the software still automatically enables PVST+ support if the port receives a BPDU with PVST+ format.

Displaying PVST+ support information

To display PVST+ information for ports on a PowerConnect, enter the following command at any level of the CLI.

```
NetIron(config)# show span pvst-mode
PVST+ Enabled on:
Port      Method
1/1       Set by configuration
1/2       Set by configuration
2/10      Set by auto-detect
3/12      Set by configuration
4/24      Set by auto-detect
```

Syntax: show span pvst-mode

This command displays the following information.

TABLE 86 CLI display of PVST+ information

This field...	Displays...
Port	The port number. **NOTE:** The command lists information only for the ports on which PVST+ support is enabled.
Method	The method by which PVST+ support was enabled on the port. The method can be one of the following: • Set by configuration – You enabled the support. • Set by auto-detect – The support was enabled automatically when the port received a PVST+ BPDU.

Configuration examples

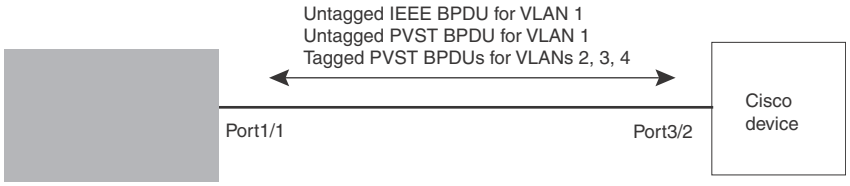
The examples use two common configurations:

- Untagged IEEE 802.1Q BPDUs on VLAN 1 and tagged PVST+ BPDUs on other VLANs
- Tagged IEEE 802.1Q BPDUs on VLAN 1 and untagged BPDUs on another VLAN

Tagged port using default VLAN 1 as its port native VLAN

In Figure 27, a PVST+ configuration uses VLAN 1 as the untagged default VLAN and VLANs 2, 3, and 4 as tagged VLANs.

FIGURE 27 Default VLAN 1 for untagged BPDUs



To implement this configuration, enter the following commands on the PowerConnect.

```
NetIron(config)# vlan-group 1 vlan 2 to 4
NetIron(config-vlan-group-1)# tagged ethernet 1/1
NetIron(config-vlan-group-1)# exit
NetIron(config)# interface ethernet 1/1
NetIron(config-if-e10000-1/1)# pvst-mode
```

These commands configure a VLAN group containing VLANs 2, 3, and 4, add port 1/1 as a tagged port to the VLANs, and enable the dual-mode feature and PVST+ support on the port. The dual-mode feature allows the port to send and receive untagged frames for the default VLAN (VLAN 1 in this case) in addition to tagged frames for VLANs 2, 3, and 4. Enabling the PVST+ support ensures that the port is ready to send and receive PVST+ BPDUs. If you do not manually enable PVST+ support, the support is not enabled until the port receives a PVST+ BPDU.

The configuration leaves the default VLAN and the port's native VLAN unchanged. The default VLAN is 1 and the port's Port Native VLAN also is 1. The dual-mode feature supports untagged frames on the default VLAN only. Thus, port 1/1 can send and receive untagged BPDUs for VLAN 1 and can send and receive tagged BPDUs for the other VLANs.

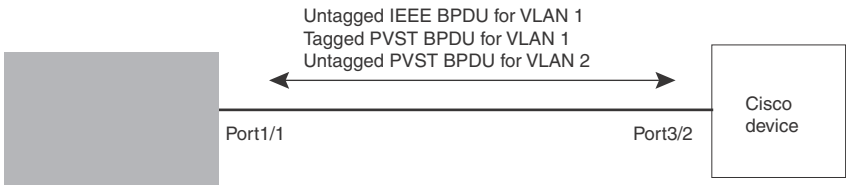
Port 1/1 will process BPDUs as follows:

- Process IEEE 802.1Q BPDUs for VLAN 1.
- Process tagged PVST BPDUs for VLANs 2, 3, and 4.
- Drop untagged PVST BPDUs for VLAN 1.

Untagged port using VLAN 2 as port native VLAN

In Figure 28, a port's Port Native VLAN is not VLAN 1. In this case, VLAN 1 uses tagged frames and VLAN 2 uses untagged frames.

FIGURE 28 Port Native VLAN 2 for untagged BPDUs



To implement this configuration, enter the following commands on the PowerConnect.

```
NetIron(config)# default-vlan-id 4000
NetIron(config)# vlan 1
NetIron(config-vlan-1)# tagged ethernet 1/1
NetIron(config-vlan-1)# exit
NetIron(config)# vlan 2
NetIron(config-vlan-2)# untagged ethernet 1/1
NetIron(config-vlan-2)# exit
NetIron(config)# interface ethernet 1/1
NetIron(config-if-e10000-1/1)# pvst-mode
NetIron(config-if-e10000-1/1)# exit
```

These commands change the default VLAN ID, configure port 1/1 as a tagged member of VLANs 1 and 2, and enable PVST+ support on port 1/1. Since VLAN 1 is tagged in this configuration, the default VLAN ID must be changed from VLAN 1 to another VLAN ID. Changing the default VLAN ID from 1 allows the port to process tagged frames for VLAN 1. VLAN 2 is the port native VLAN. The port processes untagged frames and untagged PVST BPDUs on VLAN 2.

Port 1/1 will process BPDUs as follows:

- Process IEEE 802.1Q BPDUs for VLAN 1.
- Process untagged PVST BPDUs for VLAN 2.
- Drop tagged PVST BPDUs for VLAN 1.

Note that when VLAN 1 is not the default VLAN, the ports must have an untagged VLAN enabled in order to process IEEE 802.1Q BPDUs.

For example, the following configuration is incorrect.

```
NetIron(config)# default-vlan-id 1000
NetIron(config)# vlan 1
NetIron(config-vlan-1)# tagged ethernet 1/1 to 1/2
NetIron(config-vlan-1)# exit
NetIron(config)# interface ethernet 1/1
NetIron(config-if-e10000-1/1)# pvst-mode
NetIron(config-if-e10000-1/1)# exit
NetIron(config)# interface ethernet 1/2
NetIron(config-if-e10000-1/2)# pvst-mode
NetIron(config-if-e10000-1/2)# exit
```

In the configuration above, all PVST BPDUs associated with VLAN 1 would be discarded. Since IEEE BPDUs associated with VLAN 1 are untagged, they are discarded because the ports in VLAN 1 are tagged. Effectively, the BPDUs are never processed by the Spanning Tree Protocol. STP assumes that there is no better bridge on the network and sets the ports to FORWARDING. This could cause a Layer 2 loop.

The following configuration is correct.

```
NetIron(config)# default-vlan-id 1000
NetIron(config)# vlan 1
NetIron(config-vlan-1)# tagged ethernet 1/1 to 1/2
NetIron(config-vlan-1)# exit
NetIron(config)# interface ethernet 1/1
NetIron(config-if-e10000-1/1)# pvst-mode
NetIron(config-if-e10000-1/1)# exit
NetIron(config)# interface ethernet 1/2
NetIron(config-if-e10000-1/2)# pvst-mode
NetIron(config-if-e10000-1/2)# exit
```

Setting the ports as dual-mode ensures that the untagged IEEE 802.1Q BPDUs reach the VLAN 1 instance.

802.1s Multiple Spanning Tree Protocol

Multiple Spanning Tree Protocol (MSTP) as defined in IEEE 802.1s allows you to configure multiple STP instances. This will allow several VLANs to be mapped to a reduced number of spanning-tree instances. This ensures loop-free topology for 1 or more VLANs that have the same Layer 2 topology.

NOTE
In addition to the features described in this chapter, Root Guard and BPDU Guard are supported. Refer to "Root Guard" on page 375 and "BPDU Guard" on page 377 for details.

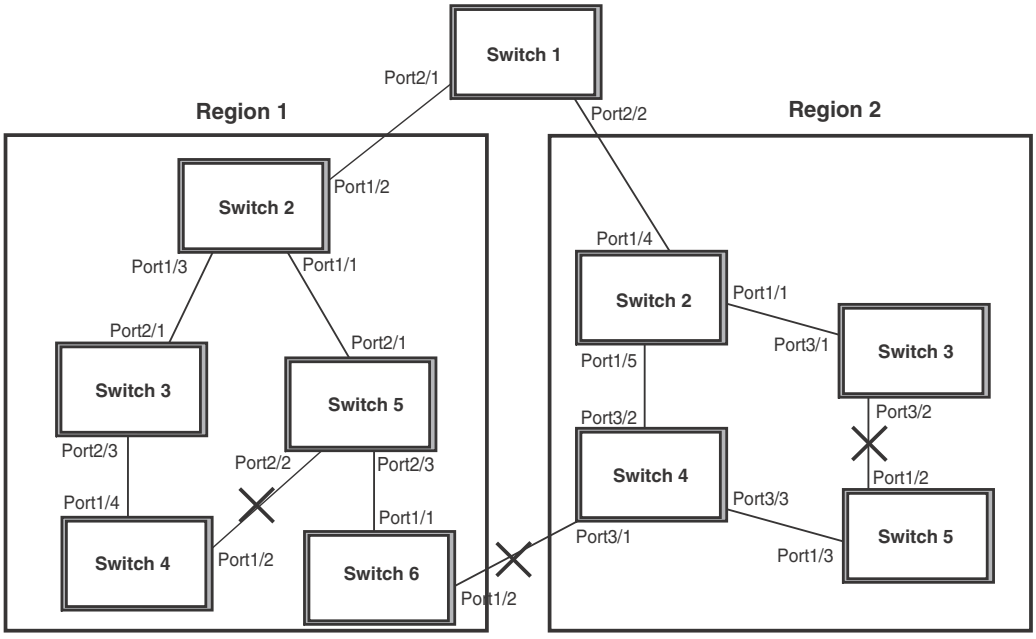
Multiple Spanning-Tree regions

Using MSTP, the entire network runs a common instance of RSTP. Within that common instance, one or more VLANs can be individually configured into distinct regions. The entire network runs the common spanning tree instance (CST) and the regions run a local instance. The local instance is known as Internal Spanning Tree (IST). The CST treats each instance of IST as a single bridge. Consequently, ports are blocked to prevent loops that might occur within an IST and also throughout the CST. In addition, MSTP can coexist with individual devices running STP or RSTP in the Common and Internal Spanning Trees instance (CIST). With the exception of the provisions for multiple instances, MSTP operates exactly like RSTP.

For example, in Figure 29 a network is configured with two regions: Region 1 and Region 2. The entire network is running an instance of CST. Each of the regions is running an instance of IST. In addition, this network contains Switch 1 running RSTP that is not configured in a region and consequently is running in the CIST instance. In this configuration, the regions are each regarded as a single bridge to the rest of the network, as is Switch 1. The CST prevents loops from occurring across the network. Consequently, a port is blocked at port 1/2 of switch 4.

Additionally, loops must be prevented in each of the IST instances. Within the IST Region 1, a port is blocked at port 1/2 of switch 4 to prevent a loop in that region. Within Region 2, a port is blocked at port 3/2 of switch 3 to prevent a loop in that region.

FIGURE 29 MSTP configured network



The following definitions describe the STP instances that define an MSTP configuration:

Common Spanning (CST) – MSTP runs a single instance of spanning tree, called the Common Spanning Tree (CST), across all the bridges in a network. This instance treats each region as a single bridge. It all other ways, it operates exactly like Rapid Spanning Tree (RSTP).

Internal Spanning Tree (IST) – Instances of spanning tree that operate within a defined region are called ISTs (Internal Spanning Tree).

Common and Internal Spanning Trees (CIST) – This is the default MSTP instance 0. It contains all of the ISTs and all bridges that are not formally configured into a region. This instance interoperates with bridges running legacy STP and RSTP implementations.

Multiple Spanning Tree Instance (MSTI) – The MSTI is identified by an MST identifier (MSTid) value between 1 and 4094. This defines an individual instance of an IST. One or more VLANs can be assigned to an MSTI. A VLAN cannot be assigned to multiple MSTIs.

MSTP Region – These are clusters of bridges that run multiple instances of the MSTP protocol. Multiple bridges detect that they are in the same region by exchanging their configuration (instance to VLAN mapping), name, and revision-level. Therefore, if you need to have two bridges in the same region, the two bridges must have identical configurations, names, and revision-levels.

Configuring MSTP

To configure a switch for MSTP, you could configure the name and the revision on each switch that is being configured for MSTP. This name is unique to each switch. You must then create an MSTP Instance and assign an ID. VLANs are then assigned to MSTP instances. These instances must be configured on all switches that interoperate with the same VLAN assignments. Port cost, priority and global parameters can then be configured for individual ports and instances. In addition, operational edge ports and point-to-point links can be created and MSTP can be disabled on individual ports.

MSTP can be configured on a router with MRP however, they are mutually exclusive on a specific VLAN. Also, MSTP can be configured on a port that is part of a LAG following the same rules as used for STP and RSTP.

Each of the commands used to configure and operate MSTP are described in the following:

- "Setting the MSTP name"
- "Setting the MSTP revision number"
- "Configuring an MSTP instance"
- "Configuring port priority and port path cost"
- "Configuring bridge priority for an MSTP instance"
- "Setting the MSTP global parameters"
- "Setting ports to be operational edge ports"
- "Setting point-to-point link"
- "Disabling MSTP on a port"
- "Forcing ports to transmit an MSTP BPDU"
- "Enabling MSTP on a switch"

Setting the MSTP name

Each switch that is running MSTP is configured with a name. It applies to the switch which can have many different VLANs that can belong to many different MSTP regions. By default, the name is the MAC address of the device.

To configure an MSTP name, use a command such as the following at the Global Configuration level.

```
NetIron(config)# mstp name mstp1
```

Syntax: [no] mstp name <*name*>

The **name** parameter defines an ASCII name for the MSTP configuration. The default name is the MAC address of the switch expressed as a string.

Setting the MSTP revision number

Each switch that is running MSTP is configured with a revision number. It applies to the switch which can have many different VLANs that can belong to many different MSTP regions.

To configure an MSTP revision number, use a command such as the following at the Global Configuration level.

```
NetIron(config)# mstp revision 4
```

Syntax: [no] mstp revision <*revision-number*>

The **revision** parameter specifies the revision level for MSTP that you are configuring on the switch. It can be a number from 0 and 65535.

Configuring an MSTP instance

An MSTP instance is configured with an MSTP ID for each region. Each region can contain one or more VLANs. To configure an MSTP instance and assign a range of VLANs, use a command such as the following at the Global Configuration level.

```
NetIron(config) # mstp instance 7 vlan 4 to 7
```

Syntax: [no] mstp instance <*instance-number*> [vlan <*vlan-id*> | vlan-group <*group-id*>]

The **instance** parameter defines the number for the instance of MSTP that you are configuring. The maximum number of instances that can be configured is 16.

The **vlan** parameter assigns one or more VLANs or a range of VLANs to the instance defined in this command.

The **vlan-group** parameter assigns one or more VLAN groups to the instance defined in this command.

Configuring port priority and port path cost

Priority and path cost can be configured for a specified instance. To configure an MSTP instance, use a command such as the following at the Global Configuration level.

```
NetIron(config)# mstp instance 7 ethernet 3/1 priority 32 path-cost 200
```

Syntax: [no] mstp instance <*instance-number*> ethernet <*slot/port*> priority <*port-priority*> path-cost <*cost*>

The <*instance-number*> variable is the number of the instance of MSTP that you are configuring priority and path cost for.

The **ethernet** <*slot/port*> parameter specifies a port within a VLAN. The priority and path cost configured with this command will apply to VLAN that the port is contained within.

You can set a **priority** to the port that gives it forwarding preference over lower priority instances within a VLAN or on the switch. A higher number for the priority variable means a lower forwarding priority. Acceptable values are 0 - 240 in increments of 16. The default value is 128.

A **path-cost** can be assigned to a port to bias traffic towards or away from a path during periods of rerouting. Possible values are 1 - 200000000.

Configuring bridge priority for an MSTP instance

Priority can be configured for a specified instance. To configure priority for an MSTP instance, use a command such as the following at the Global Configuration level.

```
NetIron(config)# mstp instance 1 priority 8192
```

Syntax: [no] mstp instance <*instance-number*> **priority** <*priority-value*>

The <*instance-number*> variable is the number for the instance of MSTP that you are configuring.

You can set a **priority** to the instance that gives it forwarding preference over lower priority instances within a VLAN or on the switch. A higher number for the priority variable means a lower forwarding priority. Acceptable values are 0 - 61440 in increments of 4096. The default value is 32768.

Setting the MSTP global parameters

MSTP has many of the options available in RSTP as well as some unique options. To configure MSTP Global parameters for all instances on a switch.

```
NetIron(config)# mstp force-version 0 forward-delay 10 hello-time 4 max-age 12
max-hops 9
```

Syntax: [no] mstp force-version <*mode-number*> **forward-delay** <*value*> **hello-time** <*value*> **max-age** <*value*> **max-hops** <*value*>

The **force-version** parameter forces the bridge to send BPDUs in a specific format. You can specify one of the following <*mode-number*> values:

- 0 – The STP compatibility mode. Only STP BPDUs will be sent. This is equivalent to single STP.
- 2 – The RSTP compatibility mode. Only RSTP BPDUS will be sent. This is equivalent to single STP.
- 3 – MSTP mode. In this default mode, only MSTP BPDUS will be sent.

The **forward-delay** <*value*> specifies how long a port waits before it forwards an RST BPDU after a topology change. This can be a value from 4 – 30 seconds. The default is 15 seconds.

The **hello-time** <*value*> parameter specifies the interval between two hello packets. The parameter can have a value from 1 – 10 seconds. The default is 2 seconds.

The **max-age** <*value*> parameter specifies the amount of time the device waits to receive a hello packet before it initiates a topology change. You can specify a value from 6 – 40 seconds. The default value is 20 seconds.

The **max-hops** <*value*> parameter specifies the maximum hop count. You can specify a value from 1 – 40 hops. The default value is 20 hops.

Setting ports to be operational edge ports

You can define specific ports as edge ports for the region in which they are configured to connect to devices (such as a host) that are not running STP, RSTP, or MSTP. If a port is connected to an end device such as a PC, the port can be configured as an edge port. To configure ports as operational edge ports enter a command such as the following.

```
NetIron(config)# mstp admin-edge-port ethernet 3/1
```

Syntax: [no] mstp admin-edge-port ethernet <*slot/port*>

The <*slot/port*> parameter specifies a port or range of ports as edge ports in the instance they are configured in.

Setting point-to-point link

You can set a point-to-point link between ports to increase the speed of convergence. To create a point-to-point link between ports, use a command such as the following at the Global Configuration level.

```
NetIron(config)# mstp admin-pt2pt-mac ethernet 2/5 ethernet 4/5
```

Syntax: [no] mstp admin-pt2pt-mac ethernet <*slot/port*>

The <*slot/port*> parameter specifies a port or range of ports to be configured for point-to-point links to increase the speed of convergence.

Disabling MSTP on a port

To disable MSTP on a specific port, use a command such as the following at the Global Configuration level.

```
NetIron(config)# mstp disable 2/1
```

Syntax: [no] mstp disable <*slot/port*>

The <*slot/port*> variable specifies the location of the port that you want to disable MSTP for.

Forcing ports to transmit an MSTP BPDU

To force a port to transmit an MSTP BPDU, use a command such as the following at the Global Configuration level.

```
NetIron(config)# mstp force-migration-check ethernet 3/1
```

Syntax: [no] mstp force-migration-check ethernet <*slot/port*>

The <*slot/port*> variable specifies the port or ports that you want to transmit an MSTP BPDU from.

Enabling MSTP on a switch

To enable MSTP on your switch, use a command such as the following at the Global Configuration level.

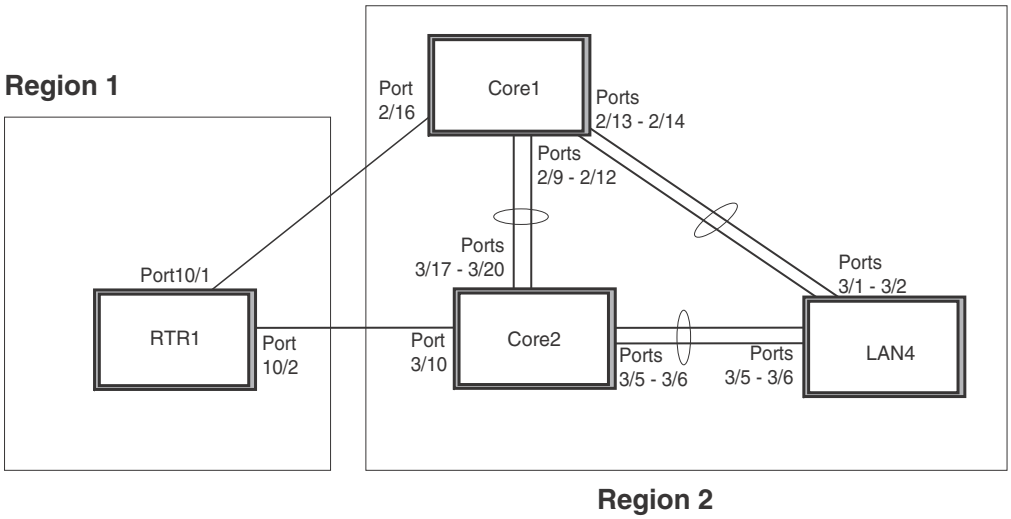
```
NetIron(config)# mstp start
```

Syntax: [no] start

Example

In Figure 30 four PowerConnect devices are configured in two regions. There are four VLANs in four instances in Region 2. Region 1 is in the CIST.

FIGURE 30 SAMPLE MSTP configuration



RTR1 configuration

```
NetIron(config-vlan-4093)tagged ethernet 10/1 to 10/2
NetIron(config-vlan-4093)exit
NetIron(config) mstp name Reg1

```

Displaying MSTP statistics

MSTP statistics can be displayed using the commands shown below.

To display all general MSTP information, enter the following command.

```
NetIron(config)#show mstp
MSTP Instance 0 (CIST) - VLANs: 1
--------------------------------------------------------------------------------
Bridge           Bridge Bridge Bridge Bridge Root   Root  Root   Root

```

Syntax: show mstp <*instance-number*>

The <*instance-number*> variable specifies the MSTP instance that you want to display information for.

TABLE 87 Output from show MSTP

This field...	Displays...
MSTP Instance	The ID of the MSTP instance whose statistics are being displayed. For the CIST, this number is 0.
VLANs:	The number of VLANs that are included in this instance of MSTP. For the CIST this number will always be 1.
Bridge Identifier	The MAC address of the bridge.
Bridge MaxAge sec	Displays configured Max Age.
Bridge Hello sec	Displays configured Hello variable.
Bridge FwdDly sec	Displays configured FwdDly variable.
Bridge Hop cnt	Displays configured Max Hop count variable.

TABLE 87 Output from show MSTP (Continued)

This field...	Displays...
Root MaxAge sec	Max Age configured on the root bridge.
Root Hello sec	Hello interval configured on the root bridge.
Root FwdDly sec	FwdDly interval configured on the root bridge.
Root Hop Cnt	Current hop count from the root bridge.
Root Bridge	Bridge identifier of the root bridge.
ExtPath Cost	The configured path cost on a link connected to this port to an external MSTP region.
Regional Root Bridge	The Regional Root Bridge is the MAC address of the Root Bridge for the local region.
IntPath Cost	The configured path cost on a link connected to this port within the internal MSTP region.
Designated Bridge	The MAC address of the bridge that sent the best BPDU that was received on this port.
Root Port	Port indicating shortest path to root. Set to "Root" if this bridge is the root bridge.
Port Num	The port number of the interface.
Pri	The configured priority of the port. The default is 128.
PortPath Cost	Configured or auto detected path cost for port.
P2P Mac	Indicates if the port is configured with a point-to-point link: • **T** – The port is configured in a point-to-point link • **F** – The port is not configured in a point-to-point link
Edge	Indicates if the port is configured as an operational edge port: • **T** – indicates that the port is defined as an edge port. • **F** – indicates that the port is not defined as an edge port
Role	The current role of the port: • Master • Root • Designated • Alternate • Backup • Disabled
State	The port's current 802.1w state. A port can have one of the following states: • Forwarding • Discarding • Learning • Disabled
Designated Cost	Port path cost to the root bridge.
Max Hop cnt	The maximum hop count configured for this instance.
Root Hop cnt	Hop count from the root bridge.

Displaying MSTP information for a specified instance

The following example displays MSTP information specified for an MSTP instance.

```
NetIron(config)#show mstp 1
MSTP Instance 1 - VLANs: 2
------------------------------------------------------------------------------
Bridge           Max RegionalRoot     IntPath   Designated       Root  Root
Identifier       Hop Bridge           Cost      Bridge           Port  Hop
hex              cnt hex                        hex                    cnt
8001000cdb80af01 20  8001000cdb80af01 0         8001000cdb80af01 Root  20

Port  Pri PortPath  Role       State      Designa-  Designated
Num       Cost                          ted cost  bridge
3/1   128 2000      MASTER     FORWARDING 0         8001000cdb80af01
```

Refer to Table 87 for details about the display parameters.

Displaying MSTP information for CIST instance 0

Instance 0 is the Common and Internal Spanning Tree Instance (CIST). When you display information for this instance there are some differences with displaying other instances. The following example displays MSTP information for CIST Instance 0.

```
NetIron(config)#show mstp 0
MSTP Instance 0 (CIST) - VLANs: 1
------------------------------------------------------------------------------
Bridge           Bridge Bridge Bridge Bridge Root   Root  Root   Root
Identifier       MaxAge Hello  FwdDly Hop    MaxAge Hello FwdDly Hop
hex              sec    sec    sec    cnt    sec    sec   sec    cnt
8000000cdb80af01 20     2      15     20     20     2     15     19
Root             ExtPath   RegionalRoot     IntPath   Designated       Root
Bridge           Cost      Bridge           Cost      Bridge           Port
hex                        hex                        hex
8000000480bb9876 2000      8000000cdb80af01 0         8000000480bb9876 3/1
Port  Pri PortPath  P2P Edge Role       State      Designa-  Designated
Num       Cost      Mac Port                      ted cost  bridge
3/1   128 2000      T   F    ROOT       FORWARDING 0         8000000480bb9876
```

To display details about the MSTP configuration, enter the following command.

```
NetIron(config)#show mstp conf
MSTP CONFIGURATION
------------------
Name     : Reg1
Revision : 1
Version  : 3 (MSTP mode)
Status   : Started

Instance VLANs
-------- ------------------------------------------------------
0        4093
```

To display details about the MSTP that is configured on the device, enter the following command.

```
NetIron(config)#show mstp detail
MSTP Instance 0 (CIST) - VLANs: 4093
--------------------------------------------------------------------------------
Bridge: 800000b000c00000 [Priority 32768, SysId 0, Mac 00b000c00000]
FwdDelay 15, HelloTime 2, MaxHops 20, TxHoldCount 6
Port 6/54 - Role: DESIGNATED - State: FORWARDING
PathCost 20000, Priority 128, OperEdge T, OperPt2PtMac F, Boundary T
Designated - Root 800000b000c00000, RegionalRoot 800000b000c00000,
Bridge 800000b000c00000, ExtCost 0, IntCost 0
ActiveTimers - helloWhen 1
MachineState - PRX-DISCARD, PTX-IDLE, PPM-SENDING_RSTP, PIM-CURRENT
PRT-ACTIVE_PORT, PST-FORWARDING, TCM-INACTIVE
BPDUs - Rcvd MST 0, RST 0, Config 0, TCN 0
Sent MST 6, RST 0, Config 0, TCN 0
```

Refer to Table 87 for explanation about the parameters in the output.

Syntax: show mstp [<*mstp-id*> | **configuration** | **detail**] [| **begin** <*string*> | **exclude** <*string*> | **include** <*string*>]

Enter an MSTP ID for <*mstp-id*>.

Configuring STP under an ESI VLAN

STP can also be configured under a VLAN that is part of a user-configured ESI. For example, to enable spanning tree on a VLAN that is part of an ESI, configure the following commands.

```
NetIron(config)# esi customer1 encapsulation cvlan
NetIron(config-esi-customer1)# vlan 100
NetIron(config-esi-customer1-vlan-100)# spanning-tree
```

Configuration considerations:

The configuration considerations are as follows:

- MSTP can only be configured under the default ESI. MSTP cannot be configured for VLANs that are configured under a user-defined ESI.
- STP can be configured for VLANs with encapsulation type B-VLAN, S-VLAN or C-VLAN
- When STP or RSTP is configured for VLANs under an ESI, the MRP members must be part of the same ESI

Configuring Rapid Spanning Tree Protocol 12

The following Rapid Spanning Tree Protocol features are supported by NetIron MLX Series devices.

- Rapid Spanning Tree Protocol
- Edge Ports
- Point-to-Point Ports
- Convergence in a Simple Topology
- Convergence in a Complex RSTP Topology
- Compatibility of RSTP with 802.1D
- RSTP support under an ESI with support for B-VLANs, S-VLANs and C-VLANs

This chapter explains the IEEE 802.1W-2001Rapid Spanning Tree Protocols (RSTP) support on the PowerConnect.

NOTE
In addition to the features described in this chapter, Root Guard and BPDU Guard. Refer to "Root Guard" on page 375 and "BPDU Guard" on page 377 for details.

IEEE 802.1W-2001 RSTP provides rapid traffic reconvergence for point-to-point links within a few milliseconds (< 500 milliseconds), following the failure of a bridge or bridge port.

This reconvergence occurs more rapidly than the reconvergence provided by the IEEE 802.1D Spanning Tree Protocol or by RSTP Draft 3 because:

- STP requires a newly selected Root port to go through listening and learning stages before traffic convergence can be achieved. The STP traffic convergence time is calculated using the following formula:

  2 x FORWARD_DELAY + BRIDGE_MAX_AGE.

- Convergence in RSTP bridges is not based on any timer values. Rather, it is based on the explicit handshakes between Designated ports and their connected Root ports to achieve convergence in less than 500 milliseconds.

NOTE
The rapid convergence will not occur on ports connected to shared media devices, such as hubs. To take advantage of the rapid convergence provided by RSTP, make sure to explicitly configure all point-to-point links in a topology.

Bridges and bridge port roles

A bridge in an RSTP rapid spanning tree topology is assigned as the root bridge if it has the highest priority (lowest bridge identifier) in the topology. Other bridges are referred to as non-root bridges.

Unique roles are assigned to ports on the root and non-root bridges. Role assignments are based on the following information contained in the BPDU (RSTp packet):

- Root bridge ID
- Path cost value
- Transmitting bridge ID
- Designated port ID

RSTP algorithm uses this information to determine if the RST BPDU received by a port is superior to the RST BPDU that the port transmits. The two values are compared in the order as given above, starting with the Root bridge ID. The RST BPDU with a lower value is considered superior. The superiority and inferiority of the RST BPDU is used to assign a role to a port.

If the value of the received RST BPDU is the same as that of the transmitted RST BPDU, then the port ID in the RST BPDUs are compared. The RST BPDU with the lower port ID is superior. Port roles are then calculated appropriately.

The port's role is included in the BPDU that it transmits. The BPDU transmitted by an RSTP port is referred to as an RST BPDU, while it is operating in RSTP mode.

Ports can have one of the following roles:

- **Root** – Provides the lowest cost path to the root bridge from a specific bridge
- **Designated** – Provides the lowest cost path to the root bridge from a LAN to which it is connected
- **Alternate** – Provides an alternate path to the root bridge when the root port goes down
- **Backup** – Provides a backup to the LAN when the Designated port goes down
- **Disabled** – Has no role in the topology

Assignment of port roles

At system start-up, all RSTP-enabled bridge ports assume a Designated role. Once start-up is complete, RSTP algorithm calculates the superiority or inferiority of the RST BPDU that is received and transmitted on a port.

On a root bridge, each port is assigned a ***Designated port*** role, except for ports on the same bridge that are physically connected together. In these type of ports, the port that receives the superior RST BPDU becomes the ***Backup port***, while the other port becomes the ***Designated port***.

On non-root bridges, ports are assigned as follows:

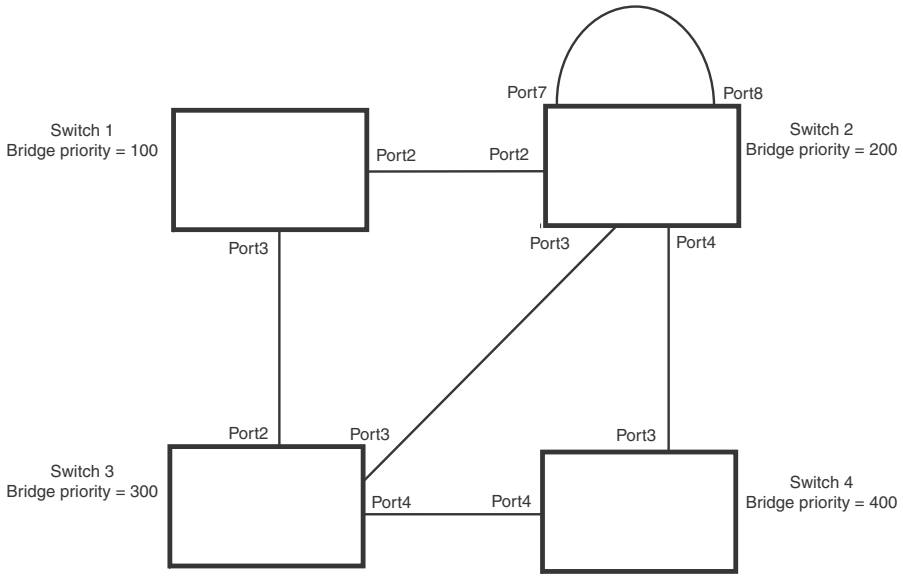
- The port that receives the RST BPDU with the lowest path cost from the root bridge becomes the ***Root port***.
- If two ports on the same bridge are physically connected, the port that receives the superior RST BPDU becomes the ***Backup port***, while the other port becomes the ***Designated port***.
- If a non-root bridge already has a Root port, then the port that receives an RST BPDU that is superior to those it can transmit becomes the ***Alternate port***.
- If the RST BPDU that a port receives is inferior to the RST BPDUs it transmits, then the port becomes a ***Designated port***.
- If the port is down or if RSTP is disabled on the port, that port is given the role of ***Disabled port***. Disabled ports have no role in the topology. However, if RSTP is enabled on a port with a link down and the link of that port comes up, then that port assumes one of the following port roles: Root, Designated, Alternate, or Backup.

The following example (Figure 31) explains role assignments in a simple RSTP topology.

NOTE
All examples in this document assume that all ports in the illustrated topologies are point-to-point links and are homogeneous (they have the same path cost value) unless otherwise specified.

The topology in Figure 31 contains four bridges. Switch 1 is the root bridge since it has the lowest bridge priority. Switch 2 through Switch 4 are non-root bridges.

FIGURE 31 Simple RSTP topology



Ports on Switch 1

All ports on Switch 1, the root bridge, are assigned Designated port roles.

Ports on Switch 2

Port2 on Switch 2 directly connects to the root bridge; therefore, Port2 is the Root port.

Switch 2's bridge priority value is superior to that of Switch 3 and Switch 4; therefore, the ports on Switch 2 that connect to Switch 3 and Switch 4 are given the Designated port role.

Furthermore, Port7 and Port8 on Switch 2 are physically connected. The RST BPDUs transmitted by Port7 are superior to those Port8 transmits. Therefore, Switch 2 is the Backup port and Port7 is the Designated port.

Ports on Switch 3

Port2 on Switch 3 directly connects to the Designated port on the root bridge; therefore, it assumes the Root port role.

The root path cost of the RST BPDUs received on Port4/Switch 3 is inferior to the RST BPDUs transmitted by the port; therefore, Port4/Switch 3 becomes the Designated port.

Similarly, Switch 3 has a bridge priority value inferior to Switch 2. Port3 on Switch 3 connects to Port 3 on Switch 2. This port will be given the Alternate port role, since a Root port is already established on this bridge.

Ports Switch 4

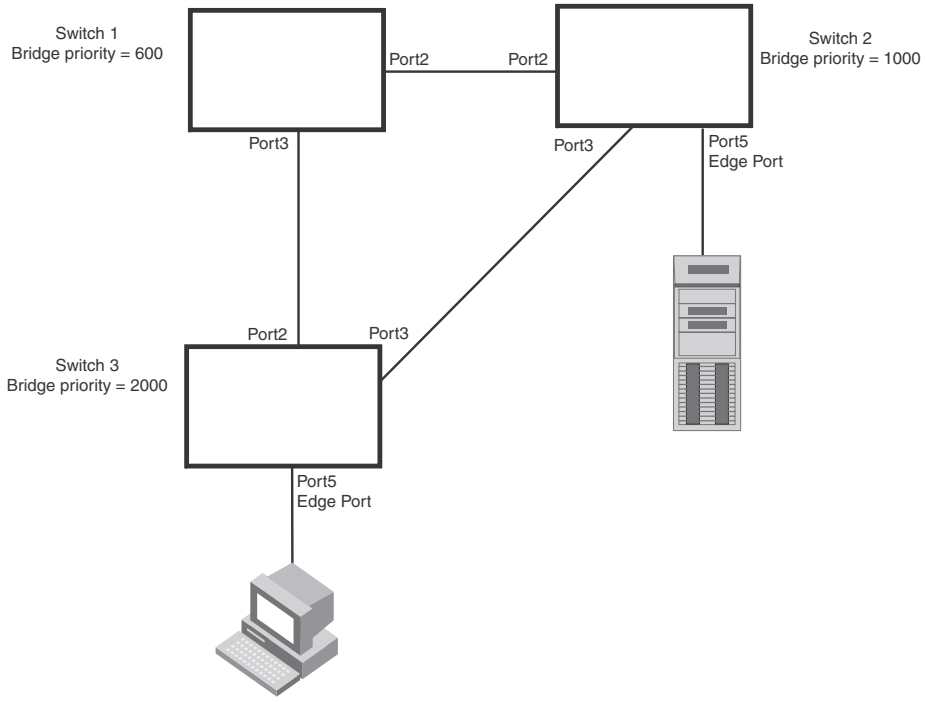
Switch 4 is not directly connected to the root bridge. It has two ports with superior incoming RST BPDUs from two separate LANs: Port3 and Port4. The RST BPDUs received on Port3 are superior to the RST BPDUs received on port 4; therefore, Port3 becomes the Root port and Port4 becomes the Alternate port.

Edge ports and Edge port roles

Dell's implementation of RSTP allows ports that are configured as Edge ports to be present in an RSTP topology. (Figure 32). Edge ports are ports of a bridge that connect to workstations or computers. Edge ports do not register any incoming BPDU activities.

Edge ports assume Designated port roles. Port flapping does not cause any topology change events on Edge ports since RSTP does not consider Edge ports in the spanning tree calculations.

FIGURE 32 Topology with edge ports



However, if any incoming RST BPDU is received from a previously configured Edge port, RSTP automatically makes the port as a non-edge port. This is extremely important to ensure a loop free Layer 2 operation since a non-edge port is part of the active RSTP topology.

The bridge detection state module can auto-detect an Edge port and a non-edge port. An administrator can also configure a port to be an Edge port. It is recommended that Edge ports are configured explicitly to take advantage of the Edge port feature, instead of allowing the protocol to auto-detect them.

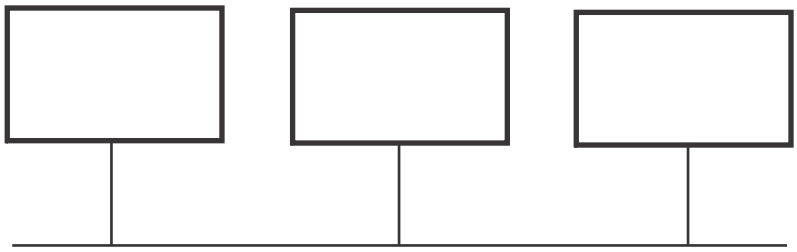
Point-to-point ports

To take advantage of the RSTP features, ports on an RSTP topology should be explicitly configured as point-to-point links. Shared media should not be configured as point-to-point links.

NOTE
Configuring shared media or non-point-to-point links as point-to-point links could lead to Layer 2 loops.

The topology in Figure 33 is an example of shared media that should not be configured as point-to-point links. In Figure 33, a port on a bridge communicates or is connected to at least two ports.

FIGURE 33 Example of shared media



Bridge port states

Ports roles can have one of the following states:

- **Forwarding** – RSTP is allowing the port to send and receive all packets.
- **Discarding** – RSTP has blocked data traffic on this port to prevent a loop. The device or VLAN can reach the root bridge using another port, whose state is forwarding. When a port is in this state, the port does not transmit or receive data frames, but the port does continue to receive RST BPDUs. This state corresponds to the listening and blocking states of 802.1D.
- **Learning** – RSTP is allowing MAC address entries to be added to the filtering database but does not permit forwarding of data frames. The device can learn the MAC addresses of frames that the port receives during this state and make corresponding entries in the MAC table.
- **Disabled** – The port is not participating in RSTP. This can occur when the port is disconnected or RSTP is administratively disabled on the port.

A port on a non-root bridge with the role of Root port is always in a forwarding state. If another port on that bridge assumes the Root port role, then the old Root port moves into a discarding state as it assumes another port role.

A port on a non-root bridge with a Designated role starts in the discarding state. When that port becomes elected to the Root port role, RSTP quickly places it into a forwarding state. However, if the Designated port is an Edge port, then the port starts and stays in a forwarding state and it cannot be elected as a Root port.

A port with an Alternate or Backup role is always in a discarding state. If the port's role changes to Designated, then the port changes into a forwarding state.

If a port on one bridge has a Designated role and that port is connected to a port on another bridge that has an Alternate or Backup role, the port with a Designated role cannot be given a Root port role until two instances of the forward delay timer expires on that port.

Edge port and non-Edge port states

As soon as a port is configured as an Edge port, it goes into a forwarding state instantly (in less than 100 msec).

When the link to a port comes up and RSTP detects that the port is an Edge port, that port instantly goes into a forwarding state.

If RSTP detects that port as a non-edge port, the port goes into a forwarding state within four seconds of link up or after two hello timer expires on the port.

Changes to port roles and states

To achieve convergence in a topology, a port's role and state changes as it receives and transmits new RST BPDUs. Changes in a port's role and state constitute a topology change. Besides the superiority and inferiority of the RST BPDU, bridge-wide and per-port state machines are used to determine a port's role as well as a port's state. Port state machines also determine when port role and state changes occur.

State machines

The bridge uses the Port Role Selection state machine to determine if port role changes are required on the bridge. This state machine performs a computation when one of the following events occur:

- New information is received on any port on the bridge
- The timer expires for the current information on a port on the bridge

Each port uses the following state machines:

- **Port Information** – This state machine keeps track of spanning-tree information currently used by the port. It records the origin of the information and ages out any information that was derived from an incoming BPDU.
- **Port Role Transition** – This state machine keeps track of the current port role and transitions the port to the appropriate role when required. It moves the Root port and the Designated port into forwarding states and moves the Alternate and Backup ports into discarding states.

- **Port Transmit** – This state machine is responsible for BPDU transmission. It checks to ensure only the maximum number of BPDUs per hello interval are sent every second. Based on what mode it is operating in, it sends out either legacy BPDUs or RST BPDUs. In this document legacy BPDUs are also referred to as STP BPDUs.
- **Port Protocol Migration** – This state machine deals with compatibility with 802.1D bridges. When a legacy BPDU is detected on a port, this state machine configures the port to transmit and receive legacy BPDUs and operate in the legacy mode.
- **Topology Change** – This state machine detects, generates, and propagates topology change notifications. It acknowledges Topology Change Notice (TCN) messages when operating in 802.1D mode. It also flushes the MAC table when a topology change event takes place.
- **Port State Transition** – This state machine transitions the port to a discarding, learning, or forwarding state and performs any necessary processing associated with the state changes.
- **Port Timers** – This state machine is responsible for triggering any of the state machines described above, based on expiration of specific port timers.

In contrast to the 802.1D standard, the RSTP standard does not have any bridge specific timers. All timers in the CLI are applied on a per-port basis, even though they are configured under bridge parameters.

RSTP state machines attempt to quickly place the ports into either a forwarding or discarding state. Root ports are quickly placed in forwarding state when both of the following events occur:

- It is assigned to be the Root port.
- It receives an RST BPDU with a proposal flag from a Designated port. The proposal flag is sent by ports with a Designated role when they are ready to move into a forwarding state.

When a the role of Root port is given to another port, the old Root port is instructed to reroot. The old Root port goes into a discarding state and negotiates with its peer port for a new role and a new state. A peer port is the port on the other bridge to which the port is connected. For example, in Figure 34, Port1 of Switch 200 is the peer port of Port2 of Switch 100.

A port with a Designated role is quickly placed into a forwarding state if one of the following occurs:

- The Designated port receives an RST BPDU that contains an agreement flag from a Root port
- The Designated port is an Edge port

However, a Designated port that is attached to an Alternate port or a Backup port must wait until the forward delay timer expires twice on that port while it is still in a Designated role, before it can proceed to the forwarding state.

Backup ports are quickly placed into discarding states.

Alternate ports are quickly placed into discarding states.

A port operating in RSTP mode may enter a learning state to allow MAC address entries to be added to the filtering database; however, this state is transient and lasts only a few milliseconds, if the port is operating in RSTP mode and if the port meets the conditions for rapid transition.

Handshake mechanisms

To rapidly transition a Designated or Root port into a forwarding state, the Port Role Transition state machine uses handshake mechanisms to ensure loop free operations. It uses one type of handshake if no Root port has been assigned on a bridge, and another type if a Root port has already been assigned.

Handshake when no root port is elected

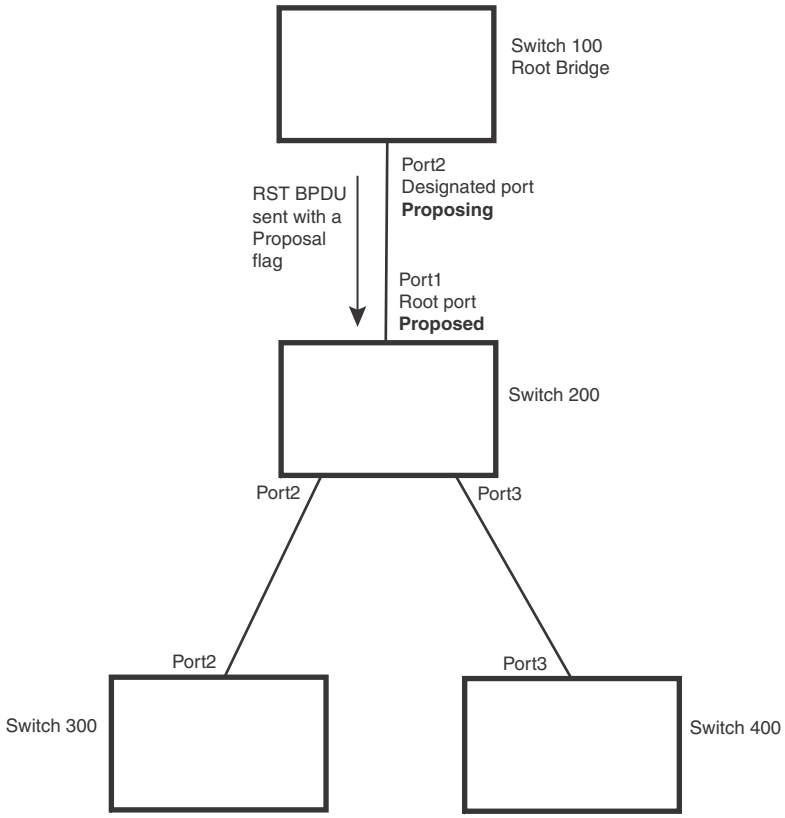
If a Root port has not been assigned on a bridge, RSTP uses the Proposing -> Proposed -> Sync -> Synced -> Agreed handshake:

- **Proposing** – The Designated port on the root bridge sends an RST BPDU packet to its peer port that contains a proposal flag. The proposal flag is a signal that indicates that the Designated port is ready to put itself in a forwarding state (Figure 34). The Designated port continues to send this flag in its RST BPDU until it is placed in a forwarding state (Figure 37) or is forced to operate in 802.1D mode. (Refer to "Compatibility of RSTP with 802.1D" on page 441)
- **Proposed** – When a port receives an RST BPDU with a proposal flag from the Designated port on its point-to-point link, it asserts the Proposed signal and one of the following occurs (Figure 34):
  - If the RST BPDU that the port receives is superior to what it can transmit, the port assumes the role of a Root port. (Refer to the section on "Bridges and bridge port roles" on page 413.)
  - If the RST BPDU that the port receives is inferior to what it can transmit, then the port is given the role of Designated port.

NOTE
Proposed will never be asserted if the port is connected on a shared media link.

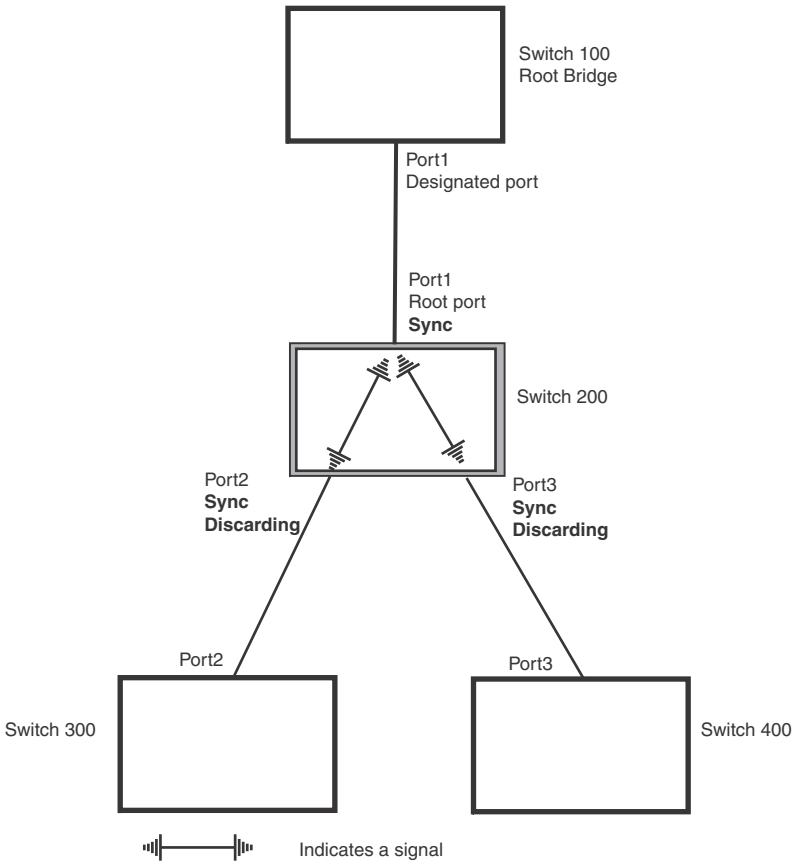
In Figure 34, Port3/Switch 200 is elected as the Root port

FIGURE 34 Proposing and proposed stage



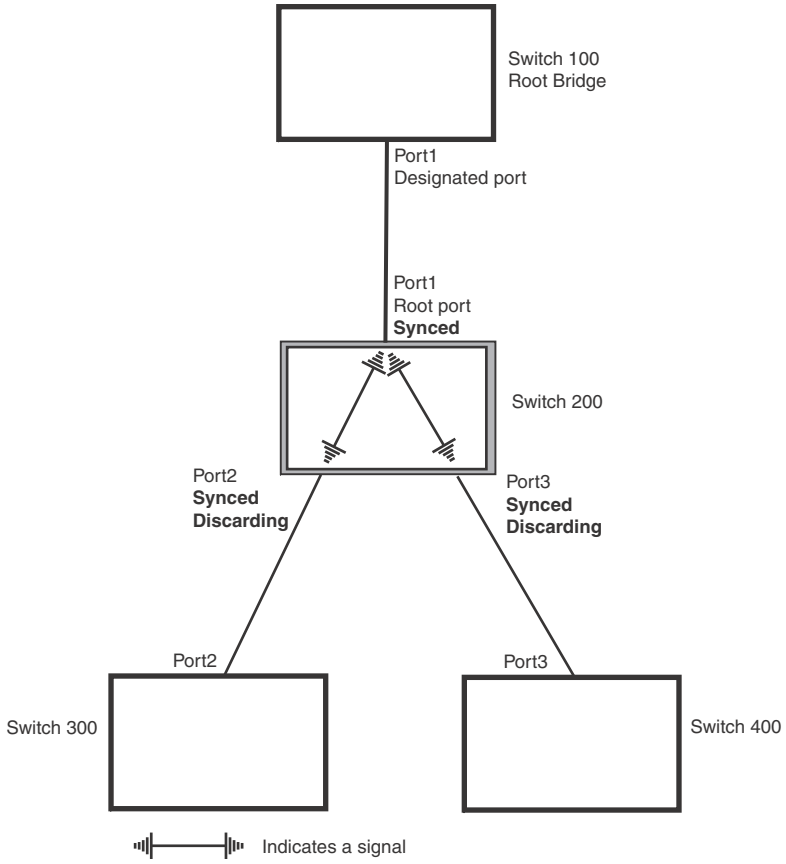
- **Sync** – Once the Root port is elected, it sets a sync signal on all the ports on the bridge. The signal tells the ports to synchronize their roles and states (Figure 35). Ports that are non-edge ports with a role of Designated port change into a discarding state. These ports have to negotiate with their peer ports to establish their new roles and states.

FIGURE 35 Sync stage



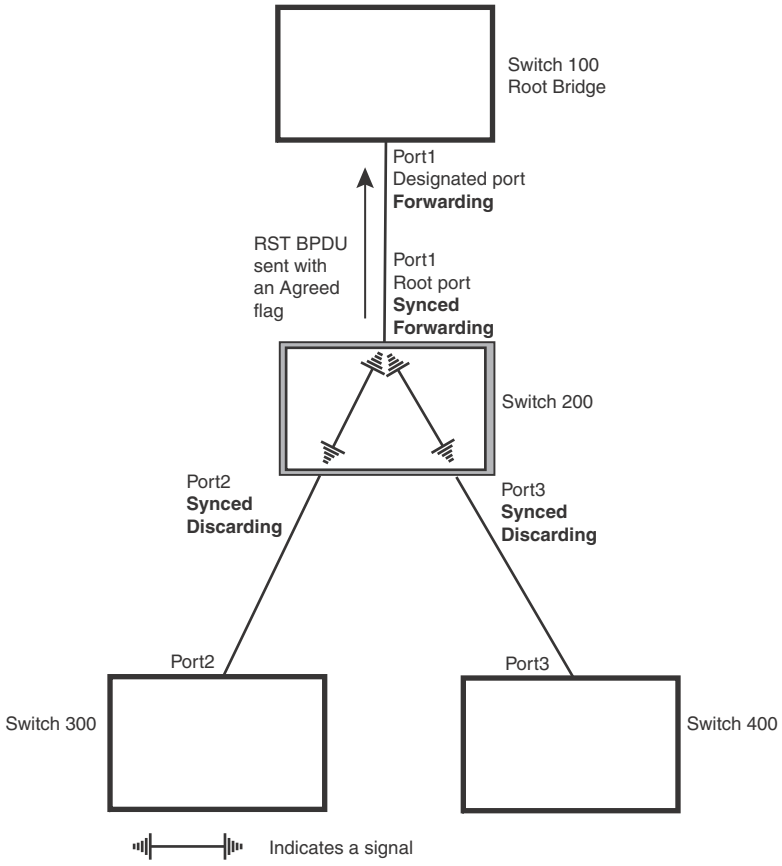
- **Synced** – Once the Designated port changes into a discarding state, it asserts a synced signal. Immediately, Alternate ports and Backup ports are synced. The Root port monitors the synced signals from all the bridge ports. Once all bridge ports asserts a synced signal, the Root port asserts its own synced signal (Figure 36).

FIGURE 36 Synced stage



- **Agreed** – The Root port sends back an RST BPDU containing an agreed flag to its peer Designated port and moves into the forwarding state. When the peer Designated port receives the RST BPDU, it rapidly transitions into a forwarding state.

FIGURE 37 Agree stage



At this point, the handshake mechanism is complete between Switch 100, the root bridge, and Switch 200.

Switch 200 updates the information on the Switch 200's Designated ports (Port2 and Port3) and identifies the new root bridge. The Designated ports send RST BPDUs, containing proposal flags, to their downstream bridges, without waiting for the hello timers to expire on them. This process starts the handshake with the downstream bridges.

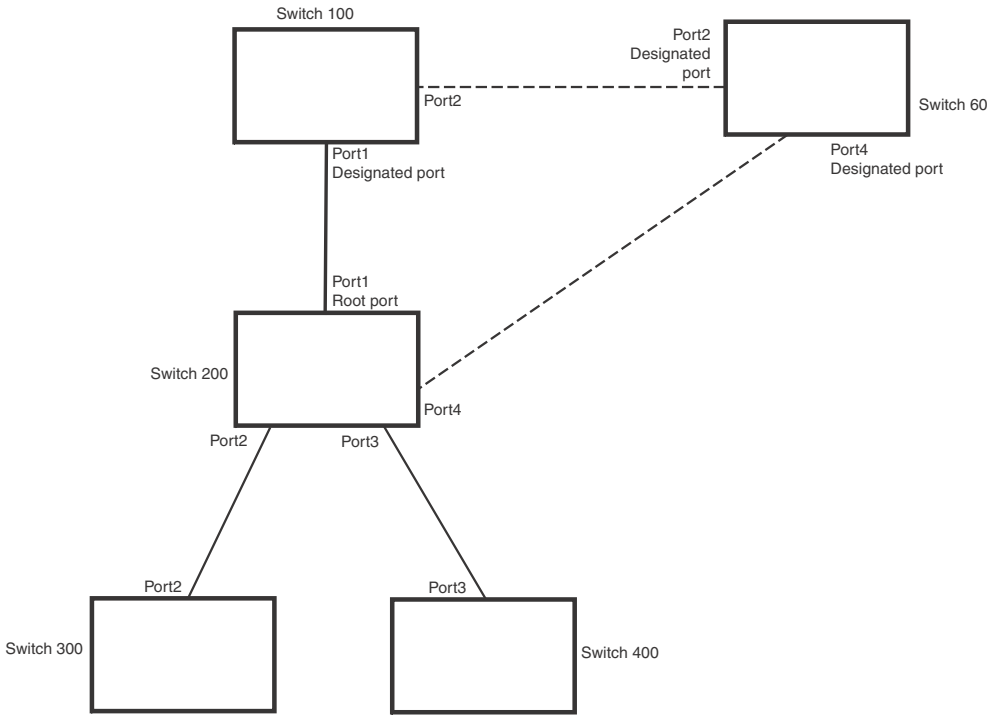
For example, Port2/Switch 200 sends an RST BPDU to Port2/Switch 300 that contains a proposal flag. Port2/Switch 300 asserts a proposed signal. Ports in Switch 300 then set sync signals on the ports to synchronize and negotiate their roles and states. Then the ports assert a synced signal and when the Root port in Switch 300 asserts it's synced signal, it sends an RST BPDU to Switch 200 with an agreed flag.

This handshake is repeated between Switch 200 and Switch 400 until all Designated and Root ports are in forwarding states.

Handshake when a root port has been elected

If a non-root bridge already has a Root port, RSTP uses a different type of handshake. For example, in Figure 38, a new root bridge is added to the topology.

FIGURE 38 Addition of a new root bridge

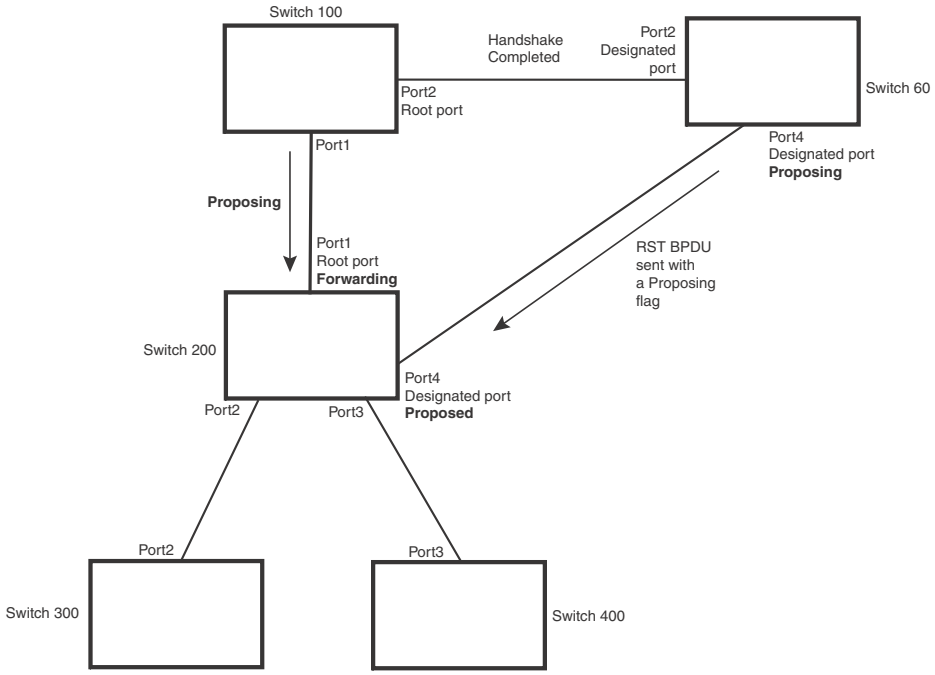


The handshake that occurs between Switch 60 and Switch 100 follows the one described in the previous section ("Handshake when no root port is elected" on page 420). The former root bridge becomes a non-root bridge and establishes a Root port (Figure 39).

However, since Switch 200 already had a Root port in a forwarding state, RSTP uses the Proposing -> Proposed -> Sync and Reroot -> Sync and Rerooted -> Rerooted and Synced -> Agreed handshake:

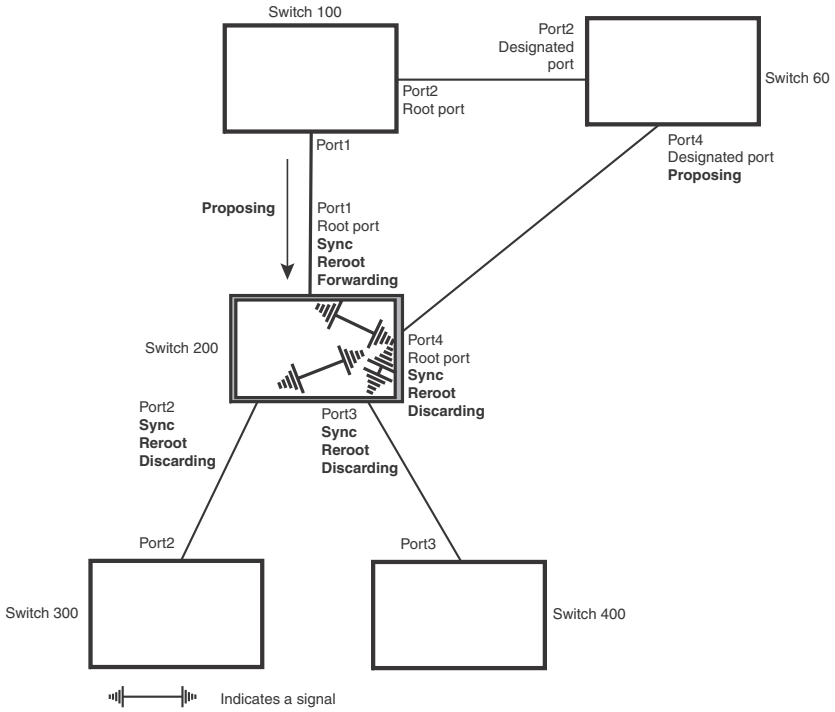
- **Proposing and Proposed** – The Designated port on the new root bridge (Port4/Switch 60) sends an RST BPDU that contains a proposing signal to Port4/Switch 200 to inform the port that it is ready to put itself in a forwarding state (Figure 39). RSTP algorithm determines that the RST BPDU that Port4/Switch 200 received is superior to what it can generate, so Port4/Switch 200 assumes a Root port role.

FIGURE 39 New root bridge sending a proposal flag



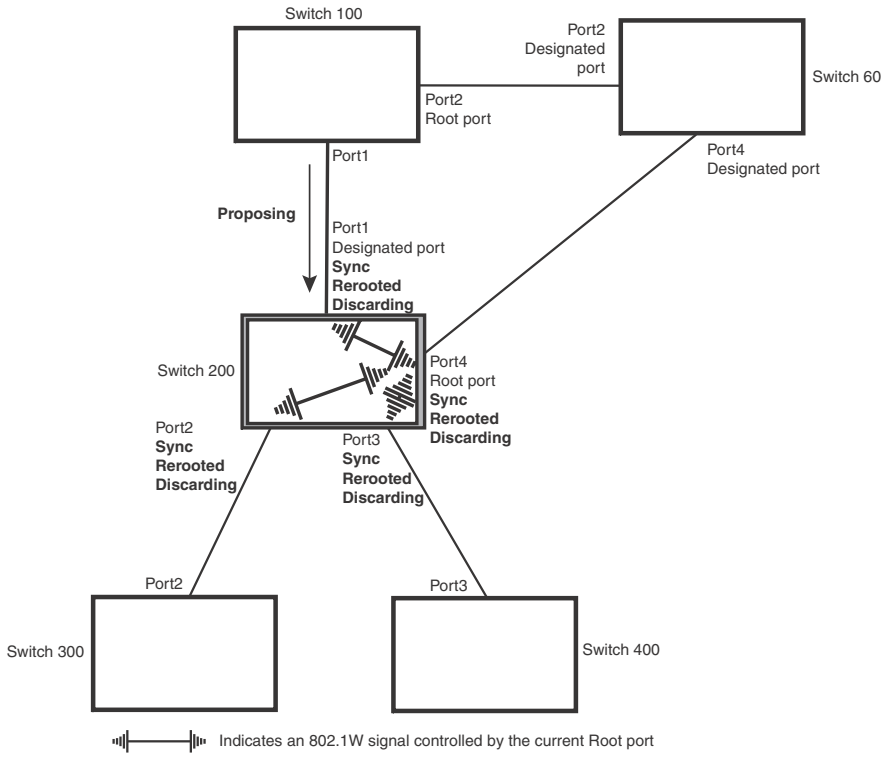
- **Sync and Reroot** – The Root port then asserts a sync and a reroot signal on all the ports on the bridge. The signal tells the ports that a new Root port has been assigned and they are to renegotiate their new roles and states. The other ports on the bridge assert their sync and reroot signals. Information about the old Root port is discarded from all ports. Designated ports change into discarding states (Figure 40).

FIGURE 40 Sync and reroot



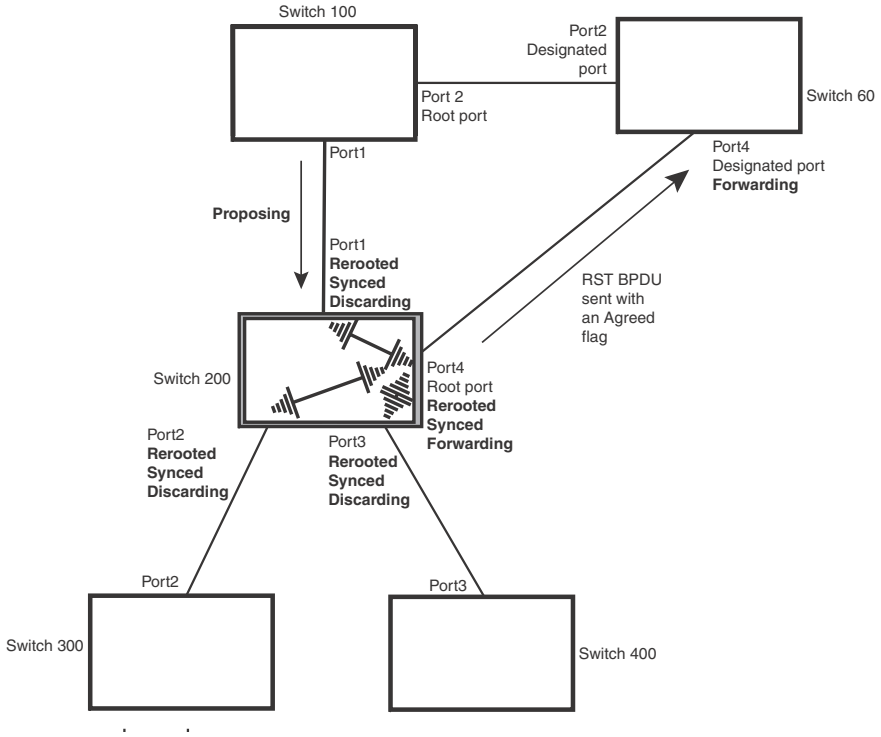
- **Sync and Rerooted** – When the ports on Switch 200 have completed the reroot phase, they assert their rerooted signals and continue to assert their sync signals as they continue in their discarding states. They also continue to negotiate their roles and states with their peer ports (Figure 41).

FIGURE 41 Sync and rerooted



- **Synced and Agree** – When all the ports on the bridge assert their synced signals, the new Root port asserts its own synced signal and sends an RST BPDU to Port4/Switch 60 that contains an agreed flag (Figure 41). The Root port also moves into a forwarding state.

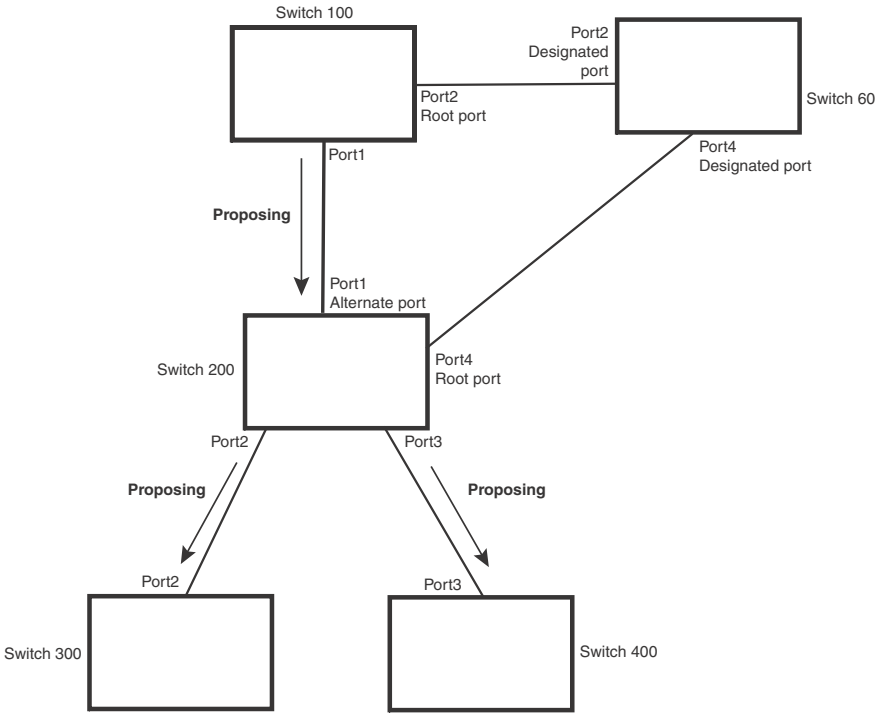
FIGURE 42 Rerooted, synced, and agreed



The old Root port on Switch 200 becomes an Alternate Port (Figure 43). Other ports on that bridge are elected to appropriate roles.

The Designated port on Switch 60 goes into a forwarding state once it receives the RST BPDU with the agreed flag.

FIGURE 43 Handshake completed after election of new root port



Recall that Switch 200 sent the agreed flag to Port4/Switch 60 and not to Port1/Switch 100 (the port that connects Switch 100 to Switch 200). Therefore, Port1/Switch 100 does not go into forwarding state instantly. It waits until two instances of the forward delay timer expires on the port before it goes into forwarding state.

At this point the handshake between the Switch 60 and Switch 200 is complete.

The remaining bridges (Switch 300 and Switch 400) may have to go through the reroot handshake if a new Root port needs to be assigned.

Convergence in a simple topology

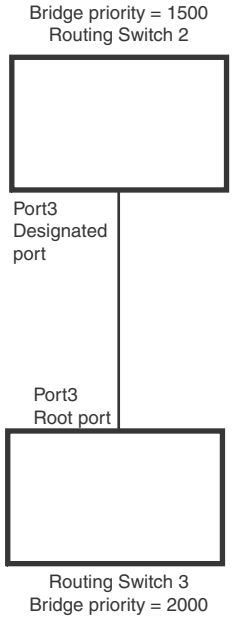
The examples in this section illustrate how RSTP convergence occurs in a simple Layer 2 topology at start-up.

NOTE
The remaining examples assume that the appropriate handshake mechanisms occur as port roles and states change.

Convergence at start up

In Figure 44, two bridges Switch 2 and Switch 3 are powered up. There are point-to-point connections between Port3/Switch 2 and Port3/Switch 3.

FIGURE 44 Convergence between two bridges



At power up, all ports on Switch 2 and Switch 3 assume Designated port roles and are at discarding states before they receive any RST BPDU.

Port3/Switch 2, with a Designated role, transmits an RST BPDU with a proposal flag to Port3/Switch 3. A ports with a Designated role sends the proposal flag in its RST BPDU when they are ready to move to a forwarding state.

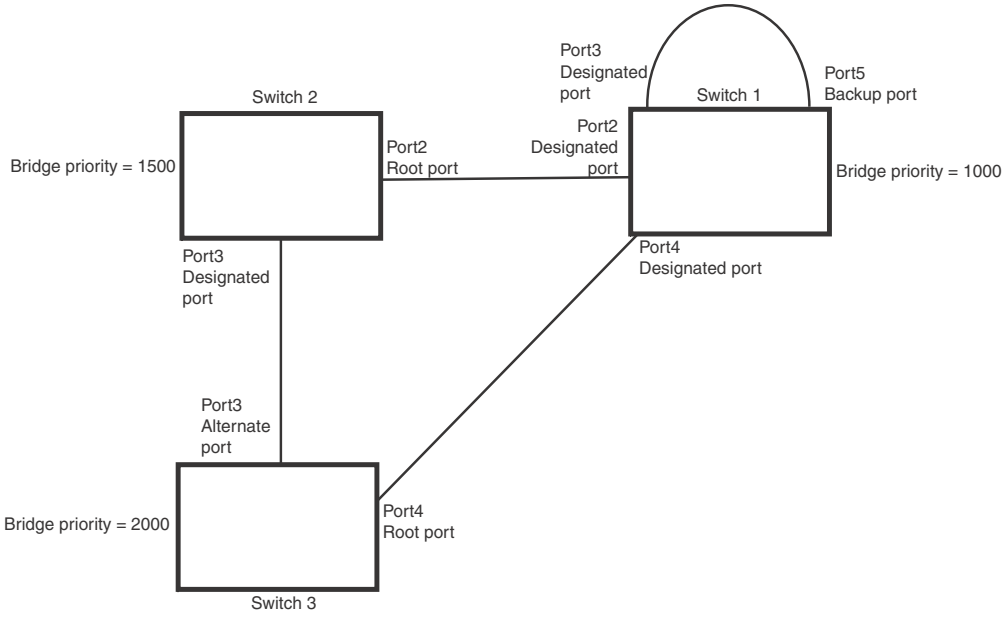
Port3/Switch 3, which starts with a role of Designated port, receives the RST BPDU and finds that it is superior to what it can transmit; therefore, Port3/Switch 3 assumes a new port role, that of a Root port. Port3/Switch 3 transmits an RST BPDU with an agreed flag back to Switch 2 and immediately goes into a forwarding state.

Port3/Switch 2 receives the RST BPDU from Port3/Switch 3 and immediately goes into a forwarding state.

Now RSTP has fully converged between the two bridges, with Port3/Switch 3 as an operational root port in forwarding state and Port3/Switch 2 as an operational Designated port in forwarding state.

Next, Switch 1 is powered up (Figure 45).

FIGURE 45 Simple Layer 2 topology



The point-to-point connections between the three bridges are as follows:

- Port2/Switch 1 and Port2/Switch 2
- Port4/Switch 1 and Port4/Switch 3
- Port3/Switch 2 and Port3/Switch 3

Ports 3 and 5 on Switch 1 are physically connected together.

At start up, the ports on Switch 1 assume Designated port roles, which are in discarding state. They begin sending RST BPDUs with proposal flags to move into a forwarding state.

When Port4/Switch 3 receives these RST BPDUs RSTP algorithm determines that they are better than the RST BPDUs that were previously received on Port3/Switch 3. Port4/Switch 3 is now selected as Root port. This new assignment signals Port3/Switch 3 to begin entering the discarding state and to assume an Alternate port role. As it goes through the transition, Port3/Switch 3 negotiates a new role and state with its peer port, Port3/Switch 2.

Port4/Switch 3 sends an RST BPDU with an agreed flag to Port4/Switch 1. Both ports go into forwarding states.

Port2/Switch 2 receives an RST BPDU. The RSTP algorithm determines that these RST BPDUs that are superior to any that any port on Switch 2 can transmit; therefore, Port2/Switch 2 assumes the role of a Root port.

The new Root port then signals all ports on the bridge to start synchronization. Since none of the ports are Edge ports, they all enter the discarding state and assume the role of Designated ports. Port3/Switch 2, which previously had a Designated role with a forwarding state, starts the discarding state. They also negotiate port roles and states with their peer ports. Port3/Switch 2 also sends an RST BPU to Port3/Switch 3 with a proposal flag to request permission go into a forwarding state.

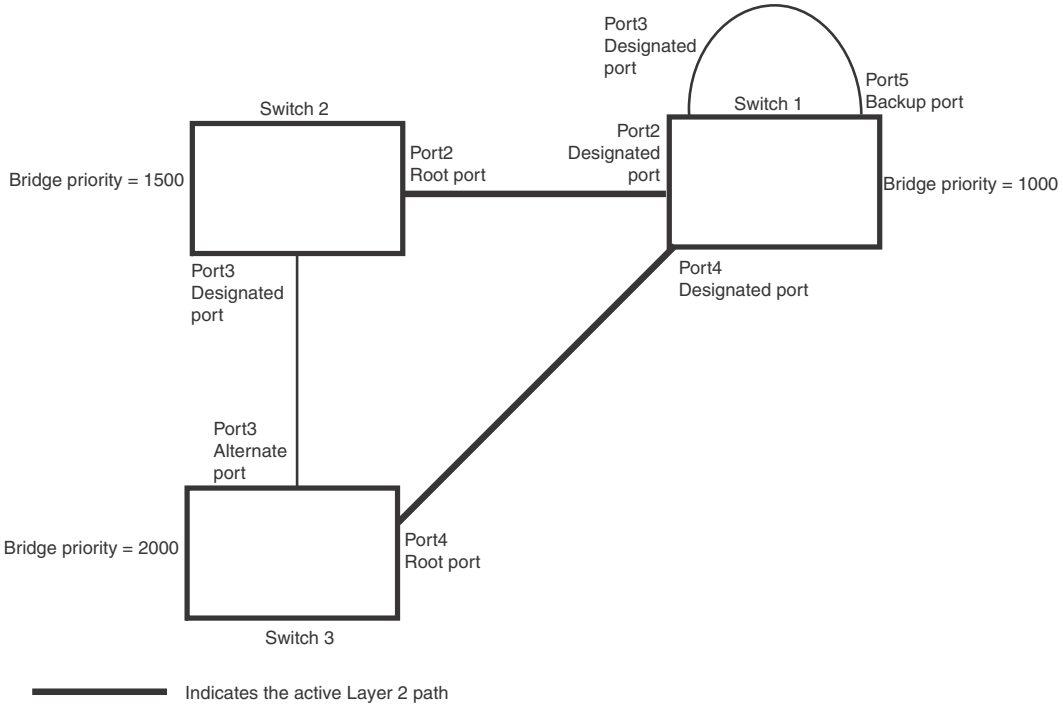
The Port2/Switch 2 bridge also sends an RST BPDU with an agreed flag Port2/Switch 1 that Port2 is the new Root port. Both ports go into forwarding states.

Now, Port3/Switch 3 is currently in a discarding state and is negotiating a port role. It received RST BPDUs from Port3/Switch 2. The RSTP algorithm determines that the RST BPDUs Port3/Switch 3 received are superior to those it can transmit; however, they are not superior to those that are currently being received by the current Root port (Port4). Therefore, Port3 retains the role of Alternate port.

Ports 3/Switch 1 and Port5/Switch 1 are physically connected. Port5/Switch 1 received RST BPDUs that are superior to those received on Port3/Switch 1; therefore, Port5/Switch 1 is given the Backup port role while Port3 is given the Designated port role. Port3/Switch 1, does not go directly into a forwarding state. It waits until the forward delay time expires twice on that port before it can proceed to the forwarding state.

Once convergence is achieved, the active Layer 2 forwarding path converges as shown in Figure 46.

FIGURE 46 Active Layer 2 path

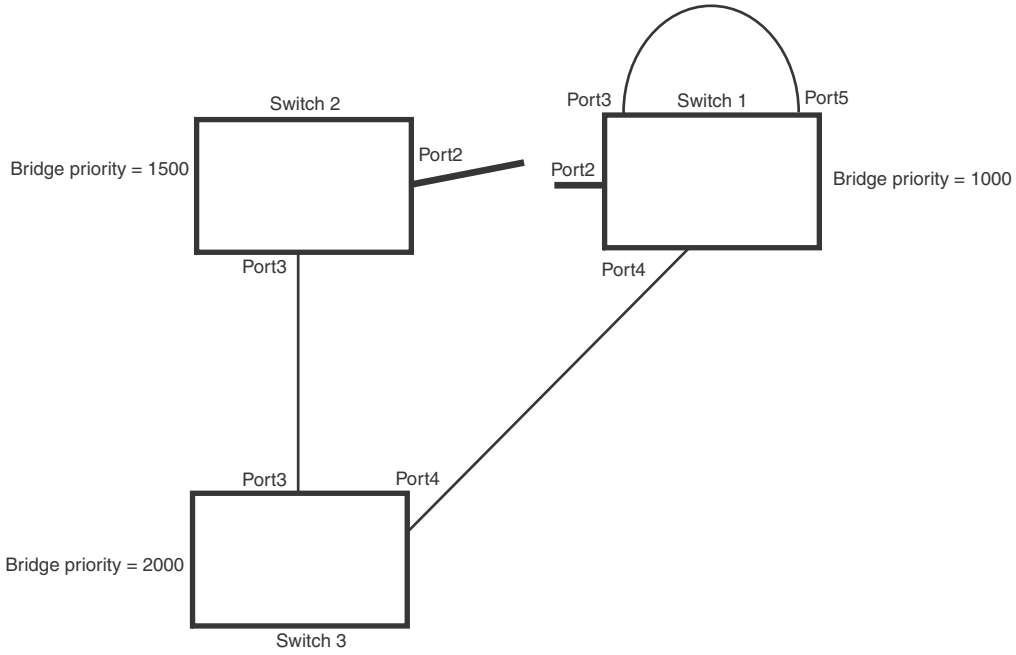


Convergence after a link failure

What happens if a link in the RSTP topology fails?

For example, Port2/Switch, which is the port that connects Switch 2 to the root bridge (Switch 1), fails. Both Switch 2 and Switch 1 notice the topology change (Figure 47).

FIGURE 47 Link failure in the topology



Switch 1 sets its Port2 into a discarding state.

At the same time, Switch 2 assumes the role of a root bridge since its root port failed and it has no operational Alternate port. Port3/Switch 2, which currently has a Designated port role, sends an RST BPDU to Switch 3. The RST BPDU contains a proposal flag and a bridge ID of Switch 2 as its root bridge ID.

When Port3/Switch 3 receives the RST BPDUs, RSTP algorithm determines that they are inferior to those that the port can transmit. Therefore, Port3/Switch 3 is given a new role, that of a Designated port. Port3/Switch 3 then sends an RST BPDU with a proposal flag to Switch 2, along with the new role information. However, the root bridge ID transmitted in the RST BPDU is still Switch 1.

When Port3/Switch 2 receives the RST BPDU, RSTP algorithm determines that it is superior to the RST BPDU that it can transmit; therefore, Port3/Switch 2 receives a new role; that of a Root port. Port3/Switch 2 then sends an RST BPDU with an agreed flag to Port3/Switch 3. Port3/Switch 2 goes into a forwarding state.

When Port3/Switch 3 receives the RST BPDU that Port3/Switch 2 sent, Port3/Switch 3 changes into a forwarding state, which then completes the full convergence of the topology.

Convergence at link restoration

When Port2/Switch 2 is restored, both Switch 2 and Switch 1 recognize the change. Port2/Switch 1 starts assuming the role of a Designated port and sends an RST BPDU containing a proposal flag to Port2/Switch 2.

When Port2/Switch 2 receives the RST BPDUs, RSTP algorithm determines that the RST BPDUs the port received are better than those received on Port3/Switch 3; therefore, Port2/Switch 2 is given the role of a Root port. All the ports on Switch 2 are informed that a new Root port has been assigned which then signals all the ports to synchronize their roles and states. Port3/Switch 2, which was the previous Root port, enters a discarding state and negotiates with other ports on the bridge to establish its new role and state, until it finally assumes the role of a Designated port.

Next, the following happens:

- Port3/Switch 2, the Designated port, sends an RST BPDU, with a proposal flag to Port3/Switch 3.
- Port2/Switch 2 also sends an RST BPDU with an agreed flag to Port2/Switch 1 and then places itself into a forwarding state.

When Port2/Switch 1 receives the RST BPDU with an agreed flag sent by Port2/Switch 2, it puts that port into a forwarding state. The topology is now fully converged.

When Port3/Switch 3 receives the RST BPDU that Port3/Switch 2 sent, RSTP algorithm determines that these RST BPDUs are superior to those that Port3/Switch 3 can transmit. Therefore, Port3/Switch 3 is given a new role, that of an Alternate port. Port3/Switch 3 immediately enters a discarding state.

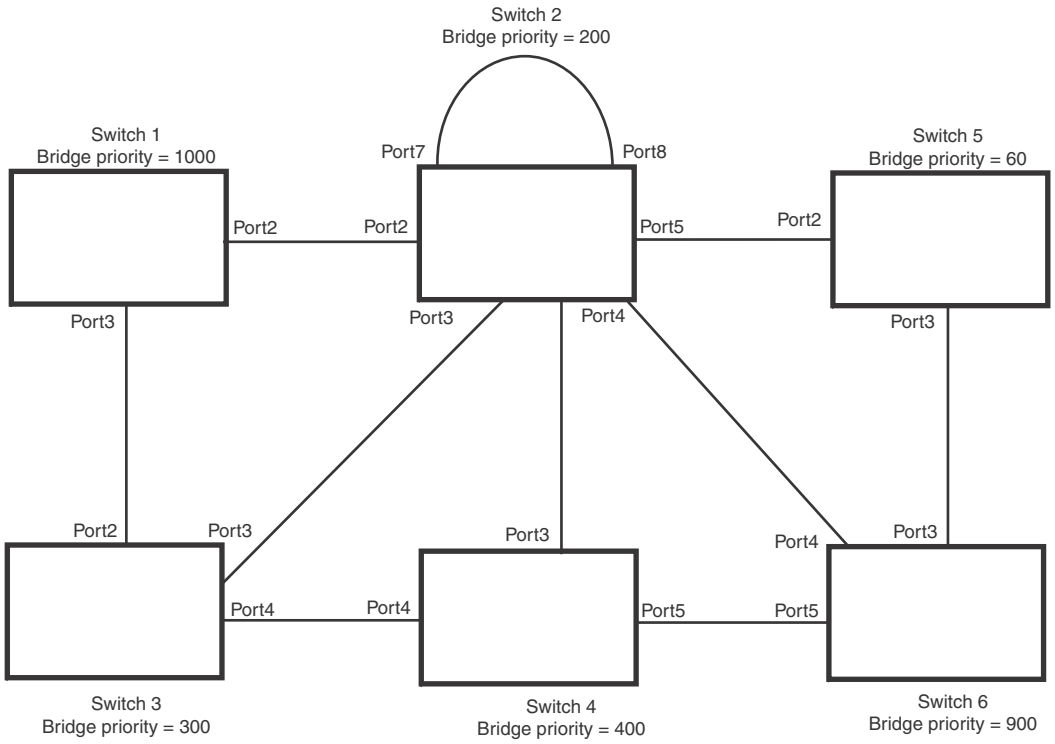
Now Port3/Switch 2 does not go into a forwarding state instantly like the Root port. It waits until the forward delay timer expires twice on that port while it is still in a Designated role, before it can proceed to the forwarding state. The wait, however, does not cause a denial of service, since the essential connectivity in the topology has already been established.

When fully restored, the topology is the same as that shown on Figure 45.

Convergence in a complex RSTP topology

The following is an example of a complex RSTP topology.

FIGURE 48 Complex RSTP topology



In Figure 48, Switch 5 is selected as the root bridge since it is the bridge with the highest priority. Lines in the figure show the point-to-point connection to the bridges in the topology.

Switch 5 sends an RST BPDU that contains a proposal flag to Port5/Switch 2. When handshakes are completed in Switch 5, Port5/Switch 2 is selected as the Root port on Switch 2. All other ports on Switch 2 are given Designated port role with discarding states.

Port5/Switch 2 then sends an RST BPDU with an agreed flag to Switch 5 to confirm that it is the new Root port and the port enters a forwarding state. Port7 and Port8 are informed of the identity of the new Root port. RSTP algorithm selects Port7 as the Designated port while Port8 becomes the Backup port.

Port3/Switch 5 sends an RST BPDU to Port3/Switch 6 with a proposal flag. When Port3/Switch 5 receives the RST BPDU, handshake mechanisms select Port3 as the Root port of Switch 6. All other ports are given a Designated port role with discarding states. Port3/Switch 6 then sends an RST BPDU with an agreed flag to Port3/Switch 5 to confirm that it is the Root port. The Root port then goes into a forwarding state.

Now, Port4/Switch 6 receives RST BPDUs that are superior to what it can transmit; therefore, it is given the Alternate port role. The port remains in discarding state.

Port5/Switch 6 receives RST BPDUs that are inferior to what it can transmit. The port is then given a Designated port role.

Next Switch 2 sends RST BPDUs with a proposal flag to Port3/Switch 4. Port3 becomes the Root port for the bridge; all other ports are given a Designated port role with discarding states. Port3/Switch 4 sends an RST BPDU with an agreed flag to Switch 2 to confirm that it is the new Root port. The port then goes into a forwarding state.

Now Port4/Switch 4 receives an RST BPDU that is superior to what it can transmit. The port is then given an Alternate port role, and remains in discarding state.

Likewise, Port5/Switch 4 receives an RST BPDU that is superior to what it can transmit. The port is also given an Alternate port role, and remains in discarding state.

Port2/Switch 2 transmits an RST BPDU with a proposal flag to Port2/Switch 1. Port2/Switch 1 becomes the Root port. All other ports on Switch 1 are given Designated port roles with discarding states.

Port2/Switch 1 sends an RST BPDU with an agreed flag to Port2/Switch 2 and Port2/Switch 1 goes into a forwarding state.

Port3/Switch 1 receives an RST BPDUs that is inferior to what it can transmit; therefore, the port retains its Designated port role and goes into forwarding state only after the forward delay timer expires twice on that port while it is still in a Designated role.

Port3/Switch 2 sends an RST BPDU to Port3/Switch 3 that contains a proposal flag. Port3/Switch 3 becomes the Root port, while all other ports on Switch 3 are given Designated port roles and go into discarding states. Port3/Switch 3 sends an RST BPDU with an agreed flag to Port3/Switch 2 and Port3/Switch 3 goes into a forwarding state.

Now, Port2/Switch 3 receives an RST BPDUs that is superior to what it can transmit so that port is given an Alternate port state.

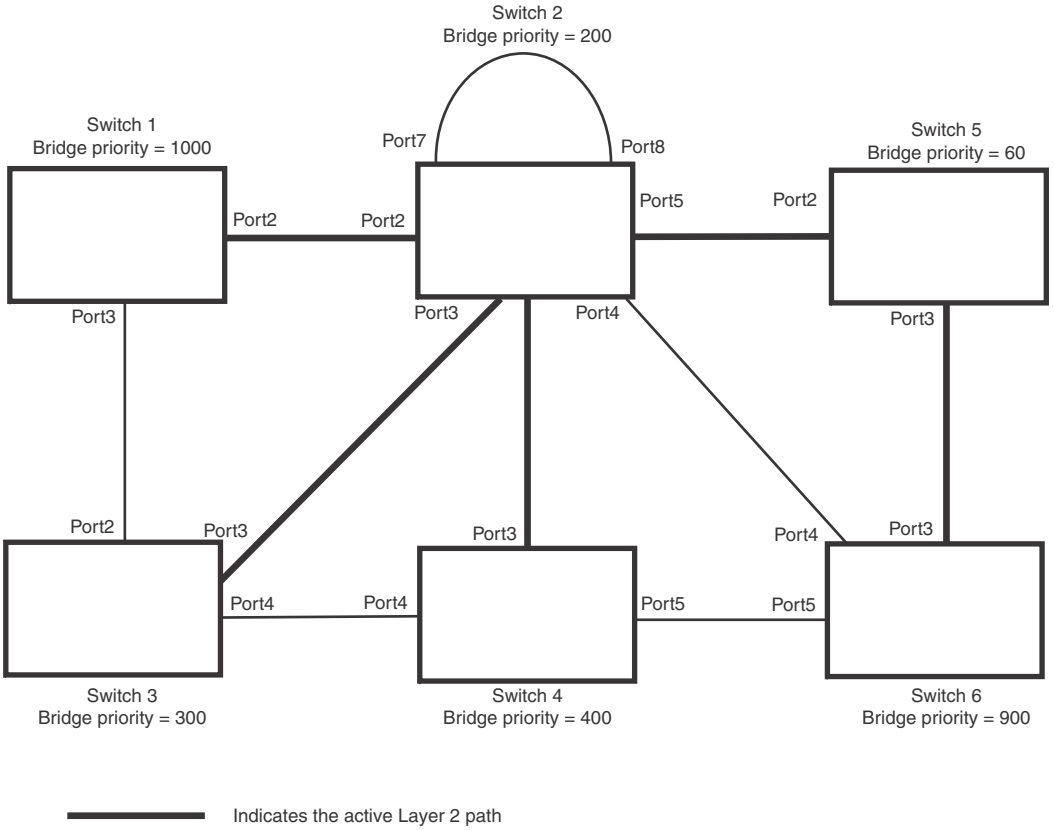
Port4/Switch 3 receives an RST BPDU that is inferior to what it can transmit; therefore, the port retains its Designated port role.

Ports on all the bridges in the topology with Designated port roles that received RST BPDUs with agreed flags go into forwarding states instantly. However, Designated ports that did not receive RST BPDUs with agreed flags must wait until the forward delay timer expires twice on those port. Only then will these port move into forwarding states.

The entire RSTP topology converges in less than 300 msec and the essential connectivity is established between the designated ports and their connected root ports.

After convergence is complete, Figure 49 shows the active Layer 2 path of the topology in Figure 48.

FIGURE 49 Active Layer 2 path in complex topology



Propagation of topology change

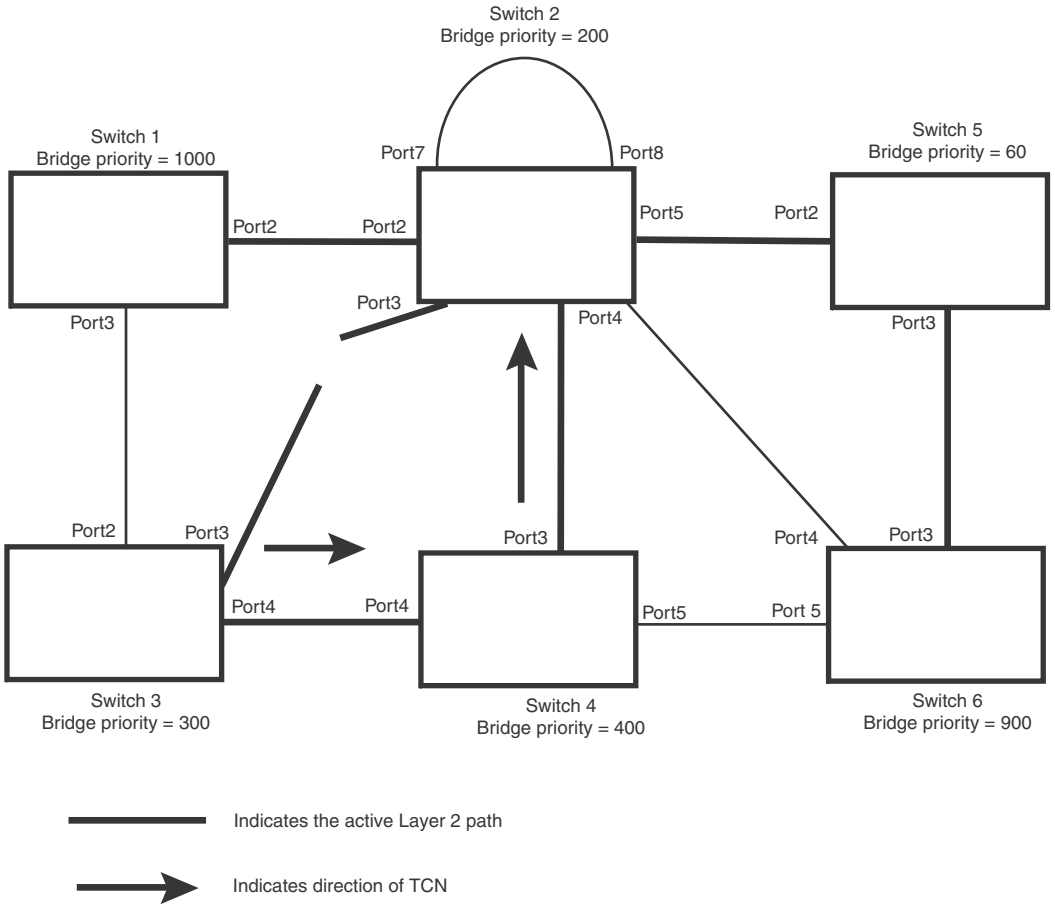
The Topology Change state machine generates and propagates the topology change notification messages on each port. When a Root port or a Designated port goes into a forwarding state, the Topology Change state machine on those ports send a topology change notice (TCN) to all the bridges in the topology to propagate the topology change.

NOTE
Edge ports, Alternate ports, or Backup ports do not need to propagate a topology change.

The TCN is sent in the RST BPDU that a port sends. Ports on other bridges in the topology then acknowledge the topology change once they receive the RST BPDU, and send the TCN to other bridges until all the bridges are informed of the topology change.

For example, Port3/Switch 2 in Figure 50, fails. Port4/Switch 3 becomes the new Root port. Port4/Switch 3 sends an RST BPDU with a TCN to Port4/Switch 4. To propagate the topology change, Port4/Switch 4 then starts a TCN timer on itself, on the bridge's Root port, and on other ports on that bridge with a Designated role. Then Port3/Switch 4 sends RST BPDU with the TCN to Port4/Switch 2. (Note the new active Layer 2 path in Figure 50.)

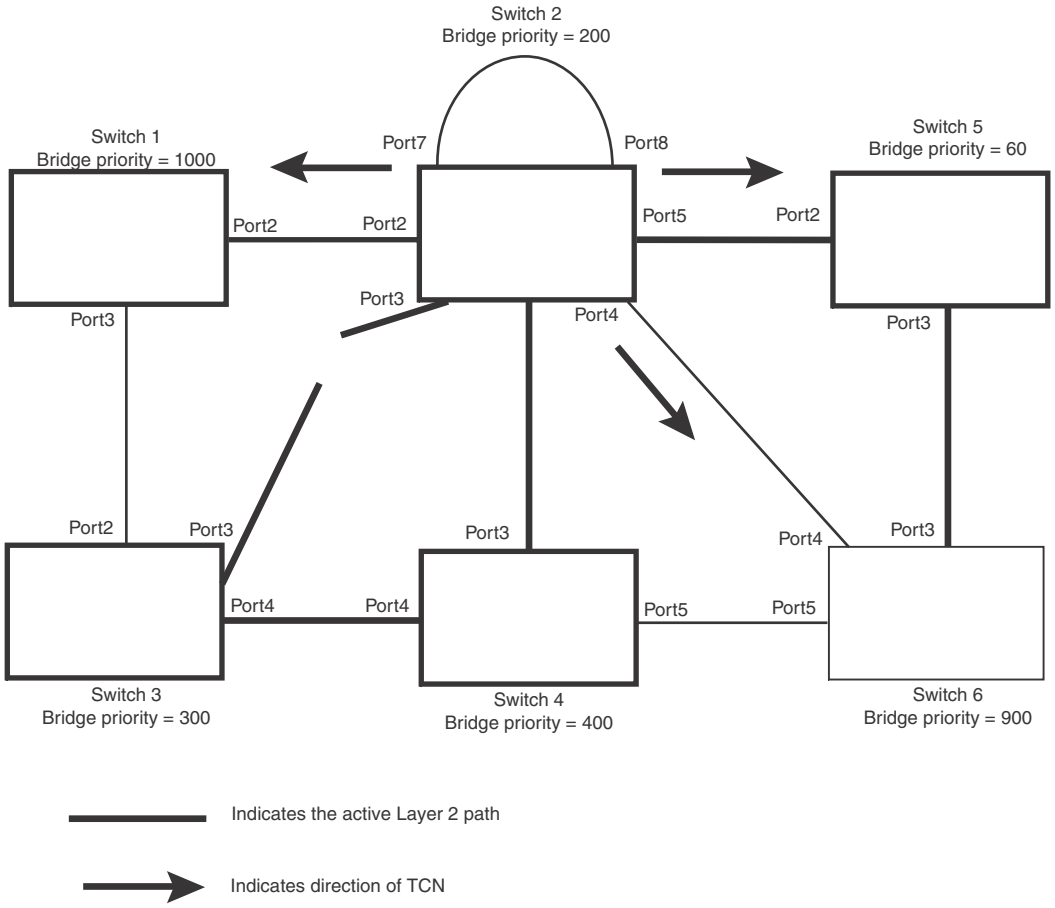
FIGURE 50 Beginning of topology change notice



Switch 2 then starts the TCN timer on the Designated ports and sends RST BPDUs that contain the TCN as follows (Figure 51):

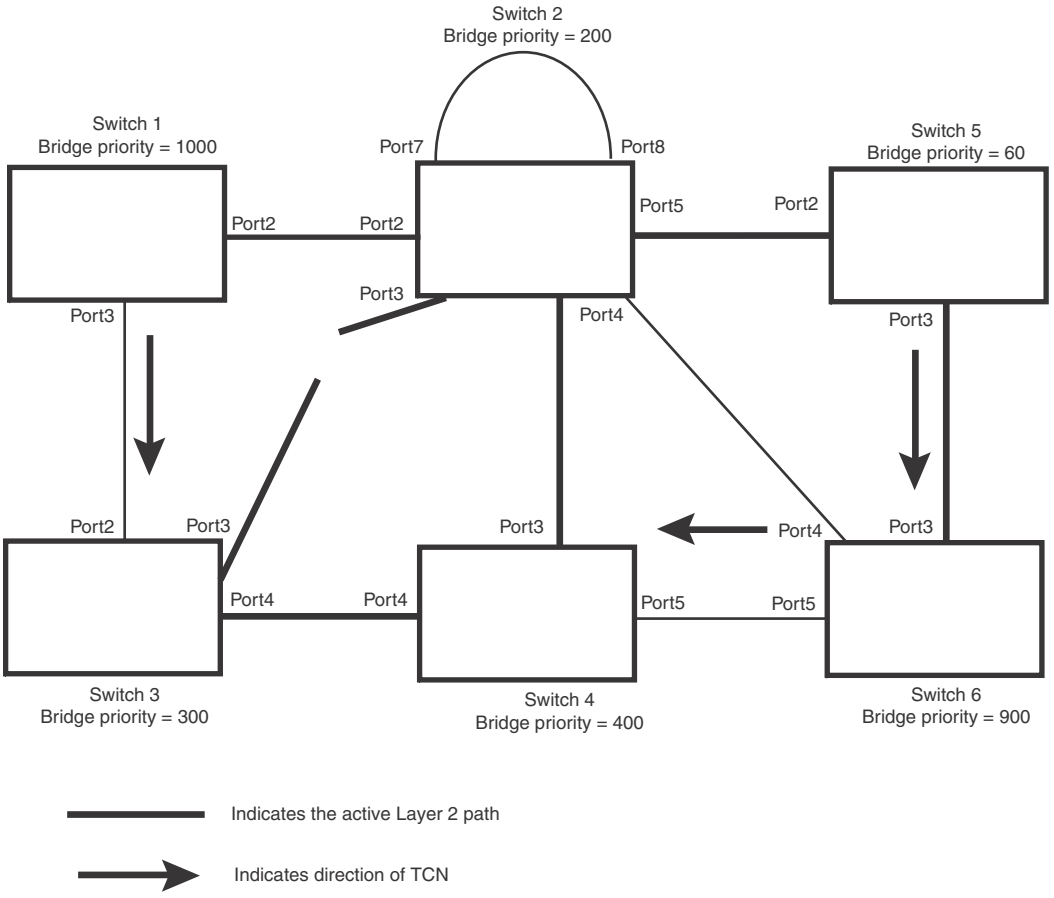
- Port5/Switch 2 sends the TCN to Port2/Switch 5
- Port4/Switch 2 sends the TCN to Port4/Switch 6
- Port2/Switch 2 sends the TCN to Port2/Switch 1

FIGURE 51 Sending TCN to bridges connected to Switch 2



Then FRY1, Switch 5, and Switch 6 send RST BPDUs that contain the TCN to Switch 3 and Switch 4 to complete the TCN propagation (Figure 52).

FIGURE 52 Completing the TCN propagation



Compatibility of RSTP with 802.1D

RSTP-enabled bridges are backward compatible with IEEE 802.1D bridges. This compatibility is managed on a per-port basis by the Port Migration state machine. **However, intermixing the two types of bridges in the network topology is not advisable if you want to take advantage of the rapid convergence feature.**

Compatibility with 802.1D means that an RSTP-enabled port can send BPDUs in the STP or 802.1D format when one of the following events occur:

- The port receives a legacy BPDU. A legacy BPDU is an STP BPDU or a BPDU in an 802.1D format. The port that receives the legacy BPDU automatically configures itself to behave like a legacy port. It sends and receives legacy BPDUs only.
- The entire bridge is configured to operate in an 802.1D mode when an administrator sets the
- bridge parameter to zero at the CLI, forcing all ports on the bridge to send legacy BPDUs only.

Once a port operates in the 802.1D mode, 802.1D convergence times are used and rapid convergence is not realized.

For example, in Figure 53, Switch 10 and Switch 30 receive legacy BPDUs from Switch 20. Ports on Switch 10 and Switch 30 begin sending BPDUs in STP format to allow them to operate transparently with Switch 20.

FIGURE 53 RSTP bridges with an 802.1D bridge

Once Switch 20 is removed from the LAN, Switch 10 and Switch 30 receive and transmit BPDUs in the STP format to and from each other. This state will continue until the administrator enables the **force-migration-check** command to force the bridge to send RSTP BPDU during a migrate time period. If ports on the bridges continue to hear only STP BPDUs after this migrate time period, those ports will return to sending STP BPDUs. However, when the ports receive RST BPDUs during the migrate time period, the ports begin sending RST BPDUs. The migrate time period is non-configurable. It has a value of three seconds.

NOTE
The IEEE standards state that RSTP bridges need to interoperate with 802.1D bridges. IEEE standards set the path cost of RSTP bridges to be between 1 and 200,000,000; whereas path cost of 802.1D bridges are set between 1 and 65,535. In order for the two bridge types to be able to interoperate in the same topology, the administrator needs to configure the bridge path cost appropriately. Path costs for either RSTP bridges or 802.1D bridges need to be changed; in most cases, path costs for RSTP bridges need to be changed.

Configuring RSTP parameters

The remaining RSTP sections explain how to configure the RSTP protocol on a PowerConnect.

You can enable or disable RSTP at the following levels:

- **Port-based VLAN** – Affects all ports within the specified port-based VLAN. When you enable or disable RSTP within a port-based VLAN, the setting overrides the global setting. Thus, you can enable RSTP for the ports within a port-based VLAN even when RSTP is globally disabled, or disable the ports within a port-based VLAN when RSTP is globally enabled.
- **Individual port** – Affects only the individual port. However, if you change the RSTP state of the primary port in a LAG group, the change affects all ports in the LAG group.

Enabling or disabling RSTP in a port-based VLAN

Use the following procedure to disable or enable RSTP on a PowerConnect on which you have configured a port-based VLAN. Changing the RSTP state in a VLAN affects only that VLAN.

To enable RSTP for all ports in a port-based VLAN, enter commands such as the following.

```
NetIron(config)# vlan 10
NetIron(config-vlan-10)# rstp
```

Syntax: [no] rstp

Enabling or disabling RSTP on a single spanning tree

To globally enable RSTP for all ports of a single spanning tree, enter the following command.

```
NetIron(config)# rstp single
```

Syntax: [no] rstp single

Disabling or enabling RSTP on a port

The **rstp** command must be used to initially enable RSTP on ports. Both commands enable RSTP on all ports that belong to the VLAN or to the single spanning tree.

Once RSTP is enabled on a port, it can be disabled on individual ports. RSTP that have been disabled on individual ports can then be enabled as required.

NOTE
If you change the RSTP state of the primary port in a LAG group, the change affects all ports in that LAG group.

To disable or enable RSTP on a port, enter commands such as the following.

```
NetIron(config)# interface 1/1
NetIron(config-if-e1000-1/1)# no spanning-tree
```

Syntax: [no] spanning-tree

Changing RSTP bridge parameters

When you make changes to RSTP bridge parameters, the changes are applied to individual ports on the bridge.

To designate a priority for a bridge, enter a command such as the following at the VLAN level.

```
NetIron(config)# vlan 20
NetIron(config-vlan-20)# rstp priority 0
```

To make this change in the default VLAN, enter the following commands.

```
NetIron(config)# vlan 1
NetIron(config-vlan-1)# rstp priority 0
```

Syntax: [**rstp forward-delay** <*value*>] | [**hello-time** <*value*>] | [**max-age** <*time*>] | [**force-version** <*value*>] | [**priority** <*value*>]

The **forward-delay** <*value*> parameter specifies how long a port waits before it forwards an RST BPDU after a topology change. Possible values: 4 – 30 seconds. The default is 15 seconds.

The **hello-time** <*value*> parameter specifies the interval between two hello packets. Possible values: 1 - 10 seconds. The default is 2 seconds.

The **max-age** <*value*> parameter specifies the amount of time the device waits to receive a hello packet before it initiates a topology change. Possible values: 6 – 40 seconds. The default is 20 seconds.

The value of **max-age** must be greater than the value of **forward-delay** to ensure that the downstream bridges do not age out faster than the upstream bridges (those bridges that are closer to the root bridge).

The **force-version** <*value*> parameter forces the bridge to send BPDUs in a specific format. You can specify one of the following values:

- 0 – The STP compatibility mode. Only STP (or legacy) BPDUs will be sent.
- 2 – The default. RST BPDUs will be sent unless a legacy bridge is detected. If a legacy bridge is detected, STP BPDUs will be sent instead.

The **priority** <*value*> parameter specifies the priority of the bridge. You can enter a value from 0 – 65535. A lower numerical value means a the bridge has a higher priority. Thus, the highest priority is 0. The default is 32768.

You can specify some or all of these parameters on the same command line.

Changing port parameters

The RSTP port commands can be enabled on individual ports or on multiple ports, such as all ports that belong to a VLAN.

The RSTP port parameters are preconfigured with default values. If the default parameters meet your network requirements, no other action is required.

You can change the following RSTP port parameters using the following methods.

```
NetIron(config)# vlan 10
NetIron(config-vlan-10)# rstp ethernet 1/5 path-cost 15 priority 64
```

At the VLAN configuration level of the CLI:

Syntax: **rstp ethernet** <*slot*>/<*portnum*> **path-cost** <*value*> | **priority** <*value*> | **[admin-edge-port]** | **[admin-pt2pt-mac]** | **[force-migration-check]**

At the interface level of the CLI:

Syntax: **rstp [admin-edge-port]** | **[admin-pt2pt-mac]**

The **ethernet** <*slot*>/<*portnum*> parameter specifies the interface used.

The **path-cost** <*value*> parameter specifies the cost of the port's path to the root bridge. RSTP prefers the path with the lowest cost. You can specify a value from 1 – 20,000,000. Table 88 shows the recommended path cost values from the IEEE standards.

TABLE 88 Recommended path cost values of RSTP

Link speed	Recommended (default) RSTP path cost values	Recommended RSTP path cost range
Less than 100 kilobits per second	200,000,000	20,000,000 – 200,000,000
1 Megabit per second	20,000,000	2,000,000 – 200,000,000
10 Megabits per second	2,000,000	200,000 – 200,000,000
100 Megabits per second	200,000	20,000 – 200,000,000
1 Gigabit per second	20,000	2,000 – 200,000,000
10 Gigabits per second	2,000	200 – 20,000
100 Gigabits per second	200	20 – 2,000
1 Terabits per second	20	2 – 200
10 Terabits per second	2	1 – 20

The **priority** <*value*> parameter specifies the preference that RSTP gives to this port relative to other ports for forwarding traffic out of the topology. You can specify a value from 0 – 240, in increments of 16. If you enter a value that is not divisible by four, the software rounds to the nearest value that is divisible by four. The default is 128. A higher numerical value means a lower priority; thus, the highest priority is 8.

Set the **admin-edge-port** to enabled or disabled. If set to enabled, then the port becomes an edge port in the domain.

Set the **admin-pt2pt-mac** to enabled or disabled. If set to enabled, then a port is connected to another port through a point-to-point link. The point-to-point link increases the speed of convergence. This parameter, however, does not auto-detect whether or not the link is a physical point-to-point link.

The **force-migration-check** parameter forces the specified port to sent one RST BPDU. If only STP BPDUs are received in response to the sent RST BPDU, then the port will go return to sending STP BPDUs.

Displaying RSTP information

You can display a summary or details of the RSTP information.

To display a summary of RSTP, use the following command.

```
NetIron(config)#show rstp vlan 10
VLAN 10 - RSTP instance 0
------------------------------------------------------------------------
RSTP (IEEE 802.1w) Bridge Parameters:

Bridge           Bridge Bridge Bridge Force    tx
Identifier       MaxAge Hello  FwdDly Version  Hold
hex              sec    sec    sec             cnt
0001000480a04000 20     2      15     Default  3

RootBridge       RootPath  DesignatedBridge Root  Max Hel Fwd
Identifier       Cost      Identifier       Port  Age lo  Dly
hex                        hex                    sec sec sec
0001000480a04000 0         0001000480a04000 Root  20  2   15

RSTP (IEEE 802.1w) Port Parameters:

      <--- Config Params -->|<-------------- Current state ----------------->
Port  Pri PortPath  P2P Edge Role       State      Designa-  Designated
Num       Cost      Mac Port                      ted cost  bridge
1/3   128 20000     T   F    DISABLED   DISABLED   0         0000000000000000
1/13  128 20000     T   F    DISABLED   DISABLED   0         0000000000000000
```

Syntax: show rstp [vlan <*vlan-id*>**]**

The **vlan** <*vlan-id*> parameter displays RSTP information for the specified port-based VLAN.

The **show RSTP display** command shows the information listed in Table 89.

TABLE 89 CLI display of RSTP summary

This field...	Displays...
VLAN ID	The port-based VLAN that owns the STP instance and the number of RSTP instances on that VLAN. VLAN 1 is the default VLAN. If you have not configured port-based VLANs on this device, all RSTP information is for VLAN 1.
Bridge IEEE RSTP Parameters	
Bridge Identifier	The ID of the bridge.
Bridge Max Age	The configured max age for this bridge. The default is 20.
Bridge Hello	The configured hello time for this bridge.The default is 2.
Bridge FwdDly	The configured forward delay time for this bridge. The default is 15.
Force-Version	The configured force version value. One of the following value is displayed: • 0 – The bridge has been forced to operate in an STP compatibility mode. • 2 – The bridge has been forced to operate in an RSTP mode. (This is the default.)
txHoldCnt	The number of BPDUs that can be transmitted per Hello Interval. The default is 3.
Root Bridge Parameters:	
Root Bridge Identifier	ID of the Root bridge that is associated with this bridge
Root Path Cost	The cost to reach the root bridge from this bridge. If the bridge is the root bridge, then this parameter shows a value of zero.
Designated Bridge Identifier	The bridge from where the root information was received.It can be from the root bridge itself, but it could also be from another bridge.
Root Port	The port on which the root information was received. This is the port that is connected to the Designated Bridge.
Max Age	The ***max age*** is derived from the Root port. An RSTP-enabled bridge uses this value, along with the hello and message age parameters to compute the effective age of an RST BPDU. The ***message age*** parameter is generated by the Designated port and transmitted in the RST BPDU. RST BPDUs transmitted by a Designated port of the root bridge contains a message value of zero. ***Effective age*** is the amount of time the Root port, Alternate port, or Backup port retains the information it received from its peer Designated port. Effective age is reset every time a port receives an RST BPDU from its Designated port. If a Root port does not receive an RST BPDU from its peer Designated port for a duration more than the effective age, the Root port ages out the existing information and recomputes the topology. If the port is operating in 802.1D compatible mode, then max age functionality is the same as in 802.1D (STP).
Hello	The hello value derived from the Root port. It is the number of seconds between two Hello packets.

TABLE 89 CLI display of RSTP summary (Continued)

This field...	Displays...
Fwd Dly	The number of seconds a non-edge Designated port waits until it can apply any of the following transitions, if the RST BPDU it receives does not have an agreed flag: • Discarding state to learning state • Learning state to forwarding state When a non-edge port receives the RST BPDU it goes into forwarding state within 4 seconds or after two hello timers expire on the port. Fwd Dly is also the number of seconds that a Root port waits for an RST BPDU with a proposal flag before it applies the state transitions listed above. If the port is operating in 802.1D compatible mode, then forward delay functionality is the same as in 802.1D (STP).
RSTP (IEEE 802.1W) Port Parameters	
Port Num	The port number shown in a slot#/port# format.
Pri	The configured priority of the port. The default is 128 or 0x80.
Port Path Cost	The configured path cost on a link connected to this port.
P2P Mac	Indicates if the point-to-point-mac parameter is configured to be a point-to-point link: • T – The link is configured as a point-to-point link. • F – The link is not configured as a point-to-point link. This is the default.
Edge port	Indicates if the port is configured as an operational Edge port: • T – The port is configured as an Edge port. • F – The port is not configured as an Edge port. This is the default.
Role	The current role of the port: • Root • Designated • Alternate • Backup • Disabled Refer to "Bridges and bridge port roles" on page 413 for definitions of the roles.
State	The port's current RSTP state. A port can have one of the following states: • Forwarding • Discarding • Learning • Disabled Refer to "Bridge port states" on page 417 and "Edge port and non-Edge port states" on page 418.
Designated Cost	The best root path cost that this port received, including the best root path cost that it can transmit.
Designated Bridge	The ID of the bridge that sent the best RST BPDU that was received on this port.

To display detailed information about RSTP, using the following command.

```
NetIron(config)#show rstp detail
VLAN 10 - RSTP instance 0
------------------------------------------------------------------
RSTP (IEEE 802.1w) Bridge Parameters:

BridgeId 0001000480a04000, RootBridgeId 0001000480a04000
Control ports - ethernet 1/3 ethernet 1/13
ForceVersion 2, MigrateTime 3, TxHoldCount 3

RSTP (IEEE 802.1w) Port Parameters:

Port 1/3 - Role: DISABLED - State: DISABLED
Port 1/13 - Role: DISABLED - State: DISABLED
```

Syntax: show rstp detail [vlan <*vlan-id*>**]**

The **vlan** <*vlan-id*> parameter displays RSTP information for the specified port-based VLAN.

The **show RSTP detail** command shows the following information.

This field...	Displays...
VLAN ID	ID of the VLAN that owns the instance of RSTP and the number of RSTP instances on that VLAN.
Bridge ID	ID of the bridge.
Control ports	Ports assigned to the VLAN
forceVersion	the configured version of the bridge: • 0 – The bridge has been forced to operate in an STP compatible mode. • 2 – The bridge has been forced to operate in an RSTP mode.
MigrateTime	The number of seconds the bridge took to migrate from STP to RSTP mode.
txHoldCount	The number of BPDUs that can be transmitted per Hello Interval. The default is 3.
Port	ID of the port in slot#/port# format.
Role	The current role of the port: • Root • Designated • Alternate • Backup • Disabled Refer to "Bridges and bridge port roles" on page 413 for definitions of the roles.
State	The port's current RSTP state. A port can have one of the following states: • Forwarding • Discarding • Learning • Disabled Refer to "Bridge port states" on page 417 and "Edge port and non-Edge port states" on page 418.

Configuring RSTP under an ESI VLAN

RSTP can also be configured under a VLAN that is part of a user-configured ESI. For example, to enable RSTP on a VLAN that is part of an ESI, configure the following commands.

```
NetIron(config)# esi customer1 encapsulation cvlan
NetIron(config-esi-customer1)# vlan 100
NetIron(config-esi-customer1-vlan-100)# rstp
```

Metro Ring Protocol 13

Overview

The following Metro Ring Protocol features are supported by the NetIron MLX Series device.

- MRP Phase 1
- MRP Phase 2
- Foundry MRP Alarm RHP
- Foundry MRP Diagnostics

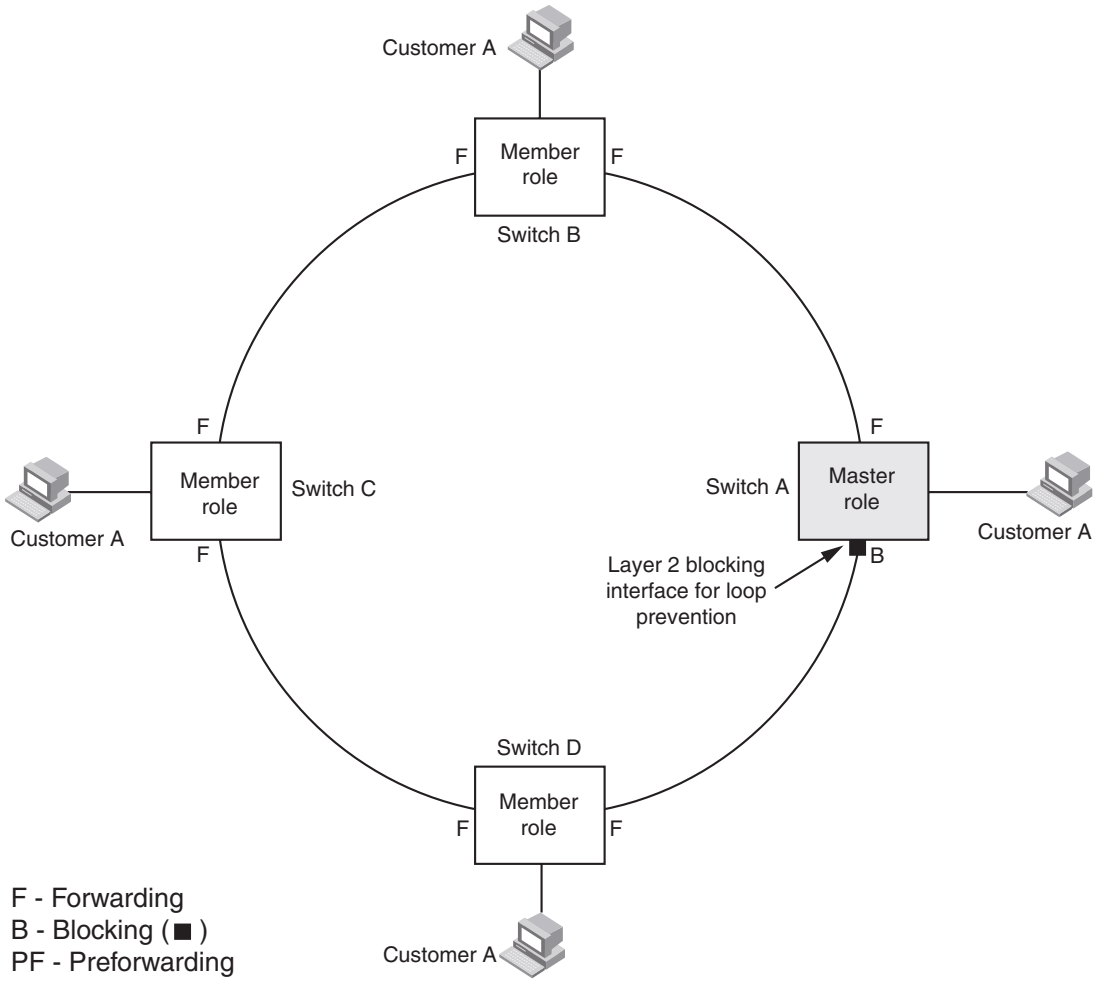
Metro Ring Protocol (MRP)

The MRP is a proprietary protocol that prevents layer 2 loops and provides fast reconvergence in ring topologies. It is an alternative to Spanning Tree Protocol (STP) and is especially useful in Metropolitan Area Networks (MANs) where using 802.1D STP has the following drawbacks:

- 802.1D recommends a maximum bridge diameter of seven nodes with standard timers. MRP is capable of many more nodes than this.
- 802.1D has a slow reconvergence time, taking many seconds or even minutes. MRP can detect and heal a break in the ring in under one second.

Figure 54 shows a simple metro ring.

FIGURE 54 MRP – normal state



The ring in this example consists of four Dell switch nodes that support MRP. Each node has two ring interfaces and the interfaces are all in one port-based vlan. There are customer networks utilising the nodes and layer 2 traffic is forwarded to and from the customer networks through the ring. Each customer interface can be in the same vlan as the ring or in a separate vlan under control of MRP as part of a topology group.

For each discrete ring one node is configured in the master role for the MRP ring. One of the two ring interfaces on the master node is configured as the primary interface, the other is the secondary interface. The primary interface originates Ring Health Packets (RHPs) which are used to monitor the health of the ring. An RHP is forwarded on the ring to the next interface until it reaches the secondary interface of the master node. On receipt of an RHP the secondary interface transitions into blocking mode to prevent a layer 2 loop.

The following MRP features are supported by Brocade NetIron XMR Series devices.

- MRP Phase 1
- MRP Phase 2
- MRP Alarm RHP

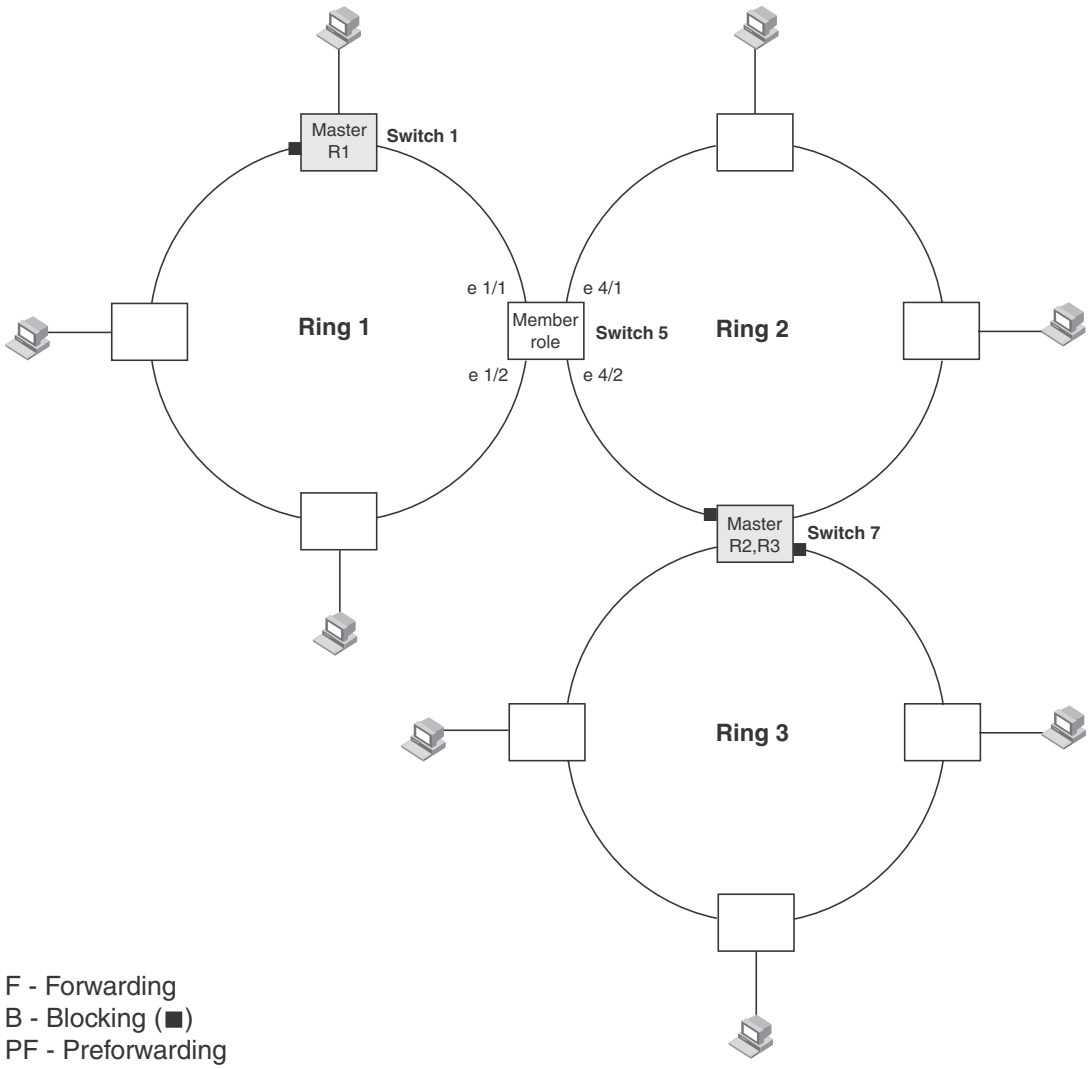
- MRP Diagnostics

NOTE
When you configure MRP, it is recommended that you disable the secondary ring interface on the master node before beginning or changing the ring configuration. Disabling an interface prevents a layer 2 loop from occurring while you are configuring MRP on the ring nodes. Once you have completed the MRP configuration and enabled it on all the nodes, you should re-enable the secondary ring interface.

MRP rings without shared interfaces (MRP Phase 1)

MRP Phase 1 allows you to configure multiple MRP rings, as shown in Figure 55, but the rings cannot share the same interfaces. For example, you cannot configure ring 1 and ring 2 to share interfaces ethernet 1/1 and 1/2 on switch 5. Each ring must remain an independent ring and RHP packets are processed within each ring.

FIGURE 55 MRP – multiple rings, no shared interfaces

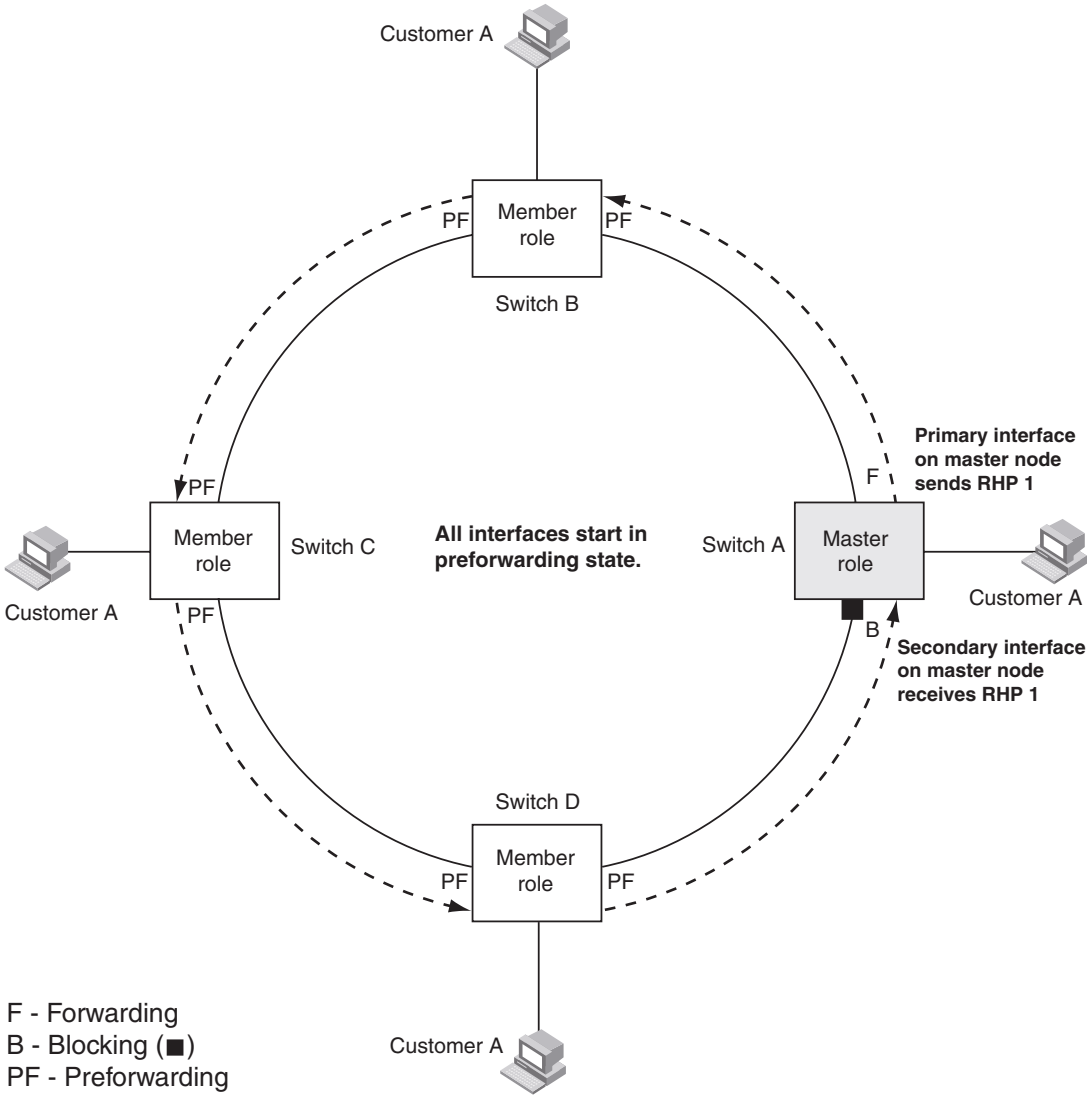


In the above example, switch 5 and switch 7 are configured with multiple MRP rings however each ring has discrete ring interfaces allocated to it to prevent any sharing. Any ring node can be the master for its ring and a node can be the master for more than one ring as shown on switch 7 due to the separation of rings.

Ring initialization

Figure 56 shows the initial state of the ring, when MRP is first enabled on the ring's switches. On the master the primary interface starts in forwarding mode and the secondary interface starts in blocking mode. All ring interfaces on member nodes begin in the preforwarding state (PF).

FIGURE 56 MRP ring – initial state



An RHP is an MRP protocol packet used to monitor the health of the ring. The source address is the MAC address of the master node and the destination MAC address is a protocol address for MRP. The Master node generates RHPs and sends them on the ring. The state of a ring interface is influenced by the RHPs.

A ring interface can have one of the following MRP states:

- **Preforwarding (PF)** – The interface will forward RHPs and learn MAC addresses but won't forward data for the ring. All ring interfaces start in this state when you enable MRP except the master node. A blocking interface transitions to preforwarding when the preforwarding timer expires and no RHP's have been received.
- **Forwarding (F)** – The interface will forward RHP's and data for the ring. On member switches an interface transitions from preforwarding to forwarding when the preforwarding time expires or the interface receives an RHP with the forwarding bit set. A break in the ring is indicated if the secondary interface on the master fails to receive an RHP within the preforwarding timer and the interface transitions from blocking to forwarding to heal the ring.

- **Blocking (B)** – The interface can process RHPs, but cannot forward data for the ring. Only the secondary interface on the master node can be blocking.

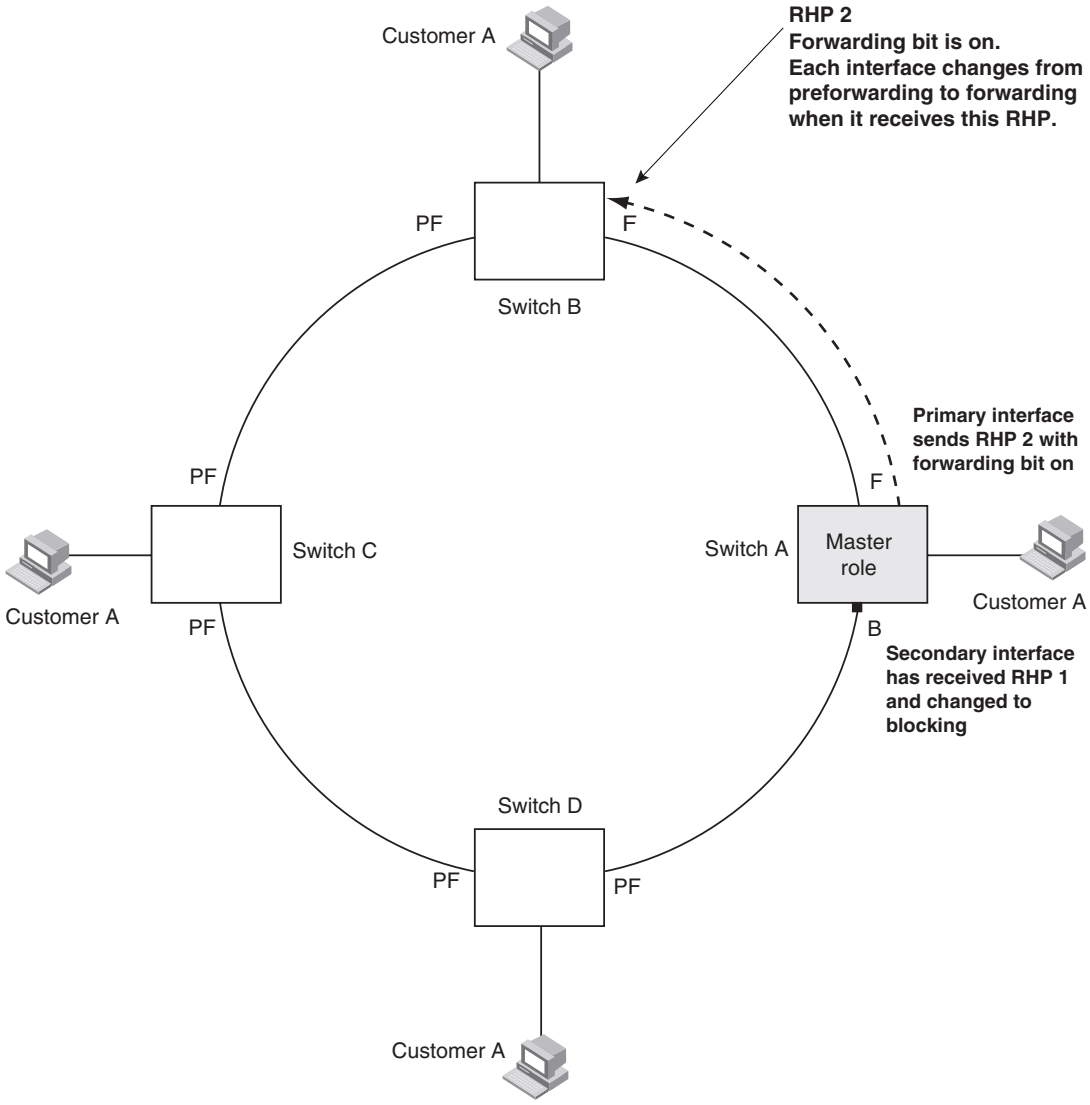
NOTE
The configured preforwarding time defines the number of milliseconds the interface will remain in a state before changing to the next state without receiving an RHP.

When MRP is enabled, all interfaces begin in the preforwarding state and the primary interface on the master node immediately sends an RHP (RHP 1 in Figure 56) onto the ring. The secondary interface on the master node listens for the RHP:

- If the secondary interface receives the RHP, all links in the ring are up and the interface changes its state to blocking. The primary interface then sends another RHP (RHP 2 in Figure 57) with its forwarding bit set on. As each of the member interfaces receives the RHP, the interfaces change their state to forwarding. Typically, this occurs in sub-second time. The ring very quickly enters the fully initialized state.
- If the secondary interface does not receive the RHP by the time the preforwarding time expires, a break has occurred in the ring. The secondary interface changes its state to forwarding. The ring is not intact, but data is still forwarded among the nodes using the links that are up.

Figure 57 shows an example.

FIGURE 57 MRP ring – from preforwarding to forwarding

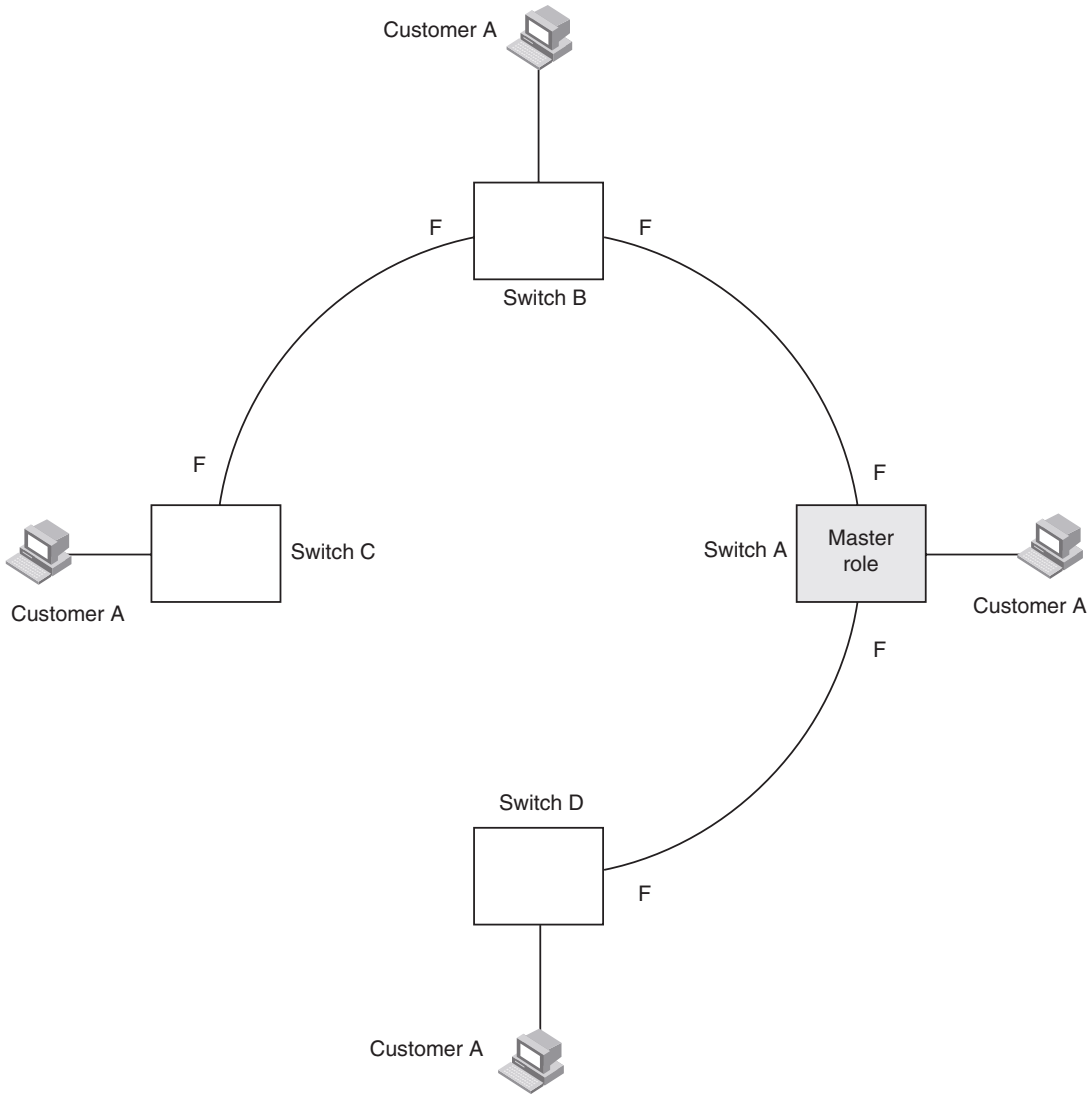


Each RHP also has a sequence number. MRP can use the sequence number to determine the round-trip time for RHPs in the ring. Refer to "Using MRP diagnostics" on page 479.

How ring breaks are detected and healed

Figure 58 shows ring interface states following a link break. MRP quickly heals the ring and preserves connectivity among the customer networks.

FIGURE 58 MRP ring – ring break



If a break in the ring occurs, MRP heals the ring by changing the states of some of the ring interfaces:

- **Blocking interface** – When the secondary interface on the master node transitions to a blocking state it sets a timer defined by the preforwarding time configured. If the timer expires before the interface receives a ring RHP, the interface changes state to preforwarding. Once the secondary interface state is preforwarding:
  - If the interface receives an RHP, the interface changes back to the blocking state and resets the timer.
  - If the interface does not receive an RHP for its ring before the preforwarding time expires, the interface changes to the forwarding state, as shown in Figure 58.
- **Forwarding interfaces** – All member interfaces remain in the forwarding state unless the physical interface is in an error condition.

When the link is repaired, the associated MRP interfaces come up in the preforwarding state allowing RHPs to be forwarded around the ring and finally reach the secondary interface on the master node:

- If an RHP reaches the master node's secondary interface, the ring is intact, the secondary interface changes to blocking. The master node sets the forwarding bit on in the next RHP. When the restored interfaces receive this RHP, they immediately change state to forwarding.
- If an RHP does not reach the master node's secondary interface, the ring is still broken. The master node does not send an RHP with the forwarding bit on. In this case, the restored interfaces remain in the preforwarding state until the preforwarding timer expires, then change to the forwarding state.

MRP alarm RHP enhancement

Prior to the enhancement detection of ring breaks were completely timer based. If the ring master fails to receive RHPs for a period of 3 "hello times" (by default the hello time is 100 ms) this indicates that the ring is broken in some manner. This initiates a topology change as described in the previous section. The convergence time associated with such an event could take several hundred milliseconds.

This enhancement enables ring nodes to rapidly notify the master of link failures. To understand the mechanism we introduce the concept of downstream switches in the ring and how member switches determine the primary and secondary ring interfaces. Remember that a primary ring interface sends RHPs and a secondary ring interface receives RHPs.

To fully understand the mechanism the reader needs to be aware of the concept of shared interfaces and interface owner ID's which are a function of MRP phase 2.

A downstream switch is defined as the next switch that will receive the ring RHP originated from the master primary interface for a particular ring. In Figure 59 switch B is downstream from the master, switch C is downstream from switch B and so on and so forth. In addition it should be noted that a member switch identifies which ring interface is secondary for each discrete ring by virtue of the receipt of RHPs for that ring. In a topology with shared interfaces a single physical interface can therefore be a primary ring interface for one ring and a secondary ring interface for another ring. It should be noted that the output of the 'show metro' command as well as the configuration will change if the primary and secondary ring interfaces of the master are swapped. This keeps the identification of interface roles consistent with the flow of RHPs for discrete ring instances.

When a link is detected to be down on a member switch secondary ring interface due to a link failure an alarm RHP, which is an RHP with the alarm bit set, is sent from the primary ring interface towards the ring master, notifying the master of the failure.

The destination MAC address in the alarm is the ring MAC address. The MAC address will be in the format 0304.8000.00xx where 'xx' is the ring number in hexadecimal.

For example ring 100 = 0304.8000.0064. This ensures that the packet is hardware forwarded all the way to the master. When the master in the ring receives this alarm the secondary interface is immediately transitioned from blocking to forwarding.

NOTE
In the event of a shared interface failing the alarm RHP packet is only sent by the owner ring of the failed interface. If all rings configured on a shared interface were to generate alarms then the respective master switches for each ring would start forwarding on both interfaces creating a loop condition. By restricting alarm generation to the owner ring we ensure that only one master switch is notified to ensure that the ring heals. The owner ring ID should be the highest priority ring configured on the shared interface.

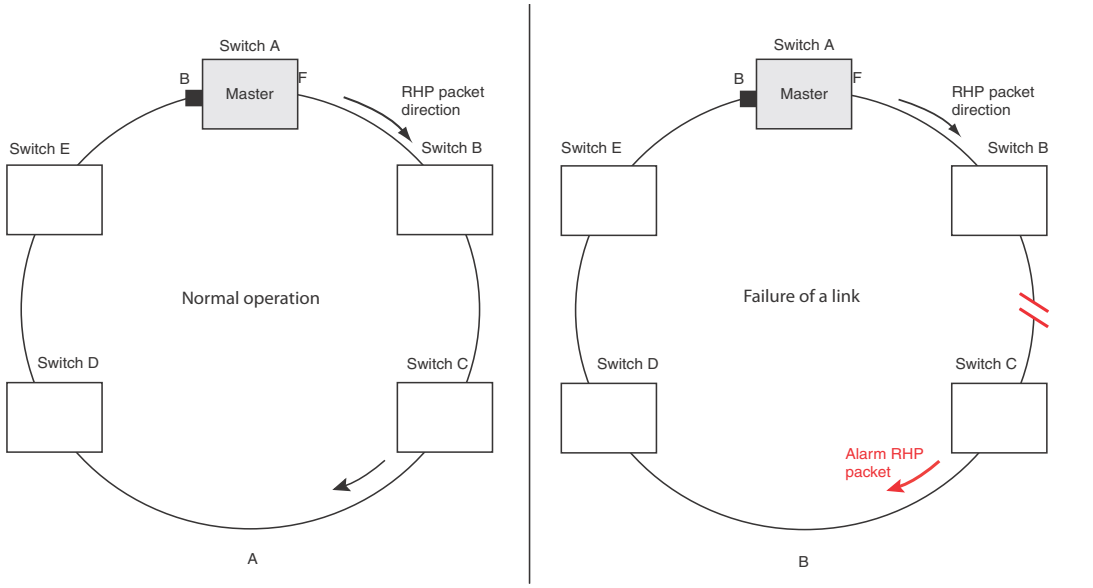
Operation of the alarm RHP enhancement is shown in Figure 59 and described below:

When the link between switch B and switch C fails, the downstream switch detects the failure of the link associated with its secondary ring interface and generates an alarm. The following is the complete sequence of events that occurs.

1. The downstream switch C detects a link down event on the link to its upstream neighbour switch B.
2. Switch C sends a single RHP packet with the alarm bit set. The RHP packet is sent in the same direction of flow as that of the normal RHP packets.
3. Switch A receives the alarm on the secondary ring interface that was sent by switch C. It is now aware that the ring is broken even though the preforwarding timer for blocking to preforwarding may not have expired.
4. Switch A immediately transitions its secondary interface from blocking to forwarding to heal the ring.
5. RHP packets continue to be sent on the primary interface by switch A to detect when the ring has been healed.

From a user perspective there is no other difference in the behavior of the ring other than the rapid convergence due to link failures. There is no CLI command required to enable this feature.

FIGURE 59 An MRP ring under normal operation (A) and after detection of a failure in the ring (B)

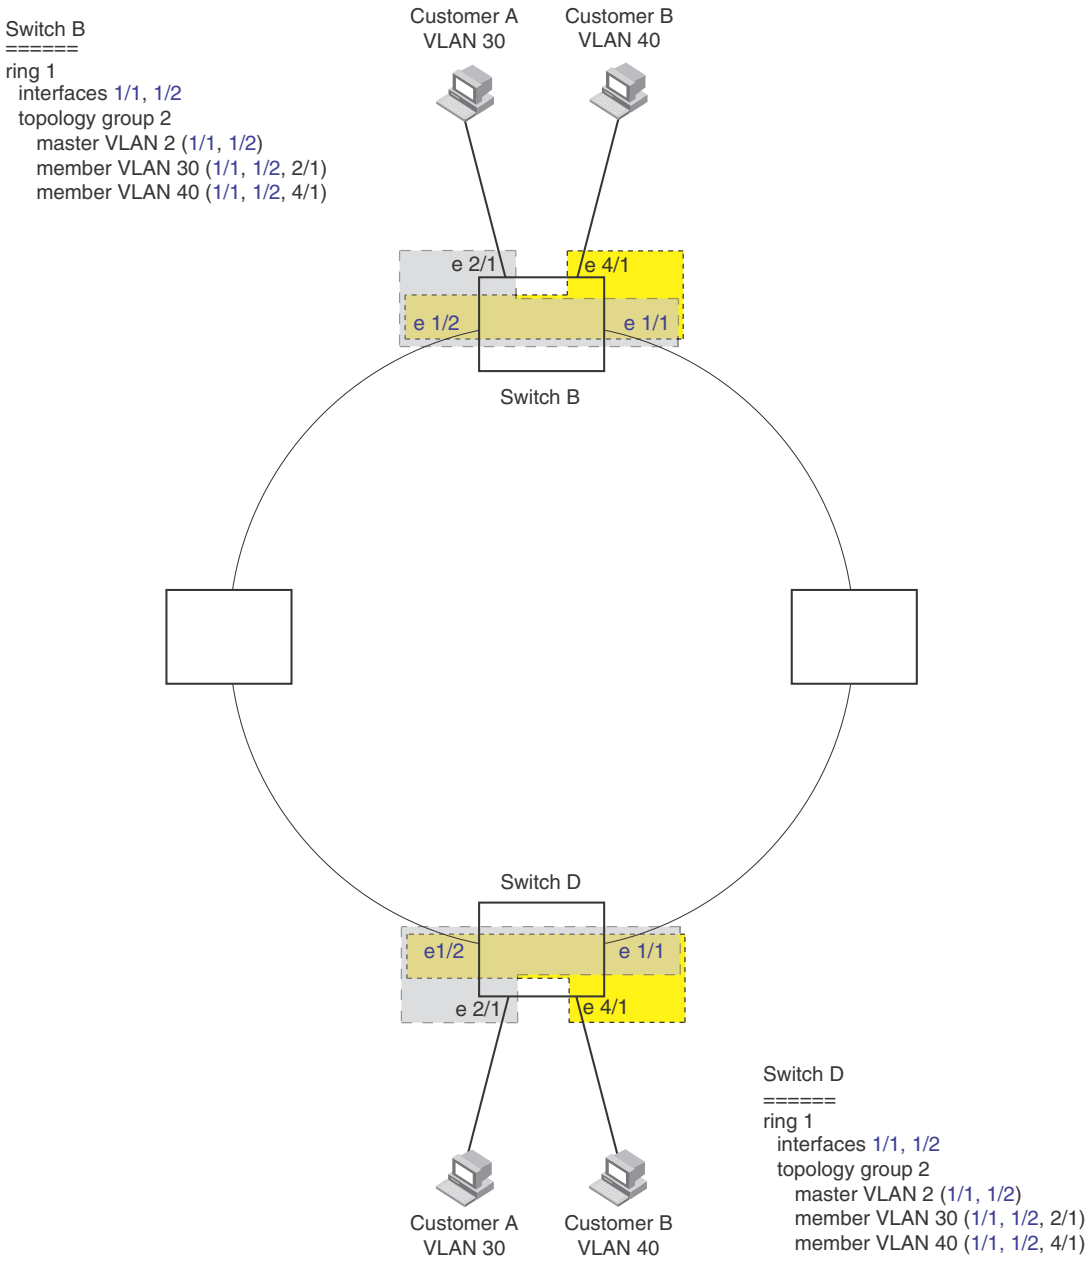


Master VLANs and member VLANs in a topology group

The reader is referred to chapter 16, "Topology Groups"for further information on topology group concepts and operation.

All the ring interfaces must be placed into the master vlan for the topology group. Customers configured with member vlans inherit the configuration of the topology group master vlan and have equivalent layer 2 connectivity across the ring. Figure 60 shows an example.

FIGURE 60 MRP ring – ring vlan and customer vlan



In this example each customer has their own vlan. Customer A has vlan 30 and customer B has vlan 40.

Customer A host attached to switch D on an interface in vlan 30 can reach the customer A host attached to switch B on an interface in vlan 30 through the ring at layer 2. The same mechanism is used to connect customer B hosts on vlan 40.

Customer A and customer B traffic is separated by using different vlans.

You can configure MRP separately on each customer vlan. However, this is impractical if you have many customers. To simplify configuration when you have a lot of customers (and therefore a lot of vlans), you can use a topology group.

A topology group enables you to control forwarding in multiple vlans using a single instance of a layer 2 protocol such as MRP. A topology group contains a master vlan and member vlans. The master vlan contains all the configuration parameters for the layer 2 protocol (STP, MRP, or VSRP). The member vlans use the layer 2 configuration of the master vlan.

In Figure 60, vlan 2 is the master vlan and contains the MRP configuration parameters for ring 1. vlan 30 and vlan 40, the customer vlans, are member vlans in the topology group. Since a topology group is used, a single instance of MRP provides redundancy and loop prevention for both the customer vlans.

If you use a topology group:

- The master vlan must contain the ring interfaces.
- The ring interfaces must be tagged as they will be used for multiple vlans.
- The member vlan for a customer must contain the two ring interfaces and the interfaces for the customer.

Refer to "MRP CLI example" on page 482 for the configuration commands required to implement the MRP configuration shown in Figure 60.

Configuring MRP

To configure MRP, perform the following tasks for each discrete ring:

- On the switch identified as the ring master disable the secondary ring interface. This manually prevents a layer 2 loop from occurring during configuration.
- Configure each switch for MRP one at a time following the planned flow of RHP's
- On each switch in the path add an MRP ring to a port-based vlan. When you add a ring, the CLI changes to the configuration level for the ring, where you can do the following:
  - On the master node configure the master ring role.
  - Specify the two MRP interfaces for the ring
  - Option: Specify a name for the ring. Dell recommends that you have a naming convention for your MRP rings and consistently apply names for all the rings in the topology.
  - Option: Change the hello time and the preforwarding time. These parameters control how quickly failover occurs if the master fails to receive RHPs for the ring.
  - Enable the ring.
- Re-enable the interface you disabled in step one. MRP will prevent loops when enabled on all devices in the ring.

When using topology groups the ring configuration must be added to the master-vlan for the group. For further information refer to 16, "Topology Groups".

Adding an MRP ring to a vlan

NOTE
If you plan to use a topology group make sure you configure MRP on the topology group's master vlan.

To add a MRP ring to a vlan, enter commands such as the following.

```
NetIron(config)# vlan 2
NetIron(config-vlan-2)# metro-ring 1
NetIron(config-vlan-2-mrp-1)# name CustomerA
NetIron(config-vlan-2-mrp-1)# ring-interface ethernet 1/1 ethernet 1/2
NetIron(config-vlan-2-mrp-1)# enable
```

These commands configure an MRP ring in vlan 2 with a ring ID of 1, a ring name of CustomerA. If the node is the master then the following command is used to specify the node as the master for the ring.

NetIron(config-vlan-2-mrp-1)# master

The ring interfaces are 1/1 and 1/2. The first interface listed will be allocated as the primary interface and the second will be allocated as the secondary interface. The primary interface initiates RHPs. The ring takes effect in vlan 2.

Syntax: [no] metro-ring <*ring-id*>

The <*ring-id*> parameter specifies the ring ID 1 – 255. Configure the same ring ID on each of the nodes in the ring.

Syntax: [no] name <*string*>

The <*string*> parameter specifies a name for the ring. The name is optional, but it can be up to 20 characters long and can include blank spaces. If you use a name that has blank spaces, enclose the name in double quotation marks (for example: "Customer A").

Syntax: [no] master

Configures this node as the master node for the ring. Enter this command only on one node in the ring. The node is a member (non-master) node by default.

Syntax: [no] ring-interface ethernet <*primary-if*> **ethernet** <*secondary-if*>

The **ethernet** <*primary-if*> parameter specifies the primary interface. On the master node, the primary interface originates RHPs. Ring control traffic will flow out of this interface by default. On member nodes the order in which you enter the interfaces does not matter as the secondary interface is determined by the receipt of RHP's from the master meaning the other interface defined in config becomes the primary. Once the ring is enabled the configuration entries on a member switch will reflect the ring direction no matter what order they are originally entered.

The **ethernet** <*secondary-if*> parameter specifies the secondary interface.

Syntax: [no] enable

The **enable** command enables the ring.

Changing the hello and preforwarding times

You can also change the RHP hello time and preforwarding time. To do so, enter commands such as the following.

```
NetIron(config-vlan-2-mrp-1)# hello-time 200
NetIron(config-vlan-2-mrp-1)# preforwarding-time 400
```

These commands change the hello time to 200 ms and change the preforwarding time to 400 ms.

Syntax: [no] hello-time <*ms*>

Syntax: [no] preforwarding-time <*ms*>

The <*ms*> specifies the number of milliseconds.

The hello time can be from 100 – 1000 (one second). The default hello time is 100 ms.

The preforwarding time can be from 200 – 5000 ms, and must be at least twice the value of the hello time and must be a multiple of the hello time. The default preforwarding time is 300 ms.

A change to the hello time or preforwarding time takes effect as soon as you enter the command.

NOTE
You can use MRP ring diagnostics to determine whether you need to change the hello time and preforwarding time. Refer to "Using MRP diagnostics".

Changing the scale timer

You are able to decrease MRP convergence time by changing the MRP scale timer tick from 100 ms to 50 ms. To do so, enter the following command:

```
NetIron(config)# scale-timer mrp
```

Syntax: [no] scale-timer mrp

Note: This command accepts no values and is put in place as it is shown above.

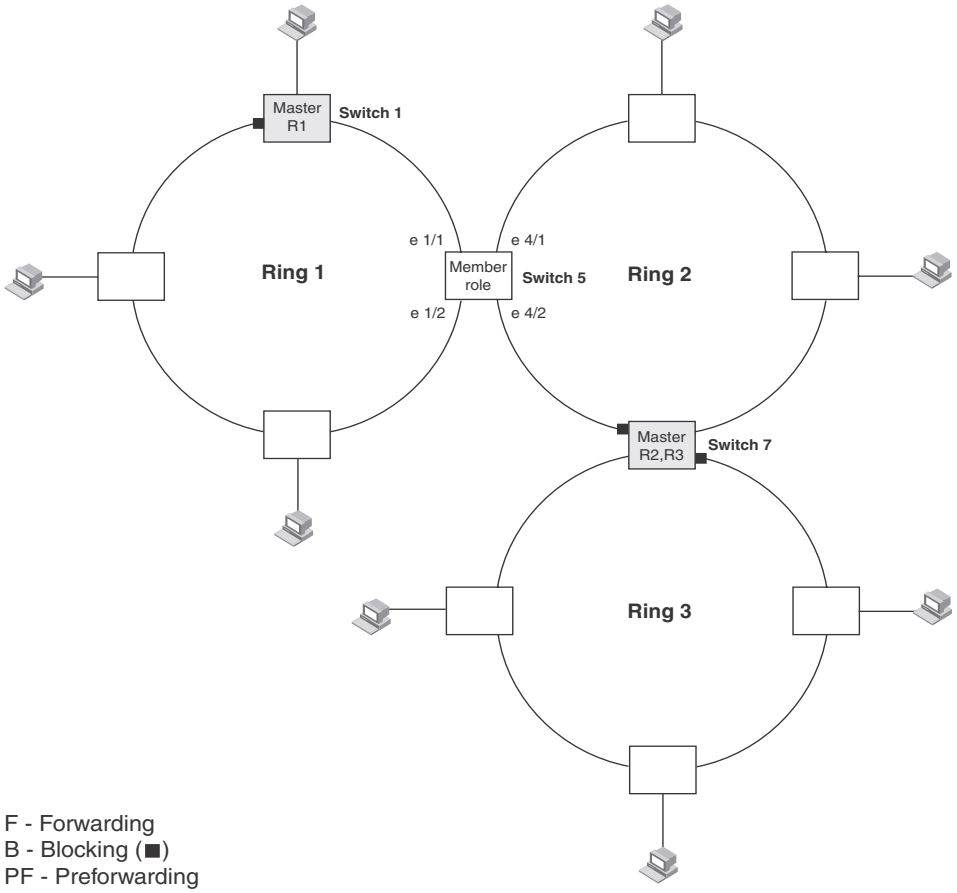
Note: Changing the scale timer affects the operation of MRP. Refer to "Tuning MRP timers" for further information.

MRP Phase 2

MRP phase 2 expands functionality by allowing a physical interface to be shared by multiple rings configured within the same vlan.

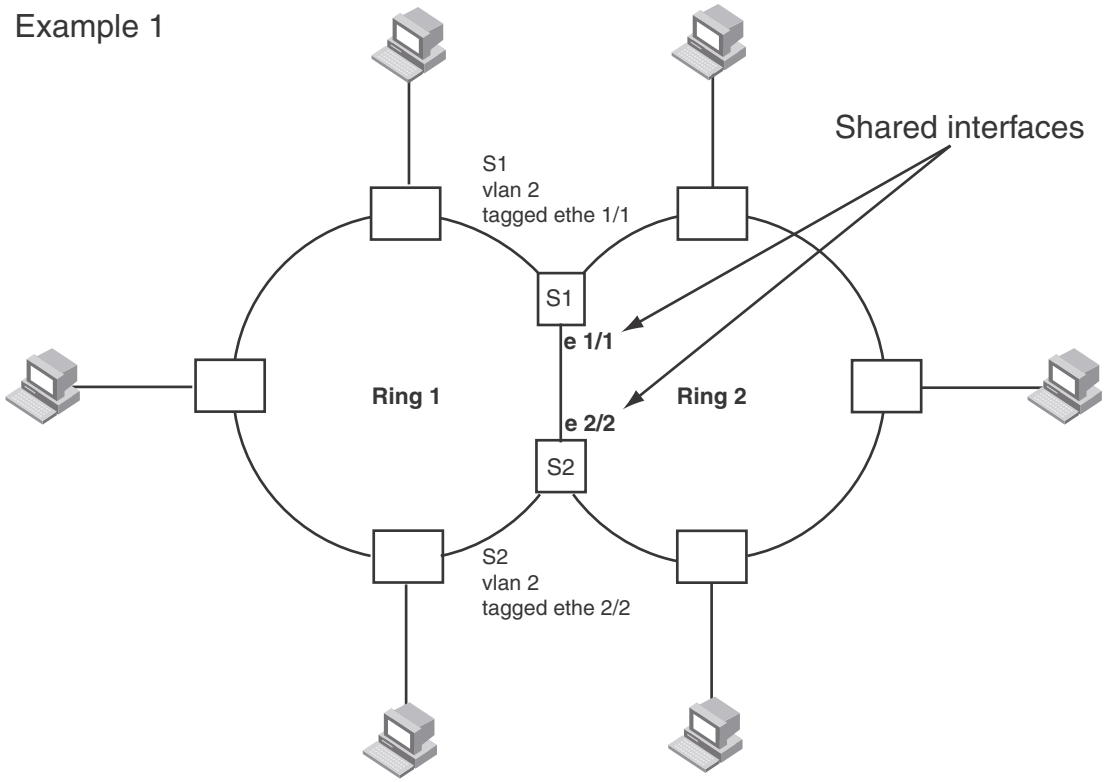
Recall that in MRP Phase 1, a node can have multiple MRP rings, but the rings cannot share the same interface. Any node can be designated as the master node for the ring. Each ring is an independent ring and RHP packets are processed within each ring exclusively.

FIGURE 61 Multiple MRP rings - phase 1



With MRP phase 2 multiple rings can be configured to share the same interface as long as the interfaces belong to the same vlan. Figure 62 shows an example of two rings that share the same interfaces on S1 and S2.

FIGURE 62 Example 1 multiple rings sharing interfaces - phase 2



On each node that will participate in ring 1, you configure the ring ID and the ring interfaces that will be used. You repeat the configuration steps for all nodes in ring 2. In a multiple ring configuration, a ring's ID determines its priority. The lower the ring ID, the higher the priority of a ring with ring ID 1 being the highest possible priority.

A key concept with MRP phase 2 is the ability to extend a single vlan across the whole topology even when multiple rings are required. Consider the example in Figure 63 where we have 3 MRP rings and a customer who needs to create neighbour relationships between all three routers depicted. The routers all have interfaces configured in a single subnet and need IP connectivity between each other.

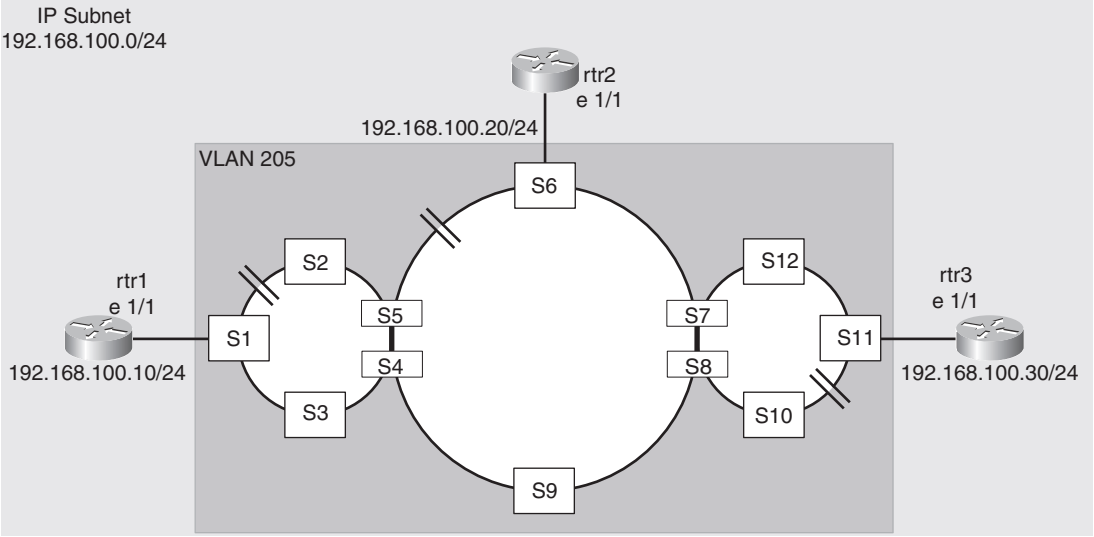
If each ring had an independant vlan then we would have to have a mechanism to move IP packets from a single IP subnet between different layer 2 topologies. By using MRP phase 2 we have multiple rings all associated with a single layer 2 topology allowing a common subnet to be distributed in the manner shown in the example. Whilst this looks nothing like a standard spanning tree network it should be treated in the same way from the perspective of a layer 2 topology, multiple paths where certain paths must be blocked to prevent loops at layer 2.

In addition it should be noted that the concept of multiple rings being associated with a single vlan describes the extent to which broadcasts will be propogated at layer 2 for that vlan. In other words a broadcast will be propogated to all ring interfaces in the layer 2 topology. The use of topology groups allows multiple vlans to effectively reuse a single layer 2 topology while maintaining a level of separation.

The obvious issue with this approach is that there must be a mechanism to prevent loops on the rings and this is the job of MRP, layer 2 loop prevention.

It is very easy to focus on the ring topology rather than the underlying layer 2 topology described by multiple rings. Design decisions are driven by the same factors as a standard spanning tree network replacing root bridges with ring masters. Traffic patterns at layer 2 are determined by which ring interfaces are forwarding and which are blocking and this in turn should drive design decisions for ring master placement as well as the direction of RHP flow from the ring masters. Traffic patterns in standard operation as well as failure mode can be determined prior to implementation allowing for appropriate capacity management on all links.

FIGURE 63 Multiple rings with one vlan spanning them



Ring interface ownership

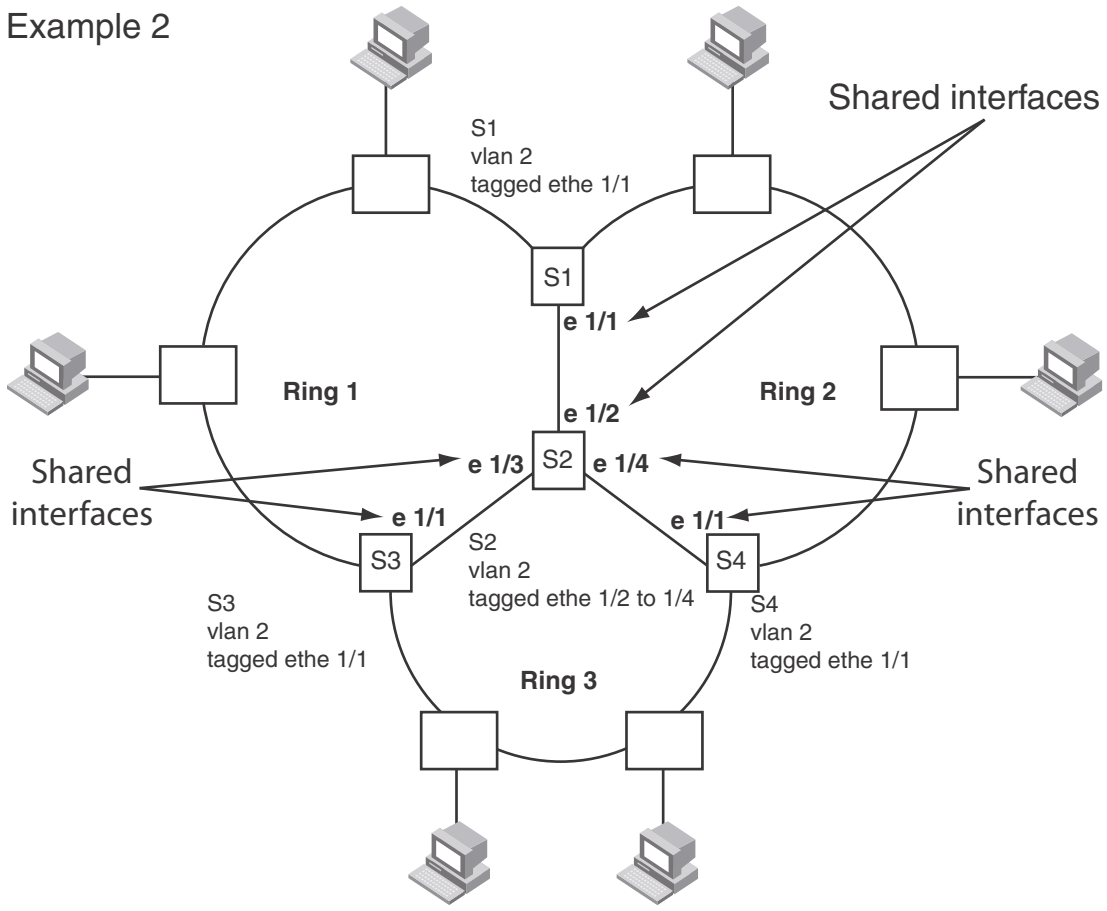
On a shared interface the highest priority ring will be the owner of the interface. In Figure 64 interface e 1/1 on S1 will be owned by ring 1 and marked as a regular interface while in ring 2 the same interface is marked as a tunnel interface in the output of the ‘show metro’ command.

On S2 interface e 1/2 is again owned by ring 1 and marked as a regular interface.

In Figure 64 the same principles of interface ownership apply. All shared interfaces on ring 1 nodes are shown as owned by ring 1 and marked as regular interfaces. Ring 2 will show shared interfaces as tunnel interfaces.

On S2 e 1/4 and S4 e 1/1 the interfaces will be owned by ring 2, as the highest priority ring on the interface, and ring 3 will show these interfaces as tunnel interfaces.

FIGURE 64 Example 2 multiple rings sharing interfaces - phase 2



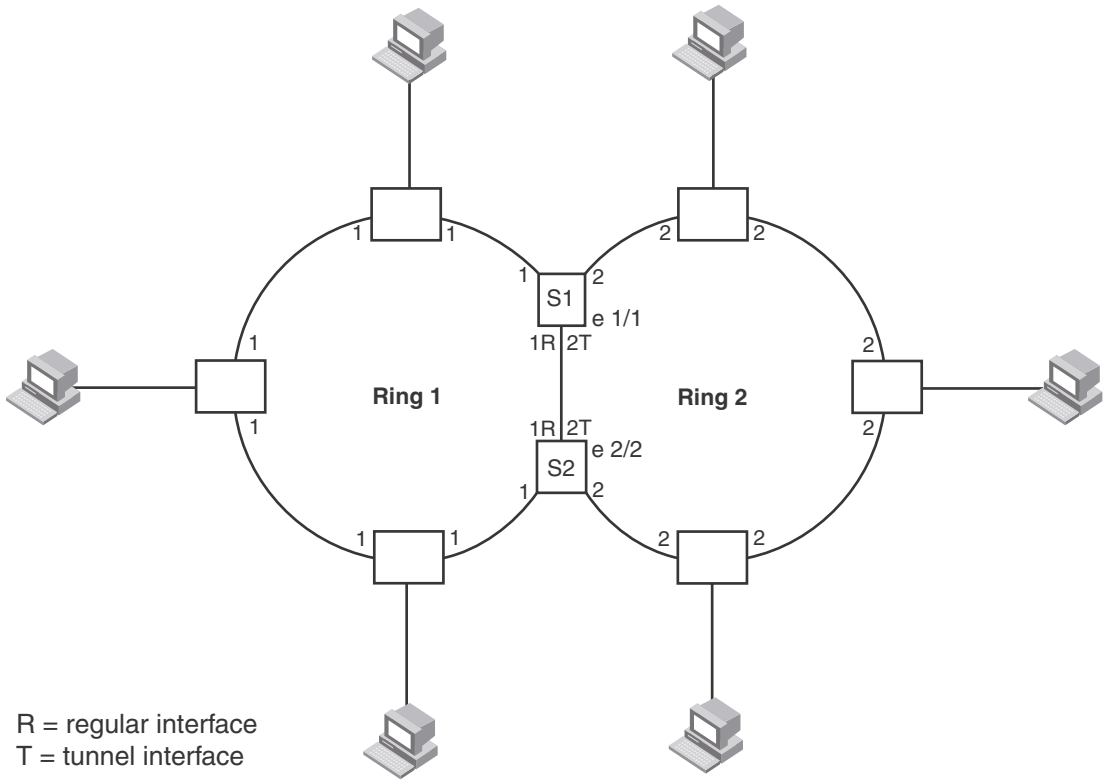
Ring interface IDs and types

For example, in Figure 65, all interfaces configured for ring 1 have a priority of 1. Interface e 1/1 on S1 and e 2/2 on S2 have a priority of 1 since 1 is the highest priority ring that shares the interface.

All interfaces on ring 2, except for e 1/1 on S1 and e 2/2 on S2 have a priority of 2.

If a node has shared interfaces then the ring interfaces that belong to the ring with the highest priority are regular interfaces for that ring and all lower priority ring interfaces are marked as tunnel interfaces. The highest priority ring configured becomes the priority for the interface.

FIGURE 65 Interface IDs and types



In Figure 65, nodes S1 and S2 have interfaces that belong to rings 1 and 2. Interface e 1/1 on S1 and e 2/2 on S2 are regular interfaces for ring 1, but they are tunnel interfaces for ring 2.

Selection of the master node for a ring

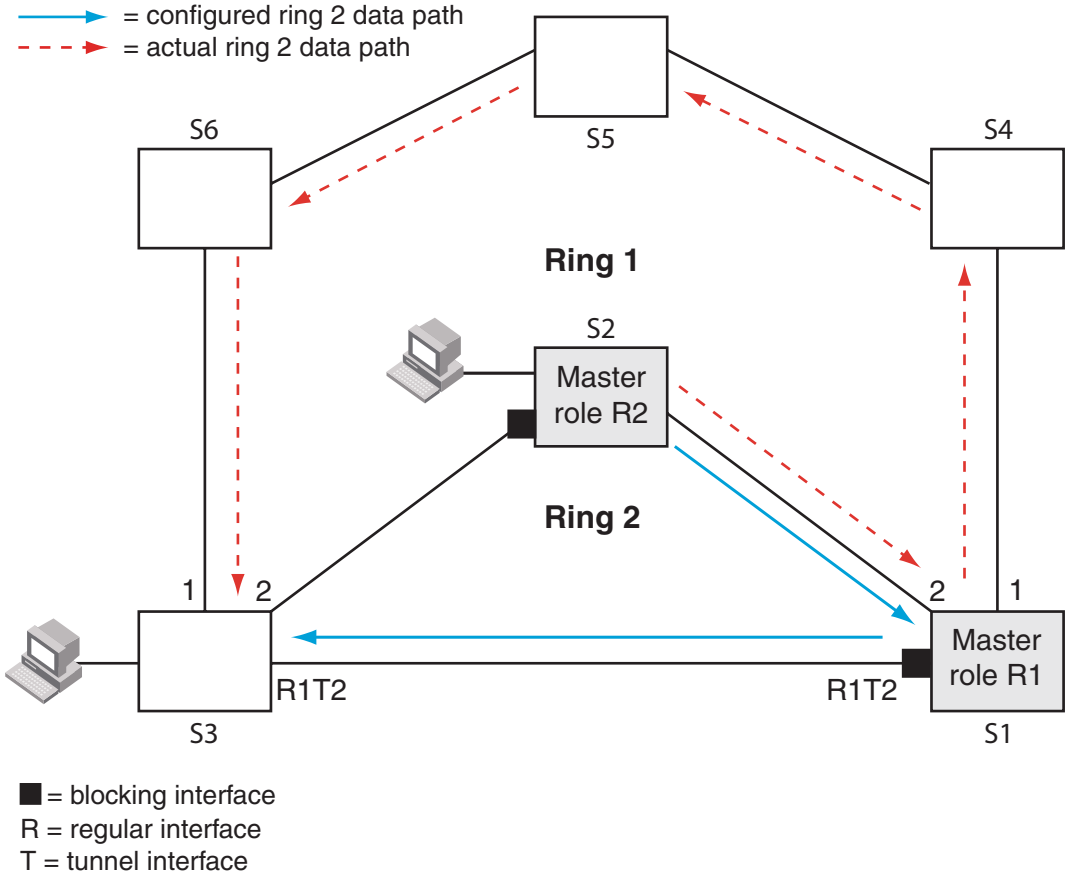
Configuring MRP rings with shared interfaces limits the nodes that can be designated as the master node for any particular ring.

- Any node on the ring that does not have any shared interfaces can be designated as the ring's master.
- You can only designate a node that has shared interfaces as master for a ring where all interfaces for the ring are marked as regular interfaces.
- On a node with shared interfaces, where you configure the role as master, the secondary ring interface should not be a shared interface. If you designate a shared interface as secondary it will be blocking under normal operation and allow RHP's but no data for lower priority rings. This can create unexpected traffic flows on the rings.

In Figure 65 any of the nodes on ring 1, even S1 or S2, can be a master node as all of the ring interfaces, even the shared interfaces between S1 and S2, are marked as regular interfaces for ring 1.

However for ring 2, neither S1 nor S2 can be a master node since the shared interfaces between S1 and S2 are marked as tunnel interfaces for ring 2.

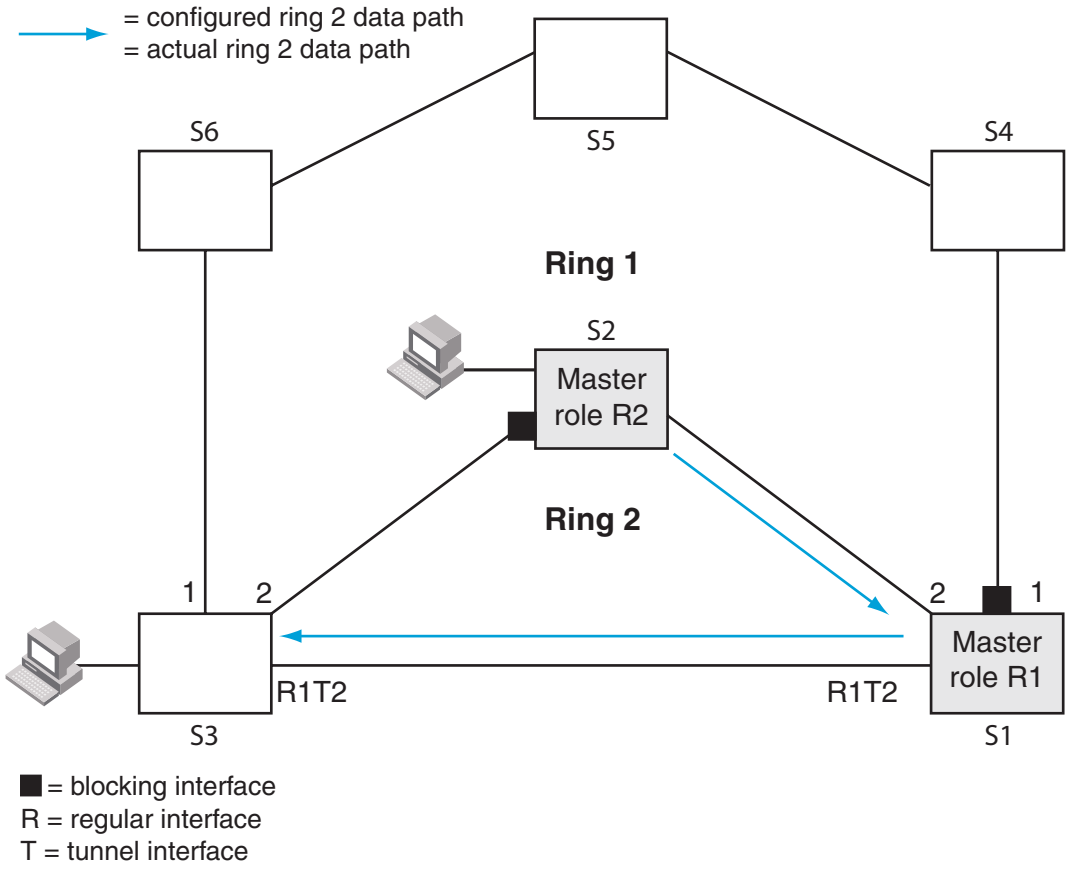
FIGURE 66 Unexpected switching path with shared interface



In Figure 66 ring 2 was configured with shared ring interfaces on S1 and S3 as depicted. S1 was configured as the master for ring 1 and the shared interface was defined as the secondary interface and subsequently blocks data. The designer intended the switching path between a host on S2 and another host on S3 to be via S1 shared interface, however due to the shared interface being blocked the actual switching path becomes S1 to S4,S5,S6 and finally S3.

Ring 2 is still operational but is not behaving in the manner which the design called for. By configuring the secondary interface on the regular port for ring 1 we obtain the expected result as shown in Figure 67.

FIGURE 67 Expected switching path with shared interface



RHP processing in rings with shared interfaces

Interfaces on an MRP ring have one of the following states:

- **Blocking (B)** – The interface can process RHPs, but cannot forward data for the ring. Only the secondary interface on the Master node can be blocking. If the interface receives RHP's for lower priority rings these RHPs will be discarded by this interface. This prevents RHP's from lower priority rings from looping in the topology.
- **Preforwarding (PF)** – The interface will forward RHPs but won't forward data for the ring. All ring interfaces start in this state when you enable MRP. A blocking interface transitions to preforwarding when the preforwarding timer expires.
- **Forwarding (F)** – The interface will forward RHP's and data for the ring. On member switches an interface transitions from preforwarding to forwarding when the preforwarding time expires or the interface receives an RHP with the forwarding bit set. A break in the ring is indicated if the secondary interface on the master fails to receive an RHP within the preforwarding timer and the interface transitions from blocking to forwarding to heal the ring. The preforwarding time is the number of milliseconds the interface will remain in the preforwarding state before changing to the Forwarding state, even without receiving an RHP.

The primary interface of the master node initiates RHP packets and sends them onto the ring. When the packet reaches a forwarding interface, MRP checks to see if the receiving interface is a regular interface or a tunnel interface:

- If the interface is a regular interface, the RHP packet is forwarded to the next interface. Forwarding of the packet continues on the ring until the secondary interface of the master node receives the packet and processes it. For the configured ring the receipt of an RHP with the same ring ID indicates the ring is healthy. RHPs for lower priority rings will be discarded without further processing at this point.
- If the interface is a tunnel interface, MRP checks the priority of the RHP packet and compares it to the priority of the tunnel interface:
  - If the RHP packet's priority is less than or equal to the interface's priority, the packet is forwarded through ring interfaces with higher priority which are in the forwarding state.
  - If the priority of the RHP packet is greater than the priority of the interface, the RHP packet is dropped. For example, if an RHP with a ring ID of 1 arrives at a tunnel interface owned by ring 2 the RHP will be dropped. If an RHP with a ring ID of 2 or 3 arrives at a tunnel interface owned by ring 2 the RHP will be forwarded.

NOTE
It is important to understand the key concept of RHPs leaking from lower priority rings to higher priority rings. Always remember that tunnel interfaces check the ring ID of an RHP before forwarding. Higher priority ring ID RHPs will be dropped.

How ring breaks are detected and healed between shared interfaces

If the link between shared interfaces breaks, the secondary interface on the highest priority ring master node changes to a preforwarding state, refer to Figure 70 on page 475. Any RHP from lower priority rings can traverse this interface and thus maintain the integrity of the lower priority rings. When the secondary interface changes state to forwarding the lower priority ring RHP's continue to traverse the interface.

This behaviour allows the ring 2 RHP's to continue around ring 1 and back to ring 2 until it reaches the secondary interface on ring 2's master node which changes to blocking mode since it receives its own RHP.

NOTE
On the ring member node, the primary and secondary interface is decided by the RHP flow from the ring master. The secondary interface is always the RHP receiver for its ring RHP's, the primary interface is always the sender of its rings RHP's. If there is no active ring master in the topology, then the running configuration on the member node will show exactly what was configured. This may change on introduction of an active ring master.

Normal flow

Figure 68 and Figure 69 show how RHP packets are forwarded in rings with shared interfaces. Figure 68 shows the flow of ring 1 RHPs while Figure 69 shows how ring 2 RHPs flow.

Interface e 2/1 is the primary interface of the ring 1 master node. The primary interface forwards an RHP packet on the ring. Since all the interfaces on ring 1 are regular interfaces, the RHP packet is forwarded until it reaches interface e 2/2, the secondary interface of the ring 1 master. Receipt of this RHP indicates a healthy ring 1 and interface e2/2 then changes to or maintains its state of blocking.

No copies of the ring 1 RHPs are forwarded on ring 2 tunnel interfaces or ring 2 regular interfaces in accordance with the rule that a higher priority RHP is not permitted to traverse a lower priority ring interface.

FIGURE 68 RHP flow on rings with shared interfaces showing ring 1 RHP flow

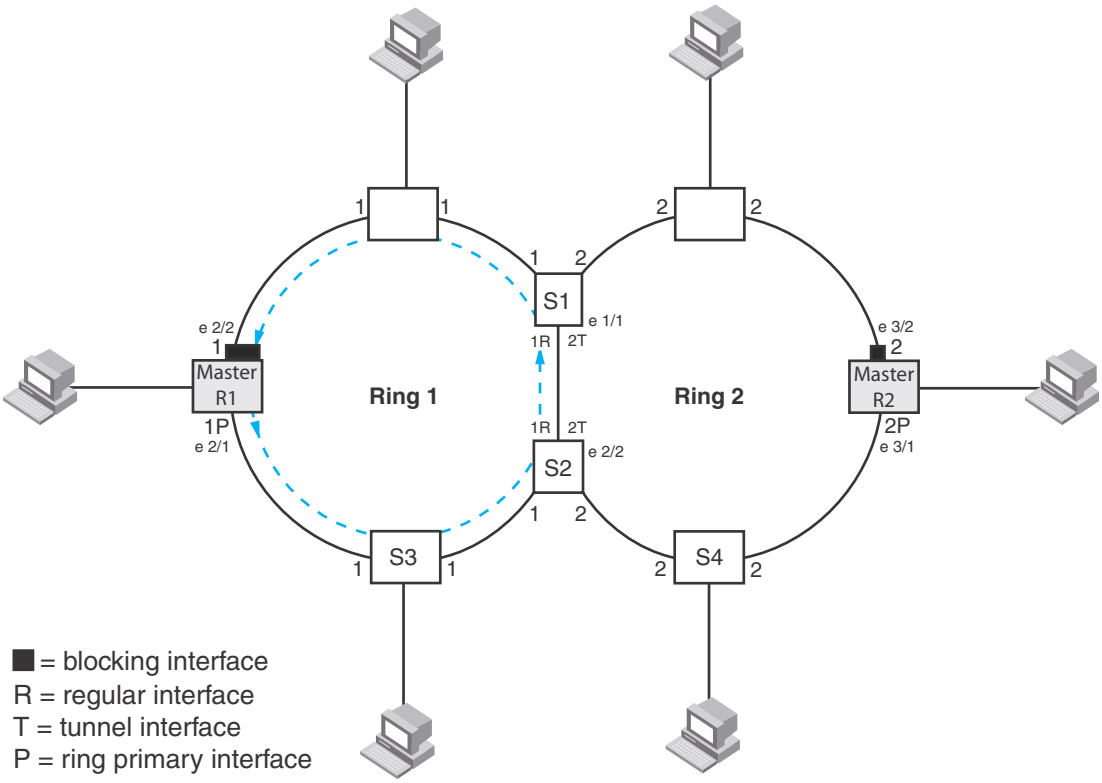


FIGURE 69 RHP flow on rings with shared interfaces showing ring 2 RHP flow

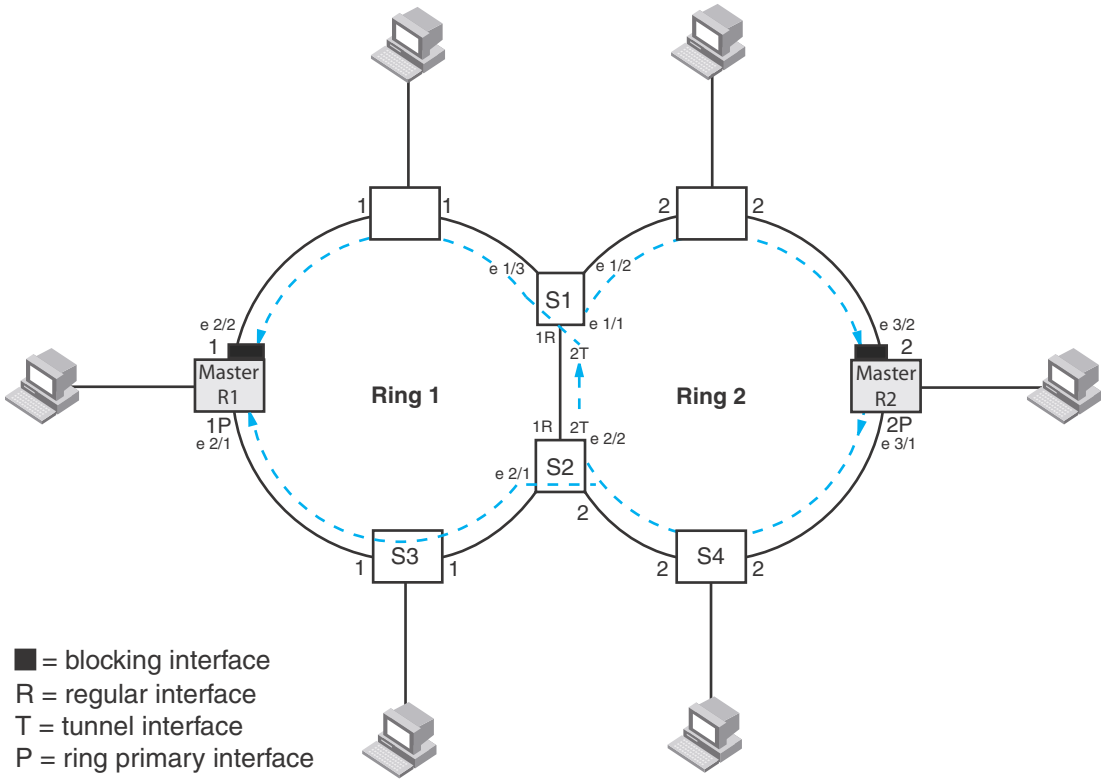


Referring to Figure 69 interface 3/1, is the primary interface of the ring 2 master node. It sends an RHP packet on the ring. Since all interfaces on S4 are regular interfaces, the RHP packet is forwarded on those interfaces.

When the RHP reaches S2:

- A copy of the RHP is sent out of regular interface e 2/1 onto ring 1. This is in accordance with the rule that a lower priority RHP can traverse a higher priority ring interface. This RHP is forwarded until it reaches the ring 1 master where it is discarded.
- A copy of the RHP is forwarded out of the ring 2 tunnel interface on e 2/2

The RHP is received by S1 on e 1/1 and then:

- A copy of the RHP is sent out of regular interface e 1/2 on ring 2
- A copy of the RHP is sent out of regulat interface e 1/3 on ring 1. This is in accordance with the rule that a lower priority RHP can traverse a higher priority ring interface. This RHP is forwarded until it reaches the ring 1 master where it is discarded.

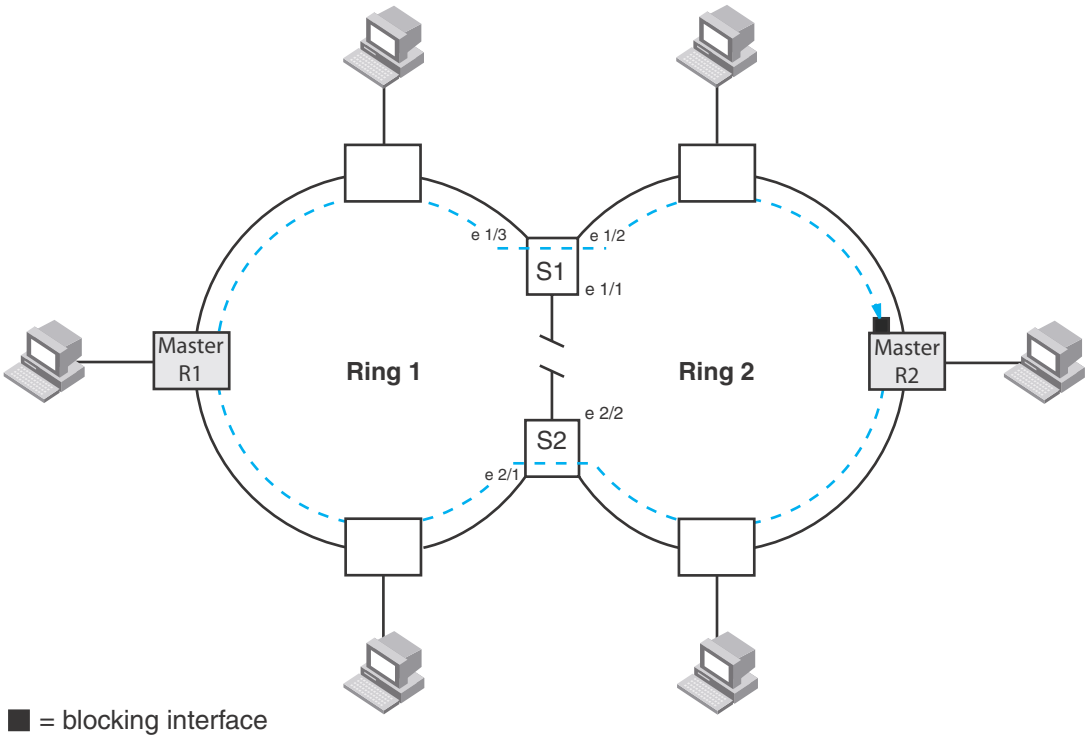
Flow when a link breaks

Referring to Figure 70 if the link between S1 and S2 fails, the secondary interface on the ring 1 master node changes to a forwarding state.

The RHPs from the master for ring 2 reach S2 and a copy of the RHP is forwarded out of e 2/1. This RHP traverses the ring 1 master and continues around ring 1 until it reaches S1. After S1 the RHP is back on ring 2 and is finally received by the master for ring 2 which keeps its secondary interface in blocking mode.

It should now be clear how the flow of lower priority RHPs over the higher priority ring ensure that both ring masters do not transition to forwarding and create a loop condition.

FIGURE 70 Flow of RHP packets when a link for shared interfaces breaks



Ring 2 RHPs follow this path until the link is restored. Once the link is restored the ring 1 master will transition its secondary ring interface to blocking and the ring 2 RHP flow is as shown in Figure 69.

NOTE
There should always be a layer 2 protocol configured in the default vlan when MRP is configured with all dual mode ports.

Configuring MRP with shared interfaces

MRP Phase 2 allows you to enter commands such as the following when configuring MRP.

```
NetIron(config)# vlan 2
NetIron(config-vlan-2)# metro-ring 1
NetIron(config-vlan-2-mrp-1)# name CustomerA
NetIron(config-vlan-2-mrp-1)# ring-interface ethernet 1/1 ethernet 1/2
NetIron(config-vlan-2-mrp-1)# enable
```

```
NetIron(config-vlan-2-mrp-1)# metro-ring 2
NetIron(config-vlan-2-mrp-2)# name CustomerB
NetIron(config-vlan-2-mrp-2)# ring-interface ethernet 1/1 ethernet 1/2
NetIron(config-vlan-2-mrp-1)# enable
```

Syntax: [no] metro-ring <*ring-id*>

The <*ring-id*> parameter specifies the ring ID, which can be from 1 – 255. Configure the same ring ID on each of the nodes in the ring.

Syntax: [no] name <*string*>

The <*string*> parameter specifies a name for the ring. The name is optional, but it can have up to 20 characters long and can include blank spaces. If you use a name that has blank spaces, enclose the name in double quotation marks (for example: “Customer A”).

Syntax: [no] ring-interface ethernet

The **ethernet** <*primary-if*> parameter specifies the primary interface. On the master node, the primary interface is the one that originates RHPs. Ring control traffic and layer 2 data traffic will flow in the outward direction from this interface by default. On member nodes, the direction of traffic flow depends on the traffic direction selected by the master node. Therefore, on a member node, the order in which you enter the interfaces does not matter.

The **ethernet** <*secondary-if*> parameter specifies the secondary interface.

Syntax: [no] enable

The **enable** command enables the ring.

Tuning MRP timers

To effectively tune MRP timers it is crucial to understand the association between the hello time and the preforwarding time.

Flushing the mac table following an MRP event

After an MRP event switches in the ring flush MAC tables and relearn to ensure correct forwarding paths. Notification to flush is carried out by sending topology change RHP’s.

Hello time

This timer specifies the interval at which RHP’s are generated by the ring master. It should be noted that this interval is applied not only to standard RHP’s but also to topology change notification RHP’s. For example: Setting the hello time to its maximum value of 15,000 ms would mean that the three topology change notification RHP’s that are sent following a ring break being detected or a ring heal event would result in Mac table flushes three times at 15 second intervals. On a busy network this would cause unnecessary impact.

Preforwarding time

The preforwarding time defines the amount of time an interface will take to move from blocking to preforwarding without RHP’s being received. It also defines the amount of time an interface will take to move from preforwarding to forwarding without RHP’s being received.

The preforwarding time must be at least 2 x hello time and must be a multiple of the hello time.

The preforwarding time for a lower priority ring must be greater than or equal to the highest higher priority ring.

For example: Setting the preforwarding time to its maximum value of 30,000 ms will mean that a break in the ring (assuming no alarm RHP's are generated) will take one minute to heal.

Setting hello and preforwarding timers appropriately

When setting timers both the hello time and the preforwarding time should be considered to ensure that the appropriate recovery time is applied on the network.

Consider a break in the network that does not generate alarm RHP's

Example 1(default values):

Preforwarding time = 300ms

Hello time = 100ms

Time to forwarding = 2 x preforwarding time = 600ms

Post recovery mac table flush time = 3 x hello time = 300ms

Full connectivity = Time to forwarding + Post recovery mac table flush time = 900ms = 0.9secs

Example 2:

Preforwarding time = 10000ms

Hello time = 100ms

Time to forwarding = 2 x preforwarding time = 20000ms

Post recovery mac table flush time = 3 x hello time = 300ms

Full connectivity = Time to forwarding + Post recovery mac table flush time = 20300ms = 20.3secs

Example 3:

Preforwarding time = 10000ms

Hello time = 5000ms

Time to forwarding = 2 x preforwarding time = 20000ms

Post recovery mac table flush time = 3 x hello time = 15000ms

Full connectivity = Time to forwarding + Post recovery mac table flush time = 35000ms = 35secs

It can therefore be seen that the hello time should not be changed on the network unless there is evidence of regular misses on the ring. Time to traverse the ring can be determined by running MRP diagnostics.

Effect of the scale timer

Changing the scale timer has a significant effect on the operation of MRP and should be considered for very high performance low latency networks where a very rapid failure detection and recovery mode is required. Achieving this rapid detection and recovery requires very stable high speed environments to prevent a high level of unnecessary topology changes in the environment.

The effect of setting the scale timer is that the time taken to move from blocking to preforwarding and preforwarding to forwarding is (preforwarding value – the hello time). This is a significant change to the operation of MRP in the default state which has been described in the previous section.

Note: When setting the timer at the CLI the actual value used will be exactly half of the input value. The examples that follow assume the corrected value.

Consider a break in the network that does not generate alarm RHP's

Example 1(default values):

Preforwarding time = 300ms

Hello time = 100ms

Time to forwarding = preforwarding time – hello time = 200ms

Post recovery mac table flush time = 3 x hello time = 300ms

Full connectivity = Time to forwarding + Post recovery mac table flush time = 500ms = 0.5secs

Example 2:

Preforwarding time = 100ms

Hello time = 50ms

Time to forwarding = preforwarding time – hello time = 50ms

Post recovery mac table flush time = 3 x hello time = 150ms

Full connectivity = Time to forwarding + Post recovery mac table flush time = 200ms = 0.2secs

Example 3:

Preforwarding time = 10000ms

Hello time = 5000ms

Time to forwarding = preforwarding time – hello time = 5000ms

Post recovery mac table flush time = 3 x hello time = 15000ms

Full connectivity = Time to forwarding + Post recovery mac table flush time = 20000ms = 20secs

Using MRP diagnostics

The MRP diagnostics feature calculates how long it takes for RHP packets to travel through the ring. When you enable MRP diagnostics, the software tracks RHP packets according to their sequence numbers and calculates how long it takes an RHP packet to travel one time through the entire ring. When you display the diagnostics, the CLI shows the average round-trip time for the RHP packets sent since you enabled diagnostics. The calculated results have a granularity of 1 microsecond.

Enabling MRP diagnostics

To enable MRP diagnostics for a ring, enter the following command on the Master node, at the configuration level for the ring.

```
NetIron(config-vlan-2-mrp-1)#diagnostics
```

Syntax: [no] diagnostics

NOTE
When using the 'show metro' command, the member node of a ring does not display correctly since the MRP RHPs are hardware forwarded (or software forwarded on the linecard), these statistics are only reflective of the MRP RHPs that made it to the management processor. In most cases, these would be TC RHPs since the MP needs to flush MACs in that case.

NOTE
This command is valid only on the master node.

Displaying MRP diagnostics

To display MRP diagnostics results, enter the following command on the Master node.

```
NetIron(config)# show metro 2 diag

Metro Ring 2 - CustomerA
=============
diagnostics results

Ring       Diag       RHP average     Recommended     Recommended
id         state      time(microsec)  hello time(ms)  Prefwing time(ms)
2          enabled    125             100             300

Diag frame sent     Diag frame lost
1230                0
```

Syntax: show metro <*ring-id*> **diag**

This display shows the following information.

TABLE 90 CLI display of MRP ring diagnostic information

This field...	Displays...
Ring id	The ring ID.
Diag state	The state of ring diagnostics.

TABLE 90 CLI display of MRP ring diagnostic information (Continued)

This field...	Displays...
RHP average time	The average round-trip time for an RHP packet on the ring. The calculated time has a granularity of 1 microsecond.
Recommended hello time	The hello time recommended by the software based on the RHP average round-trip time.
Recommended Prefwing time	The preforwarding time recommended by the software based on the RHP average round-trip time.
Diag frame sent	The number of diagnostic RHPs sent for the test.
Diag frame lost	The number of diagnostic RHPs lost during the test.

If the recommended hello time and preforwarding time are different from the actual settings and you want to change them, refer to "Configuring MRP" on page 462.

Displaying MRP information

You can display the following MRP information:

- Topology group ID associated with the MRP ring
- Ring configuration information and statistics

Displaying topology group information

To display topology group information, enter the following command.

Syntax: show topology-group [<*group-id*>]

Refer to "Displaying topology group information" on page 547 for more information.

Displaying ring information

To display ring information, enter the following command.

```
NetIron(config)# show metro
Metro Ring 10 - VLAN Type REGULAR
==============
Ring       State      Ring       Master     Topo       Hello      Prefwing
id                    role       vlan       group      time(ms)   time(ms)
10         enabled    member     7          1          100        300

Ring interfaces Interface role  Interface state interface type
ethernet 1/1    primary         forwarding      regular
ethernet 30/1   secondary       forwarding      regular

RHPs sent       RHPs rcvd       TC rcvd    TC sent    State changes
0               0               69         0          6
```

Syntax: show metro [<*ring-id*>]

This display shows the following information.

TABLE 91 CLI display of MRP ring information

This field...	Displays...
Ring id	The ring ID
State	The state of MRP. The state can be one of the following: • enabled – MRP is enabled • disabled – MRP is disabled
Ring role	Whether this node is the master for the ring. The role can be one of the following: • master • member
Topo group	The topology group ID if a topology group is configured. This field will show the value 'not conf' if no topology group is in use.
Hello time	The interval, in milliseconds, which the forwarding port on the ring's master node sends Ring Hello Packets (RHPs). Configured in increments of 100ms.
Prefwing time	The number of milliseconds a MRP interface will wait to move an interface in blocking state to preforwarding state if no RHP's are received. It is also the number of milliseconds that an interface that has entered the preforwarding state will wait before changing to the forwarding state. If a member port in the preforwarding state does not receive an RHP within the preforwarding time (Prefwing time), the port assumes that a topology change has occurred and changes to the forwarding state. The secondary port on the master node changes to blocking if it receives an RHP, but changes to forwarding if the port does not receive an RHP before the preforwarding time expires. Configured in increments of 100ms. **NOTE:** A member node's preforwarding interface also changes from preforwarding to forwarding if it receives an RHP whose forwarding bit is on.
Ring interfaces	The device's two interfaces with the ring. **NOTE:** If the interfaces are trunk groups, only the primary ports of the groups are listed.

Interface role	The interface role can be one of the following:
	• primary
	  • Master node – The interface generates RHPs.
	  • Member node – The interface forwards RHPs received on the other interface (the secondary interface).
	• secondary – The interface does not generate RHPs.
	  • Master node – The interface listens for RHPs.
	  • Member node – The interface receives RHPs.

Forwarding state	Whether MRP Forwarding is enabled on the interface. The forwarding state can be one of the following: • blocking – The interface is blocking layer 2 data traffic and RHPs • disabled – The interface is down • forwarding – The interface is forwarding layer 2 data traffic and RHPs • preforwarding – The interface is listening for RHPs but is blocking layer 2 data traffic
Interface Type	Shows if the interface is a regular port or a tunnel port.
RHPs sent	The number of RHPs sent on the interface.
RHPs rcvd	The number of RHPs received on the interface.

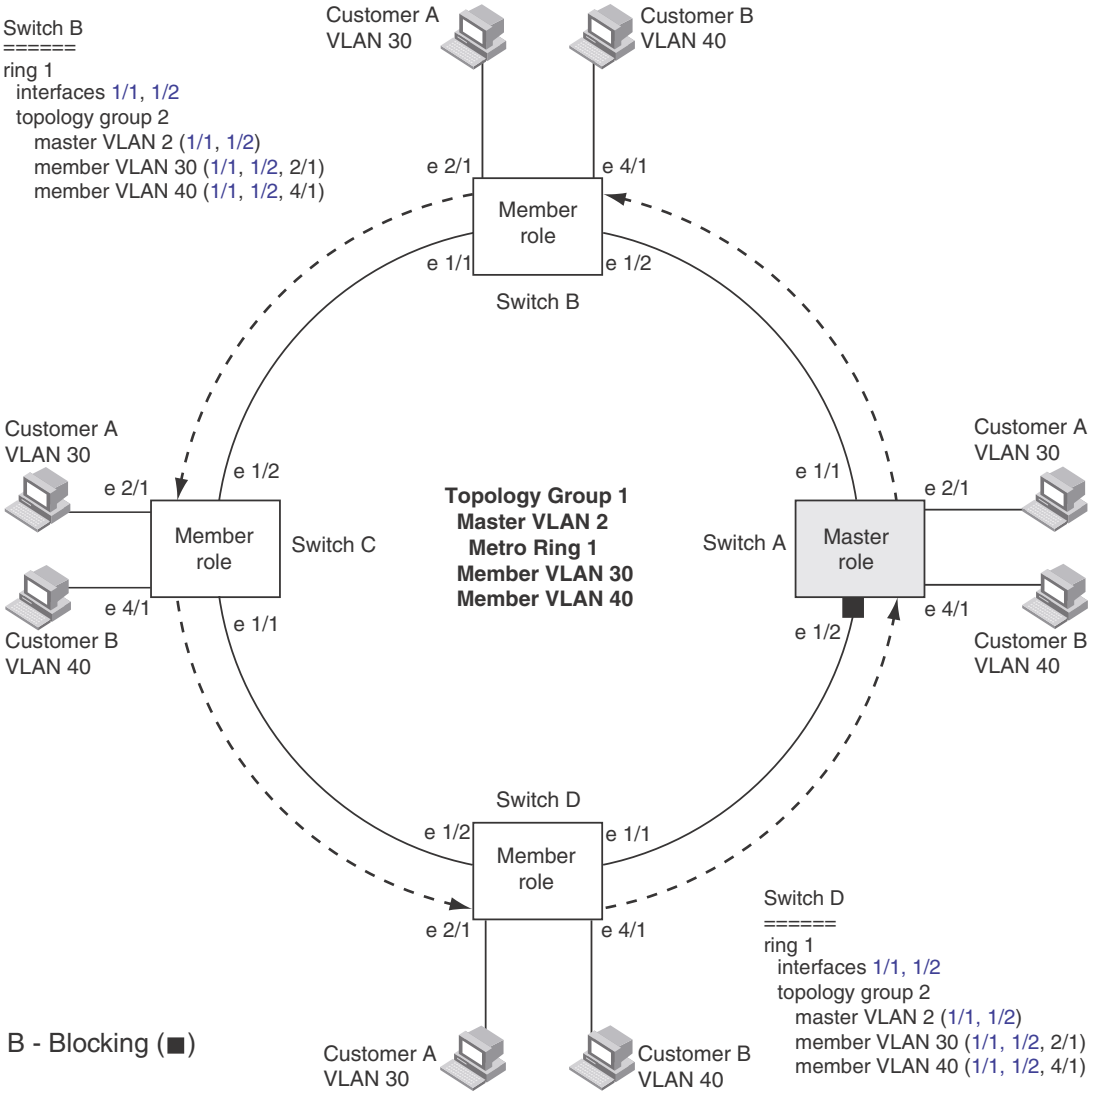
TABLE 91 CLI display of MRP ring information (Continued)

This field...	Displays...
TC RHPs rcvd	The number of Topology Change RHPs received on the interface.
State changes	The number of MRP interface state changes that have occurred. The state can be one of the states listed in the Forwarding state field.

MRP CLI example

The following examples show the CLI commands required to implement the MRP configuration shown in Figure 71.

FIGURE 71



NOTE
For simplicity, the figure shows the vlans on only two switches. The CLI examples implement the ring on all four switches.

Commands on Switch A (master node)

The following commands configure a vlan for the ring. The ring vlan must contain both of the node's interfaces with the ring. Add these interfaces as tagged interfaces, since the interfaces also must be in each of the customer vlans configured on the node.

```
NetIron(config)# vlan 2
NetIron(config-vlan-2)# tag ethernet 1/1 to 1/2
NetIron(config-vlan-2)# metro-ring 1
NetIron(config-vlan-2-mrp-1)# name "Metro A"
NetIron(config-vlan-2-mrp-1)# master
NetIron(config-vlan-2-mrp-1)# ring-interface ethernet 1/1 ethernet 1/2
NetIron(config-vlan-2-mrp-1)# enable
NetIron(config-vlan-2-mrp-1)# exit
NetIron(config-vlan-2)# exit
```

The following commands configure the customer vlans. The customer vlans must contain both the ring interfaces as well as the customer interfaces.

```
NetIron(config)# vlan 30
NetIron(config-vlan-30)# tag ethernet 1/1 to 1/2
NetIron(config-vlan-30)# tag ethernet 2/1
NetIron(config-vlan-30)# exit
NetIron(config)# vlan 40
NetIron(config-vlan-40)# tag ethernet 1/1 to 1/2
NetIron(config-vlan-40)# tag ethernet 4/1
NetIron(config-vlan-40)# exit
```

The following commands configure topology group 1 on vlan 2. The master vlan is the one that contains the MRP configuration. The member vlans use the MRP parameters of the master vlan. The control interfaces (the ones shared by the master vlan and member vlan) also share MRP state.

```
NetIron(config)# topology-group 1
NetIron(config-topo-group-1)# master-vlan 2
NetIron(config-topo-group-1)# member-vlan 30
NetIron(config-topo-group-1)# member-vlan 40
```

Commands on Switch B

The commands for configuring switches B, C, and D are similar to the commands for configuring switch A, with two differences: the nodes are not configured to be the ring master. Omitting the **master** command is required for non-master nodes.

```
NetIron(config)# vlan 2
NetIron(config-vlan-2)# tag ethernet 1/1 to 1/2
NetIron(config-vlan-2)# metro-ring 1
NetIron(config-vlan-2-mrp-1)# name "Metro A"
NetIron(config-vlan-2-mrp-1)# ring-interface ethernet 1/1 ethernet 1/2
NetIron(config-vlan-2-mrp-1)# enable
NetIron(config-vlan-2)# exit
```

```
NetIron(config)# vlan 30
NetIron(config-vlan-30)# tag ethernet 1/1 to 1/2
NetIron(config-vlan-30)# tag ethernet 2/1
NetIron(config-vlan-30)# exit
NetIron(config)# vlan 40
NetIron(config-vlan-40)# tag ethernet 1/1 to 1/2
NetIron(config-vlan-40)# tag ethernet 4/1
NetIron(config-vlan-40)# exit
NetIron(config)# topology-group 1
NetIron(config-topo-group-1)# master-vlan 2
NetIron(config-topo-group-1)# member-vlan 30
NetIron(config-topo-group-1)# member-vlan 40
```

Commands on Switch C

```
NetIron(config)# vlan 2
NetIron(config-vlan-2)# tag ethernet 1/1 to 1/2
NetIron(config-vlan-2)# metro-ring 1
NetIron(config-vlan-2-mrp-1)# name “Metro A”
NetIron(config-vlan-2-mrp-1)# ring-interface ethernet 1/1 ethernet 1/2
NetIron(config-vlan-2-mrp-1)# enable
NetIron(config-vlan-2)# exit
NetIron(config)# vlan 30
NetIron(config-vlan-30)# tag ethernet 1/1 to 1/2
NetIron(config-vlan-30)# tag ethernet 2/1
NetIron(config-vlan-30)# exit
NetIron(config)# vlan 40
NetIron(config-vlan-40)# tag ethernet 1/1 to 1/2
NetIron(config-vlan-40)# tag ethernet 4/1
NetIron(config-vlan-40)# exit
NetIron(config)# topology-group 1
NetIron(config-topo-group-1)# master-vlan 2
NetIron(config-topo-group-1)# member-vlan 30
NetIron(config-topo-group-1)# member-vlan 40
```

Commands on Switch D

```
NetIron(config)# vlan 2
NetIron(config-vlan-2)# tag ethernet 1/1 to 1/2
NetIron(config-vlan-2)# metro-ring 1
NetIron(config-vlan-2-mrp-1)# name “Metro A”
NetIron(config-vlan-2-mrp-1)# ring-interface ethernet 1/1 ethernet 1/2
NetIron(config-vlan-2-mrp-1)# enable
NetIron(config-vlan-2)# exit
NetIron(config)# vlan 30
NetIron(config-vlan-30)# tag ethernet 1/1 to 1/2
NetIron(config-vlan-30)# tag ethernet 2/1
NetIron(config-vlan-30)# exit
NetIron(config)# vlan 40
NetIron(config-vlan-40)# tag ethernet 1/1 to 1/2
NetIron(config-vlan-40)# tag ethernet 4/1
NetIron(config-vlan-40)# exit
NetIron(config)# topology-group 1
NetIron(config-topo-group-1)# master-vlan 2
NetIron(config-topo-group-1)# member-vlan 30
NetIron(config-topo-group-1)# member-vlan 40
```

Configuring MRP under an ESI VLAN

MRP can also be configured under a vlan that is part of a user-configured ESI. Configuring MRP in this scenario is exactly the same as explained before.

```
NetIron(config)# esi customer1 encapsulation cvlan
NetIron(config-esi-customer1)# vlan 100
NetIron(config-esi-customer1-vlan-100)# tag ethernet 1/1 to 1/2
NetIron(config-esi-customer1-vlan-100)# metro-ring 1
NetIron(config-esi-customer1-vlan-100-mrp-1)# name "Metro A"
NetIron(config-esi-customer1-vlan-100-mrp-1)# master
NetIron(config-esi-customer1-vlan-100-mrp-1)# ring-interface ethernet 1/1
ethernet 1/2
NetIron(config-esi-customer1-vlan-100-mrp-1)# enable
NetIron(config-esi-customer1-vlan-100-mrp-1)# exit
NetIron(config-esi-customer1-vlan-100)# exit
```

Configuration considerations

The configuration considerations are as follows:

- MRP can be configured for vlans with encapsulation type B-VLAN, S-VLAN or C-VLAN.
- When MRP is configured for vlans under an ESI, the MRP members must be part of the same ESI.

Ethernet Ring Protection Protocol 14

The following Ethernet Ring Protection (ERP) features are supported by .

- Signal fail
- Manual switch
- Forced switch
- Dual-end blocking
- Non-revertive mode
- Interconnected ring
- FDB flush optimization

Ethernet Ring Protection

Ethernet Ring Protection (ERP), a non-proprietary protocol described in ITU-T G.8032 (Version 1 and 2), integrates an Automatic Protection Switching (APS) protocol and protection switching mechanisms to provide Layer 2 loop avoidance and fast reconvergence in Layer 2 ring topologies. ERP supports multi-ring and ladder topologies. ERP can also function with IEEE 802.1ag to support link monitoring when non-participating devices exist within the Ethernet ring.

You can enable one instance of ERP on a device. Changes to a master VLAN apply to the member VLANs.

NOTE
Before configuring ERP, you must configure a VLAN and the ports you require for your deployment.

This chapter describes ERP components, features, and how to configure, and manage ERP.

Ethernet Ring Protection components

An ERP deployment consists of the following components:

- Roles assigned to devices, called Ethernet Ring Nodes (ERN)
- Interfaces
- Protocols — ERP alone or with IEEE 802.1ag
- ERP messaging
- ERP operational states
- ERP timers

ERN roles

In an Ethernet ring topology you can assign each ERN one of three roles:

- **Ring Protection Link Owner (RPL owner)** — One RPL owner must exist in each ring; its role is to prevent loops by maintaining a break in traffic flow to one configured link while no failure condition exists within the ring.
- **Non-RPL node** — Multiple non-RPL nodes, can exist in a ring; but they have no special role and perform only as ring members. Ring members apply and then forward the information received in R-APS messages.
- **Ring Protection Link (RPL) node** — RPL nodes block traffic to the segment that connects to the blocking port of the RPL owner. The RPL node is used in dual-end blocking and is part of the FDB optimization feature.

Each device can only have one role at any time. Non-ERN devices can also exist in topologies that use IEEE 802.1ag.

ERN interfaces

In addition to a role, each ERN has two configured interfaces:

- Left interface
- Right interface

Traffic enters one interface (ingress) and exits the device using the other interface (egress). The right and left interfaces are physically connected.

You must configure these left and right interfaces in the same pattern across all ERNs within a topology. For example you can assign the interfaces as left/right, left/right, left/right, and so on. It is not acceptable, however, to assign interfaces in random order, such as left/right in the configuration of one ERN and then right/left in the configuration of the next ERN.

Protocols

You can configure standalone ERP or ERP with IEEE 802.1ag support.

Using standalone ERP

When using standalone ERP, all devices have a role, and all devices participate at least as ERP members.

Ring-APS (R-APS) messages are sent at initial start-up of a configuration and periodically when link or node failures or recoveries occur. Each ERN applies the information received in the R-APS messages and forwards the received RAPS messages if both ports are in the forwarding state.

The sending ERN terminates the message when it receives a message originally sent from itself.

Configurable timers prevent ERNs from receiving outdated messages and decrease failure reporting time to allow increased stability within the topology.

To properly configure and troubleshoot ERP, an understanding of the messaging, operational states, and timers is essential. For more information about the ERP protocol, see ITU-T G.8032.

Using ERP with IEEE 802.1ag support

When you have other nonparticipating switches in the ring, you can use the IEEE 802.1ag support to perform link health checks to the next ERN.

With IEEE 802.1ag configured, the ERNs within the ring send Continuity Check Messages (CCM) to verify the integrity of their own links. If a node is not receiving CCMs or if a link goes down, a failure is reported to the ring through R-APS messages. See Figure 72.

FIGURE 72 ERP with IEEE 802.1ag support

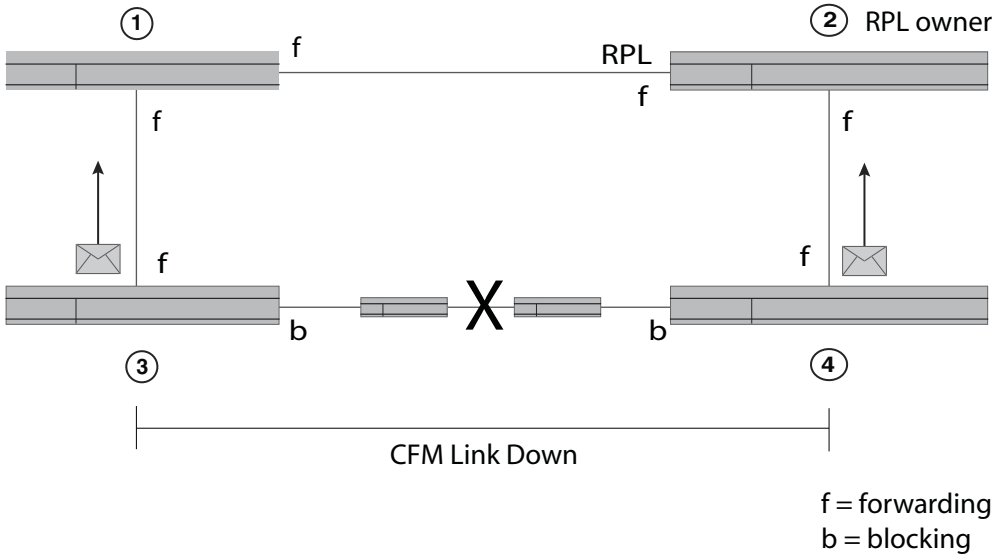


Figure 72 shows a segment with ERNs 3 and 4 and two non-participating switches located on the same network segment between them. When ERNs 3 and 4 stopped receiving CCMs, the following actions occurred on ERNs 3 and 4:

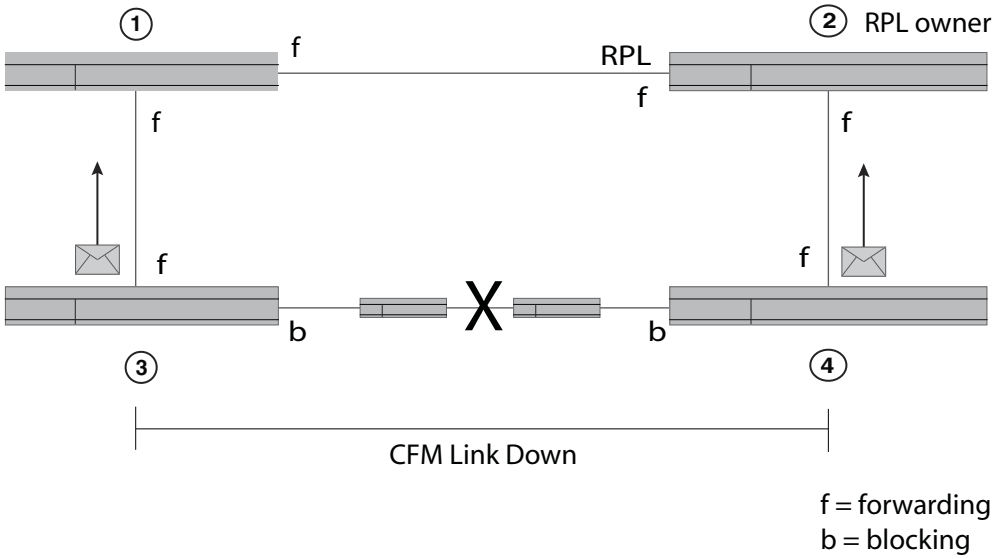
1. Blocked the failed port
2. Transmitted a R-APS (SF) message
3. Unblocked the non-failed port
4. Flushed the FDB
5. Entered the Protection state

As a result, ERN 2, the RPL owner, unblocked the RPL, and the topology became stable and loop free.

ERP messaging

In ERP, ERNs send R-APS messages. Figure 73 shows the general R-APS packet structure. For details about the packet structures, see ITU-T G.8032.

FIGURE 73 R-APS packet structure



The destination MAC address (Dst Mac) is the first element in the packet and is of the form 01-19-A7-00-00-<ERP ID>. The default value is 01. However, you can configure the ERP ID with the **raps-default-mac** command. In ITU-T G.8032 Version 1 the default value is always used.

The Node ID indicates the base MAC address and can be found in the R-APS specific information part of a R-APS message.

ERP operational states

RPL nodes can be in one of six different states in Version 2:

- Init
- Idle
- Protection state, which is designated as a signal fail (SF) event in the R-APS
- Manual-switch (MS)
- Forced-switch (FS)
- Pending (not available if using Version 1)

When an ERP topology starts up, each ERN (in Init state) transmits a R-APS (NR). After start-up, the behavior varies by assigned role. Figure 74 on page 491 shows the initialization process for an ERN.

FIGURE 74 Message exchange and actions during ERN initialization version 2

RPL owner	Non-RPL node	RPL node
Init state	Init state	Init state
1 Blocks the RPL 2 Sends a R-APS (NR) 3 Enters the Pending state.	1 Blocks the left interface 2 Sends a R-APS (NR) 3 Enters the Pending state	1 Blocks the left interface 2 Sends a R-APS (NR) 3 Enters the Pending state
4. Starts the WTR timer 5. (After the WTR expires) stops sending NR 6. Sends R-APS (NR, RB, DNF) 7. Enters the Idle state	After receiving the (NR, RB, DNF) from the RPL owner: 1 Unblocks the non-failed blocking port 2 Stops sending (NR) 3 Enters the Idle state	After receiving the (NR, RB, DNF) from the RPL owner: 1 Blocks the RPL port 2 Unblocks the other ports 3 Enters the Idle state

When the ring is in the Pending state, an ERN flushes the filtering database (FDB) if it receives any of the following state requests:

- Signal-fail (SF)
- No request (NR), RPL Blocked (RB)

NOTE
ITU-T G.8032 Version 1 does not use a Pending state, so from the Protection state ERNs enter the Idle state.

ERP timers

ERP provides various timers to ensure stability in the ring while a recovery is in progress or to prevent frequent triggering of the protection switching. All of the timers are operator configurable.

- **Guard timer** — All ERNs use a guard timer. The guard timer prevents the possibility of forming a closed loop and prevents ERNs from applying outdated R-APS messages. The guard timer activates when an ERN receives information about a local switching request, such as after a switch fail (SF), manual switch (MS), or forced switch (FS). When this timer expires, the ERN begins to apply actions from the R-APS it receives. This timer cannot be manually stopped.
- **Wait to restore (WTR) timer** — The RPL owner uses the WTR timer. The WTR timer applies to the revertive mode to prevent frequent triggering of the protection switching due to port flapping or intermittent signal failure defects. When this timer expires, the RPL owner sends a R-APS (NR, RB) through the ring.
- **Wait to Block (WTB) timers** — This wait-to-block timer is activated on the RPL owner. The RPL owner uses WTB timers before initiating an RPL block and then reverting to the idle state after operator-initiated commands, such as for FS or MS conitions, are entered. Because multiple FS commands are allowed to co-exist in a ring, the WTB timer ensures that the clearing of a single FS command does not trigger the re-blocking of the RPL. The WTB timer is defined to be 5 seconds longer than the guard timer, which is enough time to allow a reporting ERN to transmit

two R-APS messages and allow the ring to identify the latent condition.

When clearing a MS command, the WTB timer prevents the formation of a closed loop due to the RPL owner node applying an outdated remote MS request during the recovery process.

- **Hold-off timer** — Each ERN uses a hold-off timer to delay reporting a port failure. When the timer expires, the ERN checks the port status. If the issue still exists, the failure is reported. If the issue does not exist, nothing is reported.
- **Message interval** — This is an operator configurable feature for sending out R-APS messages continuously when events happen.

Initializing a new ERN

A newly configured Version 2 ERP topology with four ERNs initializes as described in this section. The ERNs have the following roles:

- ERN 2 is the RPL owner.
- ERNs 1, 3, and 4 are non-RPL nodes.

Figure 75 shows the first step of initialization beginning from ERN 4, a non-RPL node. The actions of each ERN are:

- ERN 1 takes no action. Both ports are in the forwarding state.
- ERN 2 (RPL owner) takes no action. Both ports, including the RPL port, are in the VLAN port forwarding state.
- ERN 3 takes no action. Both ports are in the forwarding state.
- From the Init state ERN 4 stops all timers (guard, WTR, WTB), blocks the left port, unblocks the right port, transmits R-APS (NR) messages, and enters the Pending state.

FIGURE 75 Initializing an ERN topology - I

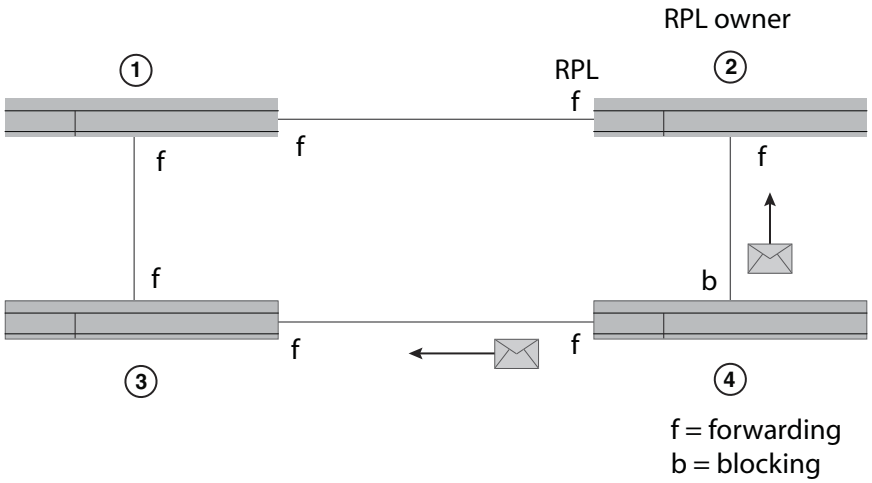


Figure 76 on page 493 shows the next sequence of events. Next, ERN 1 initializes. The actions of each ERN are:

- ERN 1 stops all timers (guard, WTR, WTB), blocks the left port, unblocks the right port, transmits R-APS (NR) messages, and enters the Pending state.

- ERN 2 takes no action. Both ports are in the forwarding state.
- ERN 3 takes no action. Both ports are in the forwarding state.
- ERN 4 stays in the Pending state, transmits R-APS (NR) messages, and continues to block the left interface.

FIGURE 76 Initializing an ERP topology - II

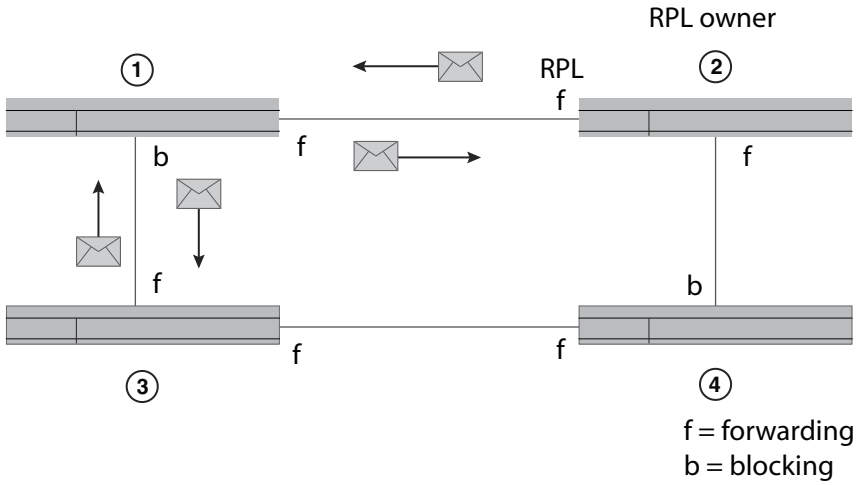

Figure 77 shows the next sequence of events. The actions of each ERN are:

- ERN 1 terminates R-APS received on the blocked port, unblocks the non-failed port, stops transmitting R-APS (NR) messages, and enters the Pending state.
- ERN 2 takes no action.
- ERN 3 takes no action.
- ERN 4 stays in the Pending state and transmits R-APS (NR) messages.

FIGURE 77 Initializing an ERP topology - III

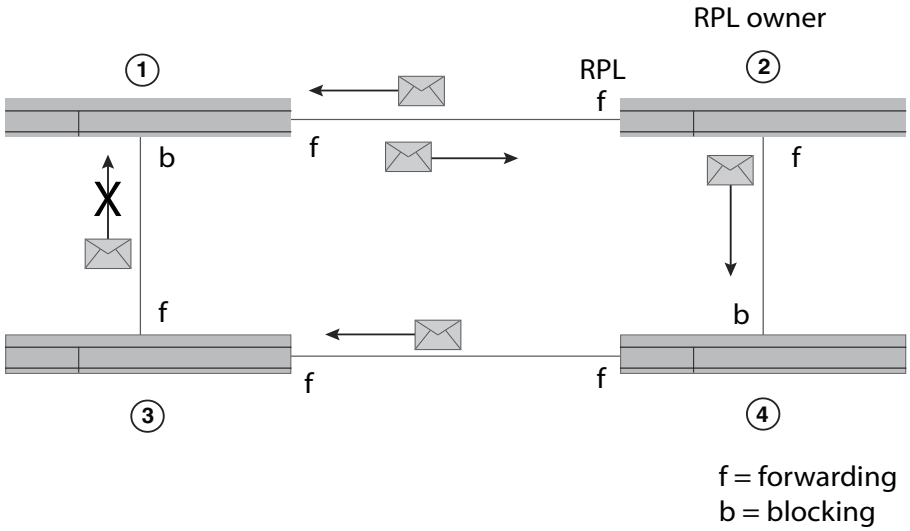

Figure 78 shows the next sequence of events. The actions of each ERN are:

- ERN 1, from the Pending state, unblocks the left interface, stops sending R-APS (NR) and stays in the Pending state. Now both interfaces are in the forwarding state.
- ERN 2 takes no action.
- ERN 3 takes no action.
- ERN 4 stays in the Pending state and transmits R-APS (NR) messages. The left interface is blocked, and the right interface is in the forwarding state.

FIGURE 78 Initializing an ERP topology - IV

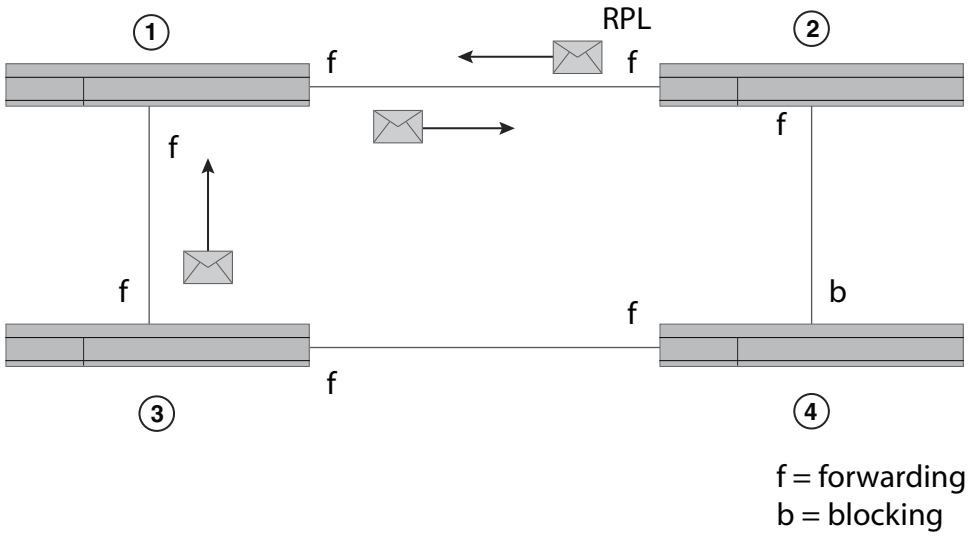

Figure 79 on page 495 shows the next sequence of events. Next ERN 2 initializes. The actions of each ERN are:

- ERN 1 stays in the Pending state.
- ERN 2 (RPL owner), from the Init state, stops the guard timer, stops the WTB timer, blocks the RPL, unblocks the non-RPL port, enters the Pending state, transmits R-APS (NR) messages, and starts the WTR timer.
- ERN 3 takes no action.

- ERN 4 stays in the Pending state and transmits R-APS (NR) messages. The left interface is blocked.

FIGURE 79 Initializing an ERP topology - V

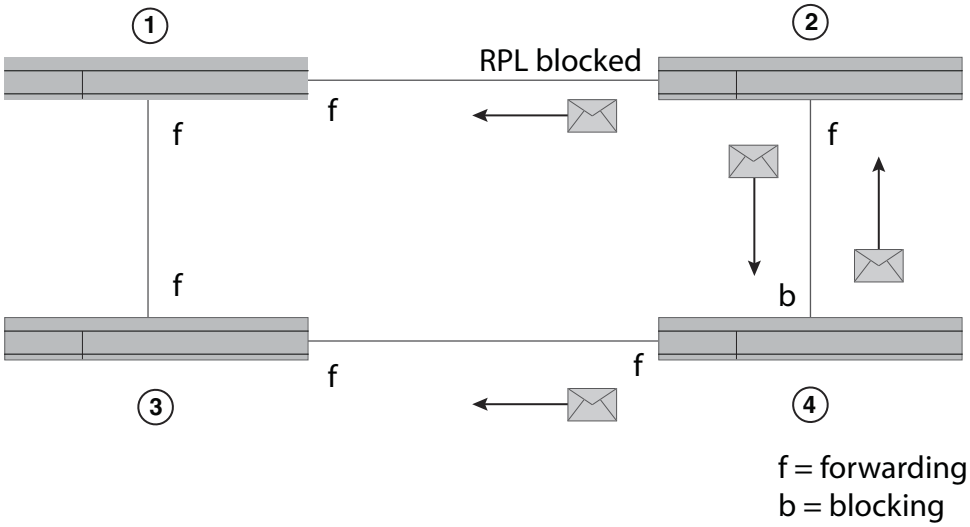

Figure 80 shows the next sequence of events. The actions of each ERN are:

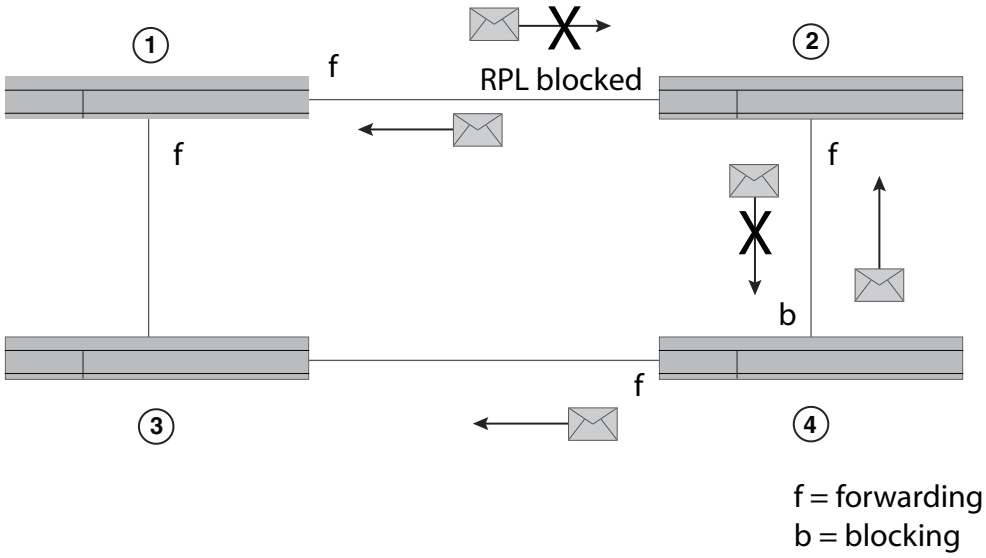
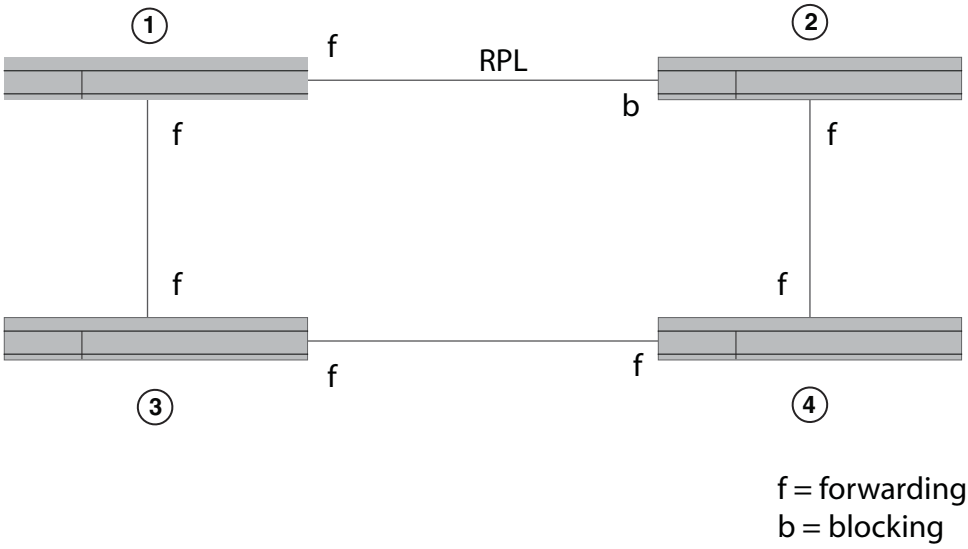
- After the WTB timer expires, ERN 2 (RPL owner in the Pending state) transmits R-APS (NR, RB), and then ERN 2 enters the Idle state.
- ERN 1, still in the Pending state, forwards R-APS (NR, RB) and enters the Idle state.
- ERN 3 takes no action.
- ERN 4 from the Pending state and stops transmitting R-APS (NR).

FIGURE 80 Initializing an ERP topology - VI



Lastly, ERNs 1, 2, and 3 are in the Idle state, and ERN 4 changes the blocking port to the forwarding state. All ERNs remain in the Idle state. See Figure 81.

FIGURE 81 Initializing an ERP topology - VII



Signal fail

Signal fail and signal fail recovery provide the mechanism to repair the ring to preserve connectivity among customer networks.

ERP guarantees that although physically the topology is a ring, logically it is loop-free. One link, called the Ring Protection Link (RPL), is blocked to traffic. When a non-RPL link fails in the ring, the signal failure mechanism triggers and causes the RPL to become forwarding. Later, signal fail recovery can occur to restore the ring to the original setup.

Convergence time is the total time that it takes for the RPL owner to receive the R-APS (NR) message and block the RPL port until the ERN with the failed link receives notice and unblocks the failed link.

Figure 82 shows a simple Ethernet ring topology before a failure. This diagram shows dual-end blocking enabled (thick line) between ERNs one (RPL node) and 6 (RPL owner). ERNs 3, 2, 4, and 5 are non-RPL nodes.

FIGURE 82 ERP topology

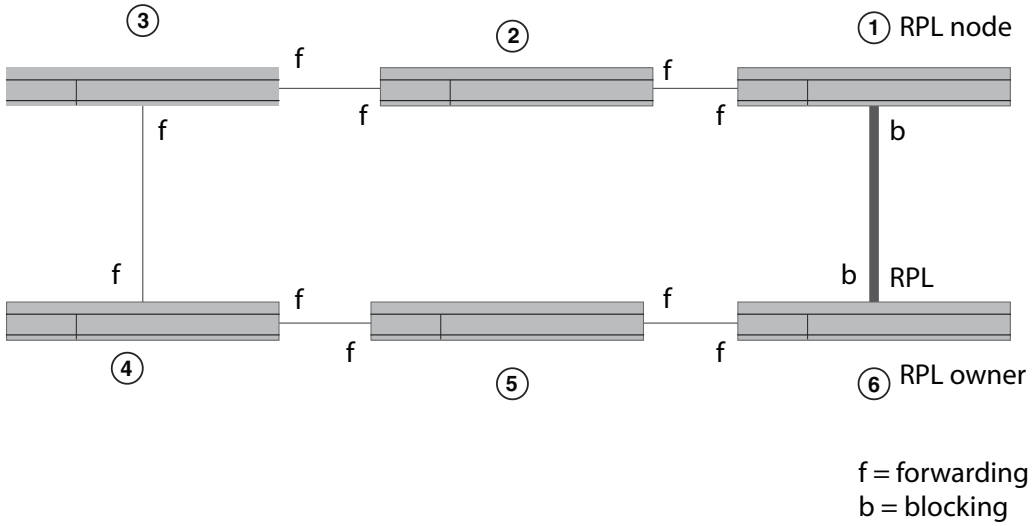


Figure 83 shows the same Ethernet ring topology after a failure at the forwarding port of ERN 4 when a signal fail triggered, and ring protection was needed. ERN 6 unblocked the RPL port and the RPL node changed the blocking port to the forwarding state.

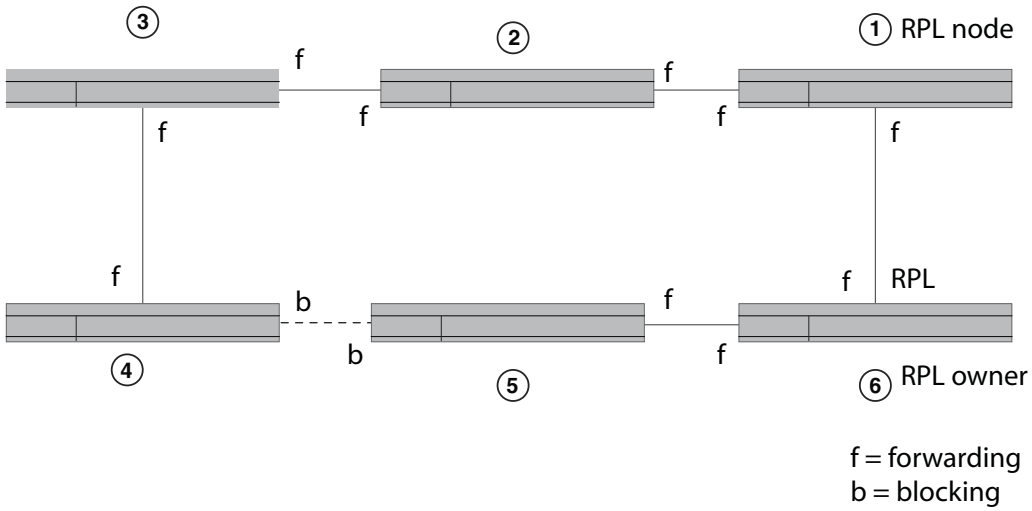
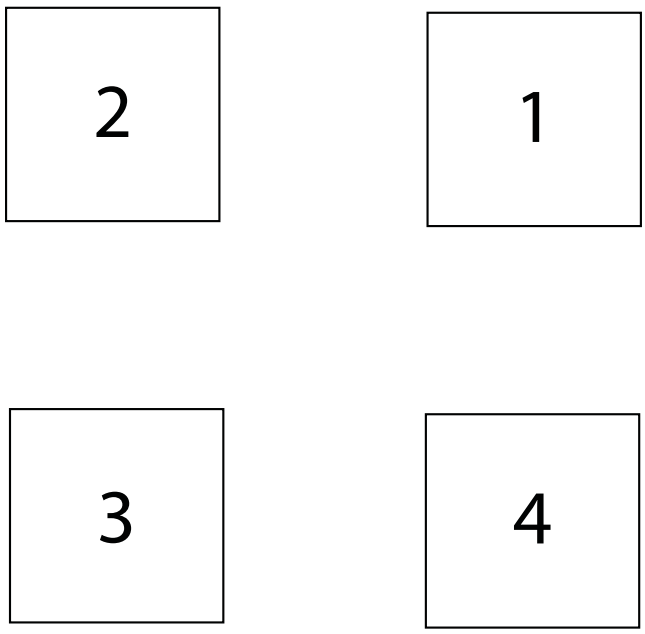
FIGURE 83 ERP topology in a Protected state



Manual switch

In the absence of a failure, an operator-initiated manual switch (MS) moves the blocking role of the RPL by blocking a different ring link and initiates the node sending a R-APS (MS) to inform the RPL owner to unblock the RPL. This can occur if no higher priority request exists in the ring. See Figure 84. The thick line between ERNs 1 and 2 indicate that dual-end blocking is enabled.

FIGURE 84 Manual Switch example



The node, which receives the R-APS (MS), forwards it to the adjacent nodes. If the receiving node is already in the Idle or Pending state, it unblocks the non-failed port and stops transmitting R-APS messages. Only one MS can exist in the topology at any time. An MS condition has to be manually cleared with the **no** command.

NOTE
If any ERN is in an FS state or in a protected state through an SF event and an operator tries to configure an MS, the ERN will reject the request.

When a manual switch is cleared by an operator on the same node on which the MS is configured, the node keeps the port in a blocking state, sends out a R-APS (NR) to the adjacent node, and starts the guard timer. Other nodes that receive the R-APS (NR) forward the message. When the RPL owner receives this message, then the RPL owner starts the WTR timer. When the WTR timer expires, the RPL owner sends out a R-APS (NR, RB), blocks the RPL, and flushes the FDB. Other nodes in the topology that receive the R-APS (NR, RB) unblock any non-failed port and flush the FDB.

Figure 84 shows a manual switch on ERN 3, which is a non-RPL node. In order to clear the MS condition, the operator must enter the manual switch command from ERN 3. The sequence of messages and actions is as shown in Figure 85 on page 499.

FIGURE 85 MS on Non-RPL node

Non-RPL node with error (ERN 3)	RPL owner (ERN 1) and RPL node (ERN2)	Other Non-RPL node (ERN 4)
From the Idle state, ERN3: 1 Blocks the MS port 2 Sends the RAPS (MS) 3 Flushes the FDB 4 Enters the manual switch (MS) state		
		From the Idle state, ERN 4: 1 Forward R-APS (MS) 2 Flush the FDB 3 Enter the MS state
	From the Idle state, ERN 1: 1 Forwards R-APS (MS) 2 Unblocks the RPL 3 Flushes the FDB 4 Enters the MS state	

After the manual switch is triggered, the operator can clear it with the **no** command and MS recovery will begin. Figure 86 shows the sequence of events during the MS recovery process.

FIGURE 86 MS recovery process

From the MS state, ERN 3: 1 Stops sending R-APS (MS) 2 Sends R-APS (NR) 3 Continues to block the port 4 Enters the Pending state			
	From the MS state, ERN 1: 1 Receives the R-APS (NR) 2 Starts the WTB timer 3 Forwards the R-APS (NR) 4 Enters the Pending state 5 After the WTB timer expires, blocks the RPL 6 Flushes the FDB 7 Sends R-APS (NR, RB) 8 Enters the Idle state	From the MS state, ERN 2: 1 Receives the R-APS (NR) 2 Forwards the R-APS (NR) 3 Enters the Pending state	From the MS state, ERN 2: 1 Receives the R-APS (NR) 2 Forwards the R-APS (NR) 3 Enters the Pending state
From the Pending state, ERN 3: 5. Receives the R-APS (NR, RB) and unblocks the blocking port 6. Forwards the R-APS (NR, RB) 7. Flushes the FDB 8. Enters the Idle state		From the Pending state, ERN 2: 4. Blocks the RPL 5. Forwards the R-APS (NR, RB) 6. Flushes the FDB 7. Enters the Idle state	From the Pending state, ERN 4: 4. Forwards the R-APS (NR, RB) 5. Flushes the FDB 6. Enters the Idle state

Forced switch

Forced switch (FS) is an operator-initiated mechanism that moves the blocking role of the RPL to a different ring link followed by unblocking the RPL, even if one or more failed links exist in the ring.

The node configured to initiate an FS blocks the port and sends out a R-APS (FS) to inform other nodes to unblock any blocked ports (including failed ones) as long as no other local request with higher priority exists. The RPL owner unblocks the RPL and flushes the FDB.

Any node accepting a R-APS (FS) message stops transmitting R-APS messages.

Multiple FS instances can be configured in the topology even when the topology is in the same segment where an FS is being cleared by **no** command. When an operator clears an FS on the same node where an FS is configured, this node keeps the port in the blocking state, sends out a R-APS (NR) to adjacent nodes, and starts the guard timer. Other nodes that receive the R-APS (NR) forward the message. When the RPL owner receives this message, the RPL owner starts the WTB timer. When the WTB timer expires, the RPL owner sends out a R-APS (NR, RB), blocks the RPL, and flushes the FDB. Other nodes in the topology that receive the R-APS (NR, RB) unblock any non-failed port and flush the FDB.

An FS request can be accepted no matter what state the topology is in. Since the local FS and R-APS (FS) are higher priority than SF; an SF occur i ng later than FS will not trigger the SF process. In addition, because the local FS and R-APS (FS) are higher priority than SF, when a node receives a R-APS (FS) without any local higher priority event, it will unblock any blocked port. The node with the failed link also unblocks the blocked port; but because the link has failed, the topology is broken into segments.

Since the local FS and R-APS (FS) are higher priority than a local SF clear when the link failure is removed without any local higher priority event, the nodes with the recovering link do not trigger SF recovery.

After the operator clears the FS condition on the node, the node starts the guard timer and sends out a R-APS (NR). When the RPL owner receives a R-APS(NR), it stops the WTB timer and starts the guard timer. The RPL owner blocks the RPL and sends out a R-APS (NR, RB). Any node receiving a R-APS (NR, RB) unblocks the non-failed blocked port. If the guard timer is still running on the node with previous FS, this node ignores R-APS messages until the guard timer expires. The topology is again broken into segments. After this node processes the R-APS (NR, RB), however, it unblocks the blocked node; and the topology is in a loop free state and in one segment.

Figure 87 shows a port failure on ERN 4.

FIGURE 87 Single forced switch scenario

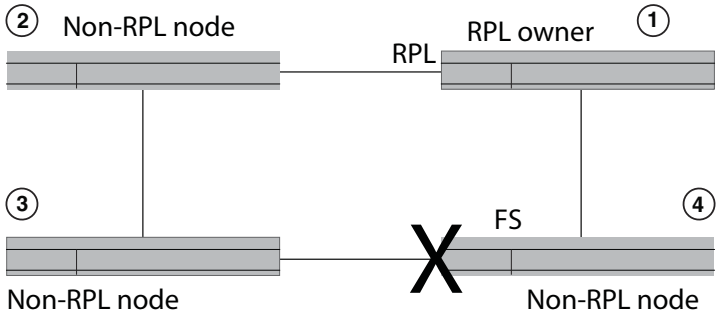

Figure 88 shows the sequential order of events triggered as a result of an operator-initiated forced switch command entered from ERN 4.

FIGURE 88 Single FS process–operator entered the forced switch command from ERN 4

RPL owner (ERN1)	Non-RPL node (ERN 2)	Non-RPL node (ERN 3)	Non-RPL node (ERN 4)
Idle	Idle	Idle	From the Idle state, ERN 4: 1 Processes the Forced Switch command 2 Blocks the requested port 3 Transmits R-APS (FS) 4 Unblocks the non-requested port 5 Flushes the FDB 6 Enters the Forced Switch (FS) state
From the Idle state, ERN 1: 1 Unblocks the RPL 2 Flushes the FDB for first time 3 Forwards R-APS(FS) 4 Enters the FS state	From the Idle state, ERN 2: 1 Unblocks the port 2 Flushes the FDB for the first time 3 Forwards R-APS(FS) 4 Enters the FS state	From the Idle state, ERN 3: 1 Unblocks the port 2 Flushes the FDB for the first time 3 Forwards R-APS(FS) 4 Enters the FS state	
From the FS state, ERN 1 forwards R-APS	From the FS state, ERN 2 forwards R-APS	From the FS state, ERN 3 forwards R-APS	From the FS state, ERN 4: 7. Transmits R-APS(FS) 8. Terminates the received R-APS on the blocking port 9. Terminates its own R-APS(FS)
All ERNs remain in FS state.			

Next, the operator enters the **no** command to clear the forced switch. For this example, the operator initiated the forced switch from ERN 4 and must clear it from ERN 4. Figure 89 on page 502 shows the forced switch recovery process in sequential order.

FIGURE 89 FS clear process

RPL owner (ERN1)	Non-RPL node (ERN 2)	Non-RPL node (ERN 3)	Non-RPL node (ERN 4)
			From the FS state, ERN 4: 1 Starts the guard timer 2 Stops transmitting R-APS(FS 3 Transmits R-APS(NR) 4 Keeps blocking the port 5 Enters Pending state
From FS state, ERN 1: 1 Forwards R-APS 2 Starts the guard timer 3 Starts the WTB timer 4 Enters Pending state			
	From FS state, ERN 2: 1 Forwards R-APS 2 Starts the guard timer 3 Enters the Pending state	From FS state, ERN 3: 1 Forwards R-APS 2 Starts the guard timer 3 Enters the Pending state	
After the WTB timer expires, from the Pending state ERN 1: 5. Blocks the RPL port 6. Transmits R-APS(NR,RB) 7. Unblocks the non-RPL port 8. Flushes the FDB 9. Enters the Idle state			
	From the Pending state, ERN 2: 4. Flushes the FDB 5. Forwards R-APS(NR,RB) 6. Enters the Idle state	From the Pending state, ERN 3: 4. Stops transmitting R-APS 5. Unblocks ports 6. Flushes the FDB 7. Forwards R-APS(NR,RB) Enters the idle state	From the Pending state, ERN 4: 6. Stops transmitting R-APS 7. Unblocks ports 8. Flushes the FDB 9. Forwards R-APS(NR,RB) 10. Enters the Idle state
From the idle state, ERN 1: 10. Receives its own R-APS(NR,RB) 11. Stops transmitting R-APS 12. Remains in the Idle state			

Double Forced Switch

A local FS is of a higher priority than a received R-APS (FS); therefore, the local FS request blocks the port even when the node receives a R-APS(FS) from another FS request of another node.

After the first FS clears, the node starts the guard timer and sends out a R-APS (NR). The adjacent nodes of the first cleared FS node will not process or forward the R-APS (NR) because they are still receiving R-APS (FS) from the second FS node. When the first FS node receives R-APS (FS) from the second FS nodes, it unblocks any blocked port and stops transmitting any lower priority R-APS messages. At this point, the topology follows the single FS process, as previously described.

Dual-end blocking

Dual-end blocking is a user configurable feature to directly conserve bandwidth of the RPL and indirectly conserve processing power of the RPL owner. When you configure a node in a major ring adjacent to the RPL owner to be an RPL node with dual-end blocking enabled, data traffic and R-APS messages will not be forwarded to the blocked port of the RPL owner.

When a failure occurs in the ring and the RPL node (not the RPL owner) receives a R-APS (of type SF, FS, or MS), the RPL node unblocks the configured dual-end blocked port. When the RPL node receives a R-APS (NR, RB), it reblocks the originally configured dual-end blocked port. To configure dual-end blocking you need to configure the RPL and dual-end blocking on both the RPL owner and the adjacent peer (RPL node).

Non-revertive mode

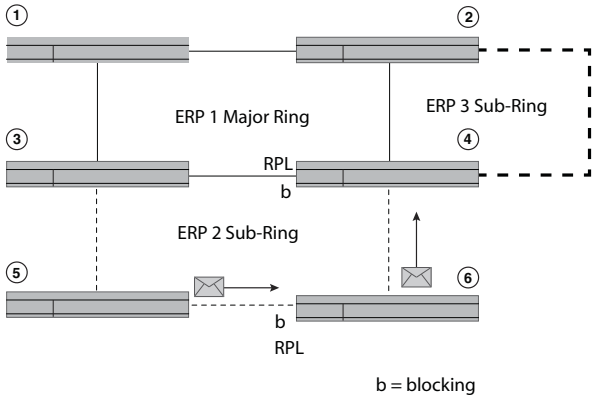
In non-revertive mode, the traffic channel is allowed to use the RPL, if it is not failed, after a switch condition clears. In the recovery from a Protection state, the RPL owner generates no response regarding the reception of NR messages. When other healthy nodes receive the NR message, there is no action in response to the message. After the operator issues a **no** command for non-revertive mode at the RPL owner, the non-revertive operation is cleared, WTB or WTR timer starts, as appropriate, and the RPL owner blocks its port to the RPL and transmits a R-APS (NR, RB) message. Upon receiving the R-APS (NR, RB), any blocking node should unblock its non-failed port.

Interconnected rings

Interconnected Rings consist of one major ring and one or more sub-rings with shared physical links. The ring links between the interconnection nodes are controlled and protected by the ERP ring to which they belong. A sub-ring is similar to the major ring in that each sub-ring has an RPL and an RPL owner. The RPL owner can be configured in any node belonging to the ring.

The dotted lines in Figure 90 on page 504 show two of the many potential sub-rings that you can configure.

FIGURE 90 Interconnected rings with major and sub rings shown



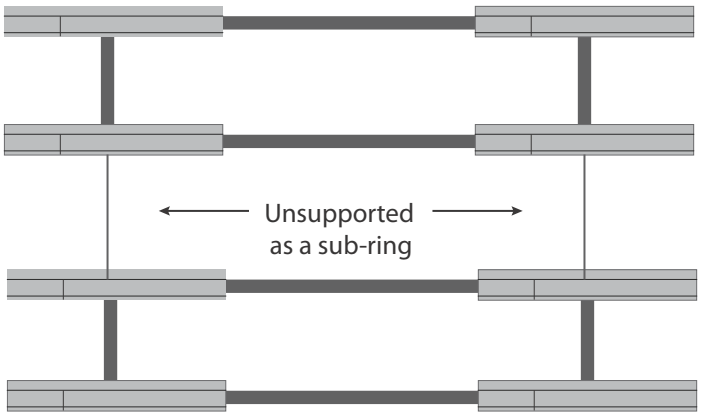
When a sub-ring initializes, each ERN in the non-closed ERP sends out a R-APS (NR). After the RPL owner receives a R-APS (NR), it blocks the RPL; and the RPL owner sends out a R-APS (NR, RB). The shared link remains blocked even if the shared link has a SF error. The blocking state in ERP means the R-APS channel is blocked at the same port where the traffic channel is blocked, except on sub-rings without use of R-APS virtual channel.

Virtual channel support is not available in release 5.1.0. A sub-ring in segments interconnecting major rings is not supported. Figure 91 on page 504 shows a major ring and two segments not supported as a sub-ring.

Blocking prevents R-APS messages received at one ring port from being forwarded to the other ring port; it does not prevent the R-APS messages locally generated at the ERP control process from being transmitted over both ring ports, and it also allows R-APS messages received at each port to be delivered to the ERP control process.

Each ERN in a major ring terminates R-APS messages received on a blocking port and does not forward the message if the port is in a blocking state. Each ERN in a sub-ring, however, still forwards the R-APS messages received on a blocking port.

FIGURE 91 Unsupported sub-ring in segments



FBD flush optimization

The FDB stores the node ID and BPR sent in the R-APS messages. When an ERN receives a new R-APS message, it compares the received node ID and BPR to the node ID and BPR in its memory. If the pair vary from the previously stored pair, the ERN deletes the previous pair and stores the new pair. The device then triggers a FDB flush unless the DNF (No Not Flush) is set in the message.

FDB optimization is achieved with the following features:

- Non-revertive mode alleviates the need to flush the FDB after a link failure with link protection (SF) condition
- Dual-end blocking decreases attempted messages and traffic to the RPL blocking port
- Interconnected ring support to decrease the latency for messaging
- Do Not Flush (DNF) messages

Configuring ERP

To configure and initialize ERP using only APS you must set up one RPL owner and one or more Non-RPL nodes. The minimum configuration tasks are listed in this section.

Before configuring ERP, however, you must have already configured a VLAN and ports.

You must perform the following minimum configuration tasks for the RPL owner:

- Configure an ERP instance
- Set the left and right interfaces
- Set the role as owner
- Set the RPL
- Enable the configuration

You must perform the following minimum configuration tasks for each non-RPL node:

- Configure an ERP instance
- Set the left and right interfaces
- Enable the configuration

Sample configuration

The following example is of an ERP configuration consisting of four devices: an RPL owner, an RPL node, and two non-RPL nodes.

NOTE
Before configuring any ERP settings, configure the VLAN and ports.

Device 1 RPL owner

NOTE
Optionally, you can configure the non-revertive mode feature. This setting can only be set on the RPL owner.

```
(config)# erp 1
(config-erp-1)#right-interface vlan 2 e 1/2
(config-erp-1)#left-interface vlan 2 e 1/1
(config-erp-1)#rpl vlan 2 e1/2
(config-erp-1)#rpl-owner
(config-erp-1)#enable
```

Device 2 RPL node

```
(config)# erp 1
(config-erp-1)#right-interface vlan 2 e 1/2
(config-erp-1)#left-interface vlan 2 e 1/1
(config-erp-1)#rpl vlan 2 e 1/1
(config-erp-1)#enable
```

Device 3 Non-RPL node

```
(config)# erp 1
(config-erp-1)#right-interface vlan 2 e 1/2
(config-erp-1)#left-interface vlan 2 e 1/1
(config-erp-1)#enable
```

Device 4 Non-RPL node

```
(config)# erp 1
(config-erp-1)#right-interface vlan 2 e 1/2
(config-erp-1)#left-interface vlan 2 e 1/1
(config-erp-1)#enable
```

Configuring ERP with IEEE 802.1ag

To configure and initialize ERP using APS and IEEE 802.1ag you must set up one RPL owner and one or more Non-RPL nodes. Other nonparticipating switches can exist in the ring.

You must perform the following minimum configuration tasks for the RPL owner:

- Configure an ERP instance
- Set the left and right interfaces
- Set the role as owner
- Set the RPL
- Enable the configuration

You must perform the following minimum configuration tasks for each non-RPL node:

- Configure an ERP instance
- Set the left and right interfaces

- Configure the maintenance entity group end points (MEP) from each ERN, which can have a role of RPL owner or non-RPL node, adjacent to switches not participating in the ERP configuration
- Enable the configuration

ERP commands

This section lists ERP configuration commands.

Assigning ERP IDs

You must assign an ERP ID. This ID number is used to:

- Filter and clear statistics associated with a particular ERP ID
- Delete the non-revertive mode in the case of an RPL owner
- Clear WTR and WTB timers

The *erp_id* value is a number from 1 to 255.

Syntax: erp <*erp_id*>

For example, to assign the number 10 to the ERP, enter:

```
(config)# erp 10
```

Naming an Ethernet Ring Node

From within the ERP configuration shell, you can optionally name an ERN with a meaningful name. The name must be 31 alphanumeric characters or fewer; and the name can use the “underscore” and “dash” special characters.

Syntax: [**no**] **name** <*erp_name*>

For example, to assign the name “to_dell1” to an ERN with ID number 10, enter:

```
(config)# erp 10
(config-erp-10)# name “to_dell1”
```

Use the **no** command to remove the name.

Configuring the default MAC ID

You can configure the MAC ID. The router appends this ID number to the end of the permanent portion of the ERP MAC address (01-19-A7-00-00- <01 or ERP ID>) in R-APS messages. By default 01-19-A7-00-00-01 is used as the dst MAC, which is always used by Version 1 of ITU-T 8032. If Version 2 is configured, then the **raps-default-mac** command can be negated by entering the **no raps-default-mac** command. The configured ERP ID will appear as the last 8-bit number in the destination MAC.

For more information about feature support for version 1 and 2, see “Setting the ITU-T G.8032 version number” on page 512.

Syntax: [no] raps-default-mac

Enabling the ERP configuration

You must apply the **enable** command to activate an ERP configuration. You can use the **no** command to disable the configuration.

Within an interconnected ring topology, in the major ring, you must first configure two interfaces. In a sub-ring, at least one interface must first be configured before enabling the ERP instance.

Syntax: [no] enable

Example of a non-RPL node configuration in a major ring:

```
(config)# erp 1
(config-erp-1)#right-interface vlan 2 e 1/2
(config-erp-1)#left-interface vlan 2 e 1/1
(config-erp-1)#enable
```

Configuring interfaces

Each ERN in a major ring must have explicitly defined left and right interfaces so that ERP can function properly. ERNs in a sub-ring must have at least one interface defined so that ERP can function properly.

For proper operation you must configure the interfaces following the same manner on each ERN, such as left/right, left/right, and so on.

Syntax: [no] left-interface [vlan <*vlan-id*> e <*slot/number*>]

Syntax: [no] right-interface [vlan <*vlan-id*> e <*slot/number*>]

Use the **no** command to remove the configuration of each interface.

Assigning the RPL owner role and setting the RPL

Each ring needs to have one RPL owner for each ring. The RPL owner's role is to block traffic on one port when no failure exists in the ring. The blocked port will be the left interface that you initially configured. After configuring the ERN to be the RPL owner, you next must set the RPL. To set the RPL you need to specify the VLAN and Ethernet slot and port.

NOTE
When you assign the role of RPL owner, you must also configure the RPL.

Syntax: [no] rpl-owner

Syntax: [no] rpl [vlan <*vlan-id*> e <*slot/number*>]

Enabling sub-rings for multi-ring and ladder topologies

In multi-ring and ladder topologies, you can enable the multi-ring feature.

Interconnected rings consists of one major ring and at least one sub-ring within the same VLAN. A sub-ring is not a complete ring. Nodes within a sub-ring can be configured as a one-arm ring. Each sub-ring must have its own RPL owner and RPL ports as appropriate.

RPL ports and the RPL owner also need to be configured in a sub-ring. All ERP features are available in both major and sub-rings.

R-APS PDUs only flow in the nodes with same ring ID. The R-APS PDU can be forwarded through the port in sub-ring blocking state.

Syntax: [no] **sub-ring**

Use the **no** command to delete the sub-ring support.

If you have six nodes you can put them in one ring. The latency time for packet transport, however, increases in big topologies even within the same VLAN, so it is better to separate them out.

Configuring non-revertive mode

After the Ethernet Ring enters a protected state, if you do not want the topology to return to the original state you can use the **non-revertive-mode** command to keep it in the new state. Enter this command on the RPL owner only, and then enter the **enable** command.

Syntax: [no] **non-revertive-mode**

Use the **no** keyword to remove the non-revertive mode setting.

Configuring and clearing a forced switch

An operator can use the forced switch (FS) mechanism when no errors, a single error, or multiple errors are present in the topology. You can enter this command multiple times. You need to explicitly specify the VLAN and Ethernet slot and port.

Syntax: [no] **forced-switch** [**vlan** <*vlan*> **e** <*slot/port*>]

Use the **no** command to remove the forced switch mechanism.

Configuring and clearing a manual switch

Manual switch (MS) is an operator-initiated process that manually blocks a desired port in a ring. You need to explicitly specify the VLAN, Ethernet slot, and port from the desired device.

Syntax: [no] **manual-switch** [**vlan** <*vlan*> **e** <*slot/port*>]

Use the **no** command to remove the manual switch mechanism.

Configuring dual-end blocking

You can configure dual-end blocking to optimize your ERP configuration. The RPL node must be adjacent to the RPL owner.

When you configure the RPL on an ERN that is adjacent to the RPL owner, you are enabling the dual-end blocking feature and changing the ERN's role to that of RPL node. You configure the RPL node with the **rpl** command. Before configuring dual-end blocking, you must verify that the RPL node is actually the correct peer and obtain the RPL link settings; an incorrect setting will cause incorrect port blocking.

NOTE
The RPL node must be a peer of the RPL owner, and the RPL must be configured on this peer; otherwise, the device will perform incorrect port blocking behavior.

Syntax: [**no**] **rpl** [**vlan** <*vlan-id*> **e** <*slot/number*>]

Configuring the guard timer

The guard timer prevents ERNs from acting upon outdated R-APS messages and prevents the possibility of forming a closed loop. The guard timer enforces a period during which an ERP topology ignores received R-APS.

This timer period should always be greater than the maximum expected forwarding delay in which an R-APS message traverses the entire ring. The longer the period of the guard timer, the longer an ERN is unaware of new or existing relevant requests transmitted from other ERN and, therefore, unable to react to them.

The guard timer is used in every ERN, once a guard timer is started, it expires by itself. While the guard timer is running, any received R-APS request/state and Status information is blocked and not forwarded to the priority logic. When the guard timer is not running, the R-APS request/state and status information is forwarded unchanged.

NOTE
The Release 5.1.0 implementation of the guard timer differs from the ITU-T G.8032 document. The standard defines the guard timer period as configurable in 10 ms increments from 10 ms to 2000 ms (2 seconds) with a default value of 500 ms.

The guard timer is activated when an ERN receives an indication that a local switching request, such as a clear signal fail, manual switch, or forced switch, is cleared.

The guard timer can be configured in 100ms increments from 1200ms to 4000ms (4 seconds); the default value is 1500ms (1.5 seconds). The guard timer cannot be stopped manually.

Syntax: **guard-time** <*time-value*>

Configuring and clearing the wait to restore timer

For SF recovery situations, you can configure the wait to restore (WTR) timer on the RPL owner to prevent frequent operation of the protection switching due to the detection of intermittent signal failures. When recovering from a Signal Failure, the WTR timer must be long enough to allow the recovering network to become stable.

This WTR timer is activated on the RPL Owner Node. When the relevant delay timer expires, the RPL owner initiates the reversion process by transmitting an R-APS (NR, RB) message. The WTR timer is deactivated when any higher priority request preempts this timer. The WTR timers may be started and stopped. A request to start running the WTR timer does not restart the WTR timer. A request to stop the WTR timer stops the WTR timer and resets its value. The Clear command can be used to stop the WTR timer. While WTR timer is running, the WTR running signal is continuously generated. After the WTR timer expires, the WTR running signal is stopped, and the WTR Expires signal is generated. When the WTR timer is stopped by the clear command, the WTR Expires signal is not generated.

When configured, the RPL owner waits until the timer expires before transmitting the R-APS(NR,RB) message to initiate the reversion process. While the timer is in effect, the WTR running signal is continuously generated. You can configure the WTR timer in 1 minute increments from 1 to 12 minutes; the default value is 5 minutes.

This timer can be stopped by issuing the **clear erp** <*erp_id*> **wtr-timer** command.

Syntax: wtr-time <*time-value*>

Testing the WTR timer

You can enter the **fast-wtr-time** command to test your configuration. Instead of having to wait 5 minutes for the timer to expire, you wait 5 seconds. This command changes the timer's unit of measure from minutes to seconds.

Syntax: [**no**] **fast-wtr-time**

Use the **no** command to return the unit of measure to minutes.

Configuring and clearing the WTB timer

The WTB timer ensures that clearing of a single FS command does not trigger the reblocking of the RPL when multiple FS situations co-exist in an Ethernet Ring. When recovering from an MS or FS command, the delay timer must be long enough to receive any latent remote FS or MS.

While it is running, the WTB running signal is continuously generated. The WTB timer is 5000ms (5 seconds) longer than the guard timer. You can configure this timer in 100 ms increments from 5100ms to 7000ms (7 seconds); the default value is 5500ms.

The WTB timer can be stopped through the CLI by entering the **clear erp** <*erp_id*> **wtb-timer** command.

Syntax: wtb-time <*time-value*>

Configuring a hold-off timer

The hold-off timer is used in each ERN to prevent unnecessary Signal Fail events due to port flapping. If you configure a non-zero hold-off timer value, when a link error occurs, the event will not be reported immediately. When the hold-off timer expires, ERP checks if the error still exists.

The hold-off timer is used in every ERN. When a new defect occurs (new SF), this event will not be reported immediately to trigger protection switching if the provisioned hold-off timer value is non-zero. Instead, the hold-off timer is started. When the hold-off timer expires, the trail that started the timer is checked as to whether a defect still exists. If one does exist, that defect is reported and protection switching is triggered.

You can configure the hold-off timer in 100ms increments from 0 to 10,000 ms (10 seconds); the default value is 0 ms. The hold-off timer value cannot be stopped through the CLI.

Syntax: holdoff-time <*time-value*>

Configuring the message interval time

The message interval time of R-APS messages continuously sent within an ERP ring can be configured. You can configure the interval in 100ms increments from 100ms to 5000ms (5 seconds); the default value is 5000ms.

Syntax: message-interval <*time-value*>

Configuring IEEE 802.1ag support

You can enable IEEE 802.1ag support by entering the **dot1ag-compliance** command. By enabling this protocol, ERNs with non-ERN switches between them can be notified when the domain goes down. You need to enter the domain name, MA name, and MEP value of the domain with which to associate this ERP.

Syntax: [**no**] **dot1ag-compliance domain-name** <*name*> **ma-name** <*name*> **mep** <*mep_value*>

Setting the ITU-T G.8032 version number

You can configure the ERP configuration to use G.8032 version 1 or 2. The default value is version 2. Table 92 lists the feature and MAC ID differences between versions 1 and 2.

NOTE
The ERP **version** command does not have a shortened form. You must enter the complete command.

TABLE 92 Feature differences between G.8032 version 1 and 2

Version	Supported ERP features	Treatment of MAC ID
1	• Signal Fail • Signal Fail recovery	Always uses 01:19:A7:00:00:01 as the ERP ID in R-APS messages
2	• Signal Fail • Signal Fail recovery • Manual Switch • Forced Switch • Non-revertive • Interconnected rings • RPL configuration on non-RPL owner	Allows use of the ERP ID for the last two bytes of the MAC ID (01:19:A7:00:00:erp-id)

Syntax: version < *version_number*>

You can view the version by entering the **show erp** command. The version appears on the top line directly after the ERP ID.

Viewing ERP operational status and clearing ERP statistics

You can view operational status and statistics and clear statistics for all links or particular links.

Viewing ERP operational status and statistics

To view ERP statistics, enter the following command on the RPL owner:

Syntax: show erp [<*enter*> | <*erp_id*>]

To view ERP information for all links, enter **show erp** followed by pressing the Enter key (carriage return). To view statistics for a particular link, enter the ERP ID after the command.

Example output:

```
NetIron#show erp 7
ERP 7(version 2)- VLAN 504
================================================================
Erp    ID     Status     Oper       Node       Topo
                         state      role       group
       1      enabled    Idle       rpl-owner  -

Ring type  WTR        WTB        Guard      Holdoff    Msg
           time(min)  time(ms)   time(ms)   time(ms)   intv(ms)
Major-ring 5          7000       2000       0          1000
```

```
I/F    Port   ERP port state    Interface status     Interface type
L      1/12   blocking          normal               rpl
R      1/11   forwarding        normal            non-rpl

RAPS sent     RAPS rcvd     RAPS dropped  RAPS ignored     Oper state changes
3             3             0             0                0
```

Table 93 summarizes the table fields and their meanings.

TABLE 93 Summary of CLI output for **show erp** command

This field...	Displays...
ERP id	The ERP ID is the number that was configured at setup. The ERN appends this number to the permanent portion of the MAC address (01-19-A7-00-00) used for ERP.
Status	Enabled or disabled
Operational state	Init, Idle, Protection, Manual Switch, Forced Switch or Pending
Node role	rpl-owner, non-rpl-node or rpl-node
Topology group	<topology group id> or "- " (- means N/A)
Ring type	Major-ring or Sub-ring
Timers	Configuration value for each timer
Interfaces (I/F)	L (left) or R (right)
Port	<slot/port>
ERP port state:	disabled, blocking, forwarding
Interface status:	normal, signal-fail, manual-switch or forced-switch
Interface type:	rpl or non-rpl
RAPS sent:	RAPS sent by MP (self generated)
RAPS rcvd:	RAPS received by MP
RAPS dropped:	RAPS dropped by MP
RAPS ignored:	RAPS ignored (for example, the guard-timer, or non regular type)

Clearing ERP statistics

You can clear ERP statistics by entering the **clear erp** <erp_id> **statistics** command to clear the statistics of one erp instance. You can clear all ERP statistics by entering the **clear erp statistics** command to clear the statistics of all erp instances.

Syntax: **clear erp** <*erp_id*> **statistics**

clear erp statistics

Virtual Switch Redundancy Protocol (VSRP) 15

The following Virtual Switch Redundancy Protocol (VSRP) features are supported by the .

- Virtual Switch Redundancy Protocol (VSRP)
- VSRP 2
- Layer 2 Redundancy
- Layer 3 VSRP
- MAC Address Failover on VSRP-Aware Devices
- VSRP Fast Start
- VSRP Slow Start
- VSRP and Foundry MRP Signaling

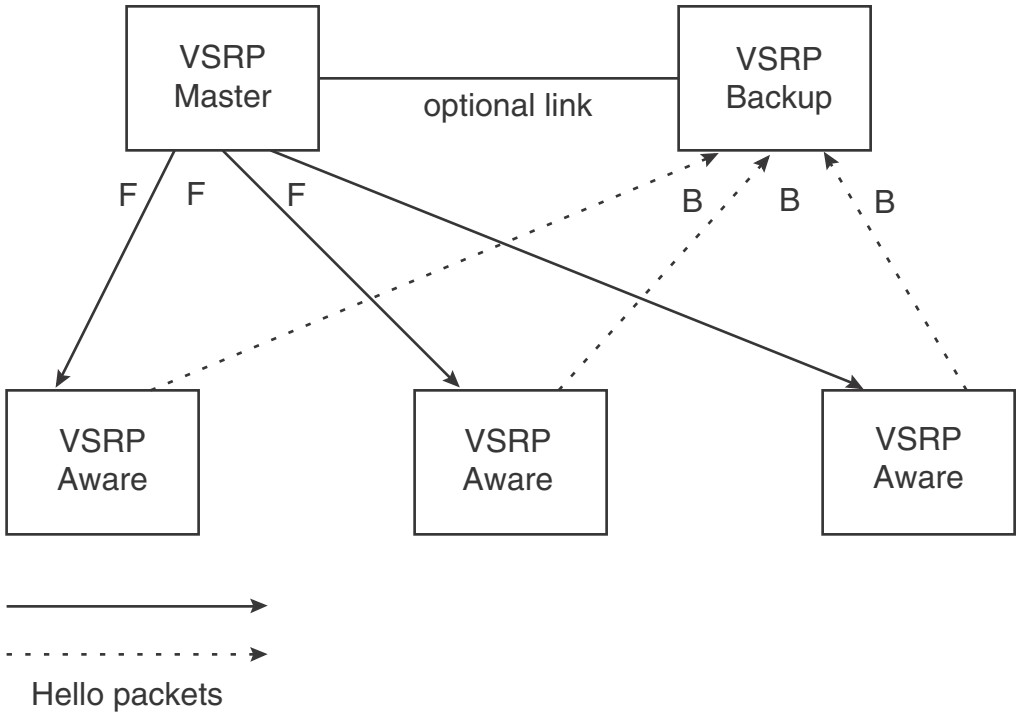
VSRP is a proprietary protocol that provides redundancy and sub-second failover in Layer 2 mesh topologies. Based on the Virtual Router Redundancy Protocol Extended (VRRPE), VSRP provides one or more backups for the PowerConnect. If the active PowerConnect becomes unavailable, one of the backups takes over as the active device and continues forwarding traffic for the network. You can use VSRP for the PowerConnect.

VSRP is a Dell proprietary protocol that provides redundancy and sub-second failover in Layer 2 and Layer 3 mesh topologies. Based on the Dell's proprietary Virtual Router Redundancy Protocol Extended (VRRPE), VSRP provides one or more backups for the device. If the active device becomes unavailable, one of the backups takes over as the active device and continues forwarding traffic for the network.

Layer 2 and Layer 3 share the same VSRP configuration information.

Figure 92 shows a VSRP configuration.

FIGURE 92 VSRP mesh – redundant paths for Layer 2 traffic



In this example, two PowerConnect devices are configured as redundant paths for VRID 1. On each PowerConnect, a Virtual Router ID (VRID) is configured on a port-based VLAN. Since VSRP is primarily a Layer 2 redundancy protocol, the VRID applies to the entire VLAN. However, you can selectively remove individual ports from the VRID if needed.

Following Master election (described below), one of the devices becomes the Master for the VRID and sets the state of all the VLAN's ports to Forwarding. The other device is a Backup and sets all the ports in its VRID VLAN to Blocking.

If a failover occurs, the Backup becomes the new Master and changes all its VRID ports to the Forwarding state.

Other devices can use the redundant paths provided by the VSRP devices. In this example, three devices use the redundant paths. A device that is not itself configured for VSRP but is connected to a device that is configured for VSRP, is ***VSRP aware***. In this example, the three devices connected to the VSRP devices are VSRP aware. A device that is VSRP aware can failover its link to the new Master in sub-second time, by changing the MAC address associated with the redundant path.

When you configure VSRP, make sure each of the non-VSRP devices connected to the VSRP devices has a separate link to each of the VSRP devices.

NOTE
If the PowerConnect is configured as the VSRP Master and it is connected to a FastIron switch (FESX, FSX, SuperX, FGS, and FLS) that is operating as a VSRP-Aware device, the FastIron switch must have the **vsrp-aware tc-vlan-flush** command configured at the VLAN level.
When the **vsrp-aware tc-vlan-flush** command is enabled on the FastIron switch, MAC addresses will be flushed at the VLAN level, instead of at the port level. MAC addresses will be flushed for every topology change (TC) received on the VSRP-aware ports.

Layer 2 redundancy

VSRP provides Layer 2 redundancy. This means that Layer 2 links are backed up.

You can configure VSRP to provide redundancy for Layer 2 only or also for Layer 3:

- Layer 2 only – The Layer 2 links are backup up but specific IP addresses are not backed up.
- Layer 2 and Layer 3 – The Layer 2 links are backup up and a specific IP address is also backed up. Layer 3 VSRP is the same as VRRPE. However, using VSRP provides redundancy at both layers at the same time.

The PowerConnect supports Layer 2 and Layer 3 redundancy. You can configure a PowerConnect for either Layer 2 only or Layer 2 and Layer 3. To configure for Layer 3, specify the IP address you are backing up.

NOTE
If you want to provide Layer 3 redundancy only, disable VSRP and use VRRPE.

Master election and failover

Each VSRP device advertises its VSRP priority in Hello messages. During Master election, the VSRP device with the highest priority for a given VRID becomes the Master for that VRID. After Master election, the Master sends Hello messages at regular intervals to inform the Backups that the Master is healthy.

If there is a tie for highest VSRP priority, the tie is resolved as follows:

- PowerConnect devices – The PowerConnect whose virtual routing interface has a higher IP address becomes the master.

VSRP failover

Each Backup listens for Hello messages from the Master. The Hello messages indicate that the Master is still available. If the Backups stop receiving Hello messages from the Master, the election process occurs again and the Backup with the highest priority becomes the new Master.

Each Backup waits for a specific period of time, the Dead Interval, to receive a new Hello message from the Master. If the Backup does not receive a Hello message from the Master by the time the Dead Interval expires, the Backup sends a Hello message of its own, which includes the Backup's VSRP priority, to advertise the Backup's intent to become the Master. If there are multiple Backups for the VRID, each Backup sends a Hello message.

When a Backup sends a Hello message announcing its intent to become the Master, the Backup also starts a hold-down timer. During the hold-down time, the Backup listens for a Hello message with a higher priority than its own:

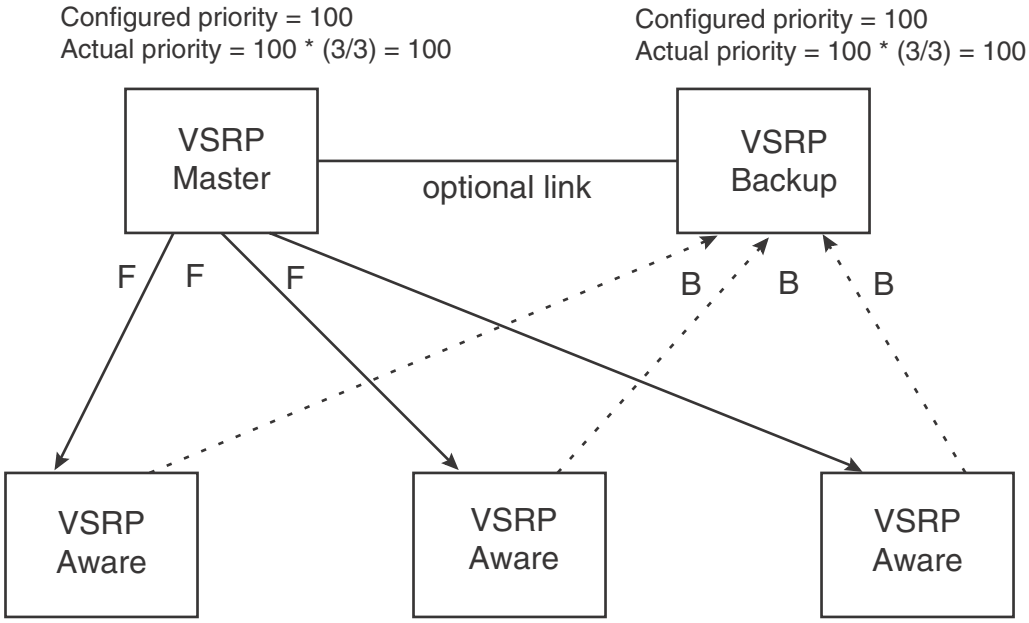
- If the Backup receives a Hello message with a higher priority than its own, the Backup resets its Dead Interval and returns to normal Backup status.
- If the Backup does not receive a Hello message with a higher priority than its own by the time the hold-down timer expires, the Backup becomes the new Master and starts forwarding Layer 2 traffic on all ports.

If you increase the timer scale value, each timer's value is divided by the scale value. To achieve sub-second failover times, you can change the scale to a value up to 10. This shortens all the VSRP timers to 10 percent of their configured values.

VSRP priority calculation

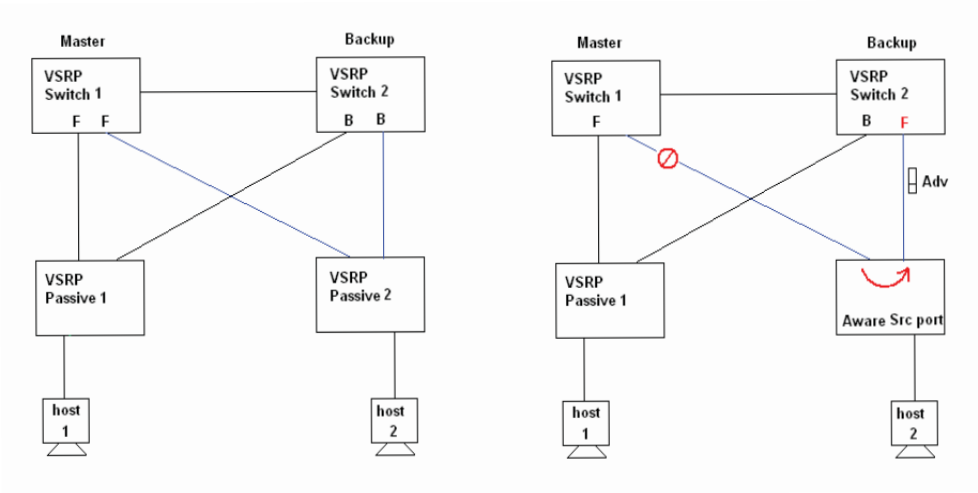
Each VSRP device has a VSRP priority for each VRID and its VLAN. The VRID is used during Master election for the VRID. By default, a device's VSRP priority is the value configured on the device (which is 100 by default). However, to ensure that a Backup with a high number of up ports for a given VRID is elected, the device reduces the priority if a port in the VRID's VLAN goes down. For example, if two Backups each have a configured priority of 100, and have three ports in VRID 1 in VLAN 10, each Backup begins with an equal priority, 100. This is shown in Figure 93

FIGURE 93 VSRP priority



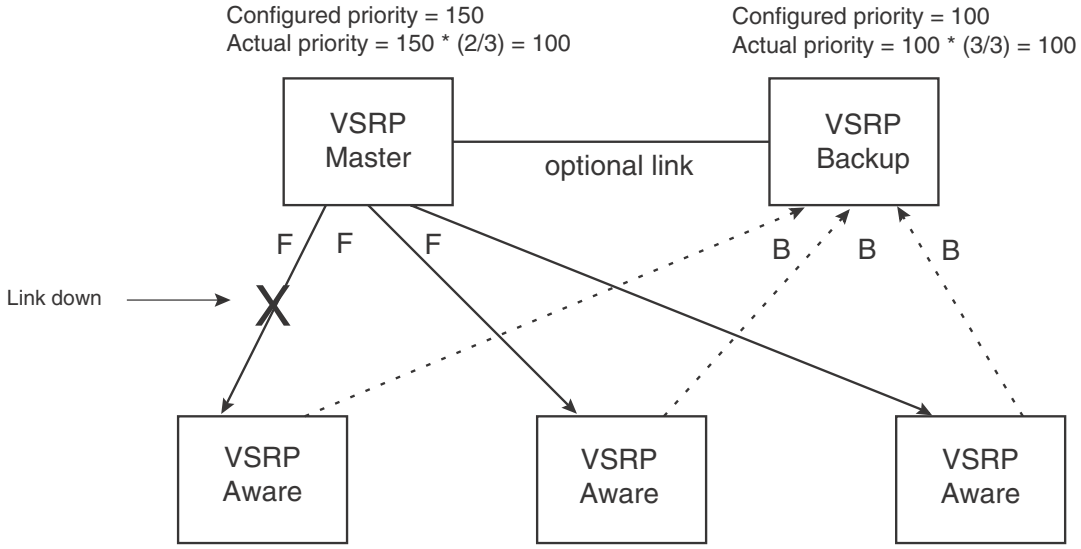
However, if one of the VRID's ports goes down on one of the Backups, that Backup's priority is reduced. If the Master's priority is reduced enough to make the priority lower than a Backup's priority, the VRID fails over to the Backup. Figure 94 shows an example.

FIGURE 94 VSRP priority recalculation



You can reduce the sensitivity of a VSRP device to failover by increasing its configured VSRP priority. For example, you can increase the configured priority of the VSRP device on the left in Figure 94 to 150. In this case, failure of a single link does not cause failover. The link failure caused the priority to be reduced to 100, which is still equal to the priority of the other device. This is shown in Figure 95.

FIGURE 95 VSRP priority bias

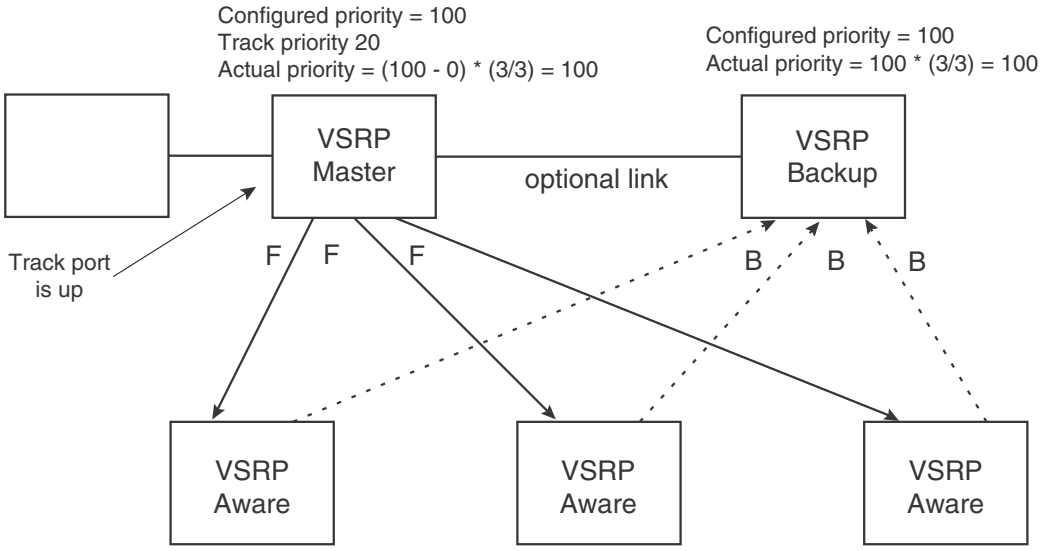


Track ports

Optionally, you can configure track ports to be included during VSRP priority calculation. In VSRP, a ***track port*** is a port that is not a member of the VRID's VLAN, but whose state is nonetheless considered when the priority is calculated. Typically, a track port represents the exit side of traffic received on the VRID ports. By default, no track ports are configured.

When you configure a track port, you assign a priority value to the port. If the port goes down, VSRP subtracts the track port's priority value from the configured VSRP priority. For example, if the you configure a track port with priority 20 and the configured VSRP priority is 100, the software subtracts 20 from 100 if the track port goes down, resulting in a VSRP priority of 80. The new priority value is used when calculating the VSRP priority. Figure 96 shows an example.

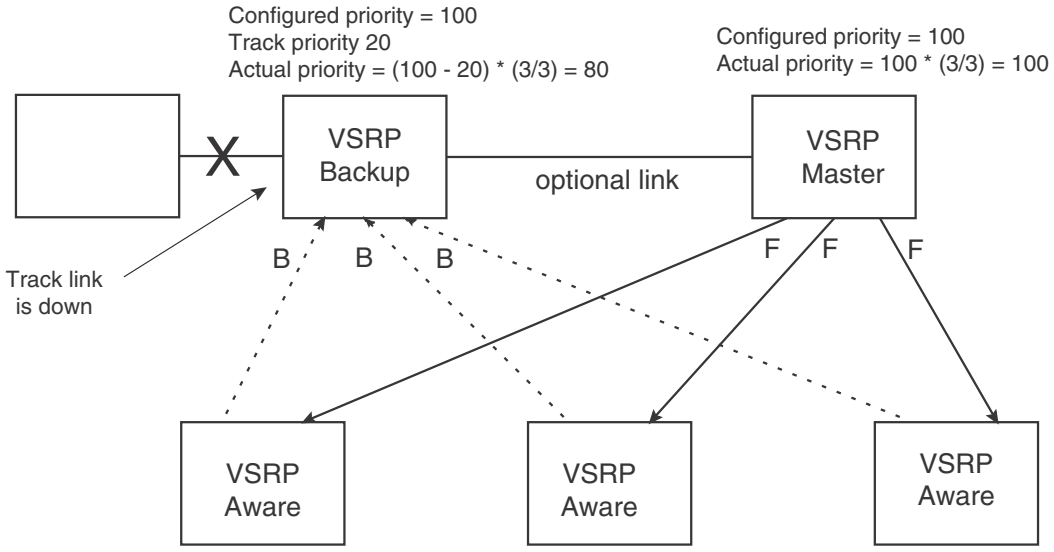
FIGURE 96 Track port priority



In Figure 96, the track port is up. SInce the port is up, the track priority does not affect the VSRP

priority calculation. If the track port goes down, the track priority does affect VSRP priority calculation, as shown in Figure 97.

FIGURE 97 Track port priority subtracted during priority calculation



MAC address failover on VSRP-aware devices

VSRP-aware devices maintain a record of each VRID and its VLAN. When the device has received a Hello message for a VRID in a given VLAN, the device creates a record for that VRID and VLAN and includes the port number in the record. Each subsequent time the device receives a Hello message for the same VRID and VLAN, the device checks the port number:

- If the port number is the same as the port that previously received a Hello message, the VSRP-aware device assumes that the message came from the same VSRP Master that sent the previous message.
- If the port number does not match, the VSRP-aware device assumes that a VSRP failover has occurred to a new Master, and moves the MAC addresses learned on the previous port to the new port.

The VRID records age out if unused. This can occur if the VSRP-aware device becomes disconnected from the Master. The VSRP-aware device will wait for a Hello message for the period of time equal to the following:

VRID Age = Dead Interval + Hold-down Interval + (3 x Hello Interval)

The values for these timers are determined by the VSRP device sending the Hello messages. If the Master uses the default timer values, the age time for VRID records on the VSRP-aware devices is as follows:

3 + 2 + (3 x 1) = 8 seconds

In this case, if the VSRP-aware device does not receive a new Hello message for a VRID in a given VLAN, on any port, the device assumes the connection to the Master is unavailable and removes the VRID record.

Configuring basic VSRP parameters

To configure VSRP, perform the following required tasks:

- Configure a port-based VLAN containing the ports for which you want to provide VSRP service.

  NOTE
  If you already have a port-based VLAN but only want to use VSRP on a sub-set of the VLANs ports, you can selectively remove ports from VSRP service in the VLAN. Refer to "Removing a port from the VRID's VLAN" on page 530.

- Configure a VRID:
  - Specify that the device is a backup. Since VSRP, like VRRPE, does not have an "owner", all VSRP devices are backups. The active device for a VRID is elected based on the VRID priority, which is configurable.
  - Enable VSRP on the VRID.

The following example shows a simple VSRP configuration.

```
NetIron(config)# vlan 200
NetIron(config-vlan-200)# tag ethernet 1/1 to 1/8
NetIron(config-vlan-200)# vsrp vrid 1
NetIron(config-vlan-200-vrid-1)# backup
NetIron(config-vlan-200-vrid-1)# enable
```

Syntax: [no] vsrp vrid <*num*>

The <*num*> parameter specifies the VRID and can be from 1 – 255.

Syntax: [no] backup [priority <*value*>**] [track-priority** <*value*>**]**

This command is required. In VSRP, all devices on which a VRID are configured are Backups. The Master is then elected based on the VSRP priority of each device. There is no "owner" device as there is in VRRP.

For information about the command's optional parameters, refer to the following:

- "Changing the backup priority" on page 530
- "Changing the default track priority" on page 533

Syntax: [no] enable | disable

Note on VSRP support when using ESI

VSRP is supported only for VLANs that are part of the default ESI. VSRP is not supported for VLANs configured under user-defined ESIs.

Configuring optional VSRP parameters

The following sections describe how to configure optional VSRP parameters.

Enabling Layer 3 VSRP

Layer 2 VSRP is enabled globally by default on the device; it just needs to be activated or enabled on a VRID. If you want to use Layer 3 VSRP, you must enable it by entering the following command at the CONFIG level.

```
NetIron(config)# router vsrp
```

Syntax: [no] router vsrp

If you want to provide Layer 3 redundancy only, you could use VRRP or VRRP-Extended. You may use **router vrrp** or **router vrrp-extended** as long as **router vsrp** is not enabled.

Disabling or re-enabling VSRP

To disable Layer 3 VSRP, enter the following command at the global CONFIG level.

```
NetIron(config)# no router vsrp
router vsrp is disabled. All vsrp config data will be lost when writing to flash
```

To re-enable the protocol, enter the following command.

```
NetIron(config)# router vsrp
```

Syntax: [no] router vsrp

Configuring authentication

If the interfaces on which you configure the VRID use authentication, the VSRP packets on those interfaces also must use the same authentication. VSRP supports the following authentication types:

- **No authentication** – The interfaces do not use authentication. This is the default.
- **Simple** – The interfaces use a simple text-string as a password in packets sent on the interface. If the interfaces use simple password authentication, the VRID configured on the interfaces must use the same authentication type and the same password.

To configure a simple password, enter a command such as the following at the interface configuration level.

```
NetIron(config-if-e10000-1/6)# ip vsrp auth-type simple-text-auth ourpword
```

This command configures the simple text password “ourpword”.

Syntax: [no] ip vsrp auth-type no-auth | simple-text-auth <*auth-data*>

The **auth-type no-auth** parameter indicates that the VRID and the interface it is configured on do not use authentication.

The **auth-type simple-text-auth** <*auth-data*> parameter indicates that the VRID and the interface it is configured on use a simple text password for authentication. The <*auth-data*> value is the password. If you use this parameter, make sure all interfaces on all the devices supporting this VRID are configured for simple password authentication and use the same password.

VSRP 2

In VSRP setup, there are always at least two VSRP switches for each VSRP instance. A passive device should always have either one access link or one trunk link connected with each VSRP switch for each VSRP instance. This can create a black hole scenario. A black hole is when VSRP failover causes data traffic from the switches/hosts which connect to VSRP passive switch to go nowhere.

VSRP 2 can detect the health of each pair/set of links for each VSRP instance.VSRP 2 detects which link of VSRP backup switch not receiving any advertisement for specific time duration. The VSRP backup switch can treat the link of the pair on the master side is down or broken and set its own link of the pair in forwarding state. The VSRP backup switch sends out gratuitous ARP for VSRP master only to this link. Other links of other VSRP instances in VSRP backup switch are still in blocking state as shown in figure Figure 98,Figure 99, and Figure 100.

FIGURE 98 Black hole scenario 1

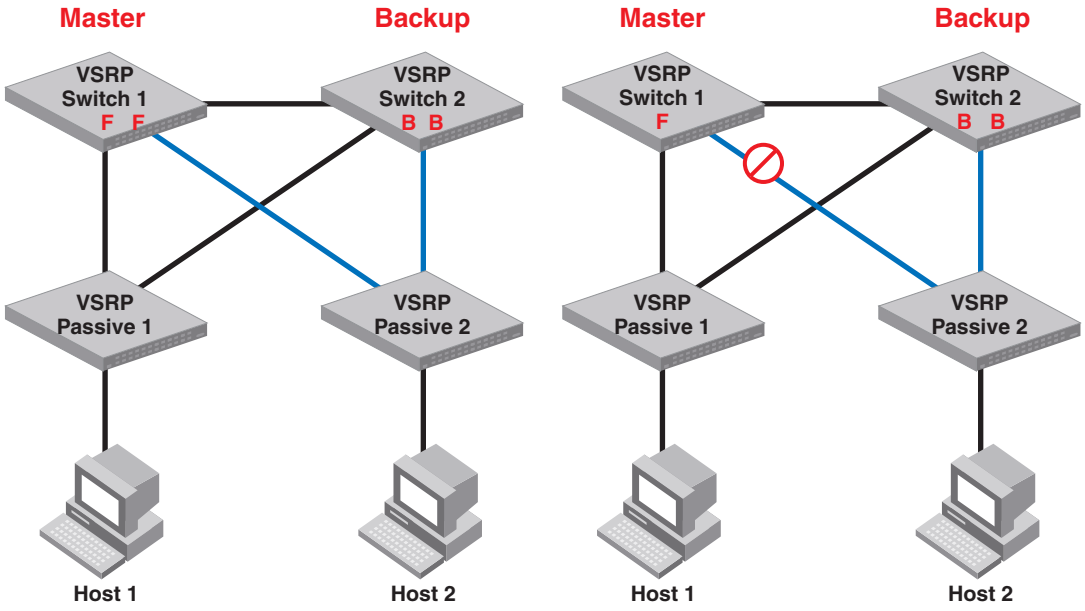


FIGURE 99 Black hole scenario 2

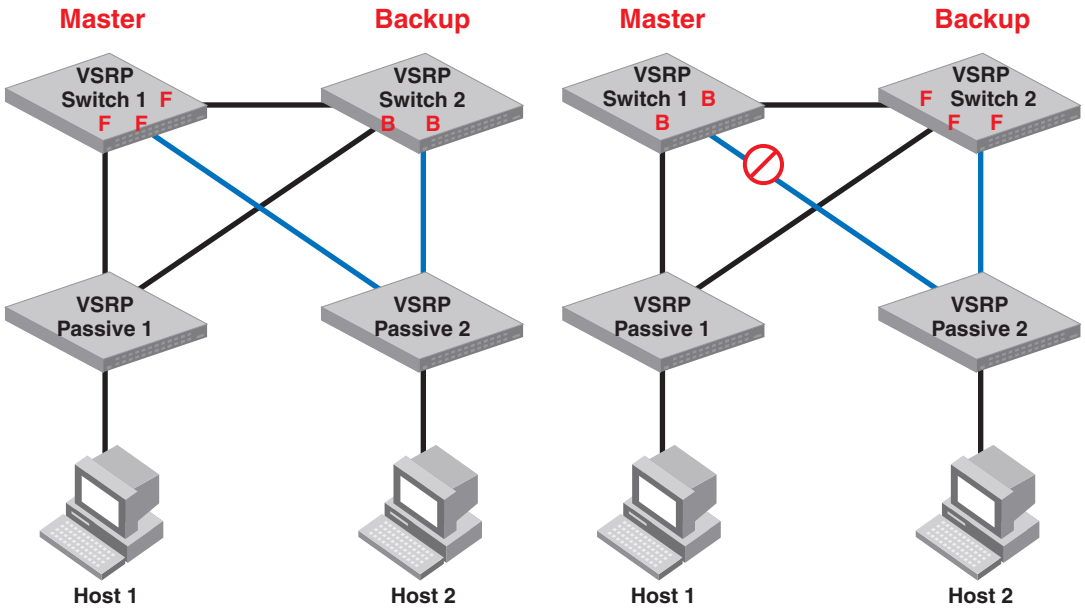

FIGURE 100 Black hole scenario 3

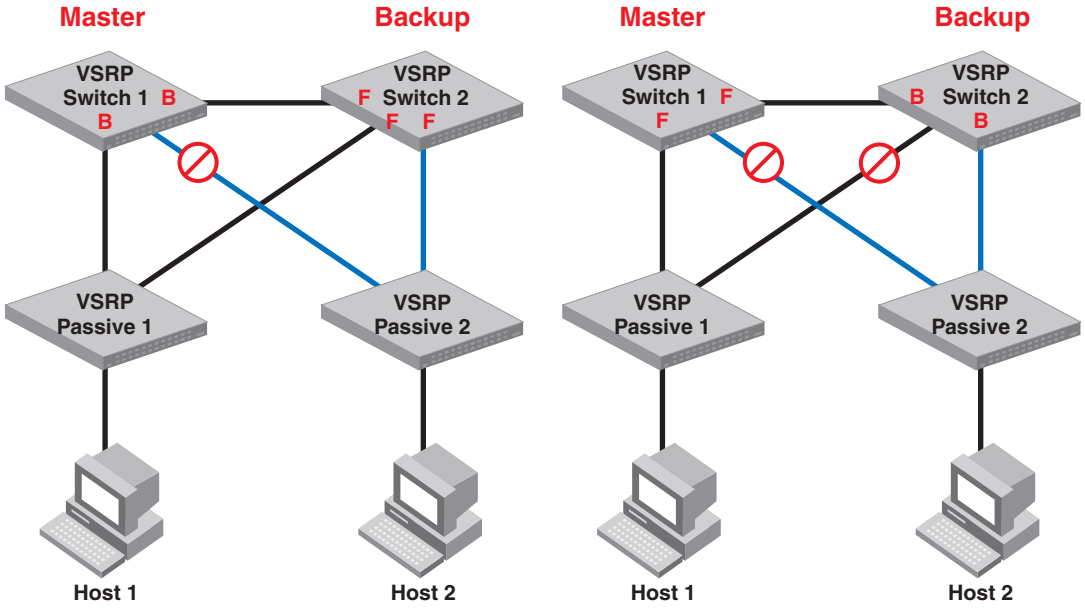
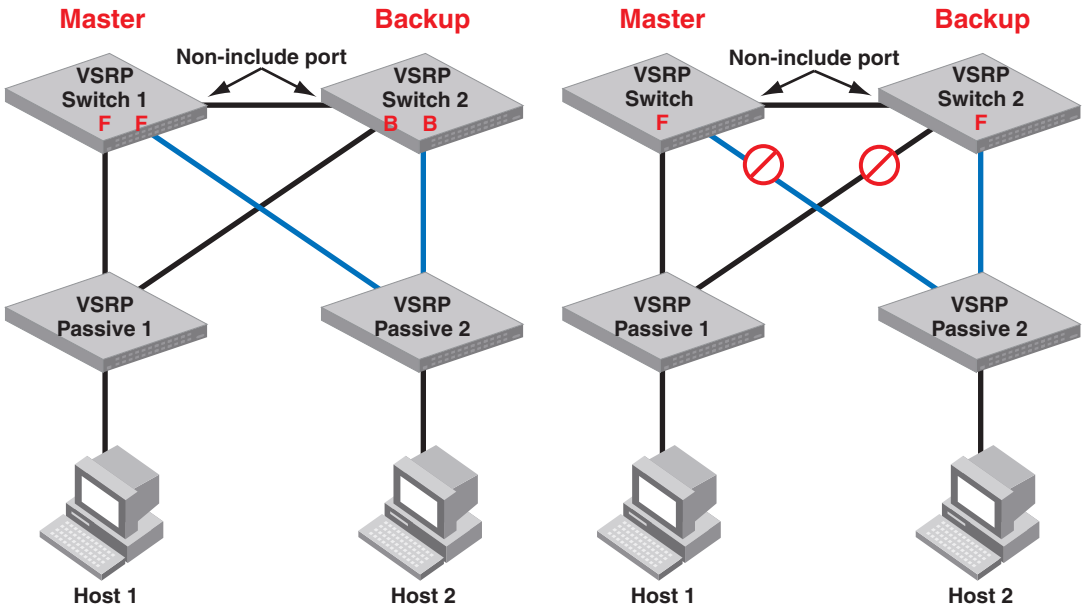


VSRP failove:

- VSRP backup set all include links in blocking state. Blocking ports drop data traffic.
- VSRP failover changes master state by current priority change.
- Current priority changes by link failure and track port failure.

FIGURE 101 Correct VSRP behavior



VSRP is switch redundancy, VSRP 2 is link redundancy.

When VSRP backup changes an include port from blocking state to forwarding state, to make the aware session changes, VSRP backup will send advertisements on the forwarding include ports every 3*hello time.

VSRP aware switches are able to change the src port of aware session and flush MACs.

For VSRP non-aware switches (other vendors), the non-aware switch will flush MACs because the link connecting VSRP master is failed.

VSRP backup will toggle the interface when it sets an include port to forwarding state by VSRP 2.

VSRP 2 doesn't change the master/backup state, only changes the port state.

The change of Master/backup state (VSRP failover) still follows the rules of current priority of VSRP.

VSRP 2 supports:

- hold-down time
- track port
- preempt-mode
- restart port
- topology groups
- VLAN groups.

- VPLS VLAN by topology group.
- L3 VSRP with a condition: non-include link in between two VSRP routers is a must.

Configuration considerations:

- If multiple VSRP instances on multiple VLAN are configured the on one side of link pair, the same VSRP instances of same VLANs must configure on another side of link pair.
- Link-pair has to be enabled or disabled on all VSRP switches for the same VSRP instance.
- Currently, VSRP 2 only supports two VSRP switches in the topology. Multiple VSRP switches may cause a loop when the link redundancy set the VSRP ports in the forwarding state in the link failed cases.
- For VSRP 2 supporting Layer 3 VSRP, it is necessary to have a non-include link in between two VSRP switches. VSRP virtual router is still in VSRP master. Layer 3 data traffic is switched by VSRP backup to VSRP master. The traffic is routed by VSRP master (virtual router).

Configuring VSRP 2

Configure VSRP see"Configuring basic VSRP parameters" on page 522 , then use the **link-redundancy** command at the interface level to enable link redundancy. To enable link redundancy, use commands such as the following.

```
NetIron(config)# vlan 10
NetIron(config-vlan-10)# vsrp vrid 10
NetIron(config-vlan-10-vsrp-vrid-10)# link-redundancy
```

After enabling link redundancy, VSRP switches to master-confirm state and the backup state creates a link redundant port list.

VSRP switches that are in initial state and master state don't need to create link redundant port list

Syntax: [no] vsrp-linkpair-id <id>

Displaying VSRP 2

To display VSRP, use the **show vsrp** command as shown below.

```
NetIron#show vsrp
VLAN 10
 Auth-type no authentication
 VRID 1
 ========
  State           Administrative-status Advertise-backup Preempt-mode Link-Red
  Backup          Enabled               Enabled          True         Enabled

  Parameter        Configured Current    Unit/Formula
  Priority         100        100        (100-0)*(3.0/3.0)
  Hello-interval   1          1           sec/10
  Dead-interval    3          3           sec/10
  Hold-interval    3          3           sec/10
  Initial-ttl      2          2           hops

  Master router 219.243.150.0 or MAC xxxx.dbf3.9600 expires in 00:00:03
  Member ports:      ethe 2/14 ethe 2/18 to 2/19
```

```
  Operational ports: ethe 2/14 ethe 2/18 to 2/19
   Forwarding ports:  ethe 2/14
Link-Redundancy-port:
  port 2/14 status FORWARD
  port 2/18 status BLOCK
  port 2/19 status BLOCK
```

Syntax: show vsrp [vrid <*num*> **| vlan** <*vlan-id*>**]**

This display shows the following information when you use the **vrid** <*num*> or **vlan** <*vlan-id*> parameter. For information about the display when you use the **aware** parameter, refer to "Displaying the active interfaces for a VRID" on page 537.

TABLE 94 CLI display of VSRP VRID or VLAN information

This field...	Displays...
Total number of VSRP routers defined	The total number of VRIDs configured on this device.
VLAN	The VLAN on which VSRP is configured.
auth-type	The authentication type in effect on the ports in the VSRP VLAN.
VRID parameters	
VRID	The VRID for which the following information is displayed.
state	This device's VSRP state for the VRID. The state can be one of the following: • initialize – VSRP is not enabled on the VRID. If the state remains "initialize" after you enable VSRP on the VRID, make sure that the VRID is also configured on the other routers Routing Switches and that the routers Routing Switches can communicate with each other. **NOTE:** If the state is "initialize" and the mode is incomplete, make sure you have specified the IP address for the VRID. • standby – This device is a Backup for the VRID. • master – This device is the Master for the VRID.
Administrative-status	The administrative status of the VRID. The administrative status can be one of the following: • disabled – The VRID is configured on the interface but VSRP or VRRPE has not been activated on the interface. • enabled – VSRP has been activated on the interface.
Advertise-backup	Whether the device is enabled to send VSRP Hello messages when it is a Backup. This field can have one of the following values: • disabled – The device does not send Hello messages when it is a Backup. • enabled – The device does send Hello messages when it is a Backup.
Preempt-mode	Whether the device can be pre-empted by a device with a higher VSRP priority after this device becomes the Master. This field can have one of the following values: • disabled – The device cannot be pre-empted. • enabled – The device can be pre-empted.

NOTE: For the following fields:

- Configured – indicates the parameter value configured on this device.
- Current – indicates the parameter value received from the Master.
- Unit – indicates the formula used tor calculating the VSRP priority and the timer scales in effect for the VSRP timers. A timer's true value is the value listed in the Configured or Current field divided by the scale value.

TABLE 94 CLI display of VSRP VRID or VLAN information (Continued)

This field...	Displays...
priority	The device's preferability for becoming the Master for the VRID. During negotiation, the Backup with the highest priority becomes the Master. If two or more Backups are tied with the highest priority, the Backup interface with the highest IP address becomes the Master for the VRID.
hello-interval	The number of seconds between Hello messages from the Master to the Backups for a given VRID.
dead-interval	The configured value for the dead interval. The dead interval is the number of seconds a Backup waits for a Hello message from the Master for the VRID before determining that the Master is no longer active. If the Master does not send a Hello message before the dead interval expires, the Backups negotiate (compare priorities) to select a new Master for the VRID. **NOTE:** If the value is 0, then you have not configured this parameter.
hold-interval	The number of seconds a Backup that intends to become the Master will wait before actually beginning to forward Layer 2 traffic for the VRID. If the Backup receives a Hello message with a higher priority than its own before the hold-down interval expires, the Backup remains in the Backup state and does not become the new Master.
initial-ttl	The number of hops a Hello message can traverse after leaving the device before the Hello message is dropped. A Foundry MRP ring counts as one hop, regardless of the number of nodes in the ring.
next hello sent in	The amount of time until the Master's dead interval expires. If the Backup does not receive a Hello message from the Master by the time the interval expires, either the IP address listed for the Master will change to the IP address of the new Master, or this router itself will become the Master. **NOTE:** This field applies only when this device is a Backup.
master router	The IP address of the master router.
Member ports	The ports in the VRID.
Operational ports	The member ports that are currently up.
Forwarding ports	The member ports that are currently in the Forwarding state. Ports that are forwarding on the Master are listed. Ports on the Standby, which are in the Blocking state, are not listed.
Link-Redundancy-port	The status os the port on which link redundancy has been configured.

Removing a port from the VRID's VLAN

By default, all the ports in the VLAN on which you configure a VRID are interfaces for the VRID. You can remove a port from the VRID while allowing it to remain in the VLAN.

Removing a port is useful in the following cases:

- There is no risk of a loop occurring, such as when the port is attached directly to an end host.
- You plan to use a port in a Foundry MRP ring.

To remove a port from a VRID, enter a command such as the following at the configuration level for the VRID.

```
NetIron(config-vlan-200-vrid-1)# no include-port ethernet 1/2
```

Syntax: [no] include-port ethernet <*slot*>/<*portnum*>

The **ethernet** <*slot*>/<*portnum*> parameter specifies the port you are removing from the VRID. The port remains in the VLAN but its forwarding state is not controlled by VSRP.

Changing the backup priority

When you enter the backup command to configure the device as a VSRP Backup for the VRID, you also can change the backup priority and the track priority:

- The backup priority is used for election of the Master. The VSRP Backup with the highest priority value for the VRID is elected as the Master for that VRID. The default priority is 100. If two or more Backups are tied with the highest priority, the Backup with the highest IP address becomes the Master for the VRID.
- The track priority is used with the track port feature. Refer to "VSRP priority calculation" on page 518 and "Changing the default track priority" on page 533.

To change the backup priority, enter a command such as the following at the configuration level for the VRID.

```
NetIron(config-vlan-200-vrid-1)# backup priority 75
```

Syntax: [no] backup [priority <*value*>**] [track-priority** <*value*>**]**

The **priority** <*value*> parameter specifies the VRRP priority for this interface and VRID. You can specify a value from 3 – 254. The default is 100.

For a description of the **track-priority** <*value*> parameter, refer to "Changing the default track priority" on page 533.

Saving the timer values received from the Master

The Hello messages sent by a VRID's master contain the VRID values for the following VSRP timers:

- Hello interval
- Dead interval
- Backup Hello interval
- Hold-down interval

By default, each Backup saves the configured timer values to its startup configuration file when you save the device's configuration.

You can configure a Backup to instead save the current timer values received from the Master when you save the configuration. Saving the current timer values instead of the configured ones helps ensure consistent timer usage for all the VRID's devices.

NOTE
The Backups always use the value of the timer scale received from the Master, regardless of whether the timer values that are saved in the configuration are the values configured on the Backup or the values received from the Master.

To configure a Backup to save the VSRP timer values received from the Master instead of the timer values configured on the Backup, enter the following command.

```
NetIron(config-vlan-200-vrid-1)# save-current-values
```

Syntax: [no] save-current-values

Changing the Time-To-Live (TTL)

A VSRP Hello packet's TTL specifies how many hops the packet can traverse before being dropped. A hop can be a router or a Layer 2 Switch. You can specify from 1 – 255. The default TTL is 2. When a VSRP device (Master or Backup) sends a VSRP HEllo packet, the device subtracts one from the TTL. Thus, if the TTL is 2, the device that originates the Hello packet sends it out with a TTL of 1. Each subsequent device that receives the packet also subtracts one from the packet's TTL. When the packet has a TTL of 1, the receiving device subtracts 1 and then drops the packet because the TTL is zero.

NOTE
A Foundry MRP ring is considered to be a single hop, regardless of the number of nodes in the ring.

To change the TTL for a VRID, enter a command such as the following at the configuration level for the VRID.

```
NetIron(config-vlan-200-vrid-1)# initial-ttl 5
```

Syntax: [no] initial-ttl <*num*>

The <*num*> parameter specifies the TTL and can be from 1 – 255. The default TTL is 2.

Changing the Hello interval

The Master periodically sends Hello messages to the Backups. To change the Hello interval, enter a command such as the following at the configuration level for the VRID.

```
NetIron(config-vlan-200-vrid-1)# hello-interval 10
```

Syntax: [no] hello-interval <*num*>

The <*num*> parameter specifies the interval and can be from 1 – 84 units of 100 milliseconds. The default is 1 unit of 100 ms.

NOTE
The default Dead interval is three times the Hello interval plus one-half second. Generally, if you change the Hello interval, you also should change the Dead interval on the Backups.

NOTE
If you change the timer scale, the change affects the actual number of seconds.

Changing the Dead interval

The Dead interval is the number of seconds a Backup waits for a Hello message from the Master before determining that the Master is dead. The default is 3 seconds. This is three times the default Hello interval.

To change the Dead interval, enter a command such as the following at the configuration level for the VRID.

```
NetIron(config-vlan-200-vrid-1)# dead-interval 30
```

Syntax: [no] dead-interval <*num*>

The <*num*> parameter specifies the interval and can be from 1 – 84 seconds. The default is 3 seconds.

NOTE
If you change the timer scale, the change affects the actual number of seconds.

Changing the Backup Hello state and interval

By default, Backups do not send Hello messages to advertise themselves to the Master. You can enable these messages if desired and also change the message interval.

To enable a Backup to send Hello messages to the Master, enter a command such as the following at the configuration level for the VRID.

```
NetIron(config-vlan-200-vrid-1)# advertise backup
```

Syntax: [no] advertise backup

When a Backup is enabled to send Hello messages, the Backup sends a Hello message to the Master every 60 seconds by default. You can change the interval to be up to 3600 seconds.

To change the Backup Hello interval, enter a command such as the following at the configuration level for the VRID.

```
NetIron(config-vlan-200-vrid-1)# backup-hello-interval 180
```

Syntax: [no] backup-hello-interval <*num*>

The <*num*> parameter specifies the message interval and can be from 60 – 3600 seconds. The default is 60 seconds.

NOTE
If you change the timer scale, the change affects the actual number of seconds.

Changing the hold-down interval

The hold-down interval prevents Layer 2 loops from occurring during failover, by delaying the new Master from forwarding traffic long enough to ensure that the failed Master is really unavailable.

To change the Hold-down interval, enter a command such as the following at the configuration level for the VRID.

```
NetIron(config-vlan-200-vrid-1)# hold-down-interval 4
```

Syntax: [no] hold-down-interval <*num*>

The <*num*> parameter specifies the hold-down interval and can be from 1 – 84 seconds. The default is 2 seconds.

NOTE
If you change the timer scale, the change affects the actual number of seconds.

Changing the default track priority

When you configure a VRID to track the link state of other interfaces, if one of the tracked interface goes down, the software changes the VSRP priority of the VRID interface.

The software reduces the VRID priority by the amount of the priority of the tracked interface that went down. For example, if the VSRP interface's priority is 100 and a tracked interface with track priority 60 goes down, the software changes the VSRP interface's priority to 40. If another tracked interface goes down, the software reduces the VRID's priority again, by the amount of the tracked interface's track priority.

The default track priority for all track ports is 1. You can change the default track priority or override the default for an individual track port:

- To change the default track priority, use the **backup track-priority** command, described below.
- To override the default track priority for a specific track port, use the **track-port** command. Refer to "Specifying a track port" on page 533.

To change the track priority, enter a command such as the following at the configuration level for the VRID.

```
NetIron(config-vlan-200-vrid-1)# backup track-priority 2
```

Syntax: [no] backup [priority <*value*>**] [track-priority** <*value*>**]**

Specifying a track port

You can configure the VRID on one interface to track the link state of another interface on the device. This capability is useful for tracking the state of the exit interface for the path for which the VRID is providing redundancy. Refer to "VSRP priority calculation" on page 518.

To configure a VRID to track an interface, enter a command such as the following at the configuration level for the VRID.

```
NetIron(config-vlan-200-vrid-1)# track-port e 2/4
```

Syntax: [no] track-port ethernet <*slot*>/<*portnum*> **| ve** <*num*> **[priority** <*num*>**]**

The **priority** <*num*> parameter changes the VSRP priority of the interface. If this interface goes down, the VRID's VSRP priority is reduced by the amount of the track port priority you specify here.

NOTE
The priority <*num*> option changes the priority of the specified interface, overriding the default track port priority. To change the default track port priority, use the **backup track-priority** <*num*> command.

Disabling or re-enabling Backup preemption

By default, a Backup that has a higher priority than another Backup that has become the Master can preempt the Master, and take over the role of Master. If you want to prevent this behavior, disable preemption.

Preemption applies only to Backups and takes effect only when the Master has failed and a Backup has assumed ownership of the VRID. The feature prevents a Backup with a higher priority from taking over as Master from another Backup that has a lower priority but has already become the Master of the VRID.

Preemption is especially useful for preventing flapping in situations where there are multiple Backups and a Backup with a lower priority than another Backup has assumed ownership, because the Backup with the higher priority was unavailable when ownership changed.

If you enable the non-preempt mode (thus disabling the preemption feature) on all the Backups, the Backup that becomes the Master following the disappearance of the Master continues to be the Master. The new Master is not preempted.

To disable preemption on a Backup, enter a command such as the following at the configuration level for the VRID.

```
NetIron(config-vlan-200-vrid-1)# non-preempt-mode
```

Syntax: [no] non-preempt-mode

Displaying VSRP information

You can display the following VSRP information:

- Configuration information and current parameter values for a VRID or VLAN
- The interfaces on a VSRP-aware device that are active for the VRID

Displaying VRID information

To display VSRP information, enter the following command.

```
NetIron# show vsrp vrid 10
    VLAN 100
     Auth-type no authentication
     VRID 100
     ========
      State           Administrative-status Advertise-backup Preempt-mode
      Master          Enabled               Disabled         True

      Parameter        Configured Current    Unit/Formula

```

Syntax: show vsrp [vrid <*num*> **| vlan** <*vlan-id*>**]**

This display shows the following information when you use the **vrid** <*num*> or **vlan** <*vlan-id*> parameter. For information about the display when you use the **aware** parameter, refer to "Displaying the active interfaces for a VRID" on page 537.

TABLE 95 CLI display of VSRP VRID or VLAN information

This field...	Displays...
Total number of VSRP routers defined	The total number of VRIDs configured on this device.
VLAN	The VLAN on which VSRP is configured.
auth-type	The authentication type in effect on the ports in the VSRP VLAN.
VRID parameters	
VRID	The VRID for which the following information is displayed.
state	This device's VSRP state for the VRID. The state can be one of the following: • initialize – VSRP is not enabled on the VRID. If the state remains "initialize" after you enable VSRP on the VRID, make sure that the VRID is also configured on the other routers Routing Switches and that the routers Routing Switches can communicate with each other. **NOTE:** If the state is "initialize" and the mode is incomplete, make sure you have specified the IP address for the VRID. • standby – This device is a Backup for the VRID. • master – This device is the Master for the VRID.
Administrative-status	The administrative status of the VRID. The administrative status can be one of the following: • disabled – The VRID is configured on the interface but VSRP or VRRPE has not been activated on the interface. • enabled – VSRP has been activated on the interface.
Advertise-backup	Whether the device is enabled to send VSRP Hello messages when it is a Backup. This field can have one of the following values: • disabled – The device does not send Hello messages when it is a Backup. • enabled – The device does send Hello messages when it is a Backup.

TABLE 95 CLI display of VSRP VRID or VLAN information (Continued)

This field...	Displays...
Preempt-mode	Whether the device can be pre-empted by a device with a higher VSRP priority after this device becomes the Master. This field can have one of the following values: • disabled – The device cannot be pre-empted. • enabled – The device can be pre-empted.
NOTE: For the following fields: • Configured – indicates the parameter value configured on this device. • Current – indicates the parameter value received from the Master. • Unit – indicates the formula used tor calculating the VSRP priority and the timer scales in effect for the VSRP timers. A timer's true value is the value listed in the Configured or Current field divided by the scale value.	
priority	The device's preferability for becoming the Master for the VRID. During negotiation, the Backup with the highest priority becomes the Master. If two or more Backups are tied with the highest priority, the Backup interface with the highest IP address becomes the Master for the VRID.
hello-interval	The number of seconds between Hello messages from the Master to the Backups for a given VRID.
dead-interval	The configured value for the dead interval. The dead interval is the number of seconds a Backup waits for a Hello message from the Master for the VRID before determining that the Master is no longer active. If the Master does not send a Hello message before the dead interval expires, the Backups negotiate (compare priorities) to select a new Master for the VRID. **NOTE:** If the value is 0, then you have not configured this parameter.
hold-interval	The number of seconds a Backup that intends to become the Master will wait before actually beginning to forward Layer 2 traffic for the VRID. If the Backup receives a Hello message with a higher priority than its own before the hold-down interval expires, the Backup remains in the Backup state and does not become the new Master.
initial-ttl	The number of hops a Hello message can traverse after leaving the device before the Hello message is dropped. **NOTE:** A Foundry MRP ring counts as one hop, regardless of the number of nodes in the ring.
next hello sent in	The amount of time until the Master's dead interval expires. If the Backup does not receive a Hello message from the Master by the time the interval expires, either the IP address listed for the Master will change to the IP address of the new Master, or this router itself will become the Master. **NOTE:** This field applies only when this device is a Backup.
master router	The IP address of the master router.
Member ports	The ports in the VRID.
Operational ports	The member ports that are currently up.
Forwarding ports	The member ports that are currently in the Forwarding state. Ports that are forwarding on the Master are listed. Ports on the Standby, which are in the Blocking state, are not listed.

Displaying the active interfaces for a VRID

On a VSRP-aware device, you can display VLAN and port information for the connections to the VSRP devices (Master and Backups).

To display the active VRID interfaces, enter the following command on the VSRP-aware device.

```
NetIron(config-vlan-200-vrid-1)# show vsrp aware

Aware port listing
VLAN ID  VRID  Last Port
100      1     3/2
200      2     4/1
```

Syntax: show vsrp aware

This display shows the following information when you use the **aware** parameter. For information about the display when you use the **vrid** <*num*> or **vlan** <*vlan-id*> parameter, refer to "Displaying VRID information" on page 534.

TABLE 96 CLI display of VSRP-aware information

This field...	Displays...
VLAN ID	The VLAN that contains the VSRP-aware device's connection with the VSRP Master and Backups.
VRID	The VRID.
Last Port	The most recent active port connection to the VRID. This is the port connected to the current Master. If a failover occurs, the VSRP-aware device changes the port to the port connected to the new Master. The VSRP-aware device uses this port to send and receive data through the backed up node.

VSRP fast start

It allows non-Dell or non-VSRP aware devices that are connected to a Dell device that is the VSRP Master to quickly switch over to the new Master when a VSRP failover occurs

This feature causes the port on a VSRP Master to restart when a VSRP failover occurs. When the port shuts down at the start of the restart, ports on the non-VSRP aware devices that are connected to the VSRP Master flush the MAC address they have learned for the VSRP master. After a specified time, the port on the previous VSRP Master (which now becomes the Backup) returns back online. Ports on the non-VSRP aware devices switch over to the new Master and learn its MAC address.

Special considerations when configuring VSRP fast start

Consider the following when configuring VSRP fats start:

- VSRP is sensitive to port status. When a port goes down, the VSRP instance lowers its priority based on the port up fraction. (refer to "VSRP priority calculation" on page 518 for more information on how priority is changed by port status). Since the VSRP fast start feature toggles port status by bringing ports down and up it can affect VSRP instances because their priorities get reduced when a port goes down. To avoid this, the VSRP fast start implementation keeps track of ports that it brings down and suppresses port down events for these ports (as concerns VSRP).

- Once a VSRP restart port is brought up by a VSRP instance, other VSRP instances (in Master state) that have this port as a member do not go to forwarding immediately. This is a safety measure that is required to prevent transitory loops. This could happen if a peer VSRP node gets completely cut off from this node and assumed Master state. In this case, where there are 2 VSRP instances that are in Master state and forwarding, the port comes up and starts forwarding immediately. This would cause a forwarding loop. To avoid this, the VSRP instance delays forwarding.

Recommendations for configuring VSRP fast start

The following recommendations apply to configurations where multiple VSRP instances are running between peer devices sharing the same set of ports:

- Multiple VSRP instances configured on the same ports can cause VSRP instances to be completely cut off from peer VSRP instances. This can cause VSRP instances to toggle back and forth between master and backup mode. For this reason, we recommend that you configure VSRP fast start on a per port basis rather than for the entire VLAN.
- We recommend that VSRP peers have a directly connected port without VSRP fast start enabled on it. This allows protocol control packets to be received and sent even if other ports between the master and standby are down.
- The VSRP restart time should be configured based on the type of connecting device since some devices can take a long time to bring a port up or down (as long as several seconds). In order to ensure that the port restart is registered by neighboring device, the restart time may need to be changed to a value higher than the default value of 1 second.

Configuring VSRP fast start

The VSRP fast start feature can be enabled on a VSRP-configured device, either on the VLAN to which the VRID of the VSRP-configured device belongs (globally) or on a port that belongs to the VRID.

To globally configure a VSRP-configured device to shut down its ports when a failover occurs, then restart after five seconds, enter the following command.

```
NetIron(configure)# vlan 100
NetIron(configure-vlan-100)# vsrp vrid 1
NetIron(configure-vlan-100-vrid-1)# restart-ports 5
```

Syntax: [no] restart-ports <*seconds*>

This command shuts down all the ports that belong to the VLAN when a failover occurs. All the ports will have the specified VRID.

To configure a single port on a VSRP-configured device to shut down when a failover occurs, then restart after a period of time, enter the following command.

```
NetIron(configure)# interface ethernet 1/1
NetIron(configure-if-1/1)# vsrp restart-port 5
```

Syntax: [no] vsrp restart-port <*seconds*>

In both commands, the <*seconds*> parameter instructs the VSRP Master to shut down its port for the specified number of seconds before it starts back up. Enter a value between 1 – 120 seconds. The default is 1 second.

Displaying ports that have VSRP fast start feature enabled

The **show vsrp vrid** command shows the ports on which the VSRP fast start feature is enabled.

```
NetIron(config-vlan-100-vrid-100)#show vsrp vrid 100
VLAN 100
  auth-type no authentication
  VRID 100
  ========
   State      Administrative-status Advertise-backup Preempt-mode save-current
   master     enabled               disabled         true         false
   Parameter        Configured Current    Unit/Formula
   priority         100        50         (100-0)*(2.0/4.0)
   hello-interval   1          1          sec/1
   dead-interval    3          3          sec/1
   hold-interval    3          3          sec/1
   initial-ttl      2          2          hops
   next hello sent in 00:00:00.3
   Member ports:      ethe 2/5 to 2/8
   Operational ports: ethe 2/5 ethe 2/8
   Forwarding ports:  ethe 2/5 ethe 2/8
   Restart ports:     2/5(1) 2/6(1) 2/7(1) 2/8(1)
```

The "Restart ports:" line lists the ports that have the VSRP fast start enabled, and the downtime for each port. Refer to Table 95 on page 535 to interpret the remaining information on the display.

VSRP slow start

In a VSRP configuration, if a Master router goes down, the Backup router with the highest priority takes over. When the Master comes back up again, it takes over from the Backup. By default, this transition from Backup back to Master takes place immediately. You can configure the VSRP slow start timer feature, which causes a specified amount of time to elapse between the time the Master is restored and when it takes over from the Backup. (This range is currently set to between 1 to 600 ticks (1/10 second to 60 seconds). This interval allows time for VSRP convergence when the Master is restored.

To set the VSRP slow start timer to 30 seconds, enter the following command.

```
NetIron(config)# router vsrp
NetIron(config-vsrp-router)# slow-start 300
```

Syntax: **[no] slow-start** <ticks>

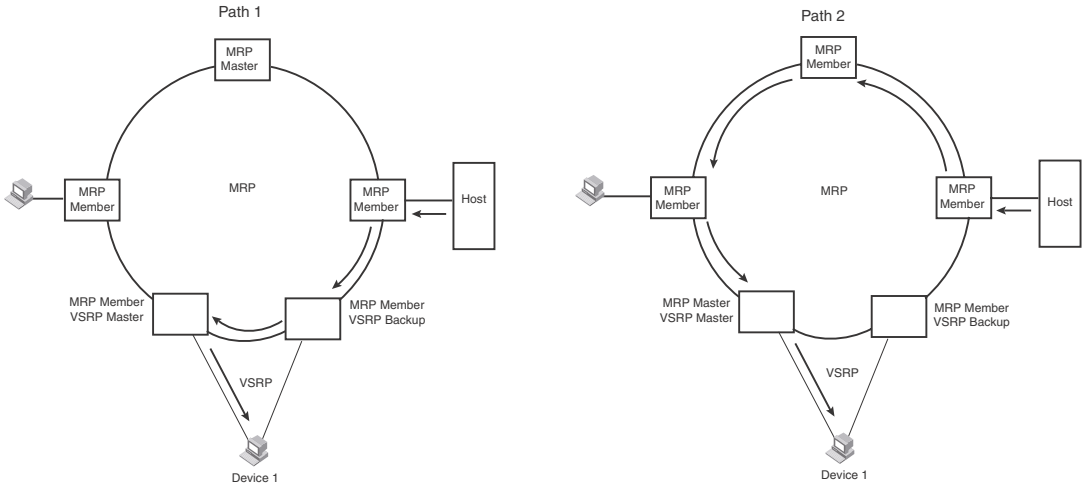
The ticks parameter can range is from 1 to 600 ticks (1/10 second to 60 seconds).

When the VSRP slow start timer is enabled, if the Master goes down, the Backup takes over immediately. If the Master subsequently comes back up again, the amount of time specified by the VSRP slow start timer elapses (in this example, 30 seconds) before the Master takes over from the Backup.

VSRP and Foundry MRP signaling

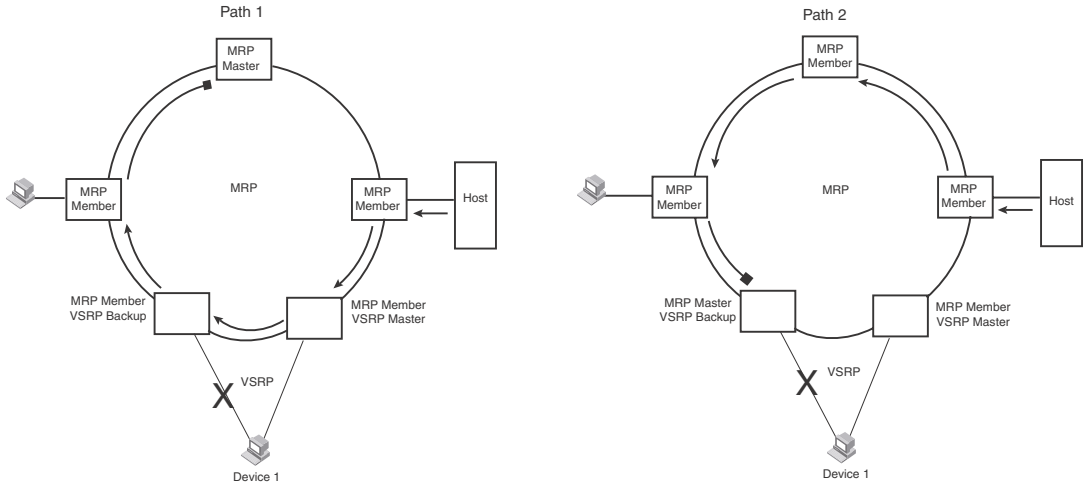
A device may connect to a Foundry MRP ring through VSRP to provide a redundant path between the device and the Foundry MRP ring. VSRP and Foundry MRP signaling, ensures rapid failover by flushing MAC addresses appropriately. The host on the Foundry MRP ring learns the MAC addresses of all devices on the Foundry MRP ring and VSRP link. From these MAC addresses, the host creates a MAC database (table), which is used to establish a data path from the host to a VSRP-linked device. Figure 102 below shows two possible data paths from the host to Device 1.

FIGURE 102 Two data paths from host on a Foundry MRP ring to a VSRP-linked device



If a VSRP failover from master to backup occurs, VSRP needs to inform Foundry MRP of the topology change; otherwise, data from the host continues along the obsolete learned path and never reach the VSRP-linked device, as shown in Figure 103.

FIGURE 103 VSRP on Foundry MRP rings that failed over

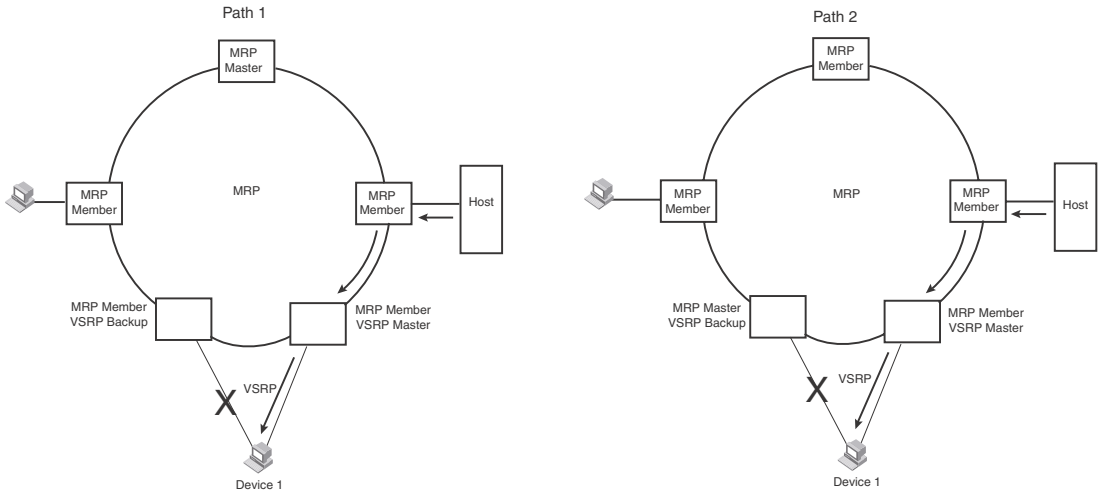


To ensure that Foundry MRP is informed of the topology change and to achieve convergence rapidly, a signaling process for the interaction between VSRP and Foundry MRP. When a VSRP node fails, a new VSRP master is selected. The new VSRP master finds all Foundry MRP instances impacted by the failover. Then each Foundry MRP instance does the following:

- The Foundry MRP node sends out a Foundry MRP PDU with the mac-flush flag set three times on the Foundry MRP ring.
- The Foundry MRP node that receives this Foundry MRP PDU empties all the MAC address entries from its interfaces that participate on the Foundry MRP ring.
- The Foundry MRP node then forwards the Foundry MRP PDU with the mac-flush flag set to the next Foundry MRP node that is in forwarding state.

The process continues until the Master Foundry MRP node's secondary (blocking) interface blocks the packet. Once the MAC address entries have been flushed, the MAC table can be rebuilt for the new path from the host to the VSRP-linked device (Figure 104).

FIGURE 104 New path established



There are no CLI commands used to configure this process.

Topology Groups 16

Overview

The following Topology Group features are supported by the NetIron MLX Series devices.

- Topology Groups
- Master VLAN and Member VLANs
- Master VLANs and Customer VLANs in Foundry MRP
- Control Ports and Free Ports
- Dual tag support for VPLS VLANs
- Adding VPLS VLANs to Topology Groups

A topology group is a named set of VLANs that share a Layer 2 control protocol. Topology groups simplify configuration and enhance scalability of Layer 2 protocols by allowing you to run a single instance of a Layer 2 protocol on multiple VLANs. One instance of the Layer 2 protocol controls all the VLANs.

For example, if a PowerConnect is deployed in a Metro network and provides forwarding for two Foundry MRP rings that each contain 128 VLANs, you can configure a topology group for each ring. If a link failure in a ring causes a topology change, the change is applied to all the VLANs in the ring's topology group. Without topology groups, you would need to configure a separate ring for each VLAN.

You can use topology groups with the following Layer 2 protocols:

- STP
- Foundry MRP
- VSRP
- RSTP

Master VLAN and member VLANs

Each topology group contains a master VLAN and can contain one or more member VLANs and VLAN groups. A definition for each of these VLAN types follows:

- **Master VLAN** – The master VLAN contains the configuration information for the Layer 2 protocol. For example, if you plan to use the topology group for Foundry MRP, the topology group's master VLAN contains the ring configuration information.
- **Member VLANs** – The member VLANs are additional VLANs that share ports with the master VLAN. The Layer 2 protocol settings for the ports in the master VLAN apply to the same ports in the member VLANs. A change to the master VLAN's Layer 2 protocol configuration or Layer 2 topology affects all the member VLANs. Member VLANs do not independently run a Layer 2 protocol. VPLS VLANs can become member VLANs within a topology group.

- **Member VLAN groups** – A VLAN group is a named set of VLANs. The VLANs within a VLAN group have the same ports and use the same values for other VLAN parameters.

When a Layer 2 topology change occurs on a port in the master VLAN, the same change is applied to that port in all the member VLANs that contain the port. For example, if you configure a topology group whose master VLAN contains ports 1/1 and 1/2, a Layer 2 state change on port 1/1 applies to port 1/1 in all the member VLANs that contain that port. However, the state change does not affect port 1/1 in VLANs that are not members of the topology group.

Master VLANs and customer VLANs in Foundry MRP

A topology group enables you to control forwarding in multiple VLANs using a single instance of a Layer 2 protocol such as Foundry MRP. For more information on topology group and Foundry MRP, refer to "Master VLANs and member VLANs in a topology group" on page 461.

Control ports and free ports

A port in a topology group can be a control port or a free port:

- **Control port** – is a port in the master VLAN and, therefore, is controlled by the Layer 2 protocol configured in the master VLAN. The same port in all the member VLANs is controlled by the master VLAN's Layer 2 protocol. Each member VLAN must contain all of the control ports. All other ports in the member VLAN are "free ports."
- **Free port** – is not controlled by the master VLAN's Layer 2 protocol. The master VLAN can contain free ports. (In this case, the Layer 2 protocol is disabled on those ports.) In addition, any ports in the member VLANs that are not also in the master VLAN are free ports.

NOTE
Because free ports are not controlled by the master port's Layer 2 protocol, they are assumed always to be in the forwarding state, when enabled.

Configuration considerations

The configuration considerations are as follows:

- You can configure up to 255 topology groups. Each group can control up to 4095 VLANs. A VLAN cannot be controlled by more than one topology group.
- The topology group must contain a master VLAN and can also contain individual member VLANs, VLAN groups, or a combination of individual member VLANs and VLAN groups. Therefore, you configure the master VLAN and member VLANs or member VLAN groups before you configure a topology group.
- After you add a VLAN as a member of a topology group, the router deletes all the Layer 2 protocol information on that VLAN.
- If you add a new master VLAN to a topology group that already has a master VLAN, the new master VLAN replaces the older master VLAN. All member VLANs and VLAN groups follow the Layer 2 protocol settings of the new master VLAN.

- If you remove the master VLAN (by entering **no master-vlan** <*vlan-id*>), the software selects the new master VLAN from member VLANs. A new candidate master VLAN will be in configured order to a member VLAN so that the first added member VLAN will be a new candidate master VLAN. Once you save and reload, a member VLAN with the youngest VLAN ID will be a new candidate master. The new master VLAN inherits the Layer 2 protocol settings of the older master VLAN.
- After you add a VLAN or VLAN group as a member of a topology group, all the Layer 2 protocol configuration information for the VLAN or group is deleted. For example, if STP is configured on a VLAN and you add the VLAN to a topology group, the STP configuration is removed from the VLAN. After you add the VLAN to a topology group, the VLAN uses the Layer 2 protocol settings of the master VLAN.

  If you remove a member VLAN or VLAN group from a topology group, you need to reconfigure the Layer 2 protocol information in the VLAN or VLAN group.
- On platforms where the Ethernet Service Instance (ESI) framework is supported, master VLANs in a topology group must either be in the default ESI or within the same ESI. Master and member VLANs cannot span multiple ESIs.

Configuring a topology group

To configure a topology group, enter commands such as the following.

```
NetIron(config)# topology-group 2
NetIron(config-topo-group-2)# master-vlan 2
NetIron(config-topo-group-2)# member-vlan 3
NetIron(config-topo-group-2)# member-vlan 4
NetIron(config-topo-group-2)# member-vlan 5
NetIron(config-topo-group-2)# member-group 2
```

The commands configure topology group 2 and add the following to it:

- VLAN 2 as master VLAN
- VLANs 3, 4, and 5 as member VLANs
- Member VLAN group 2

Syntax: [no] topology-group <*group-id*>

The command creates a topology group.The <*group-id*> parameter assigns an ID 1 – 255 to the topology group.

Syntax: [no] master-vlan <*vlan-id*>

This command adds the master VLAN to the topology group. The VLAN must already be configured. Make sure all the Layer 2 protocol settings in the VLAN are correct for your configuration before you add the VLAN to the topology group. A topology group can have only one master VLAN.

NOTE
When a port is added to a master VLAN, it will be added as a free port. Similarly when a port has to be removed from master VLAN, first disable any the Layer 2 protocol on the port, then remove the port from the master VLAN.

Syntax: [no] member-vlan <*vlan-id*>

This command adds a member VLAN to the topology group. The VLAN must already be configured.

Syntax: [no] member-group <*num*>

This command adds a VLAN group to the topology group. The <*num*> specifies a VLAN group ID. The VLAN group must already be configured.

Adding VPLS VLANs to topology groups

To add *single-tagged or untagged* VPLS VLANs as member VLANs to a topology group, use the **member-vlan vpls** command as shown in the following example.

```
NetIron(config)# topology-group 2
NetIron(config-topo-group-2)# master-vlan 2
NetIron(config-topo-group-2)# member-vlan vpls id 34 vlan 42 to 45
```

To add *dual-tagged* VPLS VLANs as member VLANs to a topology group, use the **member-vlan vpls** command as shown in the following configuration example.

```
NetIron(config)# topology-group 1
NetIron(config-topo-group-1)# master-vlan 10
NetIron(config-topo-group-1)# master-vlan 20
NetIron(config-topo-group-1)# member-vlan vpls id 5 vlan 300 inner-vlan 20 to 25
```

Syntax: [no] member-vlan vpls [id <*vpls-id*> **| name** <*vpls-name*> **}** **vlan** <*vlan-id*> **[to** <*vlan-id*> **]**

OR

Syntax: [no] member-vlan vpls [**id** <*vpls-id*> | **name** <*vpls-name*>] **vlan** <*vlan-id*> [**inner-vlan** <*inner-vlan-id*> [**to** <*inner-vlan-id*>]] ....

The **id** option allows you to specify the VPLS instance that you are configuring into the topology group by using the VPLS ID of the instance. A value in the range of 1 - 4294967294 can be entered for VPLS ID.

The **name** option allows you to specify the VPLS instance that you are configuring into the topology group by using the name of the instance.

The <*vlan-id*> variable is used with the **vlan** keyword to specify the VPLS VLAN being configured into topology group. You can specify multiple <*vlan-id*> values or specify a range of VLANs using the **to** option.

The **inner-vlan** option allows you to specify a VPLS dual-tagged (double-tagged) VLAN configuration.

NOTE
The **inner-vlan** option does not allow both outer VLAN ranges and inner VLAN ranges for a given VPLS instance. Once an outer VLAN range is specified, the inner VLAN option is not allowed. However, if a single outer VLAN is specified, the inner VLAN option and range is allowed.

NOTE
You cannot delete a topology master VLAN if the topology group has only VPLS VLAN members and no L2 VLAN members because the normal procedure for deleting a topology master VLAN is to elect another L2 VLAN as the new master. Because a VPLS VLAN cannot be a master VLAN, you must have at least one L2 VLAN as a member. If it does not currently exist, you must add a L2 VLAN before deleting a topology master.

Topology group support within an ESI

Topology groups can be configured with VLANs that are part of a user-defined ESI. (Consult Table • on page 543 to see which platform supports topology groups within an ESI.) When you configure topology groups in such a scenario, both the master and member VLANs must be part of the same ESI. If an ESI is not specified, the system assumes a reference to the default ESI. Below is an example of configuring topology groups with VLANs that are part of a user-defined ESI.

```
NetIron(config)# topology-group 2
NetIron(config-topo-group-2)# master-vlan service-esi 2
NetIron(config-topo-group-2)# member-vlan service-esi 3
NetIron(config-topo-group-2)# member-vlan service-esi 4
NetIron(config-topo-group-2)# member-vlan service-esi 5
NetIron(config-topo-group-2)# member-group service-esi 2
```

The commands configure topology group 2 and add the following to it:

- VLAN 2 in ESI "service-esi" as master VLAN
- VLANs 3, 4, and 5 in ESI "service-ESI" as member VLANs
- Member VLAN group 2

Syntax: [no] topology-group <*group-id*>

This command creates a topology group. The <*group-id*> parameter assigns an ID in the range 1 – 255 to the topology group.

Syntax: [no] master-vlan esi-name <*vlan-id*>

This command adds the master VLAN in ESI identified by the VLAN ID to the topology group. The VLAN must already be configured in the ESI "esi-name". Make sure all the Layer 2 protocol settings in the VLAN are correct for your configuration before you add the VLAN to the topology group. A topology group can have only one master VLAN.

Syntax: [no] member-vlan esi-name <*vlan-id*>

This command adds a member VLAN in ESI identified by the VLAN ID to the topology group. The VLAN must already be configured in the ESI "esi-name".

Syntax: [no] member-group esi-name <*num*>

This command adds a VLAN group in ESI identified by “esi-name” to the topology group. The <*num*> specifies a VLAN group ID. The VLAN group must already be configured.

Displaying topology group information

This section contains examples of the **show topology-group** output. Support for topology groups within an ESI is supported on a minority of platforms (listed in Table on page 547), so its example appears at the end of this section.

Displaying topology group information on a NetIron MLX series router

The **show topology-group** command offers a choice between one of two mandatory parameters. The command syntax is as follows.

Syntax: show topology-group <*group-id*> | **hw-index-table** [<*hw-index*>]

The first example in this section utilizes the first possible mandatory parameter, <*group-id*>. The second example utilizes the second possible mandatory parameter, **hw-index-table**, along with an optional variable, a hardware index number.

Display topology group information by using a Group ID

To display topology group information for group 10, enter the **show topology-group** command.

```
NetIron#show topology-group 10
Topology Group 10
=================
Topo HW Index   : 0
Master VLAN     : 10
VPLS VLAN exist : TRUE
Member VLAN     : 20
Member Group  : None
Member VPLSs  : vpls id 200 vlan 200 200 to 250
                vpls name vpls100 vlan 300 inner-vlan 5
                vpls id 5 vlan 300
                vpls id 5 vlan 300 inner-vlan 5

Syntax: show topology-group <*group-id*>

This display shows the following information:

TABLE 97 CLI display of topology group information

This field...	Displays...
Topology Group	The ID of the topology group. The range for <*group-id*> is 1 – 256.
Topo HW Index	A topology hardware index is a unique hardware ID that is assigned to a VLAN when an L2 protocol is configured on the VLAN. The VLAN that runs the L2 protocol could be a standalone L2 VLAN or a master VLAN under a topology group. The range for <*hw-index*> is 0 – 511. (The **show topology-group hw-index-table** output shows the mapping of a topology hardware index to a VLAN.)
Master-VLAN	The master VLAN for the topology group. The settings for STP, Foundry MRP, RSTP, or VSRP on the control ports in the master VLAN apply to all control ports in the member VLANs within the topology group.
VPLS VLAN exist	Indicates whether the topology group has one or more VPLS VLANs as a topology group member. The content of this field is TRUE or FALSE.
Member-VLAN	The VLAN ID of the member of the topology group.
Member VPLSs	The VPLS VLAN members in the topology group.
Control ports	The master VLAN ports that are configured with Layer 2 protocol information. The Layer 2 protocol configuration and state of these ports in the master VLAN applies to the same port numbers in all the member VLANs.
Free ports	A list of all free ports in the topology group. A free port is not controlled by the Layer 2 protocol information in the master VLAN. In the example screen output, the absence of any number indicates that no ports are free.

Display topology group information by using hardware index table numbers

Display the information for hardware index table 0..

```
NetIron#show topology-group hw-index-table  0
Total Instances : 512
Free Instances  : 511
Topo HW Index    Vlan ID
-------------    -------
0                10
```

Syntax: show topology-group hw-index-table [<*hw-index*>]

The range for <*hw-index*> is 0 – 511. If you do not specify a number for <*hw-index*>, the output screen lists all entries.

TABLE 98 Topology group information with hardware index table

This field...	Displays...
Total Instances	Total number of topology hardware indexes that have been initialized in the system.
Free Instances	Number of free topology hardware indexes that are left in the system.
Topology HW Index	A topology hardware index is assigned to a VLAN when an L2 protocol is configured on the VLAN. The VLAN that runs the L2 protocol could be a standalone L2 VLAN or a master VLAN under a topology group. The **show topology-group hw-index-table** output shows the mapping of a topology hardware index to a VLAN. The range for is 0 – 511. In the example, hardware index table 0 is mapped to the VLAN with an ID of 10.
VLAN ID	The ID of the port-based VLAN that owns the protocol instance on that VLAN. VLAN 1 is the default VLAN. If you have not configured port-based VLANs on a device, all protocol information is for VLAN 1.

Configuring VRRP and VRRP-E 17

Overview

The following VRRP and VRRP-E features are supported by the Brocade NetIron XMR Series.

- Standard VRRP
- VRRP Extended (VRRP-E)
- VRRP v2 Authentication
- VRRPv3 for IPv4 and IPv6
- VRRP-E v6
- VRRP alongside RIP
- VRRP alongside OSPF
- VRRP alongside BGP4
- VRRP Track Port
- VRRP Track Priority
- VRRP Backup Preempt
- VRRP Master Router Abdication and Reinstatement
- VRRP-Extended Slow Start
- VRRP-Extended Scale Timer
- VRRP-E Extension for Server Virtualization
- Virtual MAC address per VRID

This chapter describes how to configure the following router redundancy protocols:

- *Virtual Router Redundancy Protocol (VRRP)* – The standard router redundancy protocol described in RFC 3768. The devices support VRRP version 2 and VRRP version 3. VRRP v2 supports IPv4 environment and VRRP v3 supports IPv4 and IPv6 environment.
- *VRRP Extended (VRRP-E)* – A proprietary version of VRRP that overcomes limitations in the standard protocol. This protocol works only with Dell IP devices. The devices support VRRP-E version 2 and VRRP-E version 3. VRRP-E v2 supports IPv4 environment and VRRP-E v3 supports IPv6 environment.

NOTE
The maximum number of VRRP instances (vrid) supported per interface is 12 for both VRRP and VRRP-E.

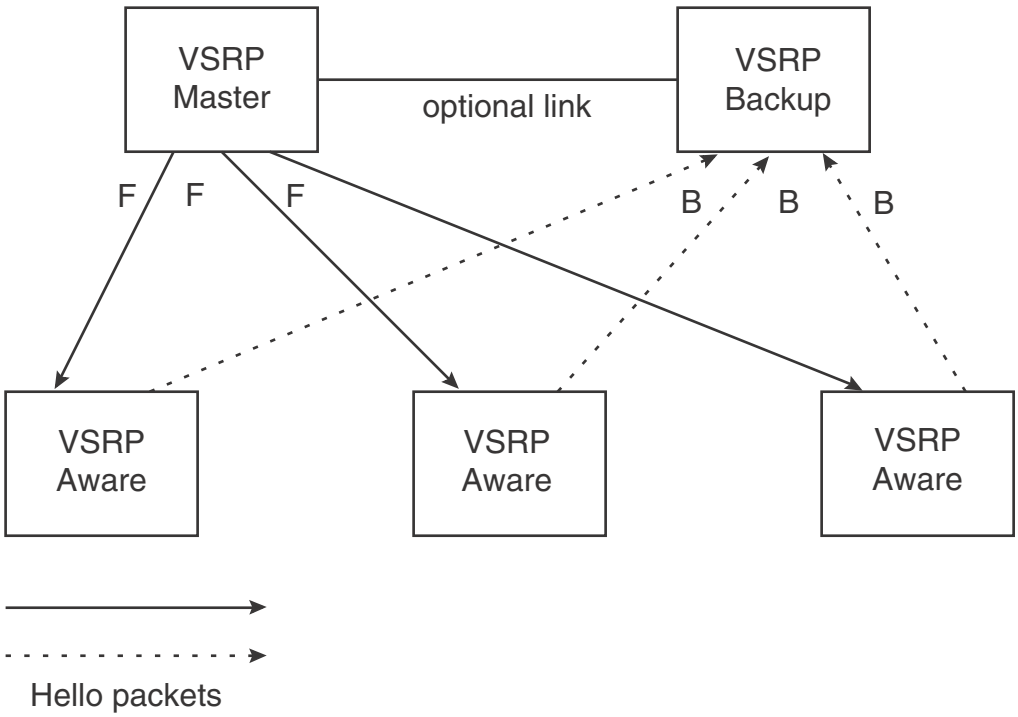
Overview of VRRP

This section presents the standard VRRP options and the options that were added in its implementation of VRRP.

Standard VRRP

VRRP is an election protocol that provides redundancy to routers within a LAN. VRRP allows you to provide alternate router paths for a host without changing the IP address or MAC address by which the host knows its gateway. Consider the situation shown in Figure 105.

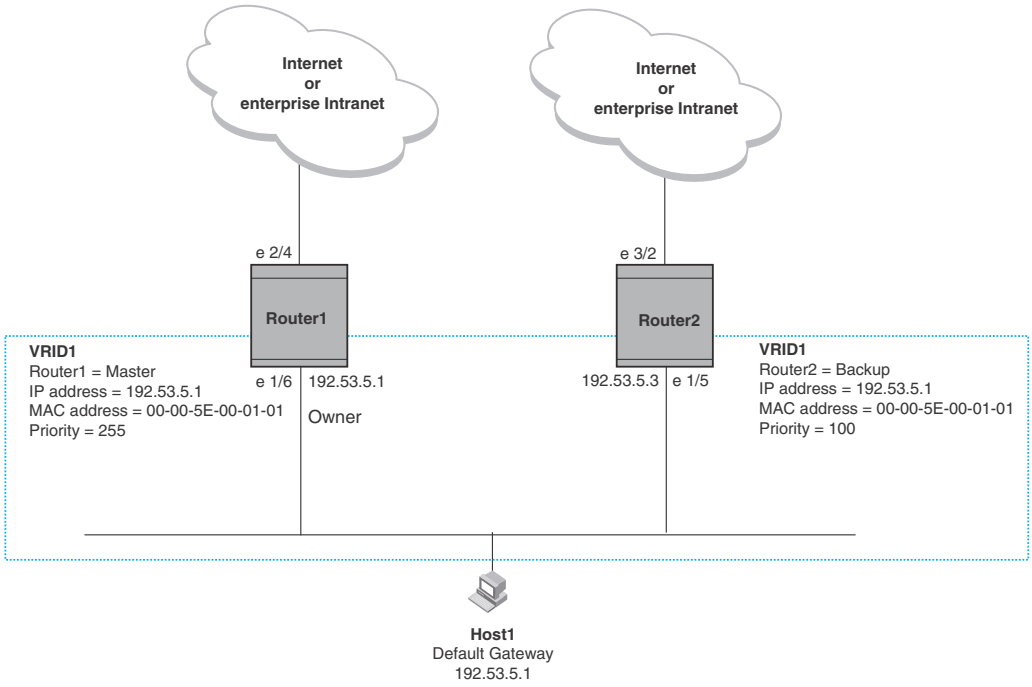
FIGURE 105 Router1 is Host1's default gateway but is a single point of failure



As shown in this example, Host1 uses 192.53.5.1 on Router1 as the host's default gateway out of the subnet. If this interface goes down, Host1 is cut off from the rest of the network. Router1 is thus a single point of failure for Host1's access to other networks.

If Router1 fails, you could configure Host1 to use Router2. Configuring one host with a different default gateway might not require too much extra administration. However, consider a more realistic network with dozens or even hundreds of hosts per subnet; reconfiguring the default gateways for all the hosts is impractical. It is much simpler to configure a VRRP virtual router on Router1 and Router2 to provide a redundant path for the hosts. If VRRP is enabled as in Figure 106, Router 2 provides the default gateway out of the subnet if Router 1 fails.

FIGURE 106 Router1 and Router2 configured as a VRRP virtual routers forredundant network access for Host1



With VRRP, you configure virtual routers that span across the physical routers. A virtual router acts as a default router for hosts on a shared LAN. For example, Figure 106 has one virtual router configured identified as VRID1.This virtual router ID is associated with Router 1 and Router 2.

Since there are more than one IP addresses configured on Router 1 and Router 2, one of the physical addresses is assigned to the virtual router. For example, in Figure 106, IP address 192.53.5.1, the IP address assigned to Router 1's interface 1/6, is assigned as the IP address of virtual router VRID1. Router 1 becomes the Owner of the virtual router VRID1 and is the router that responds to packets addresses to any of the IP addresses in virtual router VRID1.

In addition, one router in the virtual router is elected as the Master router. Other routers act as backups. The Master router is the one that forwards packets sent to the IP addresses in the virtual router and answers ARP requests for these IP addresses. The Backup router takes over for the Master router when the Master router fails.

NOTE
You can provide more redundancy by also configuring a second VRID with Router2 as the Owner and Router1 as the Backup. This type of configuration is sometimes called Multigroup VRRP.

Master router election

Virtual routers use the VRRP priority values associated with each VRRP router to determine which router becomes the Master. When you configure an Owner router, the PowerConnect automatically sets the its VRRP priority to 255, the highest VRRP priority. The router in the virtual router with the highest priority becomes the Master. Other routers become the backup and can be assigned priorities from 3 through 254. The default priority value is 100.

Virtual routers use VRID Hello messages to determine if a Master router is available. They send Hello messages to IP Multicast address 224.0.0.18 at a specified frequency. The Backup routers waits for a duration of time for a Hello message from the Master. This duration is called the Dead Interval. If a Backup router does not receive a Hello message by the time the dead interval expires, the Backup router assumes that the Master router is dead. The Backup router with the highest priority becomes the Master router. Once the Owner router becomes available, it becomes the Master router and the current Master router returns to being a backup router.

Pre-emption

If the pre-emption feature is enabled, a Backup router that is acting as the Master can be pre-empted by another Backup router that has a higher priority. This can occur the if you add a new Backup while the Owner is still available and new Backup router has a higher priority than the Backup router that is acting as Master.

Virtual router MAC address

When you configure a VRID, the software automatically assigns its MAC address as the virtual router's MAC address. The first five octets of the address are the standard MAC prefix for VRRP packets, as described in RFC 3768. The last octet is the VRID. THE VRID number becomes the final octet in the virtual router's virtual MAC address. For example, the MAC address for VRID is 000.5e00.0101.

When the virtual router becomes the Master router, it broadcasts a gratuitous ARP request containing the virtual router's MAC address for each IP address associated with the virtual router. In Figure 106, Router1 sends a gratuitous ARP with MAC address 00-00-5e-00-01-01 and IP address 192.53.5.1. Hosts use the virtual router's MAC address in routed traffic they send to their default IP gateway (in this example, 192.53.5.1).

Enhancements to VRRP

Dell has enhanced VRRP by adding the following options:

- Configuring unique virtual MAC addresses per VRID
- Track Ports and Track Priority
- Suppression of RIP Advertisements for Backed Up Interfaces
- Authentication
- VRRP operation is independent of RIP, OSPF, and BGP

Configuring unique virtual MAC addresses per VRID

In addition to system-configured standards-based virtual MAC addresses, you can manually configure a unique virtual MAC address for each IPv4 and IPv6 VRRP instance, per VRID. For NetIron MLX platform, you can configure a maximum of 2000 virtual MAC addresses.

If there is no manually configured virtual MAC address for a VRRP instance, the system automatically assigns one based on the VRRP RFC standard.

This feature is subject to the following limitations:

- This feature does not support configurable VRRP virtual MAC addresses over MCT.
- This feature has no impact on short-path forwarding for VRRP-E.

NOTE
System-assigned virtual MAC addresses and manually configured virtual MAC addresses can exist at the same time on the device under the same VRID, however the configured value takes precedence. When the configured value is deleted, the assigned value again applies.

To configure a unique VRRP or VRRP-E virtual MAC address for a VRID, complete the following steps.

1. To configure an IPv4 virtual MAC address for VRID 1 (for example), enter the following command at the configure vrid level of the CLI:

   ```
   NetIron(config-if-e1000-1/110-vrid-1)virtual-mac aaaa.bbbb.cccc
   ```

   Syntax: [**no**] **virtual-mac** <*mac-address*>

   Use the **no** version of this command to remove the configured address.

2. To configure an IPv6 virtual MAC address for VRID 1 (for example), enter the following command at the configure vrid level of the CLI:

   ```
   NetIron(config-if-e1000-1/110-ipv6-vrid-1)virtual-mac aaaa.bbbb.cccc
   ```

   Syntax: [**no**] **virtual-mac** <*ipv6 mac-address*>

   Use the **no** version of this command to remove the configured address.

3. To display IPv4 VRRP virtual MAC address configuration information about VRID 1 (for example), enter the following command:

   ```
   NetIron#show ip vrrp vrid 1

   Interface 1/1
   ----------------
   auth-type no authentication

   VRID 1 (index 1)
    interface 1/1
    state master
    administrative-status enabled
    version v2
    mode owner
    virtual mac aaaa.bbbb.cccc (configured)
    priority 255
    current priority 255
    track-priority 2
    hello-interval 1 sec
    backup hello-interval 60 sec
   ```

```
 ip-address 10.20.1.100
```

4. To display IPv4 VRRP-E virtual MAC address configuration information about VRID 1 (for example), enter the following command:

```
NetIron#show ip vrrp-extended vrid 1

Interface 1/1
---------------
auth-type no authentication

VRID 1 (index 1)
 interface 1/1
 state master
 administrative-status disabled
 mode non-owner(backup)
 virtual mac aaaa.bbbb.cccc (configured)
 priority 100
 current priority 100
 track-priority 5
 hello-interval 1 sec
 backup hello-interval 60 sec
 advertise backup disabled
 dead-interval 0 ms
 preempt-mode true
 virtual ip address 10.20.1.100
 short-path-forwarding disabled
```

5. To display IPv6 VRRP virtual MAC address configuration information for VRID 1 (for example), enter the following command:

```
NetIron#show ipv6 vrrp vrid 1

Interface 1/1
---------------
auth-type no authentication

VRID 1 (index 1)
 interface 1/1
 state master
 administrative-status enabled
 version v3
 mode non-owner(backup)
 virtual mac dddd.eeee.ffff (configured)
 priority 100
 current priority 100
 track-priority 1
 hello-interval 1000 ms
 backup hello-interval 60000 ms
 advertise backup disabled
 dead-interval 3600 ms
 preempt-mode true
 ipv6 address 10:20:1::100
 next hello sent in 400 ms
```

6. To display IPv6 VRRP-E virtual MAC address configuration information for VRID 1 (for example), enter the following command:

```
NetIron#show ipv6 vrrp-extended vrid 1

Interface 1/1
```

```
---------------
auth-type no authentication

VRID 1 (index 1)
 interface 1/1
 state master
 administrative-status enabled
 mode non-owner(backup)
 virtual mac dddd.eeee.ffff (configured)
 priority 100
 current priority 100
 track-priority 5
 hello-interval 1 sec
 backup hello-interval 60 sec
 advertise backup disabled
 dead-interval 0 ms
 preempt-mode true
 virtual ipv6 address 10:20:1::100
```

You can also identify configured virtual MAC addresses by entering the **show running-config** command, as shown in this example.

```
NetIron# show running-config interface ethernet 1/11
interface ethernet 1/11
enable
ip ospf area 0
ip address 15.1.1.15/24
```

Syntax: show running-config interface <*slot*/*port*>

Track ports and track priority

Dell enhanced VRRP by giving a VRRP router the capability to monitor the state of the interfaces on the other end of the route path through the router. For example, in Figure 106 on page 553, interface e1/6 on Router1 owns the IP address to which Host1 directs route traffic on its default gateway. The exit path for this traffic is through Router1's e2/4 interface.

Suppose interface e2/4 goes down. Even if interface e1/6 is still up, Host1 is cut off from other networks. In conventional VRRP, Router1 would continue to be the Master router despite the unavailability of the exit interface for the path the router is supporting. However, if you configure interface e1/6 to track the state of interface e2/4, if e2/4 goes down, interface e1/6 responds by changing Router1's VRRP priority to the value of the track priority. In the configuration shown in Figure 106 on page 553, Router1's priority changes from 255 to 20. One of the parameters contained in the Hello messages the Master router sends to its Backups is the Master router's priority. If the track port feature results in a change in the Master router's priority, the Backup routers quickly become aware of the change and initiate a negotiation for Master router.

In Figure 106 on page 553, the track priority results in Router1's VRRP priority becoming lower than Router2's VRRP priority. As a result, when Router2 learns that it now has a higher priority than Router1, Router2 initiates negotiation for Master router and becomes the new Master router, thus providing an open path for Host1's traffic. To take advantage of the track port feature, make sure the track priorities are always lower than the VRRP priorities. The default track priority for the router that owns the VRID IP addresses is 2. The default track priority for Backup routers is 1. If you change the track port priorities, make sure you assign a higher track priority to the Owner of the IP addresses than the track priority you assign on the Backup routers.

Suppression of RIP advertisements for backed up interfaces

The implementation also enhances VRRP by allowing you to configure the protocol to suppress RIP advertisements for the backed up paths from Backup routers. Normally, a VRRP Backup router includes route information for the interface it is backing up in RIP advertisements. As a result, other routers receive multiple paths for the interface and might sometimes unsuccessfully use the path to the Backup rather than the path to the Master. If you enable the implementation of VRRP to suppress the VRRP Backup routers from advertising the backed up interface in RIP, other routers learn only the path to the Master router for the backed up interface.

Authentication

For backward compatibility with RFC 2338,'s implementation of VRRP can use simple passwords to authenticate VRRP packets. The VRRP authentication type is not a parameter specific to the VRID. Instead, VRRP uses the authentication type associated with the interfaces on which you define the VRID. For example, if you configure your router interfaces to use a simple password to authenticate traffic, VRRP uses the same simple password and VRRP packets that do not contain the password are dropped. If your interfaces do not use authentication, neither does VRRP.

NOTE
The MD5 authentication type is not supported by VRRP or VRRP-E.

NOTE
Authentication is not supported by VRRP v3.

Forcing a master router to abdicate to a standby router

You can force a VRRP Master to abdicate (give away control) of a virtual router to a Backup by temporarily changing the Master's priority to a value less than the Backup's. When you change a VRRP Owner's priority, the change takes effect only for the current power cycle. The change is not saved to the startup configuration file when you save the configuration and is not retained across a reload or reboot. Following a reload or reboot, the VRRP Owner again has priority 255.

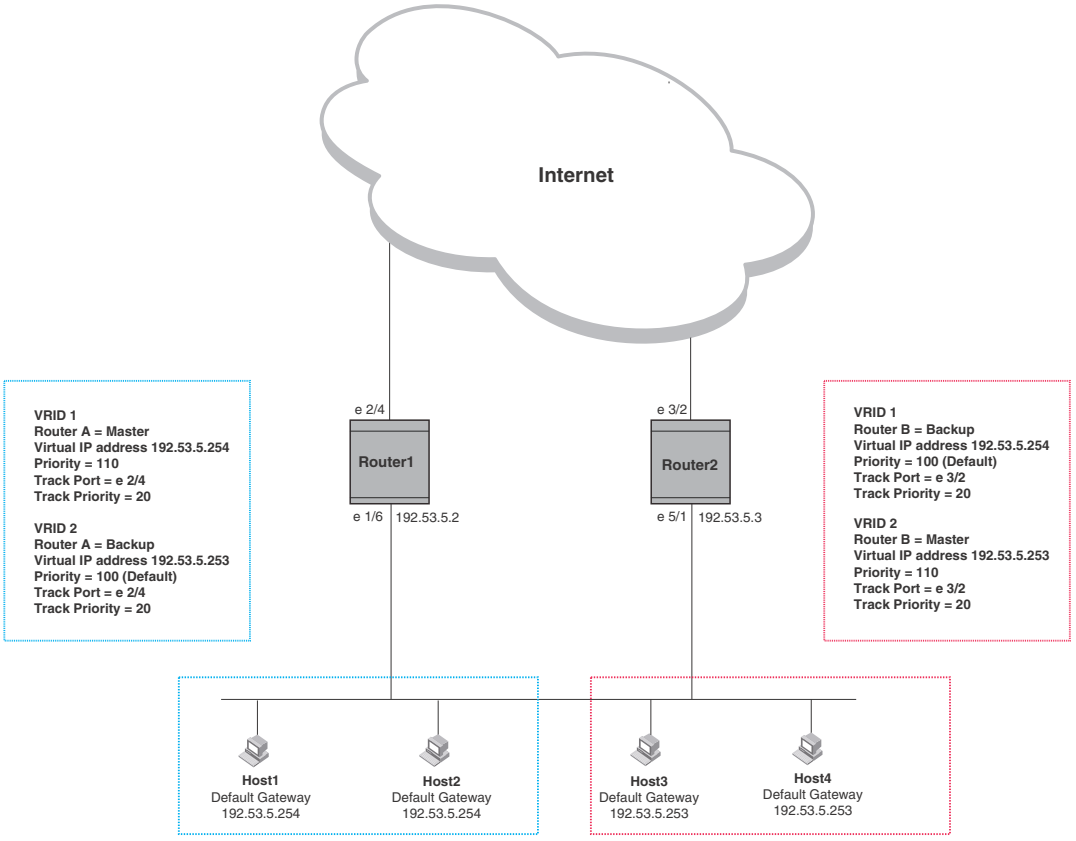
VRRP alongside RIP, OSPF, and BGP4

VRRP operation is independent of the RIP, OSPF, and BGP4 protocols. Their operation is unaffected when VRRP is enabled on a RIP, OSPF, or BGP4 interface.

Overview of VRRP-E

VRRP-E is proprietary version of VRRP that overcomes limitations in the standard protocol. Figure 107 shows an example of a VRRP-E configuration.

FIGURE 107 Router1 and Router2 are configured to provide dual redundant network access for the host



In this example, Router1 and Router2 use VRRP-E to load share as well as provide redundancy to the hosts. The load sharing is accomplished by creating two VRRP-E groups. Each group has its own virtual IP addresses. Half of the clients point to VRID 1's virtual IP address as their default gateway and the other half point to VRID 2's virtual IP address as their default gateway. This will enable some of the outbound Internet traffic to go through Router1 and the rest to go through Router2.

Router1 is the master for VRID 1 (backup priority = 110) and Router2 is the backup for VRID 1 (backup priority = 100). Router1 and Router2 both track the uplinks to the Internet. If an uplink failure occurs on Router1, its backup priority is decremented by 20 (track priority = 20), so that all traffic destined to the Internet is sent through Router2 instead.

Similarly, Router2 is the master for VRID 2 (backup priority = 110) and Router1 is the backup for VRID 2 (backup priority = 100). Router1 and Router2 are both tracking the uplinks to the Internet. If an uplink failure occurs on Router2, its backup priority is decremented by 20 (track priority = 20), so that all traffic destined to the internet is sent through Router1 instead.

The PowerConnect configured for VRRP-E can interoperate only with other Dell routers or switches.

ARP behavior with VRRP-E

In the VRRP-E implementation, the source MAC address of the gratuitous ARP sent by the VRRP-E master router will be the VRRP-E virtual MAC address. When the router (either master or backup router) sends an ARP request or reply packet, the sender's MAC address will be the MAC address of the interface on the router. When an ARP request packet for the virtual router IP address is received by the backup router, it will be forwarded to the master router to resolve the ARP. Only master router will answer the ARP request for the virtual router IP address.

Comparison of VRRP and VRRP-E

VRRP-E is similar to VRRP, but differs in the following respects:

- Owners and Backups:
  - VRRP has an Owner and one or more Backups for each virtual router. The Owner is the router that has the IP address used for the virtual router. All the other routers supporting the virtual router are Backups.
  - VRRP-E does not use Owners. All routers are Backups for a given virtual router. The router with the highest priority becomes the Master. If there is a tie for highest priority, the router with the highest IP address becomes the Master. The elected Master owns the virtual IP address and answers ping and ARP requests and so on.
- Master and Backups:
  - VRRP – The “Owner” of the IP address of the VRID is the default Master and has the highest priority (255). The precedence of the Backups is determined by their priorities. The default Master is always the Owner of the IP address of the VRID.
  - VRRP-E – The Master and Backups are selected based on their priority. You can configure any of the PowerConnect devices to be the Master by giving it the highest priority. There is no Owner.
- Virtual Router’s IP address:
  - VRRP requires that the virtual router has an IP address that is configured on the Owner router.
  - VRRP-E requires only that the virtual router’s IP address be in the same subnet as an interface configured on the VRID's interface. In fact, VRRP-E does not allow you to specify an IP address configured on the interface as the VRID IP address.
- VRID's MAC Address:
  - VRRP uses the interfaces’s actual MAC address as the source MAC address. The virtual MAC address for IPv4 VRRP is 00-00-5E-00-01-<*vrid*> and for IPv6 VRRP is 00-00-5E-00-02-<*vrid*>.The <*vrid*> is the ID of the virtual router. The Master owns the Virtual MAC address.
  - VRRP-E uses the interface’s actual MAC address as the source MAC address. The virtual MAC address for IPv4 VRRP-E and IPv6 VRRP-E is 02-E0-52-<*hash-value*>-<*vrid*>, where <*hash-value*> is a two-octet hashed value for the IP address and <*vrid*> is the virtual router ID.

    NOTE
    You cannot reuse the same VRID across IPv4 VRRP-E and IPv6 VRRP-E, if they are in the same broadcast domain.

- Hello packets:
  - VRRP sends Hello messages to IP Multicast address 224.0.0.18.
  - VRRP-E uses UDP to send Hello messages in IP multicast messages. The Hello packets use the interface’s actual MAC address and IP address as the source addresses. The destination MAC address is 01-00-5E-00-00-02, and the destination IP address is 224.0.0.2 (the well-known IP multicast address for “all routers”). Both the source and destination UDP port number is 8888. VRRP messages are encapsulated in the data portion of the packet.

- **Track ports and track priority:**
  - VRRP changes the priority of the VRID to the track priority, which typically is lower than the VRID priority and lower than the VRID's priorities configured on the Backups. For example, if the VRRP interface's priority is 100 and a tracked interface with track priority 20 goes down, the software changes the VRRP interface's priority to 20.
  - VRRP-E reduces the priority of a VRRP-E interface by the amount of a tracked interface's priority if the tracked interface's link goes down. For example, if the VRRP-E interface's priority is 200 and a tracked interface with track priority 20 goes down, the software changes the VRRP-E interface's priority to 180. If another tracked interface goes down, the software reduces the VRID's priority again, by the amount of the tracked interface's track priority.

The most important difference is that all VRRP-E routers are Backups. There is no Owner router. VRRP-E overcomes the limitations in standard VRRP by removing the Owner.

VRRP and VRRP-E parameters

Table 99 lists the VRRP and VRRP-E parameters. Most of the parameters and default values are the same for both protocols. The exceptions are noted in the table.

TABLE 99 VRRP and VRRP-E parameters

Parameter	Description	Default	Refer page...
Protocol	The Virtual Router Redundancy Protocol (VRRP) based on RFC 2338 or VRRP-Extended, Dell's enhanced implementation of VRRP	Disabled **NOTE:** Only one of the protocols can be enabled at a time.	page 564 page 567
VRRP or VRRP-E router	The PowerConnect's active participation as a VRRP or VRRP-E router. Enabling the protocol does not activate the PowerConnect for VRRP or VRRP-E. You must activate the PowerConnect as a VRRP or VRRP-E router after you configure the VRRP or VRRP-E parameters.	Inactive	page 564 page 567
Virtual Router ID (VRID)	The ID of the virtual router you are creating by configuring multiple routers to back up an IP interface. You must configure the same VRID on each router that you want to use to back up the address. No default.	None	page 564 page 567
Virtual Router IP address	This is the address you are backing up. No default. • VRRP – The virtual router IP address must be a real IP address configured on the VRID interface on one of the VRRP routers. This router is the IP address Owner and is the default Master. • VRRP-E – The virtual router IP address must be in the same subnet as a real IP address configured on the VRRP-E interface, but cannot be the same as a real IP address configured on the interface.	None	page 564 page 567

TABLE 99 VRRP and VRRP-E parameters (Continued)

Parameter	Description	Default	Refer page...
VRID MAC address	The source MAC address in VRRP or VRRP-E packets sent from the VRID interface, and the destination for packets sent to the VRID. • VRRP – A virtual MAC address defined as 00-00-5e-00-01-<*vrid*> for IPv4 VRRP and 00-00-5E-00-02-<vrid> for IPv6 VRRP. The Master owns the Virtual MAC address. • VRRP-E – A virtual MAC address defined as 02-E0-52-<*hash-value*>-<*vrid*> for IPv4 VRRP-E and IPv6 VRRP-E, where <*hash-value*> is a two-octet hashed value for the IP address and <*vrid*> is the ID of the virtual router.	Not configurable	page 554
Authentication type	The type of authentication the VRRP or VRRP-E routers use to validate VRRP or VRRP-E packets. The authentication type must match the authentication type the VRID's port uses with other routing protocols such as OSPF: • No authentication – The interfaces do not use authentication. This is the VRRP default. • Simple – The interface uses a simple text-string as a password in packets sent on the interface. If the interface uses simple password authentication, the VRID configured on the interface must use the same authentication type and the same password. **NOTE:** MD5 is not supported by VRRP or VRRP-E. Authentication is not supported by VRRP v3.	No authentication	page 558 page 569
Router type	Whether the router is an Owner or a Backup: • Owner (VRRP only) – The router on which the real IP address used by the VRID is configured. • Backup – Routers that can provide routing services for the VRID but do not have a real IP address matching the VRID.	VRRP – The Owner is always the router that has the real IP address used by the VRID. All other routers for the VRID are Backups. VRRP-E – All routers for the VRID are Backups.	page 564 page 567
Backup priority	A numeric value that determines a Backup's preferability for becoming the Master for the VRID. During negotiation, the router with the highest priority becomes the Master: • VRRP – The Owner has the highest priority (255); other routers can have a priority from 3 through 254. • VRRP-E – All routers are Backups and have the same priority by default. If two or more Backups are tied with the highest priority, the Backup interface with the highest IP address becomes the Master for the VRID.	VRRP – 255 for the Owner; 100 for each Backup VRRP-E – 100 for all Backups	page 564 page 567
Suppression of RIP advertisements	A router that is running RIP normally advertises routes to a backed up VRID even when the router is not currently the active router for the VRID. Suppression of these advertisements helps ensure that other routers do not receive invalid route paths for the VRID.	Disabled	page 570

TABLE 99 VRRP and VRRP-E parameters (Continued)

Parameter	Description	Default	Refer page...
Hello interval	The number of seconds or milliseconds between Hello messages from the Master to the Backups for a given VRID. The interval can be from 1 through 84 seconds for VRRP v2 and VRRP-E v2. The interval can be from 100 milliseconds through 8400 milliseconds for VRRP v3 and VRRP-E v3.	One second (VRRP v2 and VRRP-E v2) 1000 milliseconds (VRRP v3 and VRRP-E v3)	page 570
Dead interval	The number of seconds or milliseconds a Backup waits for a Hello message from the Master for the VRID before determining that the Master is no longer active. If the Master does not send a Hello message before the dead interval expires, the Backups negotiate (compare priorities) to select a new Master for the VRID.	Three times the Hello Interval plus one-half second	page 571
Backup Hello interval	The number of seconds between Hello messages from a Backup to the Master. The message interval can be from 60 through 3600 seconds. You must enable the Backup to send the messages. The messages are disabled by default on Backups. The current Master (whether the VRRP Owner or a Backup) sends Hello messages by default.	Disabled 60 seconds when enabled	page 571
Track port	Another PowerConnect port or virtual interface whose link status is tracked by the VRID's interface. If the link for a tracked interface goes down, the VRRP or VRRP-E priority of the VRID interface is changed, causing the devices to renegotiate for Master.	None	page 557 page 572
Track priority	A VRRP or VRRP-E priority value assigned to the tracked ports. If a tracked port's link goes down, the VRID port's VRRP or VRRP-E priority changes: • VRRP – The priority changes to the value of the tracked port's priority. • VRRP-E – The VRID port's priority is reduced by the amount of the tracked port's priority.	VRRP – 2 VRRP-E – 5	page 557 page 572
Backup preempt mode	Prevents a Backup with a higher VRRP priority from taking control of the VRID from another Backup that has a lower priority but has already assumed control of the VRID.	Enabled	page 573
Slow Start	Causes a specified amount of time to elapse between the time the original Master router is restored and when it takes over from the Backup router. For VRRP-E only.	Disabled	page 574

TABLE 99 VRRP and VRRP-E parameters (Continued)

Parameter	Description	Default	Refer page...
Scale Timer	Allows you to increase timing sensitivity across all configured or default VRRP-Extended timers. For VRRP-E only.	Disabled	page 574
short-path-forwarding	Enables VRRP-E Extension for Server Virtualization. If enabled, the traffic that is destined to the clients will travel through the short-path forwarding path (dashed line) to reach the client (as shown in Figure 24.4 on page 24-30). Any packets coming from the local subnet of the virtual IP address will be routed to the VRRP-E master router. For example, with VRRP-E Extension for Server Virtualization enabled, the traceroute output will show one extra hop that display the Backup router's interface IP address	Disabled	page 591

Configuring parameters specific to VRRP

VRRP is configured at the interface level. To implement a simple VRRP configuration using all the default values, enter the following commands.

NOTE
When you use the command **router vrrp** to enter the VRRP configuration mode, the command prompt does not change and results in the general configuration command prompt as shown in the following: NetIron`(config)#`. This differs from entering the VRRP extended mode where entering the router **vrrp-extended** command results in a command prompt such as the following: PowerConnect`(config-vrrpe-router)#`

Configuring the VRRP version

You can specify the version for the VRRP instance. For example, use the following command to configure the instance of VRRP to use VRRP v3.

```
NetIron(config-if-e100-1/3-vrid-13)# version v3
```

Syntax: [no] version <*v2 | v3*>

- VRRP v2 supports IPv4 environment
- VRRP v3 supports IPv4 and IPv6 environment

The default configuration is VRRP v2.

Configuring the Owner for IPv4

To configure the VRRP Owner router for IPv4, enter the following commands on the router.

```
NetIron1(config)# router vrrp
NetIron1(config)# interface ethernet 1/6
NetIron1(config-if-e10000-1/6)# ip address 192.53.5.1/24
NetIron1(config-if-e10000-1/6)# ip vrrp vrid 1
NetIron1(config-if-e10000-1/6-vrid-1)# owner
NetIron1(config-if-e10000-1/6-vrid-1)# ip-address 192.53.5.1
NetIron1(config-if-e10000-1/6-vrid-1)# activate
```

Syntax: [no] router vrrp

Syntax: [no] ip vrrp vrid <*num*>

Syntax: [no] owner [track-priority <*value*>**]**

Syntax: [no] activate

The <*num*> parameter specifies the virtual router ID.

The **track-priority** <*value*> parameter changes the track-port priority for this interface and VRID from the default (2) to a value from 1 through maximum VRID supported by the device.

Syntax: [no] ip-address <*ip-addr*>

The <*ip-addr*> parameter specifies the IPv4 address of the Owner router.

The IP address you assign to the Owner must be an IP address configured on an interface that belongs to the virtual router.

Refer to "Configuration rules and feature limitations for VRRP" on page 567 for additional requirements.

Configuring the Owner for IPv6

To configure the VRRP Owner router for IPv6, enter the following commands on the router.

```
NetIron1(config)# ipv6 router vrrp
NetIron1(config)# interface ethernet 1/6
NetIron1(config-if-e10000-1/6)# ipv6 address 3013::1/64
NetIron1(config-if-e10000-1/6)# ipv6 vrrp vrid 1
NetIron1(config-if-e10000-1/6-vrid-1)# owner
NetIron1(config-if-e10000-1/6-vrid-1)# ipv6-address 3013::1
NetIron1(config-if-e10000-1/6-vrid-1)# activate
```

Syntax: [**no**] **ipv6 router vrrp**

Syntax: [**no**] **ipv6 vrrp vrid** <*num*>

Syntax: [**no**] **ipv6-address** <*ipv6-addr*>

The <*num*> parameter specifies the virtual router ID.

The <*ipv6-addr*> parameter specifies the IPv6 address of the Owner router.

The IP address you assign to the Owner must be an IP address configured on an interface that belongs to the virtual router.

Refer to "Configuration rules and feature limitations for VRRP" on page 567 for additional requirements.

Configuring a Backup for IPv4

To configure the VRRP Backup router for IPv4, enter the following commands.

```
NetIron2(config)# router vrrp
NetIron2(config)# interface ethernet 1/5
NetIron2(config-if-e10000-1/5)# ip address 192.53.5.3/24
NetIron2(config-if-e10000-1/5)# ip vrrp vrid 1
NetIron2(config-if-e10000-1/5-vrid-1)# backup
NetIron2(config-if-1/5-vrid-1)# advertise backup
NetIron2(config-if-e10000-1/5-vrid-1)# ip-address 192.53.5.1
NetIron2(config-if-e10000-1/5-vrid-1)# activate
```

When you configure a Backup router, the router interface on which you are configuring the VRID must have a real IP address that is in the same subnet as the address associated with the VRID by the Owner. However, the address cannot be the same.

Syntax: [no] router vrrp

Syntax: [no] ip vrrp vrid <*num*>

Syntax: [no] backup [priority <*value*>**] [track-priority** <*value*>**]**

The <*num*> parameter specifies the virtual router ID.

The **priority** <*value*> parameter specifies the VRRP priority for this virtual router. You can specify a value from 3 through 254. The default is 100.

Enter a value from 3 through 254 for the **track-priority** <*value*> parameter if you want VRRP to monitor the state of the interface. The default is 100.

Syntax: [no] ip-address <*ip-addr*>

Refer to "Configuration rules and feature limitations for VRRP" on page 567 for additional requirements.

Configuring a Backup for IPv6

To configure the VRRP Backup router for IPv6, enter the following commands.

```
NetIron2(config)# ipv6 router vrrp
NetIron2(config)# interface ethernet 1/5
NetIron2(config-if-e10000-1/5)# ipv6 address 3013::3/64
NetIron2(config-if-e10000-1/5)# ipv6 vrrp vrid 1
NetIron2(config-if-e10000-1/5-vrid-1)# backup
NetIron2(config-if-1/5-vrid-1)# advertise backup
NetIron2(config-if-e10000-1/5-vrid-1)# ipv6-address 3013::1
NetIron2(config-if-e10000-1/5-vrid-1)# activate
```

When you configure a Backup router, the router interface on which you are configuring the VRID must have a real IP address that is in the same subnet as the address associated with the VRID by the Owner. However, the address cannot be the same.

Syntax: [**no**] **ipv6 router vrrp**

Syntax: [**no**] **ipv6-address** <*ipv6-addr*>

The <*num*> parameter specifies the virtual router ID.

The <*ipv6-addr*> parameter specifies the IPv6 address of the Backup router.

Refer to "Configuration rules and feature limitations for VRRP" on page 567 for additional requirements.

Configuration rules and feature limitations for VRRP

Consider the following rules when configuring VRRP:

- The interfaces of all routers in a virtual router must be in the same IP subnet:
- The IP addresses associated with the virtual router must already be configured on the router that will be the Owner router.
- The IP address for the virtual router must be on only one router.
- The Hello interval must be set to the same value on both the Owner and Backups for the virtual router.
- The Dead interval must be set to the same value on both the Owner and Backups for the virtual router.
- The track priority on a router must be lower than the router's VRRP priority. Also, the track priority on the Owner must be higher than the track priority on the Backups.
- The tracking-port configuration for IPv6 VRRP v3 is not allowed if the router is configured as the VRRP Owner.
- The priority configuration for IPv6 VRRP v3 is not allowed for Owner router. The Owner router's priority is always 255.
- Hitless switchover is not supported.
- The ping command is not supported for VRRP virtual IPv4 and IPv6 addresses.
- Mixed mode VRRP v2 and VRRP v3 is not supported in the same VRRP group.

Configuring parameters specific to VRRP-E

The following sections describe the configuration of the parameters specific to IPv4 and IPv6 VRRP-E.

Configuring IPv4 VRRP-E

VRRP-E is configured at the interface level. To implement a simple IPv4 VRRP-E configuration using all the default values, enter the following commands.

```
NetIron(config)# router vrrp-extended
NetIron(config)# interface ethernet 1/5
NetIron(config-if-e10000-1/5)# ip address 192.53.5.3/24
NetIron(config-if-e10000-1/5)# ip vrrp-extended vrid 1
NetIron(config-if-e10000-1/5-vrid-1)# backup priority 50 track-priority 10
NetIron(config-if-e10000-1/5-vrid-1)# ip-address 192.53.5.254
NetIron(config-if-e10000-1/5-vrid-1)# activate
```

Syntax: [no] **ip vrrp-extended vrid** <*vrid*>

Syntax: [no] **backup** [**priority** <*value*>] [**track-priority** <*value*>]

Syntax: [no] **ip-address** <*ip-addr*>

The <*vrid*> parameter specifies the virtual router ID.

The <*ip-addr*> parameter specifies the IPv4 address of the router.

Refer to the section "Authentication type" on page 569 for information on the **auth-type no-auth** | **simple-text-auth** <*auth-data*> parameters.

Also, refer to "Configuration rules and feature limitations for VRRP-E" on page 568 additional information on how to configure VRRP-E.

PowerConnect requires you to identify a VRRP-E router as a Backup before you can activate the virtual router. However, after you configure the virtual router, you can use the **backup** command to change its priority or track priority.

You also can use the **enable** command to activate the configuration. This command does the same thing as the **activate** command.

Configuring IPv6 VRRP-E

To implement a IPv6 VRRP-E configuration using all the default values, enter the following commands.

```
NetIron(config)# ipv6 router vrrp-extended
NetIron(config-ipv6-VRRP-E-router)# interface ethernet 1/5
NetIron(config-if-e10000-1/5)# ipv6 address 3013::2/64
NetIron(config-if-e10000-1/5)# ipv6 vrrp-extended vrid 1
NetIron(config-if-e10000-1/5-vrid-1)# backup priority 50 track-priority 10
NetIron(config-if-e10000-1/5-vrid-1)# ipv6-address 3013::99
NetIron(config-if-e10000-1/5-vrid-1)# activate
```

Syntax: ipv6 router vrrp-extended

Syntax: ipv6 vrrp-extended vrid <*vrid*>

Syntax: [no] ipv6-address <*ipv6-addr*>

The <*vrid*> parameter specifies the virtual router ID.

The <*ipv6-addr*> parameter specifies the IPv6 address of the router.

Configuration rules and feature limitations for VRRP-E

Consider the following rules when configuring VRRP-E:

- The interfaces of all routers in a virtual router must be in the same IP subnet.
- The IP address assigned to the virtual router cannot be configured on any of the PowerConnect devices.
- The Hello interval must be set to the same value on all the PowerConnect devices.
- The Dead interval must be set to the same value on all the PowerConnect devices.
- The track priority for a virtual router must be lower than the VRRP-E priority.
- The same VRID must not be used across IPv6 VRRP-E and IPv4 VRRP-E if they are in the same broadcast domain.
- Hitless switchover is not supported.

NOTE
If you disable VRRP-E, the PowerConnect removes all the configuration information for the disabled protocol from the running configuration. Moreover, when you save the configuration to the startup configuration after disabling the protocol, all configuration information for the disabled protocol is removed from the startup configuration.

Configuring additional VRRP and VRRP-E parameters

You can modify the following VRRP and VRRP-E parameters on each individual virtual router. These parameters apply to both protocols:

- Authentication type (if the interfaces on which you configure the virtual router use authentication)
- Backup priority
- Suppression of RIP advertisements on Backup routes for the backed up interface
- Hello interval
- Dead interval
- Backup Hello messages and message timer (Backup advertisement)
- Track port
- Track priority
- Backup preempt mode
- Master Router Abdication and Reinstatement
- VRRP-Extended Slow Start
- VRRP-Extended Scale Timer

Refer to "VRRP and VRRP-E parameters" on page 561 for a summary of the parameters and their defaults.

Authentication type

If the interfaces on which you configure the virtual router use authentication, the VRRP or VRRP-E packets on those interfaces also must use the same authentication. Dell's implementation of VRRP and VRRP-E supports the following authentication types:

- **No authentication** – The interfaces do not use authentication. This is the default for VRRP and VRRP-E.
- **Simple** – The interfaces use a simple text-string as a password in packets sent on the interface. If the interfaces use simple password authentication, the virtual router configured on the interfaces must use the same authentication type and the same password.

To configure the interface on Router1 for simple-password authentication using the password "ourpword", enter the following commands.

Configuring router 1

```
Router1(config)# interface ethernet 1/6
Router1(config-if-e10000-1/6)# ip vrrp auth-type simple-text-auth ourpword
```

Configuring router 2

```
Router2(config)# interface ethernet 1/5
Router2(config-if-e10000-1/5)# ip vrrp auth-type simple-text-auth ourpword
```

Syntax: [no] ip vrrp auth-type no-auth | simple-text-auth <*auth-data*>

The **auth-type no-auth** parameter indicates that the virtual router and the interface it is configured on do not use authentication.

The **auth-type simple-text-auth** <*auth-data*> parameter indicates that the virtual router and the interface it is configured on use a simple text password for authentication. The <*auth-data*> parameter is the password. If you use this parameter, make sure all interfaces on all the routers supporting this virtual router are configured for simple password authentication and use the same password.

NOTE
Authentication is not supported by VRRP v3.

Suppressingf RIP advertisements on backup routers for the backup up interface

Normally, a VRRP or VRRP-E backup includes route information for the virtual IP address in RIP advertisements. As a result, other routers receive multiple paths for the backup router and might sometimes unsuccessfully use the path to the backup router rather than the path to the Master.

You can prevent the backup routers from advertising route information for the interface on which they are defined by enabling suppression of the advertisements.

To suppress RIP advertisements for interface on which a backup router is defined in Router2, enter the following commands.

```
Router2(config)# router rip
Router2(config-rip-router)# use-vrrp-path
```

Syntax: [no] use-vrrp-path

The syntax is the same for VRRP and VRRP-E.

Hello interval

The Master periodically sends Hello messages to the Backups. The Backups use the Hello messages as verification that the Master is still on-line. If the Backup routers stop receiving the Hello messages for the period of time specified by the Dead interval, the Backup routers determine that the Master router is dead. At this point, the Backup router with the highest priority becomes the new Master router.

The default Dead interval is three times the Hello Interval plus one-half second. Generally, if you change the Hello interval, you also must change the Dead interval on the Backup routers.

To change the Hello interval on the Master to 10 seconds for VRRP v2 and VRRP-E v2, enter the following commands.

```
Router1(config)# interface ethernet 1/6
Router1(config-if-e10000-1/6)# ip vrrp vrid 1
Router1(config-if-e10000-1/6-vrid-1)# hello-interval 10
```

Syntax: [no] hello-interval <*value*>

The Hello interval can be from 1 through 84 seconds. The default is 1 second.

To change the Hello interval on the Master to 200 milliseconds for VRRP v3 and VRRP-E v3, enter the following commands.

```
Router1(config)# interface ethernet 1/6
Router1(config-if-e10000-1/6)# ip vrrp vrid 1
Router1(config-if-e10000-1/6-vrid-1)# hello-interval msec 200
```

Syntax: [**no**] **hello-interval** [**msec**] <*value*>

The Hello interval can be from 100 through 8400 milliseconds. The default is 1000 milliseconds.

The syntax is the same for VRRP and VRRP-E.

Dead interval

The Dead interval is the time a Backup waits for a Hello message from the Master before determining that the Master is dead. When Backups determine that the Master is dead, the Backup with the highest priority becomes the new Master. The dead interval is three times the default Hello interval (1 second) plus one-half second added by the router software. The software automatically adds one-half second to the Dead interval value you enter.

To change the Dead interval on a Backup to 30 seconds for VRRP v2 and VRRP-E v2, enter the following commands.

```
Router2(config)# interface ethernet 1/5
Router2(config-if-e10000-1/5)# ip vrrp vrid 1
Router2(config-if-e10000-1/5-vrid-1)# dead-interval 30
```

Syntax: [no] dead-interval <*value*>

The Dead interval can be from 1 through 84 seconds. The default is 3.5 seconds.

To change the Dead interval on a Backup to 600 milliseconds for VRRP v3 and VRRP-E v3, enter the following commands.

```
Router2(config)# interface ethernet 1/5
Router2(config-if-e10000-1/5)# ip vrrp vrid 1
Router2(config-if-e10000-1/5-vrid-1)# dead-interval msec 600
```

Syntax: [**no**] **dead-interval** [**msec**] <*value*>

The Dead interval can be from 100 through 8400 milliseconds. The default is 3500 milliseconds.

The syntax is the same for VRRP and VRRP-E.

Backup hello message state and interval

By default, Backup do not send Hello messages to advertise themselves to the Master. You can enable these messages if desired and also change the message interval.

To enable a Backup to send Hello messages to the Master, enter the following commands.

```
NetIron(config)# router vrrp
NetIron(config)# interface ethernet 1/6
NetIron(config-if-e10000-1/6)# ip vrrp vrid 1
NetIron(config-if-e10000-1/6-vrid-1)# advertise backup
```

Syntax: [no] advertise backup

When you enable a Backup to send Hello messages, the Backup sends a Hello messages to the Master every 60 seconds by default. You can change the interval to be up to 3600 seconds. To do so, enter the following commands.

```
NetIron(config)# router vrrp
NetIron(config)# interface ethernet 1/6
NetIron(config-if-e10000-1/6)# ip vrrp vrid 1
NetIron(config-if-e10000-1/6-vrid-1)# backup-hello-interval 180
```

Syntax: [no] backup-hello-interval <*num*>

The <*num*> parameter specifies the message interval and can be from 60 through 3600 seconds. The default is 60 seconds.

The syntax is the same for VRRP and VRRP-E.

Track port

You can configure the virtual router to track the link state of interfaces on the PowerConnect. This capability is quite useful for tracking the state of the exit interface for the path for which the virtual router is providing redundancy. Refer to "Track ports and track priority" on page 557.

To configure 1/6 on Router1 to track interface 2/4, enter the following commands.

```
Router1(config)# interface ethernet 1/6
Router1(config-if-e10000-1/6)# ip vrrp vrid 1
Router1(config-if-e10000-1/6-vrid-1)# track-port ethernet 2/4
```

Syntax: [no] track-port ethernet <*slot*>/<*portnum*> **| ve** <*num*> **[priority** <*num*>**]**

The syntax is the same for VRRP and VRRP-E.

Track priority

If you configure a virtual router to track the link state of interfaces and one of the tracked interface goes down, the software changes the VRRP or VRRP-E priority of the virtual router:

- For VRRP, the software changes the priority of the virtual router to a track priority that is lower than that of the virtual router priority and lower than the priorities configured on the Backups. For example, if the virtual router priority is 100 and a tracked interface with track priority 60 goes down, the software changes the virtual router priority to 60.
- For VRRP-E, the software reduces the virtual router priority by the amount of the priority of the tracked interface that went down. For example, if the VRRP-E interface's priority is 100 and a tracked interface with track priority 60 goes down, the software changes the VRRP-E interface's priority to 40. If another tracked interface goes down, the software reduces the virtual router's priority again, by the amount of the tracked interface's track priority.

The default track priority for a VRRP Owner is 2. The default track priority for Backups is 1.

You enter the track priority as a parameter with the **owner** or **backup** command. Refer to "Track port" on page 572.

Syntax: [no] owner [track-priority <*value*>**]**

Syntax: [no] backup [priority <*value*>**] [track-priority** <*value*>**]**

The syntax is the same for VRRP and VRRP-E.

Backup preempt

By default, a Backup that has a higher priority than another Backup that has become the Master can preempt the Master, and take over the role of Master. If you want to prevent this behavior, disable preemption.

Preemption applies only to Backups and takes effect only when the Master has failed and a Backup has assumed ownership of the virtual router. The feature prevents a Backup with a higher priority from taking over as Master from another Backup that has a lower priority but has already become the Master of the virtual router.

Preemption is especially useful for preventing flapping in situations where there are multiple Backups and a Backup with a lower priority than another Backup has assumed ownership, since the Backup with the higher priority was unavailable when ownership changed.

If you enable the non-preempt mode (thus disabling the preemption feature) on all the Backups, the Backup that becomes the Master following the disappearance of the Master continues to be the Master. The new Master is not preempted.

NOTE
In VRRP, regardless of the setting for the preempt parameter, the Owner always returns to be the Master when it comes back online.

To disable preemption on a Backup, enter the following commands.

```
Router1(config)# interface ethernet 1/6
Router1(config-if-e10000-1/6)# ip vrrp vrid 1
Router1(config-if-e10000-1/6-vrid-1)# non-preempt-mode
```

Syntax: [no] non-preempt-mode

The syntax is the same for VRRP and VRRP-E.

Master router abdication and reinstatement

To change the Master's priority, enter the following commands.

```
NetIron(config)# interface ethernet 1/6
NetIron(config-if-e10000-1/6)# ip vrrp vrid 1
NetIron(config-if-e10000-1/6-vrid-1)# owner priority 99
```

Syntax: [no] owner priority | track-priority <*num*>

The <*num*> parameter specifies the new priority and can be a number from 1 through 254.

When you press Enter, the software changes the priority of the Master to the specified priority. If the new priority is lower than at least one Backup's priority for the same virtual router, the Backup takes over and becomes the new Master until the next software reload or system reset.

To verify the change, enter the following command from any level of the CLI.

```
NetIron(config-if-e10000-1/6-vrid-1)# show ip vrrp
Total number of VRRP routers defined: 1
Interface ethernet 1/6
auth-type no authentication
VRID 1
state backup
administrative-status enabled
mode owner
```

```
priority 99
current priority 99
hello-interval 1 sec
ip-address 192.53.5.1
backup routers 192.53.5.2
```

This example shows that even though this PowerConnect is the Owner of the virtual router ("mode owner"), the PowerConnect's priority for the virtual router is only 99 and the state is now "backup" instead of "active". In addition, the administrative status is "enabled".

To change the Master's priority back to the default Owner priority 255, enter "no" followed by the command you entered to change the priority. For example, to change the priority of a VRRP Owner back to 255 from 99, enter the following command.

```
NetIron(config-if-e10000-1/6-vrid-1)# no owner priority 99
```

You cannot set the priority to 255 using the **owner priority** command.

VRRP-extended slow start

In a VRRP-E configuration, if a Master router goes down, the Backup router with the highest priority takes over after expiration of the dead interval. When the original Master router comes back up again, it takes over from the Backup router (which became the Master router when the original Master router went down). By default, this transition from Backup router back to Master router takes place after expiration of the dead interval.

You can configure the VRRP-E slow start timer feature, which causes a specified amount of time to elapse between the time the original Master router is restored and when it takes over from the Backup router (This range is currently set to between 1-60 seconds). This interval allows time for OSPF convergence when the Master is restored.

To set the VRRP-E slow start timer to 30 seconds, enter the following command.

```
NetIron(config)# router vrrp-extended
NetIron(config-vrrpe-router)# slow-start 30
```

Syntax: [no] slow-start <*seconds*>

When the VRRP-E slow start timer is enabled, if the Master router goes down, the Backup router takes over after expiration of the dead interval. If the original Master router subsequently comes back up again, the amount of time specified by the VRRP-E slow start timer elapses (in this example, 30 seconds) before the original Master router takes over from the Backup router (which became the Master router when the original Master router went down).

In the event that no other routers are currently Master, the router will immediately (after the dead-interval) become Master.

VRRP-extended scale timer

This feature allows you to increase timing sensitivity across all configured or default VRRP-Extended timers. When this command is used, all configured or default VRRP-Extended timers are divided by the value set in the command. For example: a value of 10 divides the timers by a factor of 10. Configuring a value of 10 in a network with all VRRP-Extended values set to their defaults would cause VRRP-Extended instances to send packets every 100ms (instead of every 1

second) and the backup advertisement interval of 60 seconds would be modified to 6 seconds. All other timers would be divided likewise. This would allow VRRP-Extended instances to converge within a second in the event of a VRRP-Extended master failure (this is since the default dead timer would be 300 ms).

To scale all VRRP-Extended timers by 10, use the following command.

```
NetIron(config)# scale-timer vrrp-extended 10
```

Syntax: **[no] scale-timer vrrp-extended** <*scale-factor*>

The <*scale-factor*> variable is the number that all VRRP-Extended timers values are divided by. Values can be set from 1 through 10.

NOTE
Increased timing sensitivity as a result of using this command could cause protocol flaps during times of network congestion.

NOTE
This command is not supported in VRRP v2 and VRRP v3.

Displaying VRRP and VRRP-E information for IPv4

You can display the following information for IPv4 VRRP or VRRP-E:

- "Displaying summary information"
- "Displaying detailed information"
- "Displaying statistics"
- "Displaying configuration information for VRRP and VRRP-E"

Displaying summary information

To display summary information for IPv4 VRRP or VRRP-E, enter the following command at any level of the CLI.

```
NetIron(config)# show ip vrrp brief
Total number of VRRP routers defined: 2
Flags Codes - P:Preempt 2:V2 3:V3 S:Short-Path-Fwd

Inte- VRID Current  Flags  State  Master IP       Backup IP       Virtual IP
rface      Priority               Address         Address         Address
-------------------------------------------------------------------------------
1/1   10   255      P2-    Master Local           Unknown         30.30.30.2
1/3   13   100      P2-    Master Local           Unknown         10.13.13.3
```

Syntax: **show ip vrrp [brief | ethernet** <*slot*>/<*portnum*> **| statistics | ve** <*num*> **| vrid** <*id*>**]**

Syntax: **show ip vrrp-extended [brief | ethernet** <*slot*>/<*portnum*> **| statistics | ve** <*num*> **| vrid** <*id*>**]**

The **brief** parameter displays the summary information. If you do not use this parameter, detailed information is displayed instead. Refer to "Displaying detailed information" on page 577.

The **ethernet** <*slot*>/<*portnum*> parameter specifies an Ethernet port. If you use this parameter, the command displays IPv4 VRRP or VRRP-E information only for the specified port.

The **ve** <*num*> parameter specifies a virtual interface. If you use this parameter, the command displays IPv4 VRRP or VRRP-E information only for the specified virtual interface.

The **vrid** <*id*> parameter specifies a virtual router ID. If you use this parameter, the command displays IPv4 VRRP or VRRP-E information only for the specified virtual router.

The **statistics** parameter displays statistics. Refer to "Displaying statistics" on page 580.

This display shows the following information.

TABLE 100 CLI display of VRRP or VRRP-E summary information

This field...	Displays...
Total number of VRRP (or VRRP-Extended) routers defined	The total number of virtual routers configured on this PowerConnect. **NOTE:** The total applies only to the protocol the PowerConnect is running. For example, if the PowerConnect is running VRRP-E, the total applies only to VRRP-E routers.
Interface	The interface on which VRRP or VRRP-E is configured. If VRRP or VRRP-E is configured on multiple interfaces, information for each interface is listed separately.
VRID	The ID of the virtual router configured on this interface. If multiple virtual routers are configured on the interface, information for each virtual router is listed in a separate row.
Current Priority	The current VRRP or VRRP-E priority of this PowerConnect for the virtual router.
Flags	Whether the backup preempt mode is enabled. If the backup preempt mode is enabled, this field contains a "P". If the mode is disabled, this field is blank. P:Preempt 2:V2 3:V3 2: imples VRRP Version2 3 implies VRRP Version3.
Short-Path-Fwd	Displays information about whether VRRP-E Extension for Server Virtualization is enabled or disabled.
State	This PowerConnect's VRRP or VRRP-E state for the virtual router. The state can be one of the following: • Init – The virtual router is not enabled (activated). If the state remains Init after you activate the virtual router, make sure that the virtual router is also configured on the other routers and that the routers can communicate with each other. **NOTE:** If the state is Init and the mode is incomplete, make sure you have specified the IP address for the virtual router. • Backup – This PowerConnect is a Backup for the virtual router. • Master – This PowerConnect is the Master for the virtual router.
Master addr	The IP address of the router interface that is currently the Master for the virtual router.
Backup addr	The IP addresses of the router interfaces that are currently Backups for the virtual router.
VIP	The virtual IP address that is being backed up by the virtual router.

Displaying detailed information

To display detailed information for IPv4 VRRP or VRRP-E, enter the following command at any level of the CLI.

```
NetIron(config)# show ip vrrp-extended
Total number of vrrp-extended routers defined: 1
Interface v10
----------------
auth-type no authentication
VRID 10 (index 1)
 interface v10
 state backup
 administrative-status enabled
 mode non-owner(backup)
 virtual mac 02e0.52a0.c00a
 priority 50
 current priority 50
 track-priority 5
 hello-interval 1 sec
 backup hello-interval 60 sec
 advertise backup disabled
 dead-interval 0 sec
 current dead-interval 3.6 sec
 preempt-mode true
 virtual ip address 10.10.10.254
master router 10.10.10.4 expires in 3.1 sec
short-path-forwarding enabled
```

Syntax: show ip vrrp

Syntax: show ip vrrp-extended

This display shows the following information.

TABLE 101 CLI display of VRRP or VRRP-E detailed information

This field...	Displays...
Total number of VRRP (or VRRP-Extended) routers defined	The total number of virtual routers configured on this PowerConnect. **NOTE:** The total applies only to the protocol the PowerConnect is running. For example, if the PowerConnect is running VRRP-E, the total applies only to VRRP-E routers.
Interface parameters	
Interface	The interface on which VRRP or VRRP-E is configured. If VRRP or VRRP-E is configured on multiple interfaces, information for each interface is listed separately.
auth-type	The authentication type enabled on the interface.
Virtual Router parameters	
VRID	The virtual router configured on this interface. If multiple virtual routers are configured on the interface, information for each virtual router is listed separately.

TABLE 101 CLI display of VRRP or VRRP-E detailed information (Continued)

This field...	Displays...
state	This PowerConnect's VRRP or VRRP-E state for the virtual router. The state can be one of the following: • initialize – The virtual router is not enabled (activated). If the state remains "initialize" after you activate the virtual router, make sure that the virtual router is also configured on the other routers and that the routers can communicate with each other. **NOTE:** If the state is "initialize" and the mode is incomplete, make sure you have specified the IP address for the virtual router. • backup – This PowerConnect is a Backup for the virtual router. • master – This PowerConnect is the Master for the virtual router.
administrative-status	The administrative status of the virtual router. The administrative status can be one of the following: • disabled – The virtual router is configured on the interface but VRRP or VRRP-E has not been activated on the interface. • enabled – VRRP or VRRP-E has been activated on the interface.
mode	Indicates whether the PowerConnect is the Owner or a Backup for the virtual router. **NOTE:** If "incomplete" appears after the mode, configuration for this virtual router is incomplete. For example, you might not have configured the virtual IP address that is being backup up by the virtual router. This field applies only to VRRP. All PowerConnect devices configured for VRRP-E are Backups.
virtual MAC	The virtual IP MAC address that this virtual router is backing up.
priority	The device's preferability for becoming the Master for the virtual router. During negotiation, the router with the highest priority becomes the Master. If two or more devices are tied with the highest priority, the Backup interface with the highest IP address becomes the active router for the virtual router.
current priority	The current VRRP or VRRP-E priority of this PowerConnect for the virtual router. The current priority can differ from the configured priority (refer the previous row) for the following reasons: • The virtual router is still in the initialization stage and has not become a Master or Backup yet. In this case, the current priority is 0. • The virtual router is configured with track ports and the link on a tracked interface has gone down. Refer to "Track ports and track priority" on page 557.
track priority	VRRP-E priority value assigned to the tracked port.
hello-interval	The number of seconds between Hello messages from the Master to the Backups for a given virtual router.
backup hello-interval	The number of seconds between Hello messages from a Backup to the Master.

TABLE 101 CLI display of VRRP or VRRP-E detailed information (Continued)

This field...	Displays...
advertise backup	The IP addresses of Backups that have advertised themselves to this PowerConnect by sending Hello messages. **NOTE:** Hello messages from Backups are disabled by default. You must enable the Hello messages on the Backup for the Backup to advertise itself to the current Master. Refer to "Hello interval" on page 570.
dead-interval	The configured value for the dead interval. The dead interval is the number of seconds a Backup waits for a Hello message from the Master for the virtual router before determining that the Master is no longer active. If the Master does not send a Hello message before the dead interval expires, the Backups negotiate (compare priorities) to select a new Master for the virtual router. **NOTE:** If the value is 0, then you have not configured this parameter. This field does not apply to VRRP Owners.
current dead-interval	The current value of the dead interval. This is the value actually in use by this interface for the virtual router. **NOTE:** This field does not apply to VRRP Owners.
preempt-mode	Whether the backup preempt mode is enabled. **NOTE:** This field does not apply to VRRP Owners.
virtual ip address	The virtual IP addresses that this virtual router is backing up.
backup router <*ip-addr*> expires in <*time*>	The IP addresses of Backups that have advertised themselves to this Master by sending Hello messages. The <*time*> value indicates how long before the Backup expires. A Backup expires if you disable the advertise backup option on the Backup or the Backup becomes unavailable. Otherwise, the Backup's next Hello message arrives before the Backup expires. The Hello message resets the expiration timer. An expired Backup does not necessarily affect the Master. However, if you have not disabled the advertise backup option on the Backup, then the expiration may indicate a problem with the Backup. **NOTE:** This field applies only when Hello messages are enabled on the Backups (using the advertise backup option).
next hello sent in <*time*>	How long until the Backup sends its next Hello message. **NOTE:** This field applies only when this PowerConnect is the Master and the Backup is configured to send Hello messages (the advertise backup option is enabled).
master router <*ip-addr*> expires in <*time*>	The IP address of the Master and the amount of time until the Master's dead interval expires. If the Backup does not receive a Hello message from the Master by the time the interval expires, either the IP address listed for the Master will change to the IP address of the new Master, or this PowerConnect itself will become the Master. **NOTE:** This field applies only when this PowerConnect is a Backup.

TABLE 101 CLI display of VRRP or VRRP-E detailed information (Continued)

This field...	Displays...
track port	The interfaces that the virtual router's interface is tracking. If the link for a tracked interface goes down, the VRRP or VRRP-E priority of the virtual router interface is changed, causing the devices to renegotiate for Master. **NOTE:** This field is displayed only if track interfaces are configured for this virtual router.
short-path-forwarding	Displays information about whether VRRP-E Extension for Server Virtualization is enabled or disabled.

Displaying statistics

To display IPv4 VRRP or VRRP-E statistics, enter the following command.

```
NetIron# show ip vrrp-extended statistics

Global VRRP-Extended statistics
-------------------------------
- received vrrp-extended packets with checksum errors = 0
- received vrrp-extended packets with invalid version number = 0
- received vrrp-extended packets with unknown or inactive vrid = 1480

Interface v10
----------------
VRID 1
- number of transitions to backup state = 1
- number of transitions to master state = 1
- total number of vrrp-extended packets received = 0
  . received backup advertisements = 0
  . received packets with zero priority = 0
  . received packets with invalid type = 0
  . received packets with invalid authentication type = 0
  . received packets with authentication type mismatch = 0
  . received packets with authentication failures = 0
  . received packets dropped by owner = 0
  . received packets with ip ttl errors = 0
  . received packets with ip address mismatch = 0
  . received packets with advertisement interval mismatch = 0
  . received packets with invalid length = 0
- total number of vrrp-extended packets sent = 2004
  . sent backup advertisements = 0
  . sent packets with zero priority = 0
- received arp packets dropped = 0
- received proxy arp packets dropped = 0
- received ip packets dropped = 0
```

Syntax: show ip vrrp statistics

Syntax: show ip vrrp-extended statistics

The **statistics** parameter displays the following information.

The *received vrrp packets with checksum errors* shows the number of packets that is contained in checksum errors.

The *received vrrp packets with invalid version number* shows the number of packets with invalid versions.

The *received vrrp packets with unknown or inactive vrid* shows the number of packets that contain virtual routers that are not configured on the device or its interface

Displaying VRRP and VRRP-E information for IPv6

You can display the following information for IPv6 VRRP or VRRP-E:

- "Displaying summary information"
- "Displaying detailed information"
- "Displaying statistics"
- "Displaying configuration information for VRRP and VRRP-E"

Displaying summary information

To display summary information for IPv6 VRRP or VRRP-E, enter the following command at any level of the CLI.

```
NetIron(config)# show ipv6 vrrp-extended brief
Total number of VRRP routers defined: 1
Flags Codes - P:Preempt 2:V2 3:V3 S:Short-Path-Fwd

Intf  VRID CurrPrio Flags State  Master-IPv6 Backup-IPv6 Virtual-IPv6
                                 -Address    -Address    -Address
-------------------------------------------------------------------
1/3   23   100      P3-   Master   Local     3013::2       3013::99
```

Syntax: **show ipv6 vrrp** [**brief** | **ethernet** <*slot*>/<*portnum*> | **statistics** | **ve** <*num*> | **vrid** <*id*>]

Syntax: **show ipv6 vrrp-extended** [**brief** | **ethernet** <*slot*>/<*portnum*> | **statistics** | **ve** <*num*> | **vrid** <*id*>]

The **brief** parameter displays the summary information. If you do not use this parameter, detailed information is displayed instead. Refer to "Displaying detailed information" on page 577.

The **ethernet** <*slot*>/<*portnum*> parameter specifies an Ethernet port. If you use this parameter, the command displays IPv6 VRRP or VRRP-E information only for the specified port.

The **ve** <*num*> parameter specifies a virtual interface. If you use this parameter, the command displays IPv6 VRRP or VRRP-E information only for the specified virtual interface.

The **vrid** <*id*> parameter specifies a virtual router ID. If you use this parameter, the command displays IPv6 VRRP or VRRP-E information only for the specified virtual router.

The **statistics** parameter displays statistics. Refer to "Displaying statistics" on page 580.

Displaying detailed information

To display detailed information for IPv6 VRRP or VRRP-E, enter the following command at any level of the CLI.

```
NetIron(config)# show ipv6 vrrp

Total number of VRRP routers defined: 1

Interface 1/3
----------------
auth-type no authentication

VRID 13 (index 2)
 interface 1/3
 state master
 administrative-status enabled
 version v3
 mode non-owner(backup)
 virtual mac 0000.5e00.0217
 priority 100
 current priority 100
 track-priority 1
 hello-interval 1000 ms
 backup hello-interval 60000 ms
 advertise backup disabled
 dead-interval 3000 ms
 preempt-mode true
 ipv6-address 3013::1
 next hello sent in 700 ms
 short-path-forwarding disabled
```

Syntax: show ipv6 vrrp

Syntax: show ipv6 vrrp-extended

Displaying statistics

To display IPv6 VRRP or VRRP-E statistics, enter the following command.

```
NetIron# show ipv6 vrrp statistics

Global IPv6 VRRP statistics
------------------------------
- received vrrp packets with checksum errors = 0
- received vrrp packets with invalid version number = 0
- received vrrp packets with unknown or inactive vrid = 0
Interface 1/3
----------------
VRID 13
- number of transitions to backup state = 1
- number of transitions to master state = 1
- total number of vrrp packets received = 0
. received backup advertisements = 19
. received packets with zero priority = 0
. received packets with invalid type = 0
. received packets with invalid authentication type = 0
. received packets with authentication type mismatch = 0
. received packets with authentication failures = 0
```

```
. received packets dropped by owner = 0
. received packets with ttl errors = 0
. received packets with ipv6 address mismatch = 0
. received packets with advertisement interval mismatch = 0
. received packets with invalid length = 0
- total number of vrrp packets sent = 1175
. sent backup advertisements = 0
. sent packets with zero priority = 0
- received neighbor solicitation packets dropped = 0
- received proxy neighbor solicitation packets dropped = 0
- received ipv6 packets dropped = 0
```

Syntax: show ipv6 vrrp statistics

Syntax: show ipv6 vrrp-extended statistics

Displaying configuration information for VRRP and VRRP-E

To display the current configuration information for IPv4 VRRP or VRRP-E and IPv6 VRRP or VRRP-E, enter the following command at any level of the CLI.

```
NetIron(config-if-e10000-1/3)# show run
…
router vrrp
…
interface ethernet 1/1
 port-name Port111
 enable
 ip address 30.30.30.2/28
 ip vrrp vrid 10
  owner
  ip-address 30.30.30.2
  activate
!
…
interface ethernet 1/3
 enable
 ip address 10.13.13.2/24
 ip vrrp vrid 13
  version v3
  backup
  ip-address 10.13.13.3
  activate
…
```

Syntax: show run

Clearing VRRP or VRRP-E statistics

To clear IPv4 VRRP or VRRP-E statistics, enter the following command at the Privileged EXEC level or any configuration level of the CLI.

```
NetIron(config)# clear ip vrrp statistics
```

Syntax: clear ip vrrp statistics

Syntax: clear ip vrrp-extended statistics

To clear IPv6 VRRP or VRRP-E statistics, enter the following command at the Privileged EXEC level or any configuration level of the CLI.

```
NetIron(config)# clear ipv6 vrrp statistics
```

Syntax: clear ipv6 vrrp statistics

Syntax: clear ipv6 vrrp-extended statistics

Configuration examples

The following sections contain the CLI commands options for implementing the VRRP and VRRP-E configurations shown in Figure 106 on page 553 and Figure 107 on page 558.

VRRP example for IPv4

To implement the IPv4 VRRP configuration shown in Figure 106 on page 553, enter the following commands.

Configuring router1

To configure VRRP Router1, enter the following commands.

```
Router1(config)# router vrrp
Router1(config)# interface ethernet 1/6
Router1(config-if-e10000-1/6)# ip address 192.53.5.1
Router1(config-if-e10000-1/6)# ip vrrp vrid 1
Router1(config-if-e10000-1/6-vrid-1)# owner track-priority 20
Router1(config-if-e10000-1/6-vrid-1)# track-port ethernet 2/4
Router1(config-if-e10000-1/6-vrid-1)# ip-address 192.53.5.1
Router1(config-if-e10000-1/6-vrid-1)# activate
```

NOTE
When you configure the Master (Owner), the address you enter with the **ip-address** command must already be configured on the interface.

The **ip vrrp owner** command specifies that this router owns the IP address you are associating with the virtual router. Since this router owns the IP address, this router is the default Master router and its VRRP priority is thus 255.

Configuring router2

To configure Router2 in Figure 106 on page 553 after enabling VRRP, enter the following commands.

```
Router2(config)# router vrrp
Router2(config)# interface ethernet 1/5
Router2(config-if-e10000-1/5)# ip address 192.53.5.3
Router2(config-if-e10000-1/5)# ip vrrp vrid 1
Router2(config-if-e10000-1/5-vrid-1)# backup priority 100 track-priority 19
Router2(config-if-e10000-1/5-vrid-1)# track-port ethernet 3/2
Router2(config-if-e10000-1/5-vrid-1)# ip-address 192.53.5.1
Router2(config-if-e10000-1/5-vrid-1)# activate
```

The **backup** command specifies that this router is a VRRP Backup for virtual router VRID1. The IP address entered with the **ip-address** command is the same IP address as the one entered when configuring Router1. In this case, the IP address cannot also exist on Router2, but the interface on which you are configuring the virtual router Backup must have an IP address in the same subnet. By entering the same IP address as the one associated with this virtual router on the Owner, you are configuring the Backup to back up the address, but you are not duplicating the address.

NOTE
When you configure a Backup router, the router interface on which you are configuring the virtual router must have a real IP address that is in the same subnet as the address associated with the virtual router by the Owner. However, the address cannot be the same.

The **priority** parameter establishes the router's VRRP priority in relation to the other VRRP routers in this virtual router. The **track-priority** parameter specifies the new VRRP priority that the router receives for this virtual router if the interface goes down. Refer to "Track ports and track priority" on page 557.

The **activate** command activates the virtual router configuration on this interface. The interface does not provide backup service for the virtual IP address until you activate the VRRP configuration.

Syntax: router vrrp

Syntax: ip vrrp vrid <*vrid*>

Syntax: owner [track-priority <*value*>**]**

Syntax: backup [priority <*value*>**] [track-priority** <*value*>**]**

Syntax: track-port ethernet <*slot*>/<*portnum*> **ve** <*num*>

Syntax: ip-address <*ip-addr*>

Syntax: activate

VRRP example for IPv6

To implement the VRRP configuration for IPv6, enter the following commands.

Configuring router1

To configure VRRP Router1, enter the following commands.

```
Router1(config)# ipv6 router vrrp
Router1(config)# interface ethernet 1/6
Router1(config-if-e10000-1/6)# ipv6 address 1414:1414:1414::1/64
Router1(config-if-e10000-1/6)# ipv6 vrrp vrid 1
Router1(config-if-e10000-1/6-vrid-1)# owner track-priority 20
Router1(config-if-e10000-1/6-vrid-1)# track-port ethernet 2/4
Router1(config-if-e10000-1/6-vrid-1)# ipv6-address 1414:1414:1414::1/64
Router1(config-if-e10000-1/6-vrid-1)# activate
```

NOTE
When you configure the Master (Owner), the address you enter with the **ipv6-address** command must already be configured on the interface.

The **ipv6 vrrp owner** command specifies that this router owns the IP address you are associating with the virtual router. Since this router owns the IP address, this router is the default Master router and its VRRP priority is thus 255.

Configuring router2

To configure VRRP Router2, enter the following commands.

```
Router2(config)# ipv6 router vrrp
Router2(config)# interface ethernet 1/5
Router2(config-if-e10000-1/5)# ipv6 address 1414:1414:1414::2/64
Router2(config-if-e10000-1/5)# ipv6 vrrp vrid 1
Router2(config-if-e10000-1/5-vrid-1)# backup priority 100 track-priority 19
Router2(config-if-e10000-1/5-vrid-1)# track-port ethernet 3/2
Router2(config-if-e10000-1/5-vrid-1)# ipv6-address 1414:1414:1414::1/64
Router2(config-if-e10000-1/5-vrid-1)# activate
```

The **backup** command specifies that this router is a VRRP Backup for virtual router VRID1. The IP address entered with the **ipv6-address** command is the same IP address as the one entered when configuring Router1. In this case, the IP address cannot also exist on Router2, but the interface on which you are configuring the virtual router Backup must have an IP address in the same subnet. By entering the same IP address as the one associated with this virtual router on the Owner, you are configuring the Backup to back up the address, but you are not duplicating the address.

NOTE
When you configure a Backup router, the router interface on which you are configuring the virtual router must have a real IP address that is in the same subnet as the address associated with the virtual router by the Owner. However, the address cannot be the same.

The **priority** parameter establishes the router's VRRP priority in relation to the other VRRP routers in this virtual router. The **track-priority** parameter specifies the new VRRP priority that the router receives for this virtual router if the interface goes down.

The **activate** command activates the virtual router configuration on this interface. The interface does not provide backup service for the virtual IP address until you activate the VRRP configuration.

Syntax: ipv6 router vrrp

Syntax: ipv6 vrrp vrid <*vrid*>

Syntax: owner [**track-priority** <*value*>]

Syntax: **backup** [**priority** <*value*>] [**track-priority** <*value*>]

Syntax: **track-port ethernet** <*slot*>/<*portnum*> **ve** <*num*>

Syntax: **ipv6-address** <*ip-addr*>

Syntax: **activate**

VRRP-E example for IPv4

To implement the IPv4 VRRP-E configuration shown in Figure 107 on page 558, configure the VRRP Routers as shown in the following sections.

Configuring router1

To configure VRRP Router1 in Figure 107 on page 558, enter the following commands.

```
Router1(config)# router vrrp-extended
Router1(config)# interface ethernet 1/6
Router1(config-if-e10000-1/6)# ip address 192.53.5.2/24
Router1(config-if-e10000-1/6)# ip vrrp-extended vrid 1
Router1(config-if-e10000-1/6-vrid-1)# backup priority 110 track-priority 20
Router1(config-if-e10000-1/6-vrid-1)# track-port ethernet 2/4
Router1(config-if-e10000-1/6-vrid-1)# ip-address 192.53.5.254
Router1(config-if-e10000-1/6-vrid-1)# activate
VRRP router 1 for this interface is activating
Router1(config-if-e10000-1/6-vrid-1)# exit
Router1(config)# interface ethernet 1/6
Router1(config-if-e10000-1/6)# ip vrrp-extended vrid 2
Router1(config-if-e10000-1/6-vrid-1)# backup priority 100 track-priority 20
Router1(config-if-e10000-1/6-vrid-1)# track-port ethernet 2/4
Router1(config-if-e10000-1/6-vrid-1)# ip-address 192.53.5.253
Router1(config-if-e10000-1/6-vrid-1)# activate
VRRP router 2 for this interface is activating
```

NOTE
The address you enter with the **ip-address** command cannot be the same as a real IP address configured on the interface.

Configuring router2

To configure Router2, enter the following commands.

```
Router2(config)# router vrrp-extended
Router2(config)# interface ethernet 5/1
Router2(config-if-e10000-5/1)# ip address 192.53.5.3/24
Router2(config-if-e10000-5/1)# ip vrrp-extended vrid 1
Router2(config-if-e10000-5/1-vrid-1)# backup priority 100 track-priority 20
Router2(config-if-e10000-5/1-vrid-1)# track-port ethernet 3/2
Router2(config-if-e10000-5/1-vrid-1)# ip-address 192.53.5.254
Router2(config-if-e10000-5/1-vrid-1)# activate
Router2(config-if-e10000-5/1-vrid-1)# exit
Router2(config)# interface ethernet 5/1
Router2(config-if-e10000-5/1)# ip vrrp-extended vrid 2
Router2(config-if-e10000-5/1-vrid-1)# backup priority 110 track-priority 20
Router2(config-if-e10000-5/1-vrid-1)# track-port ethernet 2/4
Router2(config-if-e10000-5/1-vrid-1)# ip-address 192.53.5.253
Router2(config-if-e10000-5/1-vrid-1)# activate
```

The **backup** command specifies that this router is a VRRP-E Backup for virtual router VRID1. The IP address entered with the **ip-address** VRRP-E command is the same IP address as the one entered when configuring Router1. In this case, the IP address cannot also exist on Router2, but the interface on which you are configuring the virtual router Backup must have an IP address in the same subnet. By entering the same IP address as the one associated with this virtual router on the Owner, you are configuring the Backup to back up the address, but you are not duplicating the address.

NOTE
When you configure a Backup router, the router interface on which you are configuring the virtual router must have a real IP address that is in the same subnet as the address associated with the virtual router by the Owner. However, the address cannot be the same.

The **priority** parameter establishes the router's VRRP-E priority in relation to the other VRRP-E routers in this virtual router. The **track-priority** parameter specifies the new VRRP-E priority that the router receives for this virtual router if the interface goes down. Refer to "Track ports and track priority" on page 557.

The **activate** command activates the virtual router configuration on this interface. The interface does not provide backup service for the virtual IP address until you activate the VRRP-E configuration. Alternatively, you can use the **enable** command. The **activate** and **enable** commands do the same thing.

Syntax: [no] **router vrrp-extended**

Syntax: [no] **ip vrrp-extended vrid** <*vrid*>

Syntax: [no] **backup** [**priority** <*value*>] [**track-priority** <*value*>]

Syntax: [no] **track-port ethernet** <*slot*>/<*portnum*> **ve** <*num*>

Syntax: [no] **ip-address** <*ip-addr*>

Syntax: [no] **activate**

VRRP-E example for IPv6

To implement the IPv6 VRRP-E configuration, configure the VRRP Routers as shown in the following sections.

Configuring router1

To configure VRRP Router1, enter the following commands.

```
Router1(config)# ipv6 router vrrp-extended
Router1(config)# interface ethernet 1/6
Router1(config-if-e10000-1/6)# ipv6 address 1414:1414:1414::3/64
Router1(config-if-e10000-1/6)# ipv6 vrrp-extended vrid 1
Router1(config-if-e10000-1/6-vrid-1)# backup priority 110 track-priority 20
Router1(config-if-e10000-1/6-vrid-1)# track-port ethernet 2/4
Router1(config-if-e10000-1/6-vrid-1)# ipv6-address 1414:1414:1414::45
Router1(config-if-e10000-1/6-vrid-1)# activate
VRRP router 1 for this interface is activating
Router1(config-if-e10000-1/6-vrid-1)# exit
Router1(config)# interface ethernet 1/6
Router1(config-if-e10000-1/6)# ipv6 vrrp-extended vrid 2
Router1(config-if-e10000-1/6-vrid-1)# backup priority 100 track-priority 20
```

```
Router1(config-if-e10000-1/6-vrid-1)# track-port ethernet 2/4
Router1(config-if-e10000-1/6-vrid-1)# ipv6-address 1414:1414:1414::44
Router1(config-if-e10000-1/6-vrid-1)# activate
VRRP router 2 for this interface is activating
```

NOTE
The address you enter with the **ipv6-address** command cannot be the same as a real IP address configured on the interface.

Configuring router2

To configure Router2, enter the following commands.

```
Router2(config)# ipv6 router vrrp-extended
Router2(config)# interface ethernet 5/1
Router2(config-if-e10000-5/1)# ipv6 address 1414:1414:1414::4/64
Router2(config-if-e10000-5/1)# ipv6 vrrp-extended vrid 1
Router2(config-if-e10000-5/1-vrid-1)# backup priority 100 track-priority 20
Router2(config-if-e10000-5/1-vrid-1)# track-port ethernet 3/2
Router2(config-if-e10000-5/1-vrid-1)# ipv6-address 1414:1414:1414::45
Router2(config-if-e10000-5/1-vrid-1)# activate
Router2(config-if-e10000-5/1-vrid-1)# exit
Router2(config)# interface ethernet 5/1
Router2(config-if-e10000-5/1)# ipv6 vrrp-extended vrid 2
Router2(config-if-e10000-5/1-vrid-1)# backup priority 110 track-priority 20
Router2(config-if-e10000-5/1-vrid-1)# track-port ethernet 2/4
Router2(config-if-e10000-5/1-vrid-1)# ipv6-address 1414:1414:1414::44
Router2(config-if-e10000-5/1-vrid-1)# activate
```

The **backup** command specifies that this router is a VRRP-E Backup for virtual router VRID1. The IP address entered with the **ipv6-address** VRRP-E command is the same IP address as the one entered when configuring Router1. In this case, the IP address cannot also exist on Router2, but the interface on which you are configuring the virtual router Backup must have an IP address in the same subnet. By entering the same IP address as the one associated with this virtual router on the Owner, you are configuring the Backup to back up the address, but you are not duplicating the address.

NOTE
When you configure a Backup router, the router interface on which you are configuring the virtual router must have a real IP address that is in the same subnet as the address associated with the virtual router by the Owner. However, the address cannot be the same.

The **priority** parameter establishes the router's VRRP-E priority in relation to the other VRRP-E routers in this virtual router. The **track-priority** parameter specifies the new VRRP-E priority that the router receives for this virtual router if the interface goes down.

The **activate** command activates the virtual router configuration on this interface. The interface does not provide backup service for the virtual IP address until you activate the VRRP-E configuration. Alternatively, you can use the **enable** command. The **activate** and **enable** commands do the same thing.

Syntax: [no] ipv6 router vrrp-extended

Syntax: [no] ipv6 vrrp-extended vrid <*vrid*>

Syntax: [no] backup [priority <*value*>**] [track-priority** <*value*>**]**

Syntax: [no] track-port ethernet <*slot*>/<*portnum*> **ve** <*num*>

Syntax: [no] ipv6-address <*ip-addr*>

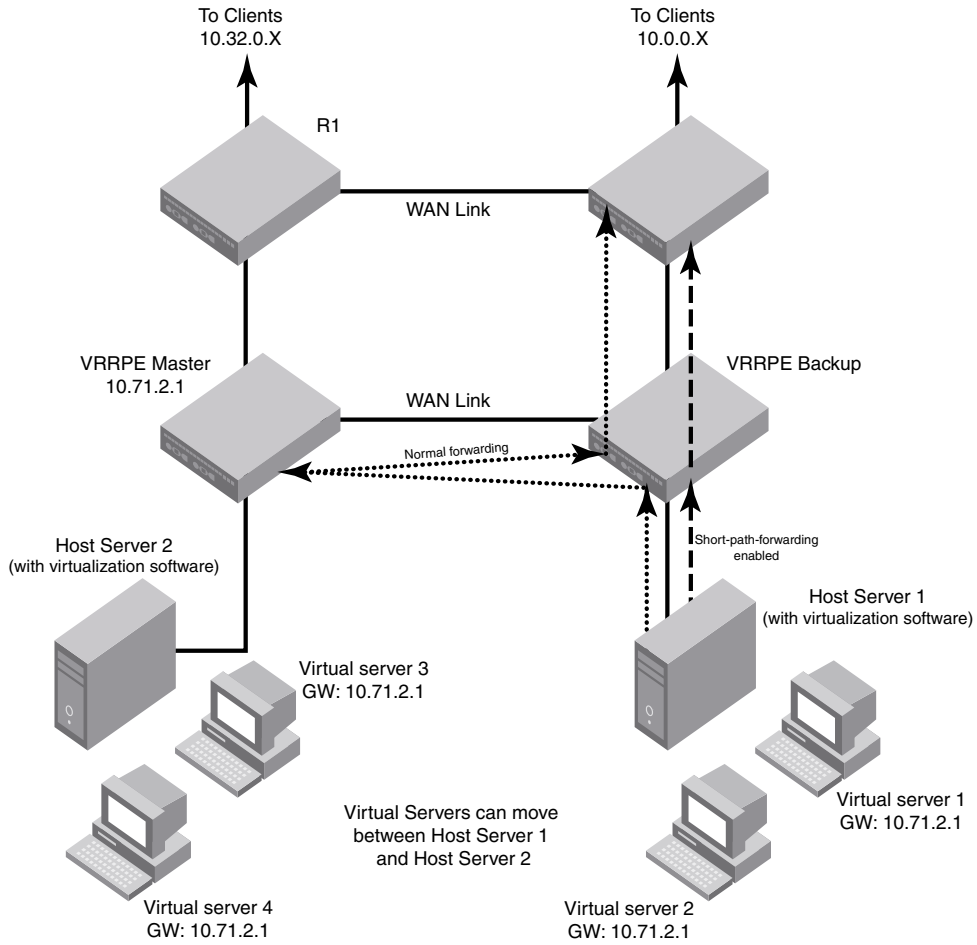
Syntax: [no] activate

VRRP-E Extension for Server Virtualization

VRRP-E is enhanced with the VRRP-E extension for Server Virtualization feature so that the PowerConnect attempts to bypass the VRRP-E master router and directly forward packets to their destination through interfaces on the Backup router.

Figure 108 shows an example of VRRP-E Extension for Server Virtualization. As shown, the virtual servers are dynamically moved between Host Server 1 and Host Server 2. Each time the virtual server is activated, it can be on a different Host Server, and sometimes the traffic crosses the WAN two times before it reaches the client. For example, in the VRRP-E implementation (without VRRP-E Extension for Server Virtualization), traffic from virtual server 1 to the client at 10.0.0.X was switched to the VRRP-E master router, then routed back to VRRP-E Backup router, and then routed to the client (the normal forwarding path, dotted lines).

FIGURE 108 Short path forwarding



VRRP-E Extension for server virtualization configuration example

Under the VRRP-E VRID configuration level, there is an option to enable short-path-forwarding.

To enable **short-path-forwarding,** enter the following commands.

```
NetIron(config)# router vrrp-extended
NetIron(config)# interface ve 10
NetIron(config-vif-10)# ip address 10.10.10.25/24
NetIron(config-vif-10)# ip vrrp-extended vrid 10
NetIron(config-vif-10-vrid-10)# backup priority 50
NetIron(config-vif-10-vrid-10)# ip-address 10.10.10.254
NetIron(config-vif-10-vrid-10)# short-path-forwarding
NetIron(config-vif-10-vrid-10)# activate
```

Syntax: [no] short-path-forwarding

Packets from the local subnet of the virtual IP address

If VRRP-E Extension for Server Virtualization is enabled, any packets coming from the local subnet of the virtual IP address will be routed to the VRRP-E master router. This is for the routes whose next-hop gateway is the master router at the Backup router. These routes are routed to the WAN instead of switching them to the master router. The new behavior includes all the packets sent to the virtual IP address that were intended for the master router, such as Telnet, ping and traceroute packets. With VRRP-E Extension for Server Virtualization enabled these packets are now routed instead of switched. Traceroute output will show one extra hop for the source IP subnet that displays the Backup router interface IP address.

The following is an example of the traceroute command output with VRRP-E Extension for Server Virtualization enabled.

```
C:\ >traceroute 10.10.10.254
Tracing route to 10.10.10.254 over a maximum of 30 hops
1    <1 ms    <1 ms    <1 ms  10.10.10.25
 2    <1 ms    <1 ms    <1 ms  10.10.10.254
Trace complete.
```

The following is an example of the traceroute command output without VRRP-E Extension for Server Virtualization enabled:

```
C:\ >traceroute 10.10.10.254
Tracing route to 10.10.10.254 over a maximum of 30 hops
1     8 ms     8 ms     8 ms  10.10.10.254
Trace complete.
```

IPv4 VRF support

VRRP-E Extension for Server Virtualization supports IPv4 VRF forwarding.

Configuration considerations

Since the VRRP-E Extension for Server Virtualization enabled port will route all the traffic sent to the VRRP-E MAC, ACL and PBR features configured on the port will be applied to this traffic.

VRRP-E Extension for Server Virtualization can be dynamically enabled or disabled before or after VRRP-E is activated. No system reload is required.

Although it is not required, it is recommended that interfaces on different routers with the same VRID have the same short-path-forwarding configuration. This will ensure that the short-path forwarding behavior is still retained after the failover. Different VRIDs can be configured differently.

Chapter

Multi-Chassis Trunking (MCT) 18

The Multi-Chassis Trunking (MCT) features are supported by the NetIron MLX Series devices.

- Multi-Chassis Trunking (MCT)
- Cluster operation features
- Multi-Chassis Trunk (MCT) for VRRP or VRRP-E

About Multi-Chassis Trunk (MCT)

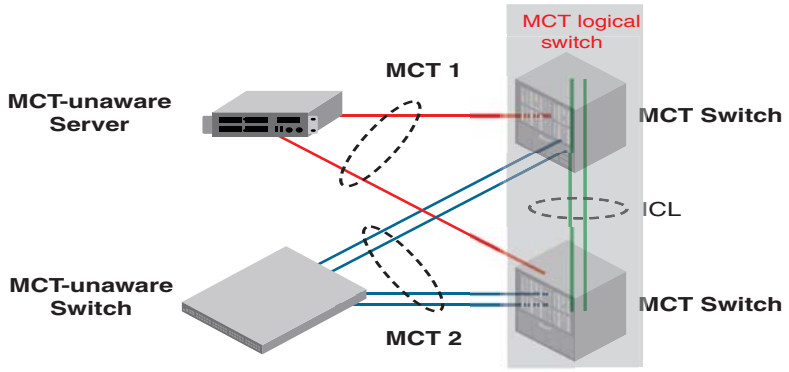
A Multi-Chassis Trunk (MCT) is a trunk that initiates at a single MCT-unaware server or switch and terminates at two MCT-aware switches.

Link Aggregation (LAG) trunks provide link level redundancy and increased capacity. However, LAG trunks do not provide switch level redundancy. If the switch to which the LAG trunk is attached fails, the entire LAG trunk loses network connectivity. With MCT, member links of the LAG are connected to two chassis. The MCT switches may be directly connected using an Inter-Chassis Link (ICL) to enable data flow and control messages between them.In this model, if one MCT switch fails, a data path will remain through the other switch.

In a MCT scenario, all links are active and can be load shared to increase bandwidth. In addition, traffic restoration can be achieved in milliseconds after an MCT link failure or MCT switch failure.

MCT is designed to increase network resilience and performance.

FIGURE 109 Chassis trunk example



Benefits to Multi-Chassis Trunking (MCT)

MCT provides the following benefits:

- Provides link level and switch level redundancy.
- Provides increased capacity because it utilizes all links (including redundant ones) for traffic transport. This contrasts with the use of the Spanning Tree Protocol, which does not use redundant links for transporting traffic.
- Provides traffic restoration in tens of milliseconds in case of link or switch failures.
- Allows servers and switches to have redundant connections to two switches and to fully utilize all links (including redundant ones) for traffic transport.
- Allows servers and switches to use standard link aggregation (802.3ad) to connect to redundant switches.
- MCT is easily deployed while enhancing existing multilayer switching without fundamentally changing the architecture.

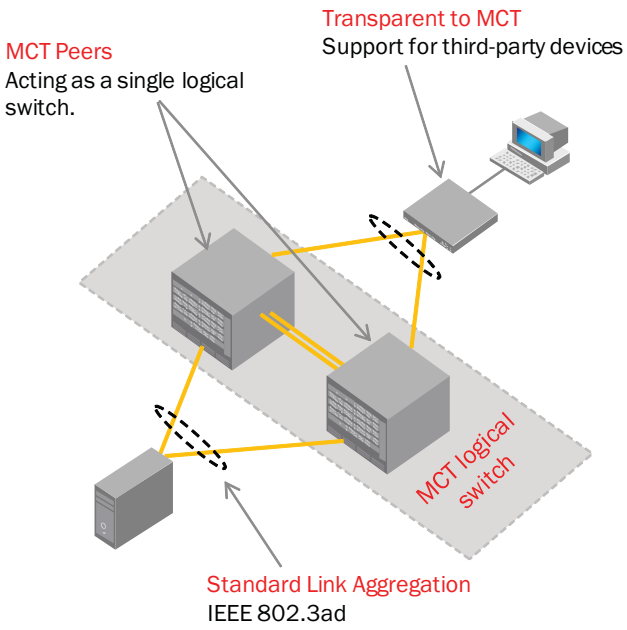
How Multi-Chassis Trunking works

The MCT is made up of the following:

- Sub-second failover in the event of a link, module, switch fabric, control plane, or node failure
- Layer 2 and Layer 3 forwarding (when using fast path forwarding) at the first hop regardless of VRRP-E state.
- Flow based load balancing rather than VLANs sharing across network links
- Ability to provide the resiliency regardless of the traffic type layer 3, layer 2 or non-IP (legacy protocols).
- Interaction with MRP to build larger resilient Layer 2 domains
- Enhancement to Link Aggregation Groups
- Provides nodal redundancy in addition to link and modular redundancy

- Operates at the physical level to provide sub-second failover

FIGURE 110 How Multi-Chassis Trunking works



MCT terminology

- ICL – Inter Chassis Link
- CCP – Cluster Communication Protocol
- CCEP – Cluster Client Edge Port
- CEP – Cluster Edge Port
- MCT VLANs - VLANs on which MCT clients are operating. These VLANs are explicitly configured in the MCT configuration by the user.
- RBridge ID – RBridge ID is a value assigned to MCT nodes and clients to uniquely identify them, and helps in associating Source MAC with a MCT node
- MDUP – MAC Database Update Protocol
- CL – Cluster Local MACs
- CCL – Cluster Client Local MACs
- CR – Cluster Remote MACs
- CCR – Cluster Client Remote MACs
- CCRR– Cluster Client RBridge Reachability
- MDB – Mac Data Base. The MDB can have multiple MAC entries for the same address
- FDB – Forwarding MAC Database. The FDM will have the best MAC only installed

Dynamic LAGs

MCT Client creates a single dynamic LAG towards the MCT nodes. For MCT nodes the dynamic Lag consists of two LAGs, each is configured on one of the MCT devices. A dynamic LAG runs Link Aggregation Control Protocol (LACP).

For the two dynamic LAGs of the MCT to behave as a single LAG from the MCT client's perspective, both of the dynamic LAGs should have the same LACP system ID and key, referred to as the MCT system ID and MCT key.

The MCT system ID and MCT key is uniquely defined for one MCT. They have the following attributes:

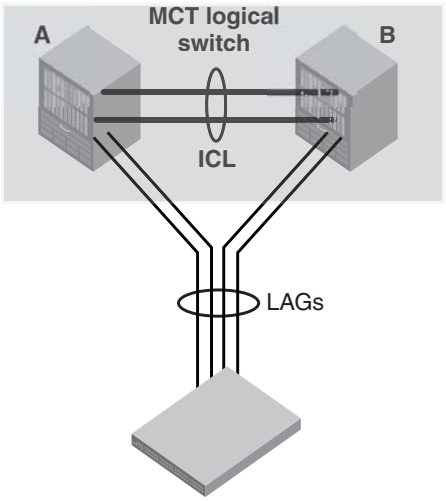
- MCT base system id = This is the system base MAC address (This is different for each system and is shown in the **show module** command output. The MAC displayed will be the first MAC address in the system).
- MCT system id = MCT base system id + cluster id
- MCT base key = 30000
- MCT key = MCT base key + client bridge id
- Each LAG link connects to one MCT node only

NOTE
Each MCT node has a unique cluster ID, and one MCT client ID.

MCT peers

Each MCT physical node, A and B, will act as an MCT peer and they are connected using an ICL. The pair of MCT peers will act as one logical switch for the access switch or server so that the MCT pair can connect using standard LAG to them. This is illustrated in Figure 111.

FIGURE 111 MCT peers



ICL traffic handling

An ICL link on the Dell device can be a single port or a static or LACP LAG. Non-MCT VLANs can co-exist with MCT VLANs on the ICL only on the NetIron MLX. For MCT VLANs, MAC learning is disabled on ICL ports.

L2 protocol packet handling

The default behavior is to forward or flood STP and RSTP BPDU packets.

If the **no cluster-l2protocol-forward** command is configured on global basis or **cluster-l2protocol-forward** disable is configured on a port, the STP protocol packets coming on the MCT VLANs are dropped.

All other L2 protocol packets will be flooded on the MCT VLANs or dropped. The **cluster-l2protocol-forward** command is not applicable to these protocol packets. It only applies to STP or RSTP BPDU packets.

Forwarding broadcast, multicast and unknown unicast traffic

Traffic received from non-ICL ports is forwarded the same way as non-MCT devices.Traffic received from an ICL port is not forwarded to the CCEP port if the peer MCT switch has the reachability to the same cluster client.

NOTE
When there is a double failure, the forwarding behavior will be unpredictable and there may be a complete traffic loss. For example, when both the ICL cluster link and any one leg of the client CCEP link fail. From the physical topology perspective, it may appear like a path is available, while traffic may not be forwarded.

Syncing interface MACs to peer MCT devices

The MCT device uses an interface MAC to identify the packets that are addressed to the switch. Such packets may be received by a peer MCT device. The peer MCT device switches packets over the ICL to the local MCT switch to be routed properly.

MCT L2 protocols

When configuring L2 protocols, you should consider the following.

MRP

- An ICL interface can not be configured as MRP secondary interface and vice-versa as the ICL cannot be BLOCKING.
- MRP can not be enabled on MCT CCEP port and vice-versa.

G.8032

- If the port is an ERP interface, it can not be enabled as a CCEP port.
- If the interface is ICL interface it can not be configured with MS, FS or RPL.
- G.8032 and MCT are not supported together.

STP

- The STP algorithm has been modified such that ICL never goes to blocking. ICL guard mechanism ensures that if ICL is going in blocking state then the port on which the superior BPDUs are being received is moved to BLOCKING state and ICL guard timer starts running on it. This timer runs as long as Superior BPDUs are received on this interface. As long as this timer runs on an interface the Superior BPDUs are dropped.
- The modified STP algorithm also ensures that the CCEP interface state on both the MCT peers is same.
- The CCEP STP state information between MCT peers is synchronized using messages that are sent over CCP.
- Only one of the MCT peers send BPDUs towards the MCT Client. It is decided by whosoever is the designated bridge on the ICL.
- New STP States:
  - BLK_BY_ICL state indicates that the superior BPDUs were being received on this interface which could have led to BLOCKING of ICL interface, due to which ICL port guard mechanism has been triggered on this port.
  - FWD_BY_MCT state indicates that the MCT peer has set the CCEP state to forwarding.
  - BLK_BY_MCT state indicates that the MCT peer has set the CCEP state to blocking.

MCT feature interaction

Use the following feature matrix when configuring MCT:

TABLE 102 MCT feature interaction matrix

Supported	Not Supported
LACP on both ICL and CCEP.	**MSTP, VSRP, RIP, OSPF, IS-IS, and BGP**
VRRP on the CCEP.	**ESI VLANs** on CCEP or ICL ports.
MRP and MRP II supported with the restriction that ICL port cannot be the secondary port of the MRP ring.	**802.1ad** on CCEP or ICL ports.
	GRE is not supported on the ICL ve interfaces
Flooding features (VLAN CPU protection, multicast flooding etc.) on cluster VLANs.	**DAI** on the CCEP ports.
UDLD as independent boxes.	**802.1ah** on CCEP or ICL ports.
Link OAM as independent boxes.	**VPLS** on CCEP or ICL ports.
802.1ag as independent boxes.	**VLL** on CCEP or ICL ports.
ARP as independent boxes.	**MPLS** on CCE or ICL ports.
STP and RSTP	**MSTP**

TABLE 102 MCT feature interaction matrix

Supported	Not Supported
L3 Routing - The IP address assignment is OK on CCEP ports for VRRP purpose. However, routing protocols would not be enabled on CCEP ports.	**Hitless Fail over** is NOT supported on the NetIron MLX, however it is compatible. If the operation is performed with cluster configuration the TCP session is reestablished. The MACs from the cluster peers will be revalidated and programmed accordingly. Dell recommends shutting down all the CCEP ports on the cluster node so that there is graceful failover and then hitless operation can be performed.
Port MAC Security on the node where it is programmed.	**Hitless Upgrade** is NOT supported, on the NetIron MLX, however it is compatible. If the operation is performed with cluster configuration the TCP session is reestablished. The MACs from the cluster peers will be revalidated and programmed accordingly. Dell recommends shutting down all the CCEP ports on the cluster node so that there is graceful failover and then hitless operation can be performed.
802.1x on the node where it is programmed.	**Multi-port MAC** are not supported on ICL or CCEP ports. Configuration will be rejected when trying to configure multi-port MAC addresses with a port mask which contains either a CCEP port or ICL port and vice-versa on the NetIron MLX.
Static MAC configuration - Static MACs are programmed on both local and remote peers as static entries.	

Configuration considerations

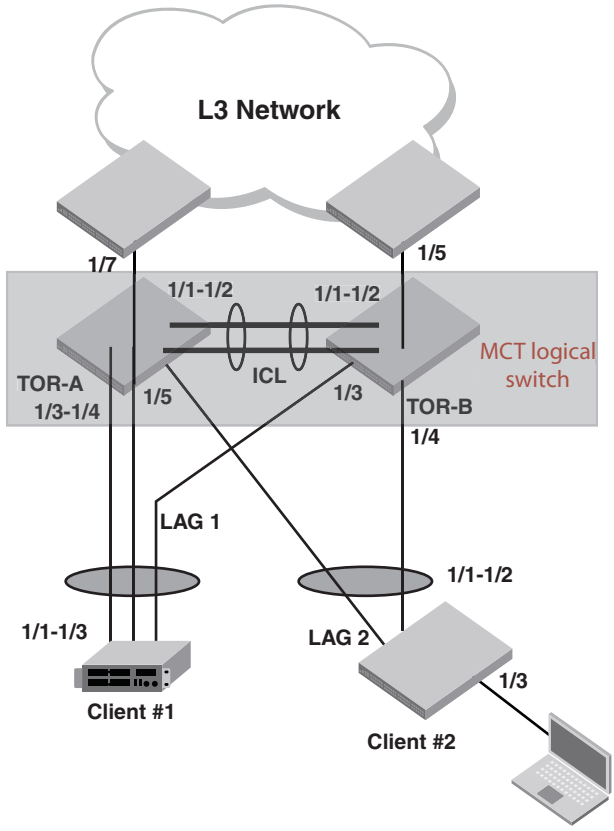
- ICL ports should be not be an untagged member of any VLAN. An ICL is preferably a LAG that provides port level redundancy and higher bandwidth for cluster communication.
- On the NetIron MLXe, ICL ports can be part of MCT VLANs as well as regular VLANs.
- MAC Database Update Protocol (MUDP) will synchronize all MAC entries for VLANs served by ICL link
- On Customer Client Edge Ports (CCEP), MCT does not support the following features: MPLS, VLL, VPLS, 802.1ah, 802.1ad and Routing protocols.
- Cluster ID should be same on both cluster switches
- Cluster rbridge ID should not conflict with any client rbridge id or the peer rbridge id
- Client rbridge ID is unique and it should be same on the cluster switches
- You can add to any ports to the session VLAN (For the purpose of adding a port to a LAG), but Dell recommends keeping only ICL ports during operation.
- An ICL interface cannot be configured as the CCEP port in any client
- CCEP ports cannot be configured as the ICL interface.
- CCEP ports on MCT node can be single port or LAG
- If ICL or client interfaces need to be configured as LAG interface then only the primary port of the LAG needs to be specified in the ICL or client configuration.
- Once the cluster is deployed, only the cluster member VLANs and client isolation mode can be modified. Other configurations are not allowed to change.

- Once the client is deployed, any configuration under client is not allowed to change.
- Clients can be added or deleted even if the cluster is deployed.
- When the cluster is undeployed all the clients in the cluster becomes inactive.
- As soon as a port is configured as an ICL port it is removed from default VLAN.
- If an ICL or CCEP is a LAG interface, the LAG has to be configured separately on each node.

Configuring MCT

Single level MCT example

FIGURE 112 Single level MCT



The following steps are task for configuring a MCT scenario as shown in Figure 112 on page 600.

NOTE
Save the current configuration files for both chassis operating in standalone mode before you begin creating a MCT.

TOR-A (Top of rack MCT capable switch)
See Figure 112 on page 600

Creating LAG-1

1. You can either assign a LAG **ID** explicitly or it will be automatically generated by the system. The LAG **ID** stays the same across system reload and hitless upgrade.

   The command to configure LAGs allows explicit configuration of the LAG ID for static and dynamic LAGs.

   To create a LAG with the LAG ID option, enter a command such as the following.

   ```
   NetIron(config)# lag 1 dynamic
   NetIron(config-lag-1)#
   ```

   Syntax: [no] lag <*name*> **[static | dynamic] [id** <*number*>**]**

   The **ID** parameter is optional. The value of the **ID** parameter that you can enter is from 1 to 256. If you do not enter a LAG **ID**, the system will generate one automatically. Once the LAG **ID** is generated the system will save it in the configuration file along with the LAG name, therefore the value will stay the same across system reload.

   NOTE
   The LAG id parameter is for static and dynamic LAGs only. No explicit configuration of a LAG id is allowed on keepalive LAGs.

   The **static** parameter specifies that the LAG with the name specified by the <*lag-name*> variable will be configured as a static LAG.

   The **dynamic** option specifies that the LAG with the name specified by the <*lag-name*> variable will be configured as a dynamic LAG.

2. Define the ports the LAG will be using as shown in the following.

   ```
   NetIron(config-lag-1)# ports ethernet 1/1 to 1/2
   ```

   Syntax: [no] ports ethernet [slot/port] | to |[slot/port]

   Use the appropriate **[slot/port]** variable to specify a Ethernet port within the LAG that you want to enable.

3. The primary port must be explicitly assigned using the **primary-port** command. To designate the primary port for the static LAG “1”, use the following command.

   ```
   NetIron(config-lag-1)# primary-port 1/1
   ```

   Syntax: [no] primary-port<*slot/port*>

   Once a primary port has been configured for a LAG, all configurations that apply to the primary port are applied to the other ports in the LAG.

   NOTE
   This configuration is only applicable for configuration of a static or dynamic LAGs

4. After configuring a LAG, you must explicitly enable it before it begins aggregating traffic. This task is accomplished by executing the deploy command within the LAG configuration. After the deploy command runs, the LAG is in the aggregating mode. Only the primary port within the LAG is available at the individual interface level. Any configuration performed on the primary port applies to all ports within the LAG. The running configuration will no longer display deployed LAG ports other than the primary port.

To deploy a LAG, at least one port must be in the LAG and the primary port must be specified for non keep-alive LAGs. After a non keep-alive LAG is deployed, a trunk is formed. If there is only one port in the LAG, a single port is formed. For a dynamic LAG, LACP is stared for each LAG port.

Use a command such as the following to deploy LAG 1

```
NetIron(config-lag-1)# deploy
```

Syntax: [no] deploy [forced | passive]

When the **deploy** command is executed:

- For a static and dynamic LAGs, the current veto mechanism is invoked to make sure the LAG can be formed. If the LAG is not vetoed, a **no** is formed with all the ports in the LAG.
- For dynamic LAGs, LACP is activated on all LAG ports. When activating LACP, use active mode if passive is not specified; otherwise, use passive mode.
- For a keep-alive LAGs, a LAG is formed, and LACP is started on the LAG port.

Once the deploy command is issued, all LAG ports will behave like a single port.

If the **no** deploy command is executed, then the LAG is removed. For dynamic LAGs, LACP is de-activated on all of the LAG ports.

If the **no deploy** command is issued and more than 1 LAG port is not disabled the command is aborted and the following error message is displayed: “Error 2 or more ports in the LAG are not disabled, un-deploy this LAG may form a loop - aborted.” Using the **forced** keyword with the **no deploy** command in the previous situation, the un-deployment of the LAG is executed.

5. Assign a name to an individual port within a LAG using the **port-name** command within the LAG configuration as shown in the following.

```
NetIron(config-lag-1)# port-name ICL-to-TOR-B:1/1 ethernet 1/1
NetIron(config-lag-1)# port-name ICL-to-TOR-B:1/2 ethernet 1/2
```

Syntax: [no] port-name <*text*> **ethernet [slot/port] | pos [slot/port]**

The <*text*> variable specifies the port name. The name can be up to 50 characters long.

Use the **ethernet** option with the appropriate **[slot/port]** variable to apply the specified name to an Ethernet port within the LAG.

Use the **pos** option with the appropriate **[slot/port]** variable to apply the specified name to a Packet-over-SONET port within the LAG.

Creating LAG 2

See Figure 112 on page 600 and “Creating LAG-1” on page 601 for additional information on creating a LAG.

1. Create LAG 2 as shown below.

```
NetIron(config)# lag 2 dynamic id 2
NetIron(config-lag-2)#
```

2. Define the ports the LAG will be using.

```
NetIron(config-lag-2)# ports ethernet 1/3  to 1/4
```

3. Deploy the LAG 2 as shown below.

```
NetIron(config-lag-2)# deploy
```

4. Assign a name to an individual port within a LAG.

```
NetIron(config-lag-2)# port-name lag-client-1:1/1 ethernet 1/3
NetIron(config-lag-2)# port-name lag-client-1:1/2 ethernet 1/4
```

Creating LAG 3

See Figure 112 on page 600 and "Creating LAG-1" on page 601 for additional information on creating a LAG.

1. Create LAG 3 as shown below.

```
NetIron(config)# lag 3 dynamic id 3
NetIron(config-lag-3)#
```

2. Define the ports the LAG will be using.

```
NetIron(config-lag-3)# ports ethernet 1/5
```

3. The primary port must be explicitly assigned using the **primary-port** command.

```
NetIron(config-lag-3)# primary-port 1/5
```

4. Deploy the LAG 3 as shown below.

```
NetIron(config-lag-3)# deploy
```

5. Assign a name to an individual port within a LAG.

```
NetIron(config-lag-2)# port-name lag-client-2:1/1 ethernet 1/5
NetIron(config-lag-2)# port-name lag-client-1:1/2 ethernet 1/4
```

Enable layer 2 switching

1. By default, PowerConnect devices supports routing over layer 2 switching. You can enable layer 2 switching globally or on individual port using the **no route-only** command. The **no route-only** and **route-only** commands prompts you for whether or not you want to change the "route-only" behavior. You must enter **y** if you want to proceed or **n** if you do not. To enable Layer 2 switching only on a specific interface, go to the interface configuration level for that interface, and add the **no route-only** command.

   Use commands such as the following to enable Layer 2 switching.

```
NetIron(config)# no route-only
```

   Syntax: [no] route-only

Creating MCT VLANs

See Figure 112 on page 600 and "MCT VLAN1" on page 603 for additional information on creating VLANs.

MCT VLAN1

1. At the global CONFIG level assign an ID to the VLAN.

```
NetIron(config)# vlan 2
```

2. Add ports to the VLAN and specify if the ports are tagged or untagged.

```
NetIron(config-vlan-2)# tagged e 1/1 to 1/8
NetIron(config-vlan-2)# no untag ether 1/1 to 1/2
```

VLAN 2

See Figure 112 on page 600 and "MCT VLAN1" on page 603 for additional information on creating VLANs.

1. Configure the VLAN name for VLAN 2.

```
NetIron(config)# vlan 2 name client-vlan
```

2. Add ports to the VLAN and specify if the ports are tagged or untagged.

```
NetIron(config-vlan-2)# untag ether 1/3 to 1/7
NetIron(config-vlan-2)# tagged ether 1/1 to 1/2
```

Create the session VLAN

See Figure 112 on page 600 and "MCT VLAN1" on page 603 for additional information on creating VLANs.

1. At the global CONFIG level assign an ID to the VLAN .

```
NetIron(config)# vlan 4090 name Session-VLAN
```

2. Add ports to the VLAN and specify if the ports are tagged or untagged.

```
NetIron(config-vlan-4090)# tagged ether 1/1 to 1/2
```

3. Configure a virtual routing interface on each IP protocol VLAN, then configure the appropriate IP routing parameters on each of the virtual routing interfaces.

```
NetIronNetIron(config-vlan-4090)# tagged ether 1/1 to 1/2
NetIron(config-vlan-4090)# router-interface ve 100
```

Assign the hostname

To configure a system name, enter commands such as the following.

```
NetIron(config)# hostname TOR-A
```

Enabling interfaces

The port can be made inactive (disable) or active (enable) by selecting the appropriate status option. The default value for a port is disabled. To enable the ports on a device for ethernet interfaces 1/1, 1/3, and 1/5, enter the following commands.

```
NetIron(config)# interface ether 1/1
NetIron(config-if-e10000-1/1)# enable

NetIron(config)# interface ether 1/3
NetIron(config-if-e10000-1/3)# enable

NetIron(config)# interface ether 1/5
NetIron(config-if-e10000-1/5)# enable
```

Syntax: [no] enable

Assigning a port name

A port name can be assigned to help identify interfaces on the network. You can assign a port name to physical ports, virtual routing interfaces, and loopback interfaces. To assign a name to a ports 1/6 and 1/7, enter the following commands.

```
NetIron(config)# interface ethe 1/6
NetIron(config-if-e10000-1/6)# port-name CEP-PC
NetIron(config-if-e10000-1/6)# enable
```

```
NetIron(config)# interface ethe 1/7
NetIron(config-if-e10000-1/7)# port-name to-L3-ECMP
NetIron(config-if-e10000-1/7)# enable
```

Syntax: [no] port-name <text>

Syntax: [no] enable

The <text> parameter is an alphanumeric string. The name can have up to 255 characters on a device and can include blanks. You do not need to use quotation marks around the string, even when it contains blanks.

Adding a virtual interface

Add a virtual interface and configure an IP address on the interface by entering commands such as the following.

```
NetIron(config)# interface ve 100
NetIron(config-vif-100)# ip address 1.1.1.1/24
```

Syntax: [no] interface [ve <*ve-id*>]

Syntax: [no] ip address <*ip-addr*> <*ip-mask*>

The <*ve-id*> variable allows you to specify a VE interface ID.

Configuring the cluster operation mode

See Figure 112 on page 600

1. To configure a device with cluster id 1, enter a command such as the following.

   ```
   NetIron(config)# cluster TOR 1
   ```

   Syntax: [**no**] **cluster** <cluster-name> <cluster-id>

   The <cluster-name> parameters specify the cluster name with a limit of 64 characters.

   The <cluster-id> parameters specify the cluster ID (1-65535).

2. Configure the local rbridge id for the cluster. This rbridge id is used by the peer to communicate with this cluster node. To configure the local rbridge, enter a command such as following

   ```
   NetIron(config-cluster-TOR)#rbridge-id 1
   ```

   Syntax: [no] rbridge-id <id>

   The <id> parameters specify the remote bridge id. Possible values are 1 - 35535 (16 bit value).

3. The cluster session VLAN can be in the range 1-4090, but cannot be default VLAN. A check is made during the cluster deploy in addition to a dynamic check. The default VLAN cannot be changed to a VLAN which is already defined as cluster session. Enter a command such as the following to create the session VLAN.

   ```
   NetIron(config-cluster-TOR)# session-vlan 4090
   ```

   Syntax: [no] session-vlan <vlan-id>

   The <vlan-id> parameters specify the VLAN range. Possible values are 1 - 4090.

4. Specify the VLAN range on which cluster is operating. This would be the range for which there would be MAC synchronization. Multiple VLAN ranges would be supported for the configuration. Enter a command such as the following to create the member VLAN.

```
NetIron(config-cluster-TOR)# member-vlan 2
```

Syntax: [no] member-vlan <x> [to <y>]

NOTE
The VLAN range is allowed to change even if cluster is deployed.

5. Specify the ICL for the cluster.The ICL interface can be a single link or trunk port. If it is a trunk port, it should be the primary port of the trunk . Only one ICL is supported. Enter a command such as the following to create the ICL for the cluster.

```
NetIron(config-cluster-TOR)#icl TOR ethernet 1/1
```

Syntax: [no] icl <icl-name> **ethernet** x/y

The <icl-name> parameter can be up to 64 characters in length.

The **ethernet** x/y parameter is the ICL interface.

6. Specify the rbridge and ICL for the peers by entering a command such as the following.

```
NetIron(config-cluster-TOR)# peer 1.1.1.2 rbridge-id 2 icl TOR
```

Syntax: [no] peer <peer-ip> **rbridge-id** <peer-rbridge> **icl** <map-icl>

The< peer-ip >parameter should be in same subnet as that of cluster management interface.

The <peer-rbridge> parameter should be different from cluster rbridge and any other client in the cluster

The <map-icl> parameter is the ICL name to reach this cluster peer.

7. The cluster can be deployed separately without any clients configured. The **deploy** command brings the cluster into effect. The following can be changed when the cluster is deployed:
   - Client isolation mode
   - Member VLANs
   - Clients added and removed.
8. The **deploy** command also preforms a consistency check of the entire cluster configuration. If anything is amiss, an error message is sent.The following specific information is checked during deployment:
   - If the cluster management VLAN is configured
   - If the cluster peer is configured
   - If the cluster ICL is configured

   Enter a command such as the following to deploy the cluster configuration.

```
NetIron(config-cluster-TOR)# deploy
```

Syntax: [no] deploy

Creating cluster client 1

See Figure 112 on page 600

1. Create a cluster client instance and change the mode to the client instance. If an instance is already present, then directly change the mode to the client instance mode.

```
NetIron(config-cluster-TOR)# client client-1
```

Syntax: [no] client <client-name>

The <client-name> parameter can be 64 characters (maximum).

2. Configure the local RBridge IDfor the cluster. This RBridge ID is used by the peer to communicate with this cluster node. To configure the local rbridge, enter a command such as following

```
NetIron(config-cluster-TOR-client-1)#rbridge-id 100
```

Syntax: [no] rbridge-id <id>

The <id> parameters specify the local bridge id. Possible values are 1 - 35535 (16 bit value).

3. The cluster session VLAN is the VLAN used by the cluster for control operations. CCP protocol runs over this VLAN. The interface can be a single link or LAG port. If it is LAG port, it should be the primary port of the LAG.

```
NetIron(config-cluster-TOR-client-1)#client-interface ether 1/3
```

Syntax: [no] client-interface <interface> interface : ethernet x/y

The **ethernet** x/y parameter is the ethernet interface.

4. Deploy the cluster client. If cluster is not deployed, the configuration will be taken but the client state machine will not be started. The consistency checks for client will be done at the time of client deploy. The following configuration checks will be preformed:

- Client interface is configured
- Client interface is not same as any other client interface or ICL interface
- Client RBridge ID is not same as cluster rbridge or any peer rbridge

Once the client is deployed, the configuration inside the client will not be allowed to change, To deploy the client configuration, enter a command such as the following.

```
NetIron(config-cluster-TOR-client-1)deploy
```

Syntax: [no] deploy

Create cluster client 2

See Figure 112 on page 600 and "Create cluster client 1" on page 613 for additional information for creating cluster clients.

1. Create a cluster client instance.

```
NetIron(config-cluster-TOR)# client client-2
```

2. Configure the client RBridge ID.

```
NetIron(config-cluster-TOR-client-2)#rbridge-id 200
```

3. Create a cluster client interface.

```
NetIron(config-cluster-TOR-client-2)#client-interface ether 1/5
```

4. Deploy the cluster client.

```
NetIron(config-cluster-TOR-client-2)deploy
```

TOR-B

Creating LAG-1

See Figure 112 on page 600 and "Creating LAG-1" on page 601 for additional information on creating a LAG.

1. Create a LAG with the LAG ID option.

```
NetIron(config)# lag 1 dynamic id 1
NetIron(config-lag-1)#
```

2. Define the port the LAG will be using.

```
NetIron(config-lag-1)# ports ethernet 1/6
```

3. The primary port must be explicitly assigned using the **primary-port** command.

```
NetIron(config-lag-1)# primary-port 1/1
```

4. Deploy a LAG as shown below.

```
NetIron(config-lag-1)# deploy
```

Assign a name to an individual port within a LAG.

```
NetIron(config-lag-1)# port-name lag-client-2:1/2 ethernet 1/6
```

Creating LAG 2

See Figure 112 on page 600 and "Creating LAG-1" on page 601 for additional information on creating a LAG.

1. Create a LAG as shown below.

```
NetIron(config)# lag 2 dynamic id 2
NetIron(config-lag-2)#
```

2. Define the port the LAG will be using.

```
NetIron(config-lag-2)# ports ethernet 1/7
```

3. The primary port must be explicitly assigned using the **primary-port** command.

```
NetIron(config-lag-2)# primary-port 1/7
```

4. Deploy a LAG as shown below.

```
NetIron(config-lag-2)# deploy
```

5. Assign a name to an individual port within a LAG.

```
NetIron(config-lag-2)# port-name lag-client-3:1/2 ethernet 1/7
```

Creating LAG 3

See Figure 112 on page 600 and "Creating LAG-1" on page 601 for additional information on creating a LAG.

1. Create a LAG as shown below.

```
NetIron(config)# lag 3 dynamic id 3
NetIron(config-lag-3)#
```

2. Define the port the LAG will be using.

```
NetIron(config-lag-3)# ports ethernet 1/3 to 1/4
```

3. The primary port must be explicitly assigned using the **primary-port** command.

```
NetIron(config-lag-3)# primary-port 1/3
```

4. Deploy a LAG as shown below.

```
NetIron(config-lag-3)# deploy
```

5. Assign a name to an individual port within a LAG.

```
NetIron(config-lag-3)# ICL-to-TOR-A:1/3 ethernet 1/3
NetIron(config-lag-3)# ICL-to-TOR-A:1/4 ethernet 1/4
```

Creating LAG 4

See Figure 112 on page 600 and "Creating LAG-1" on page 601 for additional information on creating a LAG.

1. Create a LAG as shown below.

```
NetIron(config)# lag 4 dynamic id 4
NetIron(config-lag-4)#
```

2. Define the port the LAG will be using.

```
NetIron(config-lag-4)# ports ethernet 1/5
```

3. The primary port must be explicitly assigned using the **primary-port** command.

```
NetIron(config-lag-4)# primary-port 1/5
```

4. Deploy a LAG as shown below.

```
NetIron(config-lag-4)# deploy
```

5. Assign a name to an individual port within a LAG.

```
NetIron(config-lag-3)# lag-client-1:1/2 ethernet 1/5
```

Enable layer 2 switching

1. By default, PowerConnect devices supports routing over layer 2 switching. You can enable layer 2 switching globally or on individual port using the **no route-only** command. The **no route-only** and **route-only** commands prompts you for whether or not you want to change the "route-only" behavior. You must enter **y** if you want to proceed or **n** if you do not. To enable Layer 2 switching only on a specific interface, go to the interface configuration level for that interface, and add the **no route-only** command.

   Use the following command to enable Layer 2 switching.

```
NetIron(config)# no route-only
```

   Syntax: [no] route-only

Creating VLANs

See Figure 112 on page 600

VLAN 1

See Figure 112 on page 600 and "Creating LAG-1" on page 601 for additional information on creating a LAG.

1. At the global CONFIG level assign an ID to the VLAN.

```
NetIron(config)# vlan 2
```

2. Add ports to that VLAN and specify if the ports are tagged or untagged.

```
NetIron(config-vlan-2)# tagged e 1/1 to 1/8
NetIron(config-vlan-2)# no untag ether 1/3 to 1/4
```

VLAN 2

See Figure 112 on page 600 and "Creating LAG-1" on page 601 for additional information on creating a LAG.

1. At the global CONFIG level assign an ID to the VLAN 2.

```
NetIron(config)# vlan 2 client-vlan
```

2. Add ports to that VLAN and specify if the ports are tagged or untagged.

```
NetIron(config-vlan-2)# untag ether 1/5 to 1/7
NetIron(config-vlan-2)# tagged ether 1/3 to 1/4
```

Create the session VLAN

See Figure 112 on page 600 and "Creating LAG-1" on page 601 for additional information on creating a LAG.

1. At the global CONFIG level assign an ID to the VLAN 4090.

```
NetIron(config)# vlan 4090 name Session-VLAN
```

Syntax: [no] vlan <*vlan-id*>name <*vlan-name*>

VLAN IDs can be in the range of 1 – 4090. Use the **no** form of the command to delete the VLAN from the configuration.

The VLAN ID range above 4090 has been reserved for current and future features for internal control purposes.

In addition to a VLAN number, you can assign a name to a VLAN by entering name <*vlan-name*>. Enter up to 32 characters for name.

2. Add ports to the VLAN and specify if the ports are tagged or untagged.

```
NetIron(config-vlan-4090)# tagged ether 1/3 to 1/4
```

3. Configure the appropriate IP routing parameters on each of the virtual routing interfaces.

```
NetIron(config-vlan-4090)# tagged ether 1/3 to 1/4
NetIron(config-vlan-4090)# router-interface ve 100
```

Assign the hostname

Configure a system name for the device and save the information locally in the configuration file for future reference. The information is not required for system operation but recommended. When you configure a system name, it replaces the default system name in the CLI command prompt.

To configure a system name, enter a command such as the following.

```
NetIron(config)# hostname TOR-B
```

Syntax: [no] hostname <*string*>

The name can be up to 255 alphanumeric characters. The text strings can contain blanks.

Enabling interfaces

The ports can be made inactive (disable) or active (enable) by selecting the appropriate status option. The default value for a port is disabled. To enable the ports on a device for ethernet interfaces 1/3, 1/5, 1/6,and 1/7, enter the following commands.

```
NetIron(config)# interface ether 1/3
NetIron(config-if-e10000-1/3)# enable

NetIron(config)# interface ether 1/5
NetIron(config-if-e10000-1/5)# enable

NetIron(config)# interface ether 1/6
NetIron(config-if-e10000-1/6)# enable

NetIron(config)# interface ether 1/7
NetIron(config-if-e10000-1/7)# enable
```

Syntax: [no] enable

Adding a virtual interface

Add a virtual interface and configure an IP address on the interface by entering commands such as the following.

```
NetIron(config)# interface ve 100
NetIron(config-vif-100)# ip address 1.1.1.2/24
```

Syntax: [no] interface [ve <*ve-id*>]

Syntax: [no] ip address <*ip-addr*> <*ip-mask*>

The <*ve-id*> variable allows you to specify a VE interface ID.

Configuring the cluster operation mode

The cluster can be deployed separately without any client configured. When the cluster is deployed, it will check all the deployed clients and start the state machine for the clients. See Figure 112 on page 600.

1. Configure one cluster ID or name on the device so that all route-reflector clients for the device become members of the cluster. To configure a device with cluster id 1, enter the following command.

   ```
   NetIron(config)# cluster TOR 1
   ```

   Syntax: [**no**] **cluster** <cluster-name> <cluster-id>

   The <cluster-name> parameters specify the cluster name with a limit of 64 characters.

   The <cluster-id> parameters specify the cluster ID (1-65535). The default is the device ID.

2. Configure the remote bridge id cluster on the device so all clients for the device become members of the cluster.

```
NetIron(config-cluster-TOR)#rbridge-id 2
```

Syntax: [no] rbridge-id <id>

The <id> parameters specify the remote bridge id. Possible values are 1 - 35535 (16 bit value).

3. The cluster session VLAN is in range 1-4090 but cannot be default VLAN. A check is made during the cluster deploy and in addition to a dynamic check. The default VLAN cannot be changed to a VLAN which is already defined as cluster session

```
NetIron(config-cluster-TOR)# session-vlan 4090
```

Syntax: [no] session-vlan <vlan-d>

The <vlan-id> parameters specify the VLAN range. Possible values are 1 - 4090.

4. Specify the VLAN range on which cluster is operating. This would be the range for which there would be MAC synchronization. Multiple VLAN ranges would be supported for the configuration. Enter a command such as the following to create the member VLAN.

```
NetIron(config-cluster-TOR)# member-vlan 2
```

Syntax: [no] member-vlan <x> to <y>

NOTE
The VLAN range is allowed to change even if cluster is deployed.

The new VLAN range will over-ride the previous configured range.

5. Specify the ICL for the cluster.The ICL interface can be a single link or trunk port. If it is a trunk port, it should be the primary port of the trunk. Only one ICL is supported.

```
NetIron(config-cluster-TOR)#icl TOR ethernet 1/3
```

Syntax: [no] icl <icl-name> **ethernet** x/y

The <icl-name> parameter can be 64 characters (maximum).

The **ethernet** x/y parameter is the ICL interface.

6. Specify the rbridge and ICL for the peers by entering a command such as the following.

```
NetIron(config-cluster-TOR)# peer 1.1.1.1 rbridge-id 1 icl TOR
```

Syntax: [no] peer <peer-ip> **rbridge-id** <peer-rbridge> **icl** <map-icl>

The< peer-ip >parameter should be in same subnet as that of cluster management interface.

The <peer-rbridge> parameter should be different from cluster rbridge and any other client in the cluster

The <map-icl> parameter is the ICL name to reach this cluster peer.

7. Clusters can be deployed separately without any client configured. The **deploy** command brings the cluster into effect. Once the cluster is deployed, the configuration inside the cluster can not be changed. The **deploy** command also preforms a consistency check of the entire cluster configuration. If anything is amiss, an error message is sent.The specific information checked during deploy:

    - If the cluster management VLAN is configured
    - If the cluster peer is configured
    - If the cluster ICL is configured

Enter a command such as the following to deploy the cluster configuration.

```
NetIron(config-cluster-TOR)# deploy
```

Syntax: [no] deploy

Create cluster client 1

1. Create a cluster client instance and change the mode to the client instance. If an instance is already present, then directly change the mode to client instance mode.

   ```
   NetIron(config-cluster-TOR)# client client-1
   ```

   Syntax: [no] client <client-name>

   The <client-name> parameter can be 64 characters (maximum).

2. Configure the remote bridge id cluster on the device so all clients for the device become members of the cluster.

   ```
   NetIron(config-cluster-TOR-client-1)#rbridge-id 100
   ```

   Syntax: [no] rbridge-id <id>

   The <id> parameters specify the remote bridge id. Possible values are 1 - 35535 (16 bit value).

3. Create a cluster client interface. The interface can be a single link or trunk port. If it is trunk port, it should be the primary port of the trunk.

   ```
   NetIron(config-cluster-TOR-client-1)#client-interface ether 1/5
   ```

   Syntax: [no] client-interface <interface> interface : ethernet x/y

   The **ethernet** x/y parameter is the ethernet interface.

4. Deploy the cluster client. If cluster is not deployed, the configuration will be taken but the client FSM will not be started. The consistency checks for client will be done at the time of client deploy. The following configuration checks will be preformed:

   - Client interface is configured
   - Client interface is not same as any other client interface or ICL interface
   - Client RBridge ID is not same as cluster rbridge or any peer rbridge

   Once the client is deployed, the configuration inside the client will not be allowed to change, To deploy the client configuration, enter a command such as the following.

   ```
   NetIron(config-cluster-TOR-client-1)deploy
   ```

   Syntax: [no] deploy

Create cluster client 2

See Figure 112 on page 600 and "Create cluster client 1" on page 613 for additional information on creating cluster clients.

1. Create a cluster client instance and change the mode to the client instance mode.

   ```
   NetIron(config-cluster-TOR)# client client-2
   ```

2. Configure the remote bridge id cluster on the device so all clients for the device become members of the cluster.

   ```
   NetIron(config-cluster-TOR-client-2)#rbridge-id 200
   ```

3. Create a cluster client interface.

```
NetIron(config-cluster-TOR-client-2)#client-interface ether 1/6
```

4. Deploy the cluster client.

```
NetIron(config-cluster-TOR-client-2)deploy
```

Create cluster client 3

See Figure 112 on page 600 and "Create cluster client 1" on page 613 for additional information on creating cluster clients.

1. Create a cluster client instance and change the mode to the client instance mode.

```
NetIron(config-cluster-TOR)# client client-3
```

2. Configure the remote bridge id cluster on the device so all clients for the device become members of the cluster.

```
NetIron(config-cluster-TOR-client-3)#rbridge-id 300
```

3. Create a cluster client interface. The interface can be a single link or LAG port. If it is LAG port, it should be the primary port of the LAG.

```
NetIron(config-cluster-TOR-client-2)#client-interface ether 1/7
```

4. Deploy the cluster client.

```
NetIron(config-cluster-TOR-client-2)deploy
```

Configuring Client-1

See Figure 112 on page 600 and "Creating LAG-1" on page 601 for additional information on creating a LAG.

1. Create LAG 1 as shown below.

```
NetIron(config)# lag 1 dynamic id 1
NetIron(config-lag-1)#
```

2. Define the ports the LAG will be using.

```
NetIron(config-lag-1)# enable ethernet 1/1 to 1/3
```

3. The primary port must be explicitly assigned using the **primary-port** command.

```
NetIron(config-lag-1)# primary-port 1/1
```

4. Deploy the LAG as shown below.

```
NetIron(config-lag-1)# deploy
```

5. Assign a name to an individual port within a LAG.

```
NetIron(config-lag-1)# port-name lag-to-TOR-A ethernet 1/1
NetIron(config-lag-1)# port-name lag-to-TOR-B ethernet 1/3
```

6. The port can be made inactive (disable) or active (enable) by selecting the appropriate status option. The default value for a port is disabled. To enable the port on a device for ethernet interface 1/1, enter the following command.

```
NetIron(config-if-e10000-1/1)# enable
```

Syntax: [no] enable

Configuring Client 2

See Figure 112 on page 600 and "Creating LAG-1" on page 601 for additional information on creating a LAG.

1. Create a LAG with the LAG ID option, enter a command such as the following.

```
NetIron(config)# lag 1 dynamic id 1
NetIron(config-lag-1)#
```

2. Define the ports the LAG will be using.

```
NetIron(config-lag-1)# ports ethernet 1/1 to 1/2
```

3. The primary port must be explicitly assigned using the **primary-port** command.

```
NetIron(config-lag-1)# primary-port 1/1
```

4. Deploy the LAG as shown below.

```
NetIron(config-lag-1)# deploy
```

5. Assign a name to an individual port within a LAG.

```
NetIron(config-lag-1)# port-name lag-to-TOR-A ethernet 1/1
NetIron(config-lag-1)# port-name lag-to-TOR-B ethernet 1/2
```

6. The port can be made inactive (disable) or active (enable) by selecting the appropriate status option. The default value for a port is disabled. To enable the port on a device for ethernet interface 1/1 and 1/3, enter the following commands.

```
NetIron(config)# interface ether 1/1
NetIron(config-if-e10000-1/1)# enable

NetIron(config)# interface ether 1/3
NetIron(config-if-e10000-1/3)# enable
```

Syntax: [no] enable

7. Assign a name to an individual port within a LAG.

```
NetIron(config-if-e10000-1/3)# port-name host-to-PC
NetIron(config-if-e10000-1/3)# enable
```

Optional cluster operation features

A cluster can operate in two modes:

Cluster Failover Mode

Fast-failover (default) - As soon as the ICL interface goes down the CCP goes down. All the remote MACs are flushed.

Slow-failover - Even if the ICL interface goes down the CCP waits for the hold-time before making the CCP down. Remote MACs are flushed only when the CCP is down.

To disable the fast-failover mode, enter a command such as the following.

```
NetIron(config-cluster-TOR)#peer 1.1.1.1 disable-fast-failover
```

Syntax: [no] peer <peer-ip> **disable-fast-failover**

Client isolation mode

NOTE
The CLI will allow modification of the **client-islolation** mode on MCT cluster nodes even when the cluster is deployed. You must create the same isolation mode on both cluster nodes.

Clients can operate in two modes:

Loose mode (**default**): When the CCP goes down the client performs the Master/Slave negotiation. After negotiation, the Slave shuts down its client ports whereas the Master client ports continue to forward the traffic (keep-alive VLAN configured).

If the keep-alive VLAN is not configured, both nodes become master.

```
NetIron(config-cluster-TOR)#client-isolation loose
```

Strict mode: When the CCP goes down, the client interfaces on both the cluster nodes are administratively shutdown. In this mode, the client is completely isolated from the network if CCP is not operational.

```
NetIron(config-cluster-TOR)#client-isolation strict
```

Syntax: [no] client-isolation strict

Shutdown all client interfaces

Use the **client-interfaces shutdown** command when preforming a hitless-upgrade operation. This command can be used to shutdown all the local client interfaces in the cluster. This would result in failover of traffic to the cluster peer.

```
NetIron(config-cluster-TOR)#client-interfaces shutdown
```

Syntax: [no] client-interfaces shutdown

Displaying cluster information

Use the **show cluster** command to display the entire cluster configuration and **show tech cluster** commmand to dsplay cluster configuration and operation information. See the *PowerConnect B-MLXe Diagnostic Reference* for additional information on these commands.

Keep-alive VLAN

CCRR message are used to exchange information between peers. When the CCP is up, CCRR messages are sent over CCP. When the CCP client reachability is down, you can use the **keep-alive-vlan** command under cluster context so CCRR messages are periodically sent over the keep-alive-vlan. Only one VLAN can be configured as a **keep-alive-vlan**. The VLAN can be any VLAN configured in the system

```
NetIron(config-cluster-TOR)#keep-alive-vlan 10
```

Syntax: [no] keep-alive-vlan <vlan-id>

The <vlan_id> parameters specify the VLAN range. Possible values are 1 - 4090

When the CCP is down:

- If **keep-alive-vlan** is configured, then CCRR messages are sent periodically for every 1 second over that VLAN.
- When CCP is down and keep-alive vlan is configured, Master/Slave selection is based on following criteria.
    1. If one node's CCEPs are up and other node's CCEPs are down then the node with local CCEPs down becomes Slave
    2. Otherwise, the node with higher RBridge ID becomes Slave.
- If no packetsare received from the peer for a period of 3 seconds, then the peer box is considered down.
- If **keep-alive-vlan** is not configured and both the peers are up, then both peers keep forwarding the traffic independently.

Keep-alive timers and hold-time

To specify the **keep-alive timers** and **hold-time** for the peers, enter a command such as the following.

```
NetIron(config-cluster-TOR)# peer 1.1.1.1 timers keep-alive 40 hold-time 120
```

Syntax: [no] peer <peer-ip> **timers keep-alive** <keep-alive time> **hold-time** <hold-time>

The <peer-ip> parameter should be in same subnet as that of cluster management interface.

The <keep-alive time> parameter can be 0 to 21845 (default 30 seconds.)

The <hold-time> parameter can be 3 to 65535 (default 90 seconds) must be at least 3 times the keep alive time.

NOTE
Keep-alive-vlan and keep-alive timers are not related. The keep-alive timer is used by CCP.

L2 protocol forwarding

MCT will forward or drop L2 protocol packets when corresponding features are disabled. The packets will either be forwarded as regular multicast that floods to the VLAN or dropped. When forwarded, the packet received from ICL will not be forwarded to CCEP port if the peer MCT switch has the reachability to the same cluster client.

When designing a network, the ICL port or LAG must have enough bandwidth to support all the traffic from clients (in case of client links connected to one node failure case).

For L2 forwarding, appropriate CAM profiles need to be used to be able to program all the MAC entries into the CAM (especially when using LAG interfaces on MCT nodes for ICL and client interfaces).

By default , MCT acts as a hub for STP, or RSTP. Switches connected to MCT can run STP normally. When STP, RSTP, or MSTP is enabled, the L2 protocol forwarding configuration is ignored and has no effect.

To configure L2 protocol forwarding globally, enter a command such as the following.

```
NetIron(config)#cluster-l2protocol-forward
```

To disable L2 protocol forwarding on an interface, enter a command such as the following.

```
NetIron(config-if-e1000-1/2)#cluster-l2protocol-foward disable
```

To remove L2 protocol forwarding configuration on an interface, enter a command such as the following

```
NetIron(config-if-e1000-1/2)#no cluster-l2protocol-foward <enable | disable>
```

Syntax: [no]cluster-l2protocol-forward [enable | disable]

Interface level configuration overwrites the global level configuration.

TABLE 103 L2 protocol forwarding action –MCT switch and non - MCT switch

Protocol	Destination MAC	Non- MCT switch forwarding action	MCT switch forwarding action
Untagged 802.1Q BPDU	01-80-c2-00-00-00	Flood to the VLAN	Forward to ports that are enabled by the **cluster-l2protocol-forward** command.

Loop detection MAC	Base MAC address | 0x03000000	Flood to the VLAN	Same as non-MCT switch

Port loop detection

Port loop detection is used to detect L2 loops in MCT (due to misconfiguration). When using MCT, it requires the ICL ports to be strictly tagged. The port loop detection feature supports strictly tagged ports.

Loop detection for specific VLAN on a port

Strict mode loop detection can be configured on a specific VLAN for a given port. To configure loop detection on VLAN 10 for interface 1/1, enter a command such as the following.

```
NetIron(config-if-e1000-1/1)#loop-detection vlan 10
```

Syntax: [no] loop-detection [**vlan** <vlan_id>]

Where **vlan-id** enablesLoose Mode configuration for a VLAN group.

A port can be tagged or untagged member of this VLAN.

Multiple VLANs can have loop detection configured for a given port. Loop detection BPDUs will be sent out of each configured VLAN on that port.

Loop detection shutdown-disable

Use the **loop-detection shutdown-disable** command to disable the port shutdown feature in case of loop detection. This feature will ensure that the ICL stays up when a loop detection PDU is received on the ICL. This command will be applied to both strict mode or loose mode loop detection. To configure **loop-detection shutdown-disable** to shutdown port 1/1 used for the ICL link, enter a command such as the following.

```
NetIron(config-if-e1000-1/1)#loop-detection shutdown-disable
```

Syntax: loop-detection shutdown-disable

Loop-detection shutdown-sending-port

By default, the receive-port is shutdown by loop detection. The **loop-detection shutdown-sending-port** command will shutdown the port that sent the loop detection PDUs instead of shutting down the receiving port. This will ensure that the ICL stays up when a loop detection PDU is received on the ICL.

This feature is only applicable to strict mode loop detection.

```
NetIron(config-if-e1000-1/1)#loop-detection shutdown-sending-port
```

Syntax: [no] loop-detection shutdown-sending-port

Loop-detection-syslog-duration

If any of the ports has shutdown disabled, any loop detection will be logged into the syslog. Since the port is not shutdown, loop detect PDUs will come at a very fast rate and entries into the syslog are throttled.

By default, syslog-duration is 10 minutes. The configurable range is from 10 minutes to 1440 minutes.This is a global command and any changes will be applied to all interfaces.To configure **loop-detection-syslog-duration** for every 30 minutes, enter a command such as the following.

```
NetIron(config)# loop-detection-syslog-duration 30
```

Syntax: [no] loop-detection-syslog-duration <mins>

The <mins> parameter specifies the configurable range which is from 10 minutes to 1440 minutes.

MCT failover scenarios

1. ICL interface or CCP goes down (Keep alive configured)

   When the keepalive VLAN is used and finds the cluster nodes reachability when the ICL or CCP goes down. If the peer node is reachable over keepalive VLAN, the MCT nodes perform performs the Master/Slave negotiation per client. After negotiation, the Slave shuts down its client ports whereas the Master client ports continue to forward the traffic.

   The Master/Slave negotiation is done per MCT client on the basis of RBridge Id and client Local or Remote reachability. If the client is reachable from both MCT nodes, the higher RBridge Id becomes the Master. If client is reachable from one of the MCT nodes, only then the node on which it is reachable becomes the Master.

   If the peer is not reachable over the keepalive VLAN, then both cluster nodeswill keep forwarding.

   NOTE
   Dell recommends to use keepalive VLANs with the MCT configurations. This will provide a backdoor reachability ifthe ICL interface goes down.

2. ICL interface or CCP goes down (Keep alive not configured)

   When the keepalive VLAN is not configured, both cluster nodes will keep forwarding. Use the **client-isolation strict** to remove the client interface as soon as ICL goes down and isolate the client completely

3. MCT node goes down.

   When the MCT nodes goes down, the traffic will failover to the other MCT node.

4. Hitless failover performed on one of the MCT nodes

   Traffic is switched over to the other node. However, the CCP will go down and come back up again once the hitless failover is completed.

   Use the **client-interfaces shutdown** command to shutdown all the client interfaces so that the traffic failovers to the other MCT node first. Then perform the hitless failover.

5. Client interface on one of the MCT node goes down

   When hitless failover happens on a NetIron MLX node, that node flushes all the MACs and will reestablish cluster CCP session. In this case, the user may notice some traffic impact.

6. Double failures –The ICL goes down and client interface goes down on one MCT node.

   Multiple failures could drop traffic in this scenario even if there is actual physical path is available.

Show commands

Use the **show cluster** command to display the peer and client states.

```
NetIron#show cluster

Cluster CLUSTER-1 2000
==================
Rbridge Id: 35535, Session Vlan: 2001, Keep-Alive Vlan: 201

 Client2         222        Deployed   1/40    -   Up
```

Syntax: show cluster

Use the **show cluster client** command to display additional State Machine information including the reason for Local CCEP down.

```
NetIron#show cluster mct client c2
…
State: Remote Up
Reason for Local CCEP down: "client-interfaces shutdown" command
Number of times Local CCEP down: 2
Number of times Remote CCEP down: 1
Number of times Remote Client undeployed: 1
Total CCRR packets sent: 12
Total CCRR packets received: 13
```

Syntax: show cluster client

Following reasons are displayed for Local CCEP down.

TABLE 104 Reason for Local CCEP down

Reason for Local CCEP down	means....
client-interfaces shutdown	command is configured
client-isolation strict	command is configured

TABLE 104 Reason for Local CCEP down

Reason for Local CCEP down	means....
Deploy mismatch	Client is not deployed remotely
Slave state	Client is in Slave State when CCP is down
cluster and client undeployed	Neither the Cluster or Client is deployed.
cluster undeployed	Cluster is not deployed
client undeployed	Client is not deployed

Syslogs and debugging

Syslogs are displayed when remote CCEP is state is changed or remote client is deployed or undeployed.

```
SYSLOG: Jun 1 15:43:36:<14>Jun 1 15:43:36 CES, CLUSTER FSM: Cluster mct (Id: 1),
client c2 (RBridge Id: 4) -
    Remote client deployed
SYSLOG: Jun 1 16:04:24:<14>Jun 1 16:04:24 CES, CLUSTER FSM: Cluster mct (Id: 1),
client c2 (RBridge Id: 4) -
    Remote client CCEP up
```

MAC Database Update (MDUP)

The MACs that are learned locally are given the highest priority or the cost of 0 so they are always selected as best MAC.

Each MAC is advertised with a cost. Low cost MACs are given preference over high cost MACs.

If a MAC moves from a CCEP port to a CEP port, a MAC move message is sent to the peer and the peer moves the MAC from its CCEP ports to the ICL links.

If the cost of a MAC is the same, then the MAC learned from the Lower RBridge ID wins and is installed in the FDB.

Cluster Mac types

Cluster Local MAC (CL): MACs that are learned on VLANs that belongs to cluster VLAN range and on CEP ports locally.

MACs are synchronized to the cluster peer and are subject to aging.

```
NetIron#show mac
MAC Address Port Age VLAN Type FDID TNID ESI
0000.0700.4b04 1/1 0 20 CL Default_ESI
```

Cluster Remote MAC (CR): MACs that are learned via MDUP message from the peer (CL on the peer) The MACs are always programmed on the ICL port and do not age. They are deleted only when it is deleted from the peer. A MDB entry is created for these MACs with a cost of 1, and associated with the peer rbridge id.

```
NetIron#show mac
MAC Address Port Age VLAN Type FDID TNID ESI
0000.0700.4b04 1/13 0 20 CR Default_ESI
```

Cluster Client Local MAC (CCL): MACs that are learned on VLANs that belongs to cluster VLAN range and on CCEP ports.

The MACs are synchronized to the cluster peer and are subject to aging. A MDB entry is created for these MACs with a cost of 0 and are associated with the client and cluster rbridge ids.

```
NetIron#show mac
MAC Address Port Age VLAN Type FDID TNID ESI
0000.0700.4b04 1/13 0 20 CCL Default_ESI
```

Cluster Client Remote MAC (CCR): MACs that are learned via MDUP message from the peer (CCL on the peer) The MACs are always programmed on the corresponding CCEP port and do not age. They are deleted only when it is deleted from the peer. A MDB entry is created for the MACs with the cost of 1, and are associated with the client and peer rbridge ids.

```
NetIron#show mac
MAC Address Port Age VLAN Type FDID TNID ESI
0000.0700.4b04 1/13 0 20 CCR Default_ESI
```

MAC aging

Only the local MAC entries are aged on a node. The remote MAC entries will be aged based on explict MDUP messages only.

The remote MACs learned through MDUP messages are dynamic MACs with the exception that they never age from FDB.

MAC flush

If the CEP port is down, the MACs are flushed and individual MAC deletion messages are sent to the Peer.

If the CCEP local port is down, the MACs are flushed locally and individual MAC deletion messages are sent to peer.

If the **clear mac** command is given, all the MDB and FDB are rebuilt.

If the **clear mac vlan** command is given, all the local MDB and FDB are rebuilt for that VLAN.

MAC movement happens normally on the local node.

CEP to CCEP MAC movement – MAC movement normally happens on the local node, and deletes all the other MDBs from the peer to create a new local MDB.

CCEP to CEP MAC movement - MAC movement happens normally on the local node and delete all the other MDBs from the peer to create a new local MDB.

Flooding support on VLANs

Dell support the existing VLAN hardware flooding features such as unknown-unicast-flooding and vlan-cpu-protection on cluster VLANs. However, some changes were made to the way CAM entries are programmed. To support MCT cluster VLANs, the following changes to how the CAM is programmed:

- If the ICL port is part of a PPCR, then the device will program the specific (port or VLAN) based hardware flooding CAM entries on that PPCR. This is to avoid duplicate hardware flooding packets to be sent to CCEP ports.
- On an ICL port, the FID in pram will point to MCT_VLAN_CCEP_CONTROL_FID
- On non-ICL port, the FID in pram will point to VLAN_FID

Show Commands

To display all MAC entries, use the **show mac** command as shown below:

```
NetIron# show mac
Total active entries from all ports = 120000
Type Code - ST:Static SEC:Secure 1x:Dot1x NA: NotAvail A:Allow D:Deny
CCL: Cluster Client Local CCR:Cluster Client Remote CL:Local CR:Remote
Port Type - CEP:Customer Edge PNP:Provider Network BEP:Backbone Edge
BNP:Backbone Network
Vlan Type - C:Customer S:Service B:Backbone I:ISID
MAC Address Port Age VLAN Type FDID TNID ESI
0000.0101.84ff 1/13 0 20 CCL Default_ESI
0000.0100.4780 1/13 0 20 CCR Default_ESI
0000.0800.0663 1/14 0 20 CL Default_ESI
0000.0800.0870 1/1 0 20 CR Default_ESI
```

Syntax: show mac

To display all the Cluster Local MAC entries for a cluster, use the **show mac cluster** command as shown below:

```
NetIron#show mac cluster abc
Total Cluster Enabled(CL+CR+CCL+CCR) MACs: 451
Total Cluster Local(CL) MACs: 100
Total Cluster Remote(CR) MACs: 151
Total Cluster Client Macs(CCL+CCR) for all clients: 200
Total Cluster Client Local(CCL) MACs for all clients: 200
CCL: Cluster Client Local CCR:Cluster Client Remote CL:Local CR:Remote
MAC Address Port Age VLAN Type FDID TNID ESI
0000.0700.4b04 1/13 0 20 CCL Default_ESI
0000.0800.3500 1/13 0 20 CCR Default_ESI
```

Syntax: show mac [cluster <id>|<name> <local>| <remote>]

Clear MAC commands

To clear all MACs in the system, enter a command such as the following.

```
NetIron#clear mac
```

Syntax: clear mac

Clear cluster specific MACs

To clear cluster specific MACs in the system, enter a command such as the following.

```
NetIron#clear mac cluster TOR 1 local
```

Syntax: clear mac cluster <cluster-id> | <cluster-name> { local | remote }

Clear client specific MACs

To clear client specific MACs in the system, enter a command such as the following.

```
NetIron#clear mac cluster TOR 1 client 1 local
```

Syntax: clear mac cluster <cluster-id> | <cluster-name> client <client-name> { local | remote }

Clear VLAN specific MACs

To clear VLAN specific MACs in the system, enter a command such as the following.

```
NetIron#clear mac vlan 2
```

Syntax: clear mac vlan <vlan_id>

Clear cluster VLAN specific MACs

To clear cluster VLAN specific MACs in the system, enter a command such as the following.

```
NetIron#clear mac cluster cluster TOR 1 vlan 1 local
```

Syntax: clear mac cluster <cluster_id> | <cluster-name> vlan <vlan_id> {Local | Remote}

Clear cluster client vlan specific MACs

To clear cluster client specific MACs in the system, enter a command such as the following.

```
NetIron#clear mac cluster TOR 1 vlan 2 client client 1 local
```

Syntax: clear mac cluster <cluster_id> |< cluster-name> vlan <vlan_id> client <client_name> {Local | Remote}

Displaying MDUP packet statistics

To display the statistics of MDUP packets, enter a command such as the following.

```
NetIron#show mac mdup-stats
MDUP Information
================
MDUP Data buffers in queue : 0
MDUP Statistics
===============
MDUP Update Messages sent: 7

Multi-Chassis Trunk (MCT) for VRRP or VRRP-E

One MCT switch is the VRRP or VRRP-E master router and the other MCT switch is VRRP or VRRP-E backup router

The MCT switch that acts as backup router needs to ensure that packets sent to a VRRP-E virtual IP address can be L2 switched to the VRRP-E master router for forwarding. The MCT switch that acts as master router will sync the VRRP-E MAC to the other MCT switch that acts as backup router. Both data traffic and VRRP-E control traffic travel through the ICL unless the short-path forwarding feature is enabled.

L3 traffic forwarding from CEP ports to CCEP ports

Traffic destined to the CCEP ports from the client or CEP ports follow the normal IP routing on both master and backup routers. By default, the best route should not involve the ICL link. Only when the direct link from CEP ports to CCEP ports are down will the traffic be re-routed to pass through ICL link.

ARP broadcast resolution

Assuming that switch A is VRRP-E master router and switch B is the backup router. ARP request (a broadcast packet) from S1 that is sent through direct link to switch B will be sent to switch A for processing through ICL link. Since MAC learning is disabled on ICL link, the ARP will not be learned automatically through the ICL link. When the ARP request is received by switch A, the reply will be sent through direct link from switch A to S1. If by the time the ARP reply was received the MAC address for the MCT on S1 is not learned yet, the reply packet may be flooded to both the CCEP ports and ICL ports.

Both MCT switches are VRRP or VRRP-E backup routers

In Figure 116, both MCT switches C and D need to ensure packets sent to VRRP-E virtual IP address can be L2 switched to the VRRP-E master router for forwarding. The MCT switch that has direct connection to the master router (who actually learned the VRRP-E MAC from the master) will sync the VRRP-E MAC to the other MCT switch that does not have direct connection to the master. Both data traffic and VRRP-E control traffic travel through ICL unless the short-path forwarding feature is enabled.

FIGURE 116 Example of MCTS that are Layer 2 switched

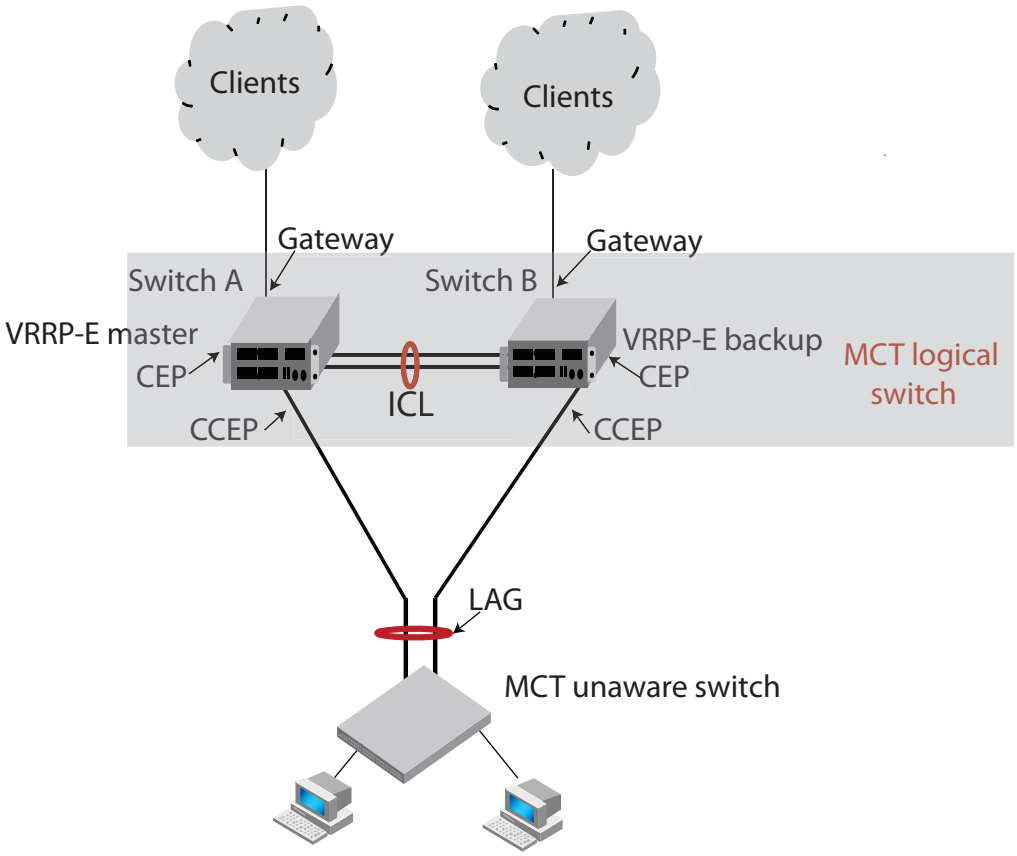

FIGURE 117 Example of MCTs that are deployed on two sites that are connected through two WAN links.

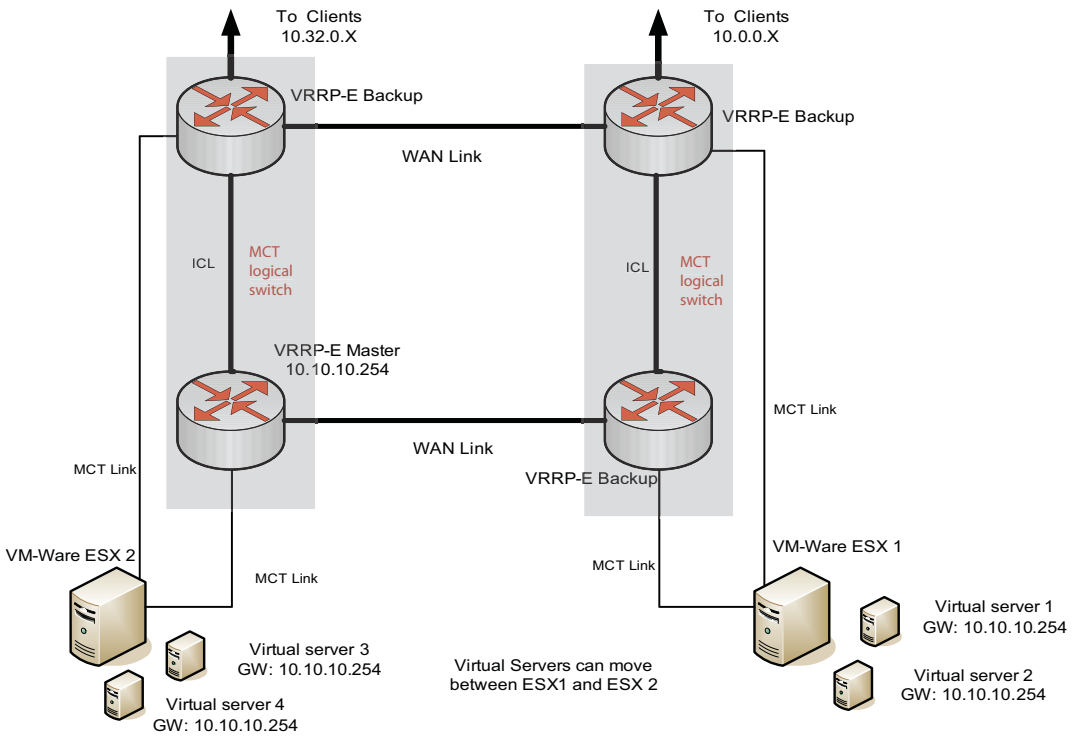

In Figure 117, MCTs are deployed on two sites that are connected through two WAN links.

- Two WAN links are completely independent. Switch A and B form MCT 1 and switch C and D form MCT 2. There are L2 protocols running on the VRRP-E routers. L2 protocols will block one of the WAN links to ensure loop-free topology.

Configuration considerations

- VRRE-E virtual MAC will be synced and learned on ICL ports on backup routers through the ICL.
- VRRP or VRRP-E master router will be broadcast hello packets to all VLAN member ports including ICL ports. Normal VLAN FID will be used for broadcasting.
- VRRP or VRRP-E backup routesr will not be flood back hello packets received from ICL ports to ICL ports, but will be flooded to other non- ICL ports.
- In the current release, MCT switches must have complete routing information using static routes for L3 forwarding.
- For MCT switches configured with VRRP or VRRP-E, track-port features can be enabled to track the link status to the core switches so the VRRP or VRRP-E failover can be triggered.

NOTE
Dell recommends disabling ICMP redirect globally to avoid unintended CPU forwarding of traffic when VRRP or VRRP-E is configured.

L3 traffic forwarding behaviors

When one MCT switch act as VRRP or VRRP-E master router and the other MCT switch is VRRP or VRRP-E backup, the following behavior will be seen:

- Packets sent to VRRP-E virtual IP address will be L2 switched to the VRRP-E master router for forwarding.
- The VRRP-E MAC will be learned by the other MCT switch that acts as backup router.
- Both data traffic and VRRP-E control traffic will need to travel through ICL unless the short-path forwarding feature is enabled.

When both MCT devices act as the VRRP or VRRP-E backup routers, the following behavior will be seen:

- Packets sent to VRRP-E virtual IP address will be L2 switched to the VRRP-E master router for forwarding.
- VRRP-E MAC will be learned by both MCT switches acting as backup routers.
- Both data traffic and VRRP-E control traffic will need to travel through ICL unless the short-path forwarding feature is enabled.

VRRP-E short-path forwarding and revertible option

The **track-port** command will monitor the status of the outgoing port on the backup. It will revert back to standard behavior (no short-path forwarding) temporarily even if short-path forwarding is configured.

Under the VRRP-E VRID configuration level, use the **short-path-forwarding** command. If the revertible option is not enabled, the default behavior will remain the same. Use the following command to enable short path forwarding.

```
NetIron(config-if-e1000-vrid-2)#short-path-forwarding revert-priority 60
```

Syntax: [no] short-path-forwarding [revert-priority <value>**]**

Use the supplied priority value as a threshold to determine if the **short-path-forwarding** behavior should be effective or not. If one or more ports tracked by the **track-port** command go down, the current priority of VRRP-E will be lowered by a specific amount configured in the **track-port** command for each port that goes down.

Once the current-priority is lower than the threshold, the **short-path-forwarding** will be temporally suspended and revert back to the regular VRRP-E forwarding behavior without **short-path-forwarding** enabled.

The reverting behavior is only temporary. If one or more of the already down ports tracked by the **track-port** command come back, it is possible that the current priority of VRRP-E will be higher than the threshold again and the **short-path-forwarding** behavior will be resumed.

Configuring IP 19

Overview

The following IP features are supported by the NetIron MLX Series devices.

- GRE IP Tunnel
- Multicast over GRE Tunnel
- ICMP Error Message Rate Increase
- Restart Global Timers
- Restart helper-mode
- ARP Inspection
- DHCP Snooping
- DHCP Relay Enhancement
- DNS queries of IPv4 DNS Servers
- DNS queries of IPv6 DNS Servers
- IRDP
- UDP Broadcast and IP Helper
- Configuring BootP/DHCP Forwarding Parameters
- IPv6 Over IPv4 Tunnels in Hardware
- Disabling Gratuitous ARP Requests for Local Proxy ARP
- Dynamic ARP Inspection (DAI)
- DHCP Option 82 insertion
- IP Source Guard
- Displaying the IP Route Table
- Jumbo Frames
- IPv4 VRF Support
- Configuring a Static IP Route between VRFs
- Naming a Static IP Route
- New minimum GRE keepalive
- Dropping Traffic Sent to the Null0 Interface in Hardware
- CAM Default Route Aggregation
- Static route to an LSP Tunnel Interface
- Statistics for GRE and Manual IPv6 Tunnels
- Multi-port static ARP

Internet Protocol (IP) is enabled by default. This chapter describes how to configure IP parameters on the PowerConnect.

Basic configuration consists of adding IP addresses and enabling a route exchange protocol. Refer to "Configuring IP addresses" on page 674.

To change some of the IP parameters from their default values or to view configuration information or statistics, refer to the following sections:

- "The IP packet flow" on page 650
- "Basic IP parameters and defaults" on page 654
- "Configuring IP parameters" on page 674

The IP packet flow

Figure 118 shows how an IP packet moves through a PowerConnect.

FIGURE 118 IP Packet flow through a PowerConnect

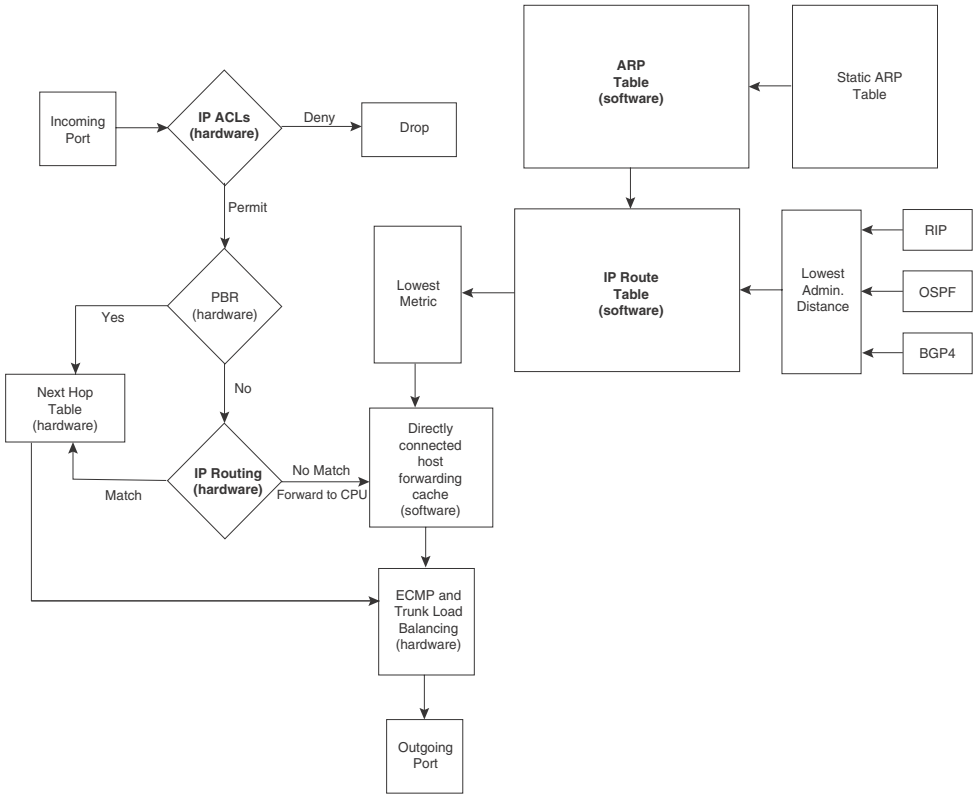

Figure 118 shows the following packet flow.

1. When the PowerConnect receives an IP packet, the PowerConnect checks for IP ACL filters on the receiving interface. If a deny filter on the interface denies the packet, the PowerConnect discards the packet and performs no further processing. If logging is enabled for the filter, then the PowerConnect generates a Syslog entry and SNMP trap message.
2. If the packet is not denied, the PowerConnect checks for Policy Based Routing (PBR). If the packet matches a PBR policy applied on the incoming port, the PBR processing is performed and either drops the packet or forwards it to a port, based on the route map rules.
3. If the incoming packet does not match PBR rules, the PowerConnect looks in the hardware IP routing table to perform IP routing. The hardware routing table is pre-loaded with the complete routing table, except for the directly connected host entries. Default and statically defined routes are also pre-loaded in the hardware routing table. If the incoming packet matches a route entry, the packet is routed according to the information provided in the route entry. The ECMP and LAG load balancing is done by the hardware, if needed, to select the outgoing port.
4. If there is no match in the IP routing table and a default route is not configured, the packet is dropped. For an IP packet whose destination IP address is to a directly connected host, the first packet is forwarded to the CPU. If the ARP is resolved and the host is reachable, the CPU creates a route entry in the hardware to route subsequent packets in hardware.

The software enables you to display the ARP cache and static ARP table, the IP route table, the IP forwarding cache.

You also can change the capacity of the following tables by changing the memory allocation for the table:

- "ARP cache table" on page 651
- "Static ARP table" on page 652
- "IP route table" on page 652
- "IP forwarding cache" on page 653

ARP cache table

The Address Resolution Protocol (ARP) is supported on the PowerConnect. Refer to "Configuring ARP parameters" on page 686.

The ARP cache contains entries that map IP addresses to MAC addresses. Generally, the entries are for devices that are directly attached to the PowerConnect.

An exception is an ARP entry for an interface-based static IP route that goes to a destination that is one or more router hops away. For this type of entry, the MAC address is either the destination device's MAC address or the MAC address of the router interface that answered an ARP request on behalf of the device, using proxy ARP.

The ARP cache can contain dynamic (learned) entries and static (user-configured) entries. The software places a dynamic entry in the ARP cache when the PowerConnect learns a device's MAC address from an ARP request or ARP reply from the device.

The software can learn an entry when the PowerConnect receives an ARP request from another IP forwarding device or an ARP reply.

Example : Dynamic entry

```
      IP Address          MAC Address         Type        Age     Port
1     207.95.6.102        0800.5afc.ea21      Dynamic     0         6
```

Each entry contains the destination device's IP address and MAC address.

Static ARP table

In addition to the ARP cache, the PowerConnect has a static ARP table.

Entries in the static ARP table are user-configured. You can add entries to the static ARP table regardless of whether the device the entry is for is connected to the PowerConnect.

The software places an entry from the static ARP table into the ARP cache when the entry's interface comes up.

Example : Static ARP entry

```
  Index   IP Address          MAC Address         Port
  1       207.95.6.111        0800.093b.d210      1/1
```

Each entry lists the information you specified when you created the entry.

To display ARP entries, refer to the following:

- "Displaying the ARP cache" on page 759
- "Displaying the static ARP table" on page 760

To configure other ARP parameters, refer to "Configuring ARP parameters" on page 686.

To increase the size of the ARP cache and static ARP table, refer to the following:

- For dynamic entries, refer to the "Displaying and modifying default settings for system parameters" on page 100. The ip-arp parameter controls the ARP cache size.

IP route table

The IP route table contains paths to IP destinations.

The IP route table can receive the paths from the following sources:

- A directly-connected destination, which means there are no router hops to the destination
- A static IP route, which is a user-configured route
- A route learned through RIP
- A route learned through OSPF
- A route learned through ISIS
- A route learned through BGP4

The IP route table contains the best path to a destination:

- When the software receives paths from more than one of the sources listed above, the software compares the administrative distance of each path and selects the path with the lowest administrative distance. The administrative distance is a protocol-independent value from 1 – 255.
- When the software receives two or more best paths from the same source and the paths have the same metric (cost), the software can load share traffic among the paths based on Layer 2, Layer 3 and TCP/UDP information.

Example : IP route table

```
Destination       NetMask           Gateway           Port   Cost   Type
1.1.0.0           255.255.0.0       99.1.1.2          1/1    2      R
```

Each IP route table entry contains the destination's IP address and subnet mask and the IP address of the next-hop router interface to the destination. Each entry also indicates the port attached to the destination or the next-hop to the destination, the route's IP metric (cost), and the type. The type indicates how the IP route table received the route.

To display the IP route table, refer to "Displaying the IP route table" on page 763.

To configure a static IP route, refer to "Configuring static routes" on page 714.

To clear a route from the IP route table, refer to "Clearing IP routes" on page 767.

To increase the size of the IP route table for learned and static routes, refer to "Displaying and modifying default settings for system parameters" on page 100.

Consider the following:

- For learned routes, modify the ip-route parameter.
- For static routes, modify the ip-static-route parameter.

IP forwarding cache

The PowerConnect maintains a software cache table for fast processing of IP packets that are forwarded or generated by the CPU. The cache also contains forwarding information that is normally contained in the IP routing table. For example, the cache contains information on the physical outgoing port, priority, VLAN, and the type of cache entry. Also, cache entries have hardware information, which is useful for debugging and aging.

There are two types of IP cache entries.

1. Directly connected host entries – These entries are created when the CPU receives the first packet destined to a directly connected host. Host entries are set to age out after a certain period if no traffic is seen for that entry.
2. Network entries – These entries are created when a route table entry is created in software. These entries are not subjected to aging. A route table entry is created when routes are learned by routing protocols such as OSPF or when routes are statically configured.

Example : IP forwarding cache

```
      IP Address       Next Hop         MAC              Type  Port  Vlan  Pri
1     192.168.1.11     DIRECT           0000.0000.0000   PU    n/a         0
```

Each IP forwarding cache entry contains the IP address of the destination, and the IP address and MAC address of the next-hop router interface to the destination. If the destination is actually an interface configured on the PowerConnect itself, as shown here, then next-hop information indicates this. The port through which the destination is reached is also listed, as well as the VLAN and Layer 4 QoS priority associated with the destination if applicable.

To display the IP forwarding cache, refer to "Displaying the forwarding cache" on page 761.

IP packet queuing

When the user wants to send a packet to a local host, the software looks up the IP in the ARP cache. If the address is found, it gets the MAC address, constructs an Ethernet header with the correct source or destination MAC addresses, and sends it.

If the address is not found in the table, ARP broadcasts a packet to every host on the Ethernet, except the one from which it received the packet. The packet contains the IP address for which an Ethernet address is sought. If a receiving host identifies the IP address as its own, it will send its Ethernet address back to the requesting host.

For management of IP packet queuing when a packet is received for a directly connected host when there is no MAC address available, the **ip drop-arp-pending-packets** command has been added to allow the packets in the CPU to be dropped.

To set all packets in the LP buffer to be dropped when ARP resolution is going on, enter a command such as the folowing:

```
NetIron(config)#ip drop-arp-pending-packets
```

Syntax: [no] ip drop-arp-pending-packets

Use the **no ip drop-arp-pending-packets command** to return to the default behavior of continue with pending IP packets while ARP resolution.

Basic IP parameters and defaults

IP is enabled by default. The following protocols are disabled by default:

- Route exchange protocols (RIP, OSPF, ISIS, BGP4)
- Multicast protocols (IGMP, PIM-DM, PIM-SM, DVMRP)
- Router redundancy protocols (VRRPE, VRRP, FSRP)

When parameter changes take effect

Most IP parameters described in this chapter are dynamic. They take effect immediately, as soon as you enter the CLI command. You can verify that a dynamic change has taken effect by displaying the running configuration. To display the running configuration, enter the **show running-config** or **write terminal** command at any CLI prompt.

To save a configuration change permanently so that the change remains in effect following a system reset or software reload, save the change to the startup configuration file. Enter the **write memory** command from the Privileged EXEC level of any configuration level of the CLI.

Changes to memory allocation require you to reload the software after you save the changes to the startup configuration file. When reloading the software is required to complete a configuration change, the procedure that describes the configuration change includes a step for reloading the software.

IP global parameters

Table 106 lists the IP global parameters for the PowerConnect, their default values, and where to find configuration information.

TABLE 106 IP global parameters

Parameter	Description	Default	See page...
IP state	The Internet Protocol, version 4	Enabled **NOTE:** You cannot disable IP.	n/a
IP address and mask notation	Format for displaying an IP address and its network mask information. You can enable one of the following: • Class-based format; example: 192.168.1.1 255.255.255.0 • Classless Interdomain Routing (CIDR) format; example: 192.168.1.1/24	Class-based **NOTE:** Changing this parameter affects the display of IP addresses, but you can enter addresses in either format regardless of the display setting.	page 674
Router ID	The value that routers use to identify themselves to other routers when exchanging route information. OSPF and BGP4 use router IDs to identify routers. RIP does not use the router ID.	The IP address configured on the lowest-numbered loopback interface. If no loopback interface is configured, then the lowest-numbered IP address configured on the device.	page 684
IP Maximum Transmission Unit (MTU)	The maximum length an Ethernet packet can be without being fragmented.	1500 bytes for Ethernet II encapsulation 1492 bytes for SNAP encapsulation	page 681
Address Resolution Protocol (ARP)	A standard IP mechanism that routers use to learn the Media Access Control (MAC) address of a device on the network. The router sends the IP address of a device in the ARP request and receives the device's MAC address in an ARP reply.	Enabled	page 686
ARP rate limiting	Lets you specify a maximum number of ARP packets the device will accept each second. If the device receives more ARP packets than you specify, the device drops additional ARP packets for the remainder of the one-second interval.	Disabled	page 687
ARP age	The amount of time the device keeps a MAC address learned through ARP in the device's ARP cache. The device resets the timer to zero each time the ARP entry is refreshed and removes the entry if the timer reaches the ARP age. **NOTE:** You also can change the ARP age on an individual interface basis. Refer to Table 107 on page 658.	Ten minutes	page 688

TABLE 106 IP global parameters (Continued)

Parameter	Description	Default	See page...
Proxy ARP	An IP mechanism a router can use to answer an ARP request on behalf of a host, by replying with the router's own MAC address instead of the host's.	Disabled	page 689
Static ARP entries	An ARP entry you place in the static ARP table. Static entries do not age out.	No entries	page 690
Time to Live (TTL)	The maximum number of routers (hops) through which a packet can pass before being discarded. Each router decreases a packet's TTL by 1 before forwarding the packet. If decreasing the TTL causes the TTL to be 0, the router drops the packet instead of forwarding it.	64 hops	page 709
Directed broadcast forwarding	A directed broadcast is a packet containing all ones (or in some cases, all zeros) in the host portion of the destination IP address. When a router forwards such a broadcast, it sends a copy of the packet out each of its enabled IP interfaces. **NOTE:** You also can enable or disable this parameter on an individual interface basis. Refer to Table 107 on page 658.	Disabled	page 709
Directed broadcast mode	The packet format the router treats as a directed broadcast. The following formats can be directed broadcast: • All ones in the host portion of the packet's destination address. • All zeroes in the host portion of the packet's destination address.	All ones **NOTE:** If you enable all-zeroes directed broadcasts, all-ones directed broadcasts remain enabled.	page 711
Source-routed packet forwarding	A source-routed packet contains a list of IP addresses through which the packet must pass to reach its destination.	Enabled	page 710
Internet Control Message Protocol (ICMP) messages	The PowerConnect can send the following types of ICMP messages: • Echo messages (ping messages) • Destination Unreachable messages • Redirect messages **NOTE:** You also can enable or disable ICMP Redirect messages on an individual interface basis. Refer to Table 107 on page 658.	Enabled	page 712 page 714

TABLE 106 IP global parameters (Continued)

Parameter	Description	Default	See page...
ICMP Router Discovery Protocol (IRDP)	An IP protocol a router can use to advertise the IP addresses of its router interfaces to directly attached hosts. You can enable or disable the protocol, and change the following protocol parameters: • Forwarding method (broadcast or multicast) • Hold time • Maximum advertisement interval • Minimum advertisement interval • Router preference level **NOTE:** You also can enable or disable IRDP and configure the parameters on an individual interface basis. Refer to Table 107 on page 658.	Disabled	page 738
Maximum BootP relay hops	The maximum number of hops away a BootP server can be located from a router and still be used by the router's clients for network booting.	Four	page 744
Maximum Frame Size	You can set a maximum frame size of all Ethernet frames that are forwarded by the system.		page 681
Domain name for Domain Name Server (DNS) resolver	A domain name you can use in place of an IP address for certain operations such as IP pings, trace routes, and Telnet management connections to the router.	None configured	page 679
DNS default gateway addresses	A list of gateways attached to the router through which clients attached to the router can reach DNSs.	None configured	page 679
IP load sharing	A feature that enables the router to balance traffic to a specific destination across multiple equal-cost paths. Load sharing is based on a combination of destination MAC address, source MAC address, destination IP address, source IP address, and IP protocol. **NOTE:** Load sharing is sometimes called Equal Cost Multi Path (ECMP).	Enabled	page 731
Maximum IP load sharing paths	The maximum number of equal-cost paths across which the PowerConnect is allowed to distribute traffic.	Four	page 731
Origination of default routes	You can enable a router to originate default routes for the following route exchange protocols, on an individual protocol basis: • RIP • OSPF • BGP4	Disabled	page 1029
Default network route	The router uses the default network route if the IP route table does not contain a route to the destination and also does not contain an explicit default route (0.0.0.0 0.0.0.0 or 0.0.0.0/0).	None configured	page 730

TABLE 106 IP global parameters (Continued)

Parameter	Description	Default	See page...
Static route	An IP route you place in the IP route table.	No entries	page 714
Source interface	The IP address the router uses as the source address for Telnet, RADIUS, or TACACS/TACACS+ packets originated by the router. The router can select the source address based on either of the following: • The lowest-numbered IP address on the interface the packet is sent on. • The lowest-numbered IP address on a specific interface. The address is used as the source for all packets of the specified type regardless of interface the packet is sent on.	The lowest-numbered IP address on the interface the packet is sent on.	page 685

IP interface parameters

Table 107 lists the interface-level IP parameters for the PowerConnect, their default values, and where to find configuration information.

TABLE 107 IP interface parameters

Parameter	Description	Default	See page...
IP state	The Internet Protocol, version 4	Enabled **NOTE:** You cannot disable IP.	n/a
IP address	A Layer 3 network interface address The PowerConnect has separate IP addresses on individual interfaces.	None configured	page 674
Encapsulation type	The format of the packets in which the router encapsulates IP datagrams. The encapsulation format can be one of the following: • Ethernet II • SNAP	Ethernet II	page 681
IP Maximum Transmission Unit (MTU)	The maximum length (number of bytes) of an encapsulated IP datagram the router can forward.	1500 for Ethernet II encapsulated packets 1492 for SNAP encapsulated packets	page 681
ARP age	Locally overrides the global setting. Refer to Table 106 on page 655.	Ten minutes	page 688
Directed broadcast forwarding	Locally overrides the global setting. Refer to Table 106 on page 655.	Disabled	page 709
ICMP Router Discovery Protocol (IRDP)	Locally overrides the global IRDP settings. Refer to Table 106 on page 655.	Disabled	page 739
ICMP Redirect messages	Locally overrides the global setting. Refer to Table 106 on page 655.	Enabled	page 714

TABLE 107 IP interface parameters (Continued)

Parameter	Description	Default	See page...
DHCP gateway stamp	The router can assist DHCP/BootP Discovery packets from one subnet to reach DHCP/BootP servers on a different subnet by placing the IP address of the router interface that receives the request in the request packet's Gateway field. You can override the default and specify the IP address to use for the Gateway field in the packets. **NOTE:** UDP broadcast forwarding for client DHCP/BootP requests (bootpc) must be enabled and you must configure an IP helper address (the server's IP address or a directed broadcast to the server's subnet) on the port connected to the client.	The lowest-numbered IP address on the interface that receives the request	page 744
UDP broadcast forwarding	The router can forward UDP broadcast packets for UDP applications such as BootP. By forwarding the UDP broadcasts, the router enables clients on one subnet to find servers attached to other subnets. **NOTE:** To completely enable a client's UDP application request to find a server on another subnet, you must configure an IP helper address consisting of the server's IP address or the directed broadcast address for the subnet that contains the server. Refer to the next row.	The router helps forward broadcasts for the following UDP application protocols: • bootps • dns • netbios-dgm • netbios-ns • tacacs • tftp • time	page 741
IP helper address	The IP address of a UDP application server (such as a BootP or DHCP server) or a directed broadcast address. IP helper addresses allow the router to forward requests for certain UDP applications from a client on one subnet to a server on another subnet.	None configured	page 742

GRE IP tunnel

Multi-Service Ironware software supports the tunneling of packets with the Generic Routing Encapsulation (GRE) mechanism over an IP network, as described in RFC 2784. With GRE, packets are encapsulated in a transport protocol packet at a tunnel source and delivered to a tunnel destination, where they are unpacked and made available for delivery.

Considerations in implementing this feature

The considerations in implementing this feature are as follows:

- As a point-to-point tunnel configuration, GRE requires both ends of the tunnel to be configured.
- Only four-byte GRE headers are supported at the ingress (even though eight-byte headers can be processed at a transit node or the egress point).
- A PowerConnect router does not support the key and sequence numbering option with GRE (per RFC 2890).
- The current maximum number of tunnels is 8192 (with default as 256 tunnels).

Figure 119 describes the GRE header format.

FIGURE 119 GRE header format

Checksum – This field is assumed to be zero in this version. If set to 1 means that the **Checksum** (optional) and **Reserved** (optional) fields are present and the Checksum (optional) field contains valid information.

Reserved0 – Bits 6:0 of the field are reserved for future use and must be set to 0 in transmitted packets. If bits 11:7 of the field are non-0, then a receiver must discard the packet. This field is assumed to be 0 in this version.

Ver – This field must be set to 0. This field is assumed to be 0 in this version.

Protocol Type – This field contains the EtherType of the payload protocol.

For details on configuring a GRE IP tunnel, refer to "To display the currently configured Martian addresses refer to "Displaying martian addressing information" on page 774." on page 746.

GRE MTU enhancements

Enhancements have been introduced to support GRE MTU in support of RFC 4459. This includes support for the following:

- Signaling the Lower MTU to the Sources as described in Section 3.2 of RFC 4459
- Fragmentation of the Inner packet as described in Section 3.4 of RFC 4459

This enhancement also allows you to set a specific MTU value for packets entering a configured GRE tunnel. Packets whose size is greater than the configured value are fragmented and encapsulated with IP/GRE headers for transit through the tunnel. This feature supports Jumbo packets although they may be fragmented based on the MTU value configured.

Configuring a GRE IP Tunnel

To configure a GRE IP Tunnel, configure the following parameters:

- "CAM restrictions"
- Maximum Number of Tunnels (optional)
- Tunnel Interface
- Source Address or Source Interface for the Tunnel
- Destination address for the Tunnel
- GRE Encapsulation
- IP address for the Tunnel
- Keep Alive Support (optional)
- TTL Value (optional)
- TOS Value (optional)
- MTU Value (optional)

Configuration considerations

1. To enable keepalive when a GRE source and destination are directly connected, you must disable ICMP redirect on the tunnel source port on the GRE nodes. Otherwise, the keepalive packets go to the CPU where they can degrade CPU performance.
2. Whenever multiple IP addresses are configured on a tunnel source, the primary address of the tunnel is always used for forming the tunnel connections. Consequently, you must carefully check the configurations when configuring the tunnel destination.
3. GRE tunneling is not supported for non-default VRFs.
4. When a GRE tunnel is configured, you cannot configure the same routing protocol on the tunnel through which you learn the route to the tunnel destination. For example, if the PowerConnect learns the tunnel destination route through OSPF protocol, you cannot configure the OSPF protocol on the same Tunnel and vice-versa. When a tunnel has OSPF configured, the PowerConnect cannot learn the tunnel destination route through OSPF. This could cause the system to become unstable.

NOTE
With GRE Dynamic-cam mode, at the Egress node, when a GRE packet is received, Dell programs the CAM entries to forward the packets based on Inner DPA. These host CAM entries will be aging even if the traffic is hitting that CAM entries. This will cause the CAM entries to become aged out and recreated which could cause a small packet loss.

Configuring ECMP for routes through an IP GRE tunnel

If multiple routes are using IP GRE tunnels to a destination, packets are automatically load-balanced between tunnels. This feature allows for load distribution of traffic among the available IP GRE tunnels. If the routes to a destination are both normal IP routes and routes through IP GRE tunnels, ECMP is not enabled.

CAM restrictions

CAMs are partitioned on a PowerConnect router by a variety of profiles that you can select for your specific application.

To implement a CAM partition for a GRE tunnel, enter a command such as the following.

```
NetIron(config)# cam-partition profile ipv4
```

Syntax: [no] cam-partition profile [ipv4 | ipv4-ipv6 | ipv4-vpls | ipv4-vpn | ipv6 | l2-metro | l2-metro-2 | mpls-l3vpn | mpls-l3vpn-2 | mpls-vpls | mpls-vpls-2 | mpls-vpn-vpls | multi-service]

The **ipv4** parameter adjusts the CAM partitions, as described in the tables below to optimize the router for IPv4 applications.

The **ipv4-ipv6** parameter adjusts the CAM partitions, as described in the tables below to optimize the router for IPv4 and IPv6 dual stack applications

The **ipv4-vpls** parameter adjusts the CAM partitions, as described in the tables below to optimize the router for IPv4 and MPLS VPLS applications

The **ipv4-vpn** parameter adjusts the CAM partitions, as described in the tables below to optimize the router for IPv4 and MPLS Layer-3 VPN applications

The **ipv6** parameter adjusts the CAM partitions, as described in the tables below to optimize the router for IPv6 applications.

The **l2-metro** parameter adjusts the CAM partitions, as described in the tables below to optimize the router for Layer 2 Metro applications.

The **l2-metro-2** parameter provides another alternative to **l2-metro** to optimize the router for Layer 2 Metro applications.

The **mpls-l3vpn** parameter adjusts the CAM partitions, as described in the tables below, to optimize the router for Layer 3, BGP or MPLS VPN applications.

The **mpls-l3vpn-2** parameter provides another alternative to **mpls-l3vpn** to optimize the router for Layer 3, BGP or MPLS VPN applications.

The **mpls-vpls** parameter adjusts the CAM partitions, as described in the tables below to optimize the router for MPLS VPLS applications.

The **mpls-vpls-2** parameter provides another alternative to **mpls-vpls** to optimize the router for MPLS VPLS applications. It adjusts the CAM partitions, as described in the tables below.

The **mpls-vpn-vpls** parameter adjusts the CAM partitions, as described in the tables below, to optimize the router for MPLS Layer-3 and Layer-2 VPN applications.

The **multi-service** parameter adjusts the CAM partitions, as described in the tables below to optimize the router for Multi-Service applications.

NOTE
You must reload your PowerConnect router for this command to take effect.

Configuring the maximum number of tunnels supported

You can configure the devices to support a specified number of tunnels using the following command.

```
NetIron(config)# system-max ip-tunnels 512
NetIron(config)# write memory
```

Syntax: system-max ip-tunnels <*number*>

The <*number*> variable specifies the number of GRE tunnels that can be supported.

NOTE
Multicast over GRE tunnels for PIM can support up to the default system max of 256 tunnels if the required hardware resources are available.

NOTE
You must write this command to memory and perform a system reload for this command to take effect.

Configuring a tunnel interface

To configure a tunnel interface, use a the following command.

```
NetIron(config)# interface tunnel 1
NetIron(config-tnif-1)
```

Syntax: [no] interface tunnel <*tunnel id*>

The <*tunnel-id*> variable is numerical value that identifies the tunnel being configured. Possible range is from 1 to the maximum configured tunnels in the system.

Configuring a source address or source interface for a tunnel interface

To configure a source address for a specific tunnel interface, enter the following command.

```
NetIron(config)# interface tunnel 1
NetIron(config-tnif-1)tunnel source 35.0.8.108
```

To configure a source interface for a specific tunnel interface, enter the following command.

```
NetIron(config)# interface tunnel 100
NetIron(config-tnif-100)tunnel source ethernet 3/1
```

Syntax: [no] tunnel source <*ip-address*> **|** <*port-no*>

You can specify either of the following:

The <*ip-address*> variable is the source IP address being configured for the specified tunnel.
The <*port-no*> variable is the source slot or port of the interface being configured for the specified tunnel. When you configure a source interface, there must be at least one IP address configured on that interface. Otherwise, the interface will not be added to the tunnel configuration and an error message like the following will be displayed: " Error - Tunnel source interface 3/1 has no configured ip address.

It can be a physical or virtual interface (ve).

Configuring a destination address for a tunnel interface

To configure a destination address for a specific tunnel interface, enter the following command.

```
NetIron(config)# interface tunnel 1
NetIron(config-tnif-1)tunnel destination 131.108.5.2
```

Syntax: [no] tunnel destination <*ip-address*>

The <*ip-address*> variable is destination IP address being configured for the specified tunnel.

NOTE
If GRE is configured with a tunnel destination reachable over LAG ports, load balancing will only work with the following LAG types: server LAG or LACP with server LAG. Traffic cannot be load-balanced across multiple ports of a switch LAG.

Configuring a tunnel interface for GRE encapsulation

To configure a specified tunnel interface for GRE encapsulation, enter the following command.

```
NetIron(config)# interface tunnel 1
NetIron(config-tnif-1)tunnel mode gre ip
```

Syntax: [no] tunnel mode gre ip

The **gre** parameter specifies that the tunnel will use GRE encapsulation

The **Ip** parameter specifies that the tunnel protocol is IP.

Configuring an IP address for a tunnel interface

To configure an IP address for a specified tunnel interface, enter the following command.

```
NetIron(config)# interface tunnel 1
NetIron(config-tnif-1)ip address 10.10.3.1/24
```

Syntax: [no] ip address <*ip-address*>

The <*ip-address*> variable is the IP address being configured for the specified tunnel interface.

Configuring keep alive support

This parameter is optional. It lets the router maintain a tunnel in an up or down state based upon the periodic sending of keep alive packets and the monitoring of responses to the packet. If the packets fail to reach the tunnel's far end more frequently than the configured number of retries, the tunnel is placed in a down state. A keep alive packet is a GRE IP packet with no payload.

To configure the keep alive option, enter the following command.

```
NetIron(config)# interface tunnel 1
NetIron(config-tnif-1)keepalive 5 4
```

Syntax: [no] keepalive <*seconds*> <*retries*>

The <*seconds*> variable specifies the number of seconds between each initiation of a keep alive message. The range for this interval is 1 – 32767 seconds. The default value is 10 seconds.

The <*retries*> variable specifies the number of times that a packet is sent before the system places the tunnel in the down state. Possible values are from 1 – 255. The default number of retires is 3.

Configuring a TTL value

This is an optional parameter that allows you to set the Time-to-Live value for the outer IP header of the GRE tunnel packets.

To configure the TTL value, enter the following command.

```
NetIron(config)# interface tunnel 1
NetIron(config-tnif-1)tunnel ttl 100
```

Syntax: [no] tunnel ttl <*ttl-value*>

The <*ttl–value*> variable specifies a TTL value for the outer IP header. Possible values are 1 - 255. The default value is 255.

Configuring a TOS value

This is an optional parameter that allows you to set the TOS value for the outer IP header of the GRE tunnel packets.

To configure the TOS value, enter the following command.

```
NetIron(config)# interface tunnel 1
NetIron(config-tnif-1)tunnel tos 100
```

Syntax: [no] tunnel tos <*tos-value*>

The <*tos-value*> variable specifies a TOS value for the outer IP header.

Configuring GRE session enforce check

The **gre-session-enforce-check** command lets you enable the GRE session enforce check. When a GRE packet arrives and this feature is enabled, the system tries to match the GRE packet source and destination address pair with the tunnel configured destination and source pair. If the pairs do not match, hardware drops the packet.

To configure the GRE session enforce check, go to the IP tunnel policy context, and then enter the **gre-session-enforce-check** command.

```
NetIron(config)#ip-tunnel-policy
NetIron(config-ip-tunnel-policy)#gre-session-enforce-check
```

Syntax: [no] gre-session-enforce-check

To disable the GRE session enforce check, use the **no** form of this command. This command is disabled by default. You might have to write the configuration to memory and reload the system whenever the configuration of this command is changed because a one-time creation of a source-ingress CAM partition is necessary. The system prompts you if the memory write and reload are required.

The first-time execution of certain commands necessitates the creation of a source-ingress CAM partition, after which you write to memory and reload. These commands are **gre-session-enforce-check**, **ipv6-session-enforce-check**, and **accounting-enable**. After this CAM partition is created, it is not necessary to follow either of the other two commands with a memory write and reload.

Configuring a maximum MTU value for a tunnel interface

You can set an MTU value for packets entering the tunnel. Packets that exceed either the default MTU value of 1476 bytes or the value that you set using this command are fragmented for transit through the tunnel. The default MTU value is set to 1476.

The following command allows you to change the MTU value for packets transiting “tunnel 1”.

```
NetIron(config)# interface tunnel 1
NetIron(config-tnif-1)tunnel mtu 1500
```

Syntax: [no] tunnel mtu <*packet-size*>

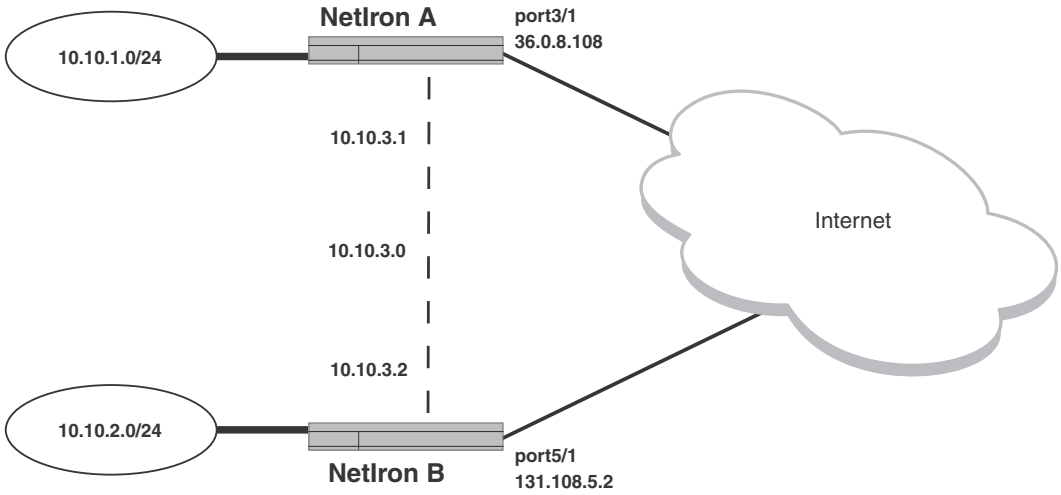
The <*packet-size*> variable specifies the maximum MTU size in bytes for the packets transiting the tunnel.

NOTE
To prevent packet loss after the 24 byte GRE header is added, make sure that any physical interface that is carrying GRE tunnel traffic has an IP MTU setting at least 24 bytes greater than the tunnel MTU setting.

Example of a GRE IP tunnel configuration

In this example, a GRE IP Tunnel is configured between the PowerConnect A router and the PowerConnect B router. Traffic between networks 10.10.1.0/24 and 10.10.2.0/24 is encapsulated in a GRE IP packet sent through the tunnel on the 10.10.3.0 network. and unpacked and sent the destination network. A static route is configured at each router to go through the tunnel interface to the target network.

FIGURE 120 GRE IP tunnel configuration example



Configuration example for PowerConnect A

```
NetIron(config)# interface ethernet 3/1
NetIron(config-int-e10000-3/1)# ip address 36.0.8.108/24
NetIron(config)# interface tunnel 1
NetIron(config-tnif-1)# tunnel source 36.0.8.108
NetIron(config-tnif-1)# tunnel destination 131.108.5.2
NetIron(config-tnif-1)# tunnel mode gre ip
NetIron(config-tnif-1)# ip address 10.10.3.1/24
NetIron(config-tnif-1)# keepalive 5 4
NetIron(config-tnif-1)# exit
NetIron(config)# ip route 10.10.2.0/24 10.10.3.2
```

Configuration example for PowerConnect B

```
NetIron(config)# interface ethernet 5/1
NetIron(config-if-e10000-5/1)# ip address 131.108.5.2/24
NetIron(config)# interface tunnel 1
NetIron(config-tnif-1)# tunnel source ethernet 5/1
NetIron(config-tnif-1)# tunnel destination 36.0.8.108
NetIron(config-tnif-1)# tunnel mode gre ip
NetIron(config-tnif-1)# keepalive 5 4
NetIron(config-tnif-1)# ip address 10.10.3.2/24
NetIron(config-tnif-1)# exit
NetIron(config)# ip route 10.10.1.0/24 10.10.3.1
```

Displaying GRE tunneling information

You can display GRE tunneling information using the **show ip interface, show ip route** and **show interface tunnel** commands as shown in the following.

```
NetIron# show ip interface tunnel 1
Interface Tunnel 1
  port enabled
  port state: UP
  ip address: 110.255.255.13/24
  Port belongs to VRF: default
  encapsulation: ETHERNET, mtu: 1476
  directed-broadcast-forwarding: disabled
  ip icmp redirect: enabled
  No inbound ip access-list is set
  No outbound ip access-list is set
  No Helper Addresses are configured.
```

Syntax: show ip interface tunnel <*tunnel-no*>

The show ip route command displays routes that are pointing to a GRE tunnel as shown in the following.

```
NetIron# show ip route
     Total number of IP routes: 6
     Type Codes - B:BGP D:Connected I:ISIS S:Static R:RIP O:OSPF; Cost -
     Destination     Gateway         Port         Cost       Type
     2 10.10.10.0/24  DIRECT          gre_tnl 1     0/0        D

NetIron# show interface tunnel 1
    Tunnel1 is up, line protocol is up
    Hardware is Tunnel
    Tunnel source 45.45.3.3
    Tunnel destination is 45.45.48.1
    Tunnel mode gre ip
     No port name
     Internet address is 110.255.255.13/24,
    Tunnel TOS 0, Tunnel TTL 255 MTU 1476 bytes
    Keepalive is not Enabled
```

Syntax: show interface tunnel <*tunnel-no*>

Multicast over GRE tunnel

Multi-Service Ironware software supports Multicast over a point-to-point GRE tunnel. Multicast over a GRE tunnel allows multicast packets to be transported through a GRE tunnel across an IP cloud towards its receiver. A GRE tunnel is provisioned at each end of the IP cloud. A GRE tunnel is a virtual IP tunnel; the IP tunnel source can also be a VE interface. The IP cloud sitting in between the two GRE endpoints serves as a PIM enabled logical link. As bidirectional control messages are sent over the GRE tunnel, the multicast distribution tree is established across the IP cloud. Multicast data is encapsulated with a predefined GRE header at the ingress node. The GRE packet is routed within the IP cloud using the outer unicast GRE destination address. As the packet reaches the egress node of the tunnel, the packet is decapsulated. The multicast packet continues on its way to the multicast distribution tree to reach its receivers.

Configuring PIM GRE tunnel

The PowerConnect PIM GRE tunnel configuration allows you to enable PIM Sparse (PIM-SM) and PIM Dense (PIM-DM) on a GRE tunnel.

Enabling PIM-SM on a GRE tunnel interface

To enable PIM-SM on a GRE Tunnel Interface, enter the following command.

```
NetIron(config)#interface tunnel 20
NetIron(config-tnif-20)#ip pim-sparse
```

Syntax: [no] ip pim-sparse

Enabling PIM-DM on a GRE tunnel interface

To enable PIM-DM on a GRE Tunnel Interface, enter the following command.

```
NetIron(config)#interface tunnel 20
NetIron(config-tnif-20)#ip pim
```

Syntax: [no] ip pim

Configuring PIM GRE tunnel using the strict RPF check

The NetIron PIM GRE tunnel configuration allows you to enforce strict rpf check rules on (s,g) entry on a GRE tunnel interface. The (s,g) entry uses the GRE tunnel as a RPF interface. During unicast routing transit, GRE tunnel packets may arrive at different physical interfaces. The **ip pim tunnel rpf-strict** command allows you to limit a specific port to accept the (s,g) GRE tunnel traffic.

NOTE
The configuration is not recommended for all users, it is only needed if the user wants to override the default behavior.

When the GRE encapsulated multicast packet is received, hardware processing attempts to find a match in the CAM session based on the inner (s,g) entry. If hardware processing cannot find the inner (s,g) entry in the CAM session, the packet will be dropped. If the **ip pim tunnel rpf-strict** command is configured on a GRE tunnel interface, hardware processing will check on the (s,g) entry, and verify that the packet matches the physical port on the GRE tunnel interface, and the GRE tunnel vlan id.

To limit a specific port to accept the (s,g) GRE tunnel traffic, enter the following command.

```
NetIron(config)#interface tunnel 20
NetIron(config-tnif-20)#ip pim tunnel rpf-strict
```

Syntax: [no] ip pim tunnel [rpf-strict]

The rpf-strict option allows you to set the strict rpf check on the multicast entry.

Tunnel statistics for a GRE tunnel or IPv6 manual tunnel

At a global level, you can enable the collection of statistics for generic routing encapsulation (GRE) tunnels and manual IPv6 tunnels. With this feature, the PowerConnect router collects the statistics for GRE and IPv6 manual tunnels and displays packet counters for tunnels at the management processor (MP). This feature collects and displays unicast and multicast packets over both directions of the tunnels.

Statistics collection is not enabled by default, so you need to enter the IP tunnel policy configuration level and then execute the accounting-enable command to start collecting the statistics for GRE and IPv6 manual tunnels. This procedure is described in "Enabling tunnel statistics" on page 671. This required preliminary ensures that the source-ingress CAM partition is

not allocated unless statistics collection or tunnel session enforcement checks are actually needed. (Because the statistics enable does not enforce the GRE and IPv6 tunnel session checks by default, these capabilities have their own enable commands in the IP tunnel policy CLI level. The applicable commands are described in "Configuring IPv6 session enforce check" on page 672 and "Configuring IPv6 session enforce check" on page 672.) You can view examples of related show command output in "Displaying GRE and manual IPv6 tunnel statistics" on page 770.

The remainder of this introduction to tunnel statistics describes reload behavior for certain commands and detailed notes and restrictions that apply to the support for tunnel statistics.

Reload behavior and the source-ingress CAM partition

When one of the three tunnel-related commands is configured at the CLI level for IP tunnel policy (entered by use of the **ip-tunnel-policy** command), you might need to save the configuration and reload the router to create the required source-ingress-CAM partition. If the memory write and reload are needed, the system prompts for these steps after you finish the enable commands. The condition for which you might need to write and reload is the absence of the source-ingress-CAM partition. If this partition does not exist, the first time that you run either the **gre-session-enforce-check**, **ipv6-session-enforce-check**, or **accounting-enable** command, the system prompts you. Thereafter, when you run any of these three commands to disable or enable a feature, the system does not prompt. Removing any of the configurations can be done at anytime and does not necessitate a reload. The new configuration immediately becomes effective, but the source-ingress CAM partition is removed only upon the next reload.

Operational notes

The subsections that following describe operational characters that relate to the statistics collection.

Source-ingress-CAM partition

The CAM profile restrictions for this feature are the same as those for the tunnel session enforce-check configuration. This feature is not supported in those CAM profiles for which the system cannot allocate the source-ingress-CAM partition that is needed to support the accounting and session check enforcement. The CLI engine checks for compliance and rejects an attempt to enable statistics in this situation. Currently the following CAM profiles are not supported for IP tunnel statistics:

- IPv6
- L2-metro-2
- MPLS-L3VPN-2
- MPLS-VPLS-2
- MPLS-VPN-VPLS

6to4 automatic tunnels

Statistics collection is supported only for manual IPv6 and GRE tunnels. The system does not support statistics collection for 6to4 automatic IPv6 tunnels because, for automatic 6to4 tunnels, only tunnel source-ip is configured, and the destination is known only at runtime when a remote node tries to use this tunnel. The destination points can come up or go down without the local router having any information on how many destinations are to be used for 6to4 tunnels. This uncertainty can cause scalability issues, so neither statistics collection nor session-enforce check are not supported for 6to4 automatic tunnels.

Multicast-over-GRE packets

This feature counts multicast-over-GRE packets. You can see the multicast packet count by using the show interface tunnel <*tunnel-id*> command. You can use other CLI commands to display the aggregate unicast and multicast statistics for the GRE tunnels. For a description of all the applicable show commands, refer to "Displaying GRE and manual IPv6 tunnel statistics" on page 770.

Statistics polling on the MP and LP

The LP module polls the statistics once every second. For every one second, the module polls the statistics either for 5000 entries or until the completion of a specific application. (The same polling mechanism is also used for other applications, such as IP, MPLS, L3VPN, VLL, VPLS and IP Tunnel.) After all the applications are polled, the system waits for 220 seconds to schedule the next polling event. However, the LP module synchronizes statistics to the MP every 30 seconds, so 30 seconds is the granularity of statistics.

The LP synchronizes statistics to the MP in background every 30 seconds, and the MP stores the statistics for all tunnels for every LP module. If a LP module at either the tunnel ingress or egress, the system uses the current stored statistics for that LP module for display (and continue to poll the rest of working modules to get the latest statistics). This mechanism ensures that the tunnel counters never go down (if no clear statistics command is performed on the tunnel).

When a tunnel is down, the LP does not poll the statistics for that tunnel. The LP keeps the old counters as is until you explicitly clear them on the CLI. These counters are displayed when the tunnel is down. When the tunnel comes back up, it resumes polling and adds the new packet counts to the stored statistics and displays the updated statistics.

Clearing the statistics

When you execute the clear statistics tunnel [tunnel-id] command, the operation clears statistics for either one or all of the tunnels regardless of the circumstance—whether the tunnel is up or down, on an ingress or egress module, and so on. Refer to "Clearing GRE tunnel and manual IPv6 tunnel statistics" on page 672 for a description of the clear statistics tunnel command.

Tunneled packets that encounter an ACL

If a packet reaches the ACL permit or deny clauses for the inner IPv4 or IPv6 addresses when it comes through the IP tunnel at the egress node, the packet is not counted as a receive-from-tunnel packet. Instead, it is counted as an ACL packet. You can view ACL packets by using the show access-list accounting command.

Switchover behavior

The LP sends statistics to both the active and the standby MP modules. If an MP switches over, the new-active MP polls the statistics again so it can display the latest statistics. The counters are equal to or greater than the statistics before the switchover for the working modules. If any module goes down before the switchover, the new active MP uses the stored counters to display the statistics for that module.

Hitless operating system upgrade behavior

When a hitless operating system (OS) upgrade occurs, the tunnel statistics are saved and retrieved after the reset of the LP is complete. The system can retrieve the old statistics and do the polling to get the latest PRAM statistics. After the hitless upgrade, the system can display the correct packet counters.

Behavior after an LP failure

If LP module goes down, the counters for that LP are preserved. After the LP comes back up, the preserved counters for that LP can be displayed.

Feature scalability

The system supports statistics for all tunnels because the source ingress CAM partition has 16000 entries that can support the statistics for all tunnels.

Enabling IP tunnel or manual IPv6 statistics

This section describes how to enable and clear statistics for GRE or manual IPv6 tunnels. The enable for this feature is global in scope. The enabling command is one of three enable commands that you run in the IP tunnel policy context of the CLI. (These commands are **gre-session-enforce-check**, **ipv6-session-enforce-check**, and **accounting-enable**. The **ip-tunnel-policy** command puts the CLI in the mode for executing them.) To see examples of tunnel statistics, refer to "Displaying GRE and manual IPv6 tunnel statistics" on page 770.

Enabling tunnel statistics

To enable the GRE tunnel or manual IPv6 tunnel statistics, go to the IP tunnel policy mode of the CLI and execute the accounting-enable command, as the following example illustrates.

```
NetIron(config)#ip-tunnel-policy
NetIron(config-ip-tunnel-policy)#accounting-enable
```

Syntax: [no] accounting-enable

To turn off tunnel statistics gathering, prepend the no keyword to the accounting-enable command.

The system might prompt you to write the configuration to memory and reload the system. If the system has not yet allocated a source-ingress CAM partition, it prompts you to write the results of the current configuration to memory and reload the system.

The first-time execution of certain commands can prompt the allocation of a source-ingress CAM partition that is required by certain features. These commands are **gre-session-enforce-check**, **ipv6-session-enforce-check**, and **accounting-enable**. After this CAM partition is allocated, you do not need to do the memory write and reload after the first-time execution of the other two commands.

Clearing GRE tunnel and manual IPv6 tunnel statistics

You can clear all of the statistics for either one or all tunnels by using the clear statistics tunnel command, as the following example illustrates.

```
NetIron#clear statistics tunnel 1
```

Syntax: clear statistics tunnel [tunnel ID]

To clear statistics for a specific tunnel, include the ID of that tunnel.

Configuring IPv6 session enforce check

You can enable the IPv6 session enforce check by using the **ipv6-session-enforce-check** command. When an IPv6 packet arrives and this feature is enabled, the system tries to match the Ipv6 packet source and destination address pair with the tunnel configured destination and source pair. If the pairs do not match, the packet is dropped in hardware.

To configure the IPv6 session enforce check, go to the IP tunnel policy context and enter the **ipv6-sessionenforce-check** command.

```
NetIron(config)#ip-tunnel-policy
NetIron(config-ip-tunnel-policy)#ipv6-session-enforce-check
```

Syntax: [no] ipv6-session-enforce-check

To disable the IPv6 session enforce check, use the no form of this command.

The system might prompt you to write the configuration to memory and reload the system. If the system has not yet allocated a source-ingress CAM partition, it prompts you to write the results of the current configuration to memory and reload the system.

The first-time execution of certain commands can prompt the allocation of a source-ingress CAM partition that is required by certain features. These commands are gre-session-enforce-check, ipv6-session-enforce-check, and accounting-enable. After this CAM partition is allocated, you do not need to do the memory write and reload after the first-time execution of the other two commands.

NOTE
The **ipv6-sessions-enforce-check** command is not supported for 6to4 automatic tunnels.

Restart global timers

Restart contains two global timers that:

- Limit the amount of time used for re-syncing routes between the backup Management module and Interface modules (LPs) within the same chassis
- Allow a buffer time for protocols to converge and solve dependencies among each other

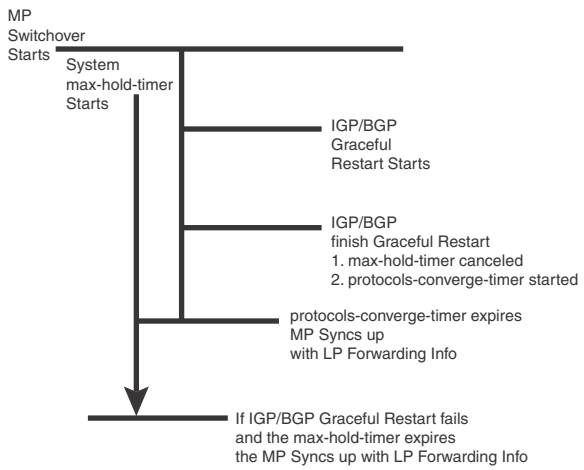
If the protocol-based restart features are configured when a Management module (MP) performs a switchover to the its backup, routes are maintained on the LPs through the protocol-based restart processes for a specified period of time while the new MP learns the network routes. Once the MP learns all of its routes, the routes from the MP are synced with the routes on the LPs.

The two timers introduced here are called the **max-hold-timer** and the **protocols-converge-timer**.

The process of syncing routes between a new MP and its LPs using the new timers are illustrated in Figure 121 and described in the following steps.

1. The MP switchover from active to redundant MP begins.
2. The system **max-hold- timer** starts.
3. The IGP/BGP restart process begins.
4. If the IGP/BGP restart process is completed before the system **max-hold-timer** expires, the system **max-hold-timer** is cancelled and the **protocols-converge-timer** starts.
5. Once the **protocols-converge-timer** expires, the MP syncs up forwarding information with the LPs.
6. If the system **max-hold-timer** expires before the IGP/BGP restart process is completed, the MP syncs up forwarding information with the LPs at that time and the **protocols-converge-timer** is never started.

FIGURE 121 MP to LP re-syncing process



Configuring the graceful-restart max-hold-timer

This timer defines the maximum hold time before a management module syncs up new forwarding information to interface modules during the restart process. While the default value of 300 seconds will work in most cases, if a router is loaded with a very large number of routes and OSPF/BGP peering adjacencies you might want to fine-tune your router's performance by increasing this value.

The value of this timer can be set using the command shown in the following.

```
NetIron(config)# graceful-restart max-hold-timer 500
```

Syntax: [no]graceful-restart max-hold-timer <*hold-time*>

The <*hold-time*> variable is the maximum number of seconds that a management routing module waits before it syncs up new forwarding information to the interface modules during a restart. The range for the hold time is 30 – 3600 seconds. The default time is 300 seconds.

Graceful-restart protocols-converge-timer

This timer defines the time that a PowerConnect router waits for restarting protocols to converge at the final step in the restart process. In a heavily loaded system where BGP/OSPF/GRE/Static protocols can have a dependency on each other, their restart procedures may also depend on each other. This timer is to allow protocols to solve inter-dependencies after individual restart processes and before routing modules sync up new forwarding information to interface module. The default value of 5 seconds will work in most cases but if a system is heavily loaded and has protocols that depend on each other, you might want to fine-tune your system by increasing this value.

The value of this timer can be set using the command shown in the following.

```
NetIron(config)# graceful-restart protocols-converge-timer 20
```

Syntax: [no]graceful-restart protocols-converge-timer <*hold-time*>

The <*hold-time*> variable is the maximum hold time in seconds before management routing modules sync up new forwarding information to interface modules during restart. The range of permissible values is 0 to 1200 seconds. The default value is 5 seconds.

Configuring IP parameters

Some parameters can be configured globally while others can be configured on individual interfaces. Some parameters can be configured globally and overridden for individual interfaces.

Configuring IP addresses

You can configure an IP address on the following types of the PowerConnect interfaces:

- Ethernet port
- Virtual routing interface (also called a Virtual Ethernet or “VE”)
- Loopback interface

By default, you can configure up to 24 IP addresses on each interface.

NOTE
After you configure a virtual routing interface on a VLAN, you cannot configure Layer 3 interface parameters on individual ports in the VLAN. Instead, you must configure the parameters on the virtual routing interface itself.
Also, after an IP address is configured on an interface, the hardware is programmed to route all IP packets that are received on the interface. Consequently, all IP packets not destined for this device’s MAC address are not bridged and are dropped.

The PowerConnect supports both classical IP network masks (Class A, B, and C subnet masks, and so on) and Classless Interdomain Routing (CIDR) network prefix masks.

- To enter a classical network mask, enter the mask in IP address format. For example, enter "209.157.22.99 255.255.255.0" for an IP address with a Class-C subnet mask.
- To enter a prefix network mask, enter a forward slash (/) and the number of bits in the mask immediately after the IP address. For example, enter "209.157.22.99/24" for an IP address that has a network mask with 24 significant bits (ones).

By default, the CLI displays network masks in classical IP address format (example: 255.255.255.0). You can change the display to prefix format.

Assigning an IP address to an Ethernet port

To assign an IP address to port 1/1, enter the following commands.

```
NetIron(config)# interface ethernet 1/1
NetIron(config-if-e1000-1/1)# ip address 192.45.6.1 255.255.255.0
```

NOTE
You also can enter the IP address and mask in CIDR format, as follows.

```
NetIron(config-if-e10000-1/1)# ip address 192.45.6.1/24
```

Syntax: [no]**interface ethernet** <*slot/port*>

Syntax: [no] **ip address** <*ip-addr*> <*ip-mask*> | <*ip-addr*>/<*mask-bits*> **[ospf-ignore | ospf-passive | secondary]**

The **ospf-ignore** | **ospf-passive** parameters modify the PowerConnect defaults for adjacency formation and interface advertisement. Use one of these parameters if you are configuring multiple IP subnet addresses on the interface but you want to prevent OSPF from running on some of the subnets:

- **ospf-passive** – disables adjacency formation with OSPF neighbors (but does not disable advertisement of the interface into OSPF). By default, when OSPF is enabled on an interface, the software forms OSPF router adjacencies between each primary IP address on the interface and the OSPF neighbor attached to the interface.
- **ospf-ignore** – disables OSPF adjacency formation and advertisement of the interface into OSPF. The subnet is completely ignored by OSPF.

Use the **secondary** parameter if you have already configured an IP address within the same subnet on the interface.

NOTE
When you configure more than one address in the same subnet, all but the first address are secondary addresses and do not form OSPF adjacencies.

Assigning an IP address to a loopback interface

Loopback interfaces are always up, regardless of the states of physical interfaces. They can add stability to the network because they are not subject to route flap problems that can occur due to unstable links between a PowerConnect and other devices.

You can configure up to 64 loopback interfaces on a PowerConnect router.

You can add up to 24 IP addresses to each loopback interface.

NOTE
If you configure the PowerConnect to use a loopback interface to communicate with a BGP4 neighbor, you also must configure a loopback interface on the neighbor and configure the neighbor to use that loopback interface to communicate with the PowerConnect.

To add a loopback interface, entehr commands such as those shown in the following example.

```
NetIron(config-bgp-router)# exit
NetIron(config)# int loopback 1
NetIron(config-lbif-1)# ip address 10.0.0.1/24
```

Syntax: [no]interface loopback <*num*>

For the syntax of the IP address, refer to "Assigning an IP address to an Ethernet port" on page 675.

Assigning an IP address to a virtual interface

A virtual interface is a logical port associated with a Layer 3 Virtual LAN (VLAN) configured on a PowerConnect.

NOTE
Other sections in this chapter that describe how to configure interface parameters also apply to virtual interfaces.

NOTE
The PowerConnect uses the lowest MAC address on the device (the MAC address of port 1 or 1/1) as the MAC address for all ports within all virtual interfaces you configure on the device.

To add a virtual interface to a VLAN and configure an IP address on the interface, enter commands such as the following.

```
NetIron(config)# vlan 2 name IP-Subnet_1.1.2.0/24
NetIron(config-vlan-2)# untag e1/1 to 1/4
NetIron(config-vlan-2)# router-interface ve1
NetIron(config-vlan-2)# interface ve1
NetIron(config-vif-1)# ip address 1.1.2.1/24
```

The first two commands create a Layer 3 protocol-based VLAN named "IP-Subnet_1.1.2.0/24" and add a range of untagged ports to the VLAN. The **router-interface** command creates virtual interface 1 as the routing interface for the VLAN. The last two commands change to the interface configuration level for the virtual interface and assign an IP address to the interface.

Syntax: [no]router-interface ve <*num*>

Syntax: [no]interface ve <*num*>

The <*num*> parameter specifies the virtual interface number. You can specify from 1 to the maximum number of virtual interfaces supported on the device. To display the maximum number of virtual interfaces supported on the device, enter the **show default values** command. The maximum is listed in the System Parameters section, in the Current column of the virtual-interface row.

For the syntax of the IP address, refer to "Assigning an IP address to an Ethernet port" on page 675.

Assigning a MAC address to a virtual interface

By default, the PowerConnect uses the MAC address of the first port (1 or 1/1) as the MAC address for all virtual routing interfaces configured on the device. You can specify a different MAC address for the virtual routing interfaces. If you specify another MAC address for the virtual routing interfaces, the address applies to all the virtual routing interfaces configured on the device. To specify the MAC address for virtual routing interfaces, enter commands such as the following.

```
NetIron(config)# virtual-interface-mac aaaa.bbbb.cccc
NetIron(config)# write memory
NetIron(config)# end
NetIron# reload
```

Syntax: [no] virtual-interface-mac <*mac-addr*>

Enter the MAC address in the following format: HHHH.HHHH.HHHH

NOTE
You must save the configuration and reload the software to place the change into effect.

Deleting an IP address

To delete an IP address, enter a command such as the following.

```
NetIron(config-if-e1000-1/1)# no ip address 1.1.2.1
```

This command deletes IP address 1.1.2.1. You do not need to enter the subnet mask.

To delete all IP addresses from an interface, enter the following command.

```
NetIron(config-if-e1000-1/1)# no ip address *
```

Syntax: no ip address <*ip-addr*>

Enabling hardware forwarding of IP option packets based on L3 destination

The IP option field in an IP header is variable in length. A packet can have zero or more options and an option can have either of the following forms:

- a single octet of option-type
- an option-type octet, an option-length octet, and option-data octets

The option-type octet consists of the following three fields:

- 1 bit copied flag
- 2 bits option class
- 5 bits option number

By default, IP option packets are sent to the CPU for forwarding. When configured on a physical interface, the **ignore-options** command directs the router to ignore all options in IP option packets that are received at the configured port. These packets are then treated as if there were no options configured and forwarded based on their Layer-3 destination. The **ignore-options** command is configured as shown in the following.

```
NetIron(config)# interface ethernet 1/1
NetIron(config-if-e1000-1/1)# ignore-options
```

Syntax: [no] ignore-options

This command only applies to IP option packets in the default VRF.

When the **ignore-options** command is configured on a port, RSVP router alert packets incoming on that port will not be sent to the CPU. Consequently, MPLS should not be configured on a physical port where the **ignore-options** command is configured.

Using the ignore-options command in a LAG configuration

The **ignore-options** command can be used on a LAG but it must apply to all ports on the LAG. This applies to both static and LACP LAGs as described in the following:

Configuring the ignore-options command on a static LAG

To configure the **ignore-options** command on a static LAG, each port on the LAG must be configured with the command. You can do this by configuring the command on each port before the LAG configuration or configuring the **ignore-options** command on the primary port of the LAG which automatically applies the command to all ports on the LAG as shown in the following.

```
NetIron(config)# trunk e 3/1 to 3/4

trunk transaction done.
NetIron(config-trunk-3/1-3/4)# exit
NetIron(config)# interface ethernet 3/1
NetIron(config-if-e1000-3/1)# ignore-options
```

If the LAG is removed, the **ignore-options** command will be propagated to all ports that were previously in the LAG.

If you try to create a LAG where some of the ports have the **ignore-options** command configured and some do not, the LAG will not be allowed as shown in the following example.

```
NetIron(config)# trunk e 3/1 to 3/2
port 3/1 ignore-options is Enabled, but port 3/2 ignore-options is Disabled
Error: port 3/1 and port 3/2 have different configurations

trunk transaction failed:  trunk Config Vetoed
```

Configuring the ignore-options command on a LACP LAG

Just as with static LAGs, if you want to configure the **ignore-options** command on an LACP LAG, the command must be enabled on all ports within the LAG. If it is not, the LACP LAG will not be accepted as shown in the following.

```
NetIron(config)#lag sta_lag static
NetIron(config-lag-sta_lag)#ports e 1/3 to 1/4
NetIron(config-lag-sta_lag)#primary-port 1/3
NetIron(config-lag-sta_lag)#deploy
NetIron(config-lag-sta_lag)#int e 1/3
NetIron(config-if-e1000-1/3)#ignore-options

NetIron(config)#lag sta_lag static
NetIron(config-lag-sta_lag)#ports e 1/3 e 1/4
NetIron(config-lag-sta_lag)#primary-port 1/3
NetIron(config-lag-sta_lag)#deploy
port 1/3 ignore-options is Enabled, but port 1/4 ignore-options is Disabled
Error: port 1/3 and port 1/4 have different configurations
LAG sta_lag deployment failed!

NetIron(config)#int e 1/3
```

```
NetIron(config-if-e1000-1/3)#ignore-options
NetIron(config-if-e1000-1/3)#lag dyn_lag dynamic
NetIron(config-lag-dyn_lag)#ports e 1/3 e 1/4
NetIron(config-lag-dyn_lag)#primary-port 1/3
NetIron(config-lag-dyn_lag)#deploy
port 1/3 ignore-options is Enabled, but port 1/4 ignore-options is Disabled
Error: port 1/3 and port 1/4 have different configurations
LAG dyn_lag deployment failed!
```

Configuring domain name server (DNS) resolver

The DNS resolver lets you use a host name to perform Telnet, ping, and traceroute commands. You can also define a DNS domain on a PowerConnect and thereby recognize all hosts within that domain. After you define a domain name, the PowerConnect automatically appends the appropriate domain to the host and forwards it to the domain name server.

For example, if the domain “newyork.com” is defined on a PowerConnect and you want to initiate a ping to host “NYC01” on that domain, you need to reference only the host name in the command instead of the host name and its domain name. For example, you could enter either of the following commands to initiate the ping.

```
NetIron# ping nyc01
NetIron# ping nyc01.newyork.com
```

Multiple DNS queries can be executed simultaneously, making it possible for the PowerConnect device to run multiple simultaneous Telnet, ping or traceroute commands using host names.

Defining an IPv4 DNS entry

You can define up to four DNS servers for each DNS entry. The first entry serves as the primary default address. If a query to the primary address fails to be resolved after three attempts, the next gateway address is queried (also up to three times). This process continues for each defined gateway address until the query is resolved. The order in which the default gateway addresses are polled is the same as the order in which you enter them.

Suppose you want to define the domain name of newyork.com on a device and then define four possible default DNS gateway addresses. To do so using IPv4 addressing, you would enter the following commands.

```
NetIron(config)# ip dns domain-name newyork.com
NetIron(config)# ip dns server-address 209.157.22.199 205.96.7.15 208.95.7.25
201.98.7.15
```

Syntax: [no] ip dns server-address <*ip-addr*> [<*ip-addr*>] [<*ip-addr*>] [<*ip-addr*>]

In this example, the first IP address in the **ip dns server-address...** command becomes the primary gateway address and all others are secondary addresses. Because IP address 201.98.7.15 is the last address listed, it is also the last address consulted to resolve a query.

DNS queries of IPv4 and IPv6 DNS servers

IPv4 and IPv6 DNS record queries search through IPv4 and IPv6 DNS servers as described in the following:

For IPv4 DNS record queries:

- Loop thru all configured IPv4 DNS servers,

- If no IPv4 DNS servers were configured, then loop through all configured IPv6 DNS servers (if any).

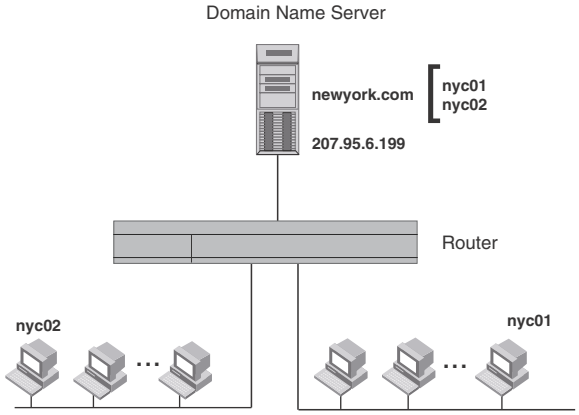
For IPv6 DNS record queries:

- Loop thru all configured IPv6 DNS servers,
- If no IPv6 DNS servers were configured, then loop through all configured IPv4 DNS servers (if any).

Using a DNS name to initiate a trace route

Suppose you want to trace the route from a PowerConnect to a remote server identified as NYC02 on domain newyork.com.

FIGURE 122 Querying a host on the newyork.com domain



Because the newyork.com domain is already defined on the PowerConnect, you need to enter only the host name, NYC02, as noted below.

```
NetIron# traceroute nyc02
```

Syntax: [no] traceroute <*host-ip-addr*> **[maxttl** <*value*>*] [minttl* <*value*>**] [numeric] [timeout** <*value*>**]**
[source-ip <*ip addr*>**]**

The only required parameter is the IP address of the host at the other end of the route.

After you enter the command, a message indicating that the DNS query is in process and the current gateway address (IP address of the domain name server) being queried appear on the screen.

```
Type Control-c to abort
Sending DNS Query to 209.157.22.199
Tracing Route to IP node 209.157.22.80
To ABORT Trace Route, Please use stop-traceroute command.
 Traced route to target IP node 209.157.22.80:
   IP Address          Round Trip Time1    Round Trip Time2
  207.95.6.30         93 msec             121 msec
```

NOTE
In the above example, 209.157.22.199 is the IP address of the domain name server (default DNS gateway address), and 209.157.22.80 represents the IP address of the NYC02 host.

Using Telnet and Secure Shell

Up to six inbound and five outbound Telnet connections can be supported simultaneously by the PowerConnect device. For detailed information about the use of Telnet on the PowerConnect, please see "Using Telnet" on page 2011. The PowerConnect also supports Secure Shell (SSH) access to management functions; for further information, please refer to "Using Secure Shell" on page 2013.

Changing the encapsulation type for IP packets

The PowerConnect encapsulates IP packets into Layer 2 packets, to send the IP packets on the network. A Layer 2 packet is also called a MAC layer packet or an Ethernet frame. The MAC address of the PowerConnect interface sending the packet is the source address of the Layer 2 packet. The Layer 2 packet's destination address can be one of the following:

- The MAC address of the IP packet's destination. In this case, the destination device is directly connected to the PowerConnect.
- The MAC address of the next-hop gateway toward the packet's destination.
- An Ethernet broadcast address.

The entire IP packet, including the source address, destination address, other control information, and the data, is placed in the data portion of the Layer 2 packet. Typically, an Ethernet network uses one of two different formats of Layer 2 packet:

- Ethernet II
- Ethernet SNAP (also called IEEE 802.3)

The control portions of these packets differ slightly. All IP devices on an Ethernet network must use the same format. The PowerConnect uses Ethernet II by default. You can change the IP encapsulation to Ethernet SNAP on individual ports if needed.

NOTE
All devices connected to the PowerConnect port must use the same encapsulation type.

To change the IP encapsulation type on interface 1/5 to Ethernet SNAP, enter the following commands.

```
NetIron(config)# int e 1/5
NetIron(config-if-e1000-1/5)# ip encapsulation snap
```

Syntax: [no] ip encapsulation snap | ethernet-2

Setting the maximum frame size globally

You can set the default maximum frame size to control the maximum size of Ethernet frames that the Ethernet MAC framers will accept or transmit. The size is counted from the beginning of Ethernet header to the end of CRC field. The default maximum frame size must be greater than an IP MTU value set using the "Globally changing the IP MTU" on page 683.

To set a maximum frame size that applies to the router for Ethernet ports, enter a command such as the following.

```
NetIron(config)# default-max-frame-size 2000
NetIron(config)# write memory
NetIron(config)# reload
```

Syntax: [no] default-max-frame-size <*bytes*>

Enter 64 – 9216 for <*bytes*>. If you have POS interface modules installed in a router, you need to consider the value of the pos-default-max-frame-size setting as described in "Setting the maximum frame size globally for POS modules" on page 190.

NOTE
You must run the **write memory** command and reload the PowerConnect router for the **default-max-frame-size** command to take effect.

Changing the MTU

The IP MTU is the maximum length of an IP packet that a Layer 2 packet can contain. If an IP packet is larger than the IP MTU allowed by the Layer 2 packet, the PowerConnect fragments the IP packet into multiple parts that will fit into Layer 2 packets, and sends the parts of the fragmented IP packet separately, in different Layer 2 packets. The device that receives the multiple fragments of the IP packet reassembles the fragments into the original packet. The default IP MTU is 1500 bytes for Ethernet II packets. You can change the IP MTU globally or for individual IP interfaces. You can increase the IP MTU size to accommodate large packet sizes, such as jumbo packets, globally or on individual IP interfaces. However, IP MTU cannot be set higher than the maximum frame size, minus 18.

NOTE
For multicast data traffic, frames are not fragmented and the IP mtu setting is ignored.

For jumbo packets, the PowerConnect supports hardware forwarding of Layer 3 jumbo packets. Layer 3 IP unicast jumbo packets received on a port that supports the frame's IP MTU size and forwarded to another port that also supports the frame's IP MTU size are forwarded in hardware.

NOTE
Policy Based Routing (PBR) currently does not support this IP MTU feature.

Configuration considerations for increasing the IP MTU:

- The maximum value of an IP MTU cannot exceed the configured maximum frame size, minus 18. For example, global IP MTU cannot exceed the value of **default-max-frame-size**, minus 18 bytes. IP MTU for an interface cannot exceed the value of the maximum frame size configured, minus 18 bytes. The 18 bytes is used for IP overhead, VLAN tagging, etc.
- When you increase the IP MTU size of for an IP interface, the increase uses system resources. Increase the IP MTU size only on the IP interfaces that need it. For example, if you have one IP interface connected to a server that uses jumbo frames and two other IP interfaces connected to clients that can support the jumbo frames, increase the IP MTU only on those three IP interfaces. Leave the IP MTU size on the other IP interfaces at the default value (1500 bytes). Globally increase the IP MTU size only if needed.

How To determine the actual MTU value

An IPv4 interface can obtain it's MTU value from any of the following sources:

- Default IP MTU setting
- Global MTU Setting
- Interface MTU Setting

An interface determines its actual MTU value through the process described below.

1. If an IPv4 Interface MTU value is configured, that value will be used.
2. If an IPv4 Interface MTU value is not configured and an IPv4 Global MTU value is configured, the configured global MTU value will be used.
3. If neither an IPv4 Interface MTU value or an IPv4 Global MTU value are configured, the default IPv4 MTU value of 1500 will be used.

Globally changing the IP MTU

At the global CLI level, the **ip mtu** command has been deprecated. The new command is **ip global-mtu** command. After upgrading to release 04.1.00, the old command syntax will no longer be accepted except at system bootup time.

To globally enable jumbo support on all IP interfaces, enter commands such as the following.

```
NetIron(config)# ip global-mtu 5000
NetIron(config)# write memory
```

If the old command syntax is entered, the following error message will display on the console:

```
NetIron(config)#ip mtu 800
ERROR - Command deprecated. Keyword mtu is replaced by global-mtu.
```

Syntax: [no] ip global-mtu <*bytes*>

The <*bytes*> parameter specifies the maximum IP packet size to be forwarded on a port. You may enter any number within the range of 576 – 9198. However, this value must be 18 bytes less than the value of the global maximum frame size.

If you are using POS interface modules in your PowerConnect router, the value must not exceed the value set using the **pos-default-max-frame-size** command.

Changing the maximum transmission unit on an individual interface

By default, the maximum IP MTU sizes are as follows:

- 1500 bytes – The maximum for Ethernet II encapsulation

NOTE
The IP MTU configured at the IP interface level takes precedence over the IP MTU configured at the global level for that IP interface.

To change the IP MTU for interface 1/5 to 1000, enter the following commands.

```
NetIron(config)# int e 1/5
NetIron(config-if-e10000-5)# ip mtu 1000
```

Syntax: [no] ip mtu <bytes>

The <*bytes*> variable specifies the IP MTU. However, the value of IP MTU on an interface cannot exceed the configured value **default-max-frame-size**, minus 18 bytes. The default IP MTU for Ethernet II packets is 1500.

Changing the router ID

In most configurations, a PowerConnect has multiple IP addresses, usually configured on different interfaces. As a result, a PowerConnect's identity to other devices varies depending on the interface to which the other device is attached. Some routing protocols, including OSPF and BGP4, identify a PowerConnect by just one of the IP addresses configured on the PowerConnect, regardless of the interfaces that connect the PowerConnect devices. This IP address is the router ID.

NOTE
RIP does not use the router ID.

NOTE
If you change the router ID, all current BGP4 sessions are cleared.

By default, the router ID on a PowerConnect is one of the following:

- If the router has loopback interfaces, the default router ID is the IP address configured on the lowest numbered loopback interface configured on the PowerConnect. For example, if you configure loopback interfaces 1, 2, and 3 as follows, the default router ID is 9.9.9.9/24:
  - Loopback interface 1, 9.9.9.9/24
  - Loopback interface 2, 4.4.4.4/24
  - Loopback interface 3, 1.1.1.1/24
- If the device does not have any loopback interfaces, the default router ID is the lowest numbered IP interface configured on the device.

If you prefer, you can explicitly set the router ID to any valid IP address. The IP address should not be in use on another device in the network.

You can set a router ID for a specific VRF as described within this section. In order to make the route ID calculation more deterministic, the router calculates the router-id value during bootup and does not calculate or change the router-id value unless the IP address used for the router-id value on the router is deleted, or the **clear router-id** command is issued. Additionally, setting a router-id value overrides the existing router-id value and takes effect immediately. Once a router-id value set by a user is removed using the **no ip router-id x.x.x.x** command, the router will again recalculate the router-id value based on current information.

NOTE
The PowerConnect uses the same router ID for both OSPF and BGP4. If the router is already configured for OSPF, you may want to use the router ID that is already in use on the router rather than set a new one. To display the router ID, enter the **show ip** command at any CLI level.

To change the router ID, enter a command such as the following.

```
NetIron(config)# ip router-id 209.157.22.26
```

Syntax: [no]ip router-id <*ip-addr*>

The <*ip-addr*> can be any valid, unique IP address.

To set the router ID within a VRF, enter a command such as the following.

```
NetIron(config)# ip vrf blue
NetIron(config-ip-vrf-blue)# ip router-id 209.157.22.26
```

Syntax: [no]ip router-id <*ip-addr*>

NOTE
The command for setting the router ID for a specified VRF is exactly the same as for the default VRF. The only difference is that when setting it for a specific VRF, the **ip router-id** command is configured within the VRF as shown in the example.

NOTE
You can specify an IP address used for an interface, but do not specify an IP address in use by another device.

Recalculating the router ID

You can use the **clear ip router-id** command to direct a router to recalculate the IP router ID. This can be done for the default VRF or for a specified VRF, as shown in the following.

```
NetIron(config)# clear ip router-id
```

Syntax: **clear ip router-id [vrf** <*vrf-name*> **]**

Using this command without the **vrf** option recalculates the IP router ID for the default VRF.

You can use the **vrf** option to recalculate the IP router ID for a specific VRF that is specified by the <*vrf-name*> variable.

Specifying a single source interface for Telnet, SSH, SNTP, TFTP, TACACS/TACACS+, or RADIUS packets

When the PowerConnect originates a Telnet, SSH, SNTP, TFTP, TACACS/TACACS+, or RADIUS packet, the source address of the packet is the lowest-numbered IP address on the interface that sends the packet. You can configure the PowerConnect to always use the lowest-numbered IP address on a specific interface as the source addresses for these types of packets. When you configure the PowerConnect to use a single source interface for all Telnet, TACACS/TACACS+, or RADIUS packets, the PowerConnect uses the same IP address as the source for all packets of the specified type, regardless of the ports that actually sends the packets.

Identifying a single source IP address for Telnet, SSH, SNTP, TFTP, TACACS/TACACS+, or RADIUS packets provides the following benefits:

- If your Telnet, SSH, SNTP, TFTP, TACACS/TACACS+, or RADIUS server is configured to accept packets only from specific IP addresses, you can use this feature to simplify configuration of the server by configuring the device to always send the packets from the same link or source address.
- If you specify a loopback interface as the single source for Telnet, SSH, SNTP, TFTP, TACACS/TACACS+, or RADIUS packets, servers can receive the packets regardless of the states of individual links. Thus, if a link to the server becomes unavailable but the client or server can be reached through another link, the client or server still receives the packets, and the packets still have the source IP address of the loopback interface.

The software contains separate CLI commands for specifying the source interface for Telnet, SSH, SNTP, TFTP, TACACS/TACACS+, or RADIUS packets. You can configure a source interface for one or more of these types of packets separately.

Configuring an interface as the source for Syslog packets

You can configure the device to use the lowest-numbered IP or IPv6 address configured on a loopback interface, virtual interface, or Ethernet port as the source for all Syslog packets from the device. The software uses the lowest-numbered IP or IPv6 address configured on the interface as the source IP address for the packets.

For example, to specify the lowest-numbered IP address configured on a virtual interface as the device's source for all Syslog packets, enter commands such as the following.

```
NetIron(config)# int ve 1
NetIron(config-vif-1)# ip address 10.0.0.4/24
NetIron(config-vif-1)# exit
NetIron(config)# ip syslog source-interface ve 1
```

The commands in this example configure virtual interface 1, assign IP address 10.0.0.4/24 to the interface, then designate the interface's address as the source address for all Syslog packets.

Syntax: [no] ip syslog source-interface ethernet [<*slotnum*>**/]**<*portnum*> **| loopback** <*num*> **| ve** <*num*>

The <*num*> parameter is a loopback interface or virtual interface number. If you specify an Ethernet, the <*slotnum*>/]<*portnum*> is the port's number including the slot number, if you are configuring a device.

The default is the lowest-numbered IP or IPv6 address configured on the port through which the packet is sent. The address therefore changes, by default, depending on the port.

With this new command, the source ip of syslog is no longer controlled by the **snmp-server trap-source** command.

Configuring ARP parameters

Address Resolution Protocol (ARP) is a standard IP protocol that enables the PowerConnect to obtain the MAC address of another device's interface when the PowerConnect knows the IP address of the interface. ARP is enabled by default and cannot be disabled.

How ARP works

The PowerConnect router needs to know a destination's MAC address when forwarding traffic, because the PowerConnect router encapsulates the IP packet in a Layer 2 packet (MAC layer packet) and sends the Layer 2 packet to a MAC interface on a device directly attached to the PowerConnect router. The device can be the packet's final destination or the next-hop router toward the destination.

The PowerConnect router encapsulates IP packets in Layer 2 packets regardless of whether the ultimate destination is locally attached or is multiple router hops away. Since the PowerConnect router's IP route table and IP forwarding cache contain IP address information but not MAC address information, the PowerConnect router cannot forward IP packets based solely on the information in the route table or forwarding cache. The PowerConnect router needs to know the MAC address that corresponds with the IP address of either the packet's locally attached destination or the next-hop router that leads to the destination.

For example, to forward a packet whose destination is multiple router hops away, the PowerConnect router must send the packet to the next-hop router toward its destination, or to a default route or default network route if the IP route table does not contain a route to the packet's destination. In each case, the PowerConnect router must encapsulate the packet and address it to the MAC address of a locally attached device, the next-hop router toward the IP packet's destination.

To obtain the MAC address required for forwarding a datagram, the PowerConnect router does the following:

- First, the PowerConnect router looks in the ARP cache (not the static ARP table) for an entry that lists the MAC address for the IP address. The ARP cache maps IP addresses to MAC addresses. The cache also lists the port attached to the device and, if the entry is dynamic, the age of the entry. A dynamic ARP entry enters the cache when the PowerConnect receives an ARP reply or receives an ARP request (which contains the sender's IP address and MAC address). A static entry enters the ARP cache from the static ARP table (which is a separate table) when the interface for the entry comes up.

  To ensure the accuracy of the ARP cache, each dynamic entry has its own age timer. The timer is reset to zero each time the PowerConnect router receives an ARP reply or ARP request containing the IP address and MAC address of the entry. If a dynamic entry reaches its maximum allowable age, the entry times out and the software removes the entry from the table. Static entries do not age out and can be removed only by you.
- If the ARP cache does not contain an entry for the destination IP address, the PowerConnect router broadcasts an ARP request out all its IP interfaces. The ARP request contains the IP address of the destination. If the device with the IP address is directly attached to the PowerConnect router, the device sends an ARP response containing its MAC address. The response is a unicast packet addressed directly to the PowerConnect router. The PowerConnect router places the information from the ARP response into the ARP cache.

  ARP requests contain the IP address and MAC address of the sender, so all devices that receive the request learn the MAC address and IP address of the sender and can update their own ARP caches accordingly.

  NOTE
  The ARP request broadcast is a MAC broadcast, which means the broadcast goes only to devices that are directly attached to the PowerConnect router. A MAC broadcast is not routed to other networks. However, some routers, including the PowerConnect router, can be configured to reply to ARP requests from one network on behalf of devices on another network. Refer to "Enabling proxy ARP" on page 689.

NOTE
If the router receives an ARP request packet that it is unable to deliver to the final destination because of the ARP timeout and no ARP response is received (the PowerConnect router knows of no route to the destination address), the router sends an ICMP Host Unreachable message to the source.

Rate limiting ARP packets

For rate-limiting purposes, ARP traffic destined for the CPU is assigned a separate global QoS ID 0xFFE. You can configure the rate-limit parameters using the following global CONFIG command.

```
NetIron(config)# ip rate-limit arp policy-map <policy-map-name>
```

By default, the rate-limit parameters for QoS ID 0xFFE will be initialized to allow line-rate traffic. The rate-limit parameters specified using the policy-map are applicable on a per-PPCR basis.

To display ARP accounting statistics, enter the following command.

```
NetIron(config)# show rate-limit arp
```

This command displays the byte counters corresponding to QoS ID 0xFFE.

```
NetIron(config)# clear rate-limit arp
```

This command clears the byte counters corresponding to QoS ID 0xFFE.

When priority-based rate limiting is enabled, QoS IDs 0x3FE, 0x7FE and 0xBFE will be re-mapped to 0xFFE. When priority-based rate limiting is disabled, QoS IDs 0x3FE, 0x7FE and 0xBFE will not be re-mapped to 0xFFE. In either case, only QoS ID 0xFFE will be added to the list of used QoS IDs.

To enable the dynamic addition, deletion, or change in rate-limit values of a policy-map, enter the following command.

```
NetIron(config)# ip rate-limit arp policy-map <policy-map-name>
```

This command takes effect automatically, without unbinding and rebinding the ARP RL policy. If the ARP Rate Limit policy specifies an undefined policy-map, rate limit values are initialized to line-rate values. Dynamic enabling and disabling of priority based rate limiting on a global basis takes effect automatically for the ARP RL policy.

NOTE
ARP packets destined for the CPU will be not be rate-limited by interface-level L2 RL-ACLs. To rate-limit switched ARP packets using interface-level L2 ACLs, you must define an explicit ACL filter with an “etype arp” option, as shown in the following example:

To define an explicit ACL filter, enter commands similar to the following.

```
NetIron(config)# access-list 410 permit any any any etype arp
NetIron(config)# int eth 4/1
NetIron(config-if-e10000-4/1)# rate-limit in access-gr 410 policy-map view
```

NOTE
Since ARP packets are broadcast packets, ARP packets are switched by default within a VLAN by the CPU. Thus to rate-limit switched ARP packets using interface-level L2 ACLs, you must also configure vlan-cpu-protection.

Changing the ARP aging period

When the PowerConnect places an entry in the ARP cache, the PowerConnect router also starts an aging timer for the entry. The aging timer ensures that the ARP cache does not retain learned entries that are no longer valid. An entry can become invalid when the device with the MAC address of the entry is no longer on the network.

The ARP age affects dynamic (learned) entries only, not static entries. The default ARP age is ten minutes. On the PowerConnect router, you can change the ARP age to a value from 0 – 240 minutes. If you set the ARP age to zero, aging is disabled and entries do not age out.

To globally change the ARP aging parameter to 20 minutes, enter the following command.

```
NetIron(config)# ip arp-age 20
```

Syntax: [no]ip arp-age <*num*>

The <*num*> parameter specifies the number of minutes and can be from 0 – 240. The default is 10. If you specify 0, aging is disabled.

To override the globally configured IP ARP age on an individual interface, enter a command such as the following at the interface configuration level.

```
NetIron(config-if-e1000-1/1)# ip arp-age 30
```

Enabling proxy ARP

Proxy ARP allows the PowerConnect router to answer ARP requests from devices on one network on behalf of devices in another network. Since ARP requests are MAC-layer broadcasts, they reach only the devices that are directly connected to the sender of the ARP request. Thus, ARP requests do not cross routers.

For example, if Proxy ARP is enabled on the PowerConnect router connected to two subnets, 10.10.10.0/24 and 20.20.20.0/24, the PowerConnect router can respond to an ARP request from 10.10.10.69 for the MAC address of the device with IP address 20.20.20.69. In standard ARP, a request from a device in the 10.10.10.0/24 subnet cannot reach a device in the 20.20.20.0 subnet if the subnets are on different network cables, and thus is not answered.

NOTE
An ARP request from one subnet can reach another subnet when both subnets are on the same physical segment (Ethernet cable), since MAC-layer broadcasts reach all the devices on the segment.

Proxy ARP is disabled by default.

To enable IP proxy ARP, enter the following command.

```
NetIron(config)# ip proxy-arp
```

To again disable IP proxy ARP, enter the following command.

```
NetIron(config)# no ip proxy-arp
```

Syntax: [no] ip proxy-arp

Enabling local proxy ARP

Under some Layer-2 configurations such as uplink-switch or private VLAN, broadcast packets are not flooded to every port in a VLAN. In these configurations, an ARP request from one host may not reach another host. Enabling the Local Proxy ARP feature on a port directs the router to reply on behalf of a target host if it exists. The ARP reply returned contains the router's mac address instead of the mac address of the target host. In this transaction, the traffic sent to the target host is Layer-3 forwarded rather than Layer-2 switched.

To enable Local Proxy ARP, the global-level command **ip proxy-arp** must first be enabled as described in "Enabling proxy ARP" on page 689. After **ip proxy-arp** has been enabled globally, Local Proxy ARP can be enabled on a specified interface using the following command.

```
NetIron(config-if-e1000-1/1)# interface ethernet 1/1
NetIron(config)# ip local-proxy-arp
```

Syntax: [no] ip local-proxy-arp

Disabling gratuitous ARP requests for local proxy ARP

When the Local Proxy ARP is configured under the IP interface, the PowerConnect router will reply to ARP requests on behalf of the hosts inside the subnet using its own MAC address. Refer to "Enabling local proxy ARP" on page 689 for information on configuring the **Local Proxy ARP** command. In this configuration, when a host comes up, the host tries to ping its own IP address to make sure there is no duplicated IP address by issuing a gratuitous ARP request to its only IP address. The PowerConnect router will reply to this request because it is required under the Local Proxy ARP configuration. When the host receives the ARP reply, the host incorrectly assumes that there is another host using the same IP address.

A gratuitous ARP request packet is defined as an ARP request packet with the sender protocol address that equals to the target protocol address. By disabling Gratuitous ARP Requests for Local Proxy ARP, you are able to control whether to reply to gratuitous ARP requests under the Local Proxy ARP configuration.

To enable the ignore-gratuitous-arp parameter when the **ip local-proxy-arp** command is turned on, enter the following command.

```
NetIron(config-if-e1000-1/6)# ip local-proxy-arp ignore-gratuitous-arp
```

To disable only the ignore-gratuitous-arp parameter when the Local Proxy ARP is configured, enter the following command.

```
NetIron(config-if-e1000-1/6)# no ip local-proxy-arp ignore-gratuitous-arp
```

To disable both the **Local Proxy ARP** command and the ignore-gratuitous-arp parameter, enter the following command.

```
NetIron(config-if-e1000-1/6)# no ip-local-proxy-arp
```

Syntax: [no] ip local-proxy-arp [ignore-gratuitous-arp]

When using the **no ip local-proxy-arp ignore-gratuitous-arp** command, only the ignore-gratuitous-arp parameter is turned off. The **ip-local-proxy-arp** command is still turned on.

The PowerConnect drops all ARP packets that are sent from its own interface. When the ignore-gratuitous-arp parameter is turned on, the PowerConnect will not reply to a gratuitous ARP request even if the target protocol address matches the configured interface IP address.

Creating static ARP entries

The PowerConnect router has a static ARP table, in addition to the regular ARP cache. The static ARP table contains entries that you configure.

Static entries are useful in cases where you want to pre-configure an entry for a device that is not connected to the PowerConnect router, or you want to prevent a particular entry from aging out. The software removes a dynamic entry from the ARP cache if the ARP aging interval expires before the entry is refreshed. Static entries do not age out, regardless of whether the device receives an ARP request from the device that has the entry's address.

You can increase the number of configurable static ARP entries. Refer to "Changing the ARP timer" on page 691.

To display the ARP cache and static ARP table, refer to the following:

- To display the ARP table, refer to "Displaying the ARP cache" on page 759.
- To display the static ARP table, refer to "Displaying the static ARP table" on page 760.

- To create a static ARP entry for a static MAC entry, refer to "Creating ARP entries" on page 695.

Changing the ARP timer

When an entry is initially added to the ARP table, it is listed as "Pending." When it is in this state, a series of ARP requests are made to determine if it is a valid entry. If the first attempt succeeds, the status of the entry is changed to "dynamic." It is then subject to the normal rules for dynamic entries. If three attempts fail, the entry is removed from the table.

The ARP timer determines the amount of time that elapses after the ARP request is sent before determining that the request has failed.The **arp-timer** command allows you change the length of the ARP timer as shown in the following.

```
NetIron(config)# ip arp timer 12
```

Syntax: [no] ip arp-timer <*timer-value*>

The <*timer-value*> variable has now been changed so that you are able to enter a value between 1 and 500. Each increment represents 100 ms. Consequently, the minimum value of 1 equals 100 ms.

The default value is 10 which equals 1 sec.

This value can be used to adjust how frequently an ARP request is sent out for a pending ARP entry.

Changing the ARP pending retry timer

The ARP Pending Retry Timer for PowerConnect will send out three ARP request packets for the configured period until ARP is resolved to prevent large amounts of ARP requests from flooding the network during network host scanning activity. The ARP Pending Retry Timer is configurable depending upon the requirements of your system configurations.

The **arp-pending-retry-timer** command allows you to change the length of the ARP pending retry timer as shown in the following.

```
NetIron(config)# ip arp-pending-retry-timer 120
```

Syntax: [no] ip arp-pending-retry-timer <*timer-value*>

The <*timer-value*> variable is a value between 10 to 3600 seconds. The default value is 60 seconds.

Dynamic ARP inspection

NOTE
This feature is supported on Layer 2 and Layer 3 code.

Dynamic ARP Inspection (DAI) enables the device to intercept and examine all ARP request and response packets in a subnet and discard those packets with invalid IP to MAC address bindings. DAI can prevent common man-in-the-middle (MiM) attacks such as ARP cache poisoning, and disallow mis-configuration of client IP addresses.

ARP poisoning

ARP provides IP communication within a Layer 2 broadcast domain by mapping an IP address to a MAC address. Before a host can talk to another host, it must map the IP address to a MAC address first. If the host does not have the mapping in its DAI table, it creates an ARP request to resolve the mapping. All computers on the subnet will receive and process the ARP requests, and the host whose IP address matches the IP address in the request will send an ARP reply.

An ARP poisoning attack can target hosts, switches, and routers connected to the Layer 2 network by poisoning the ARP caches of systems connected to the subnet and by intercepting traffic intended for other hosts on the subnet. For instance, a malicious host can reply to an ARP request with its own MAC address, thereby causing other hosts on the same subnet to store this information in their DAI tables or replace the existing ARP entry. Furthermore, a host can send gratuitous replies without having received any ARP requests. A malicious host can also send out ARP packets claiming to have an IP address that actually belongs to another host (e.g. the default router). After the attack, all traffic from the device under attack flows through the attacker's computer and then to the router, switch, or host.

How DAI works

DAI allows only valid ARP requests and responses to be forwarded.

A device on which ARP Inspection is configured does the following:

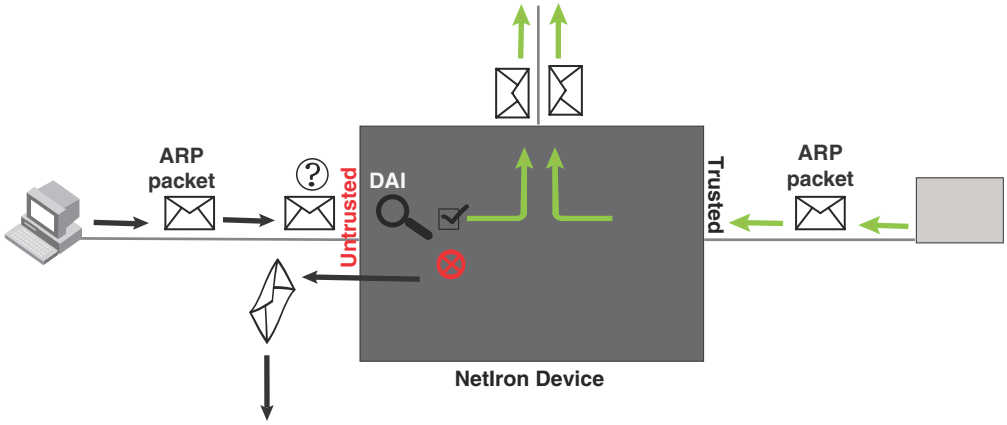
- Intercepts ARP packets received by the system CPU
- Inspects all ARP requests and responses received on untrusted ports
- Verifies that each of the intercepted packets has a valid IP-to-MAC address binding before updating the ARP table, or before forwarding the packet to the appropriate destination
- Drops invalid ARP packets

When you enable ARP Inspection on a VLAN, by default, all member ports are untrusted. You must manually configure trusted ports. In a typical network configuration, ports connected to host ports are untrusted. You configure ports connected to other switches or routers as trusted.

DAI inspects ARP packets received on untrusted ports, as shown in Figure 123. DAI carries out the inspection based on IP-to-MAC address bindings stored in a trusted binding database. For the PowerConnect device, the binding database is the ARP table, which supports DAI, DHCP snooping, and IP Source Guard. To inspect an ARP request packet, DAI checks the source IP and source MAC address against the ARP table. For an ARP reply packet, DAI checks the source IP, source MAC, destination IP, and destination MAC addresses. DAI forwards the valid packets and discards those with invalid IP-to-MAC address bindings.

When ARP packets reach a trusted port, DAI lets them through, as shown in Figure 123.

FIGURE 123 Dynamic ARP inspection at work



ARP entries

DAI uses the IP/MAC mappings in the ARP table to validate ARP packets received on untrusted ports. ARP entries in the ARP table derive from the following:

- **ARP Inspection** – statically configured VRF+VLAN +IP/MAC mapping.
- **ARP** – statically configured VRF+IP/MAC/port mapping.
- **DHCP-Snooping ARP** – information collected from snooping DHCP packets when DHCP snooping is enabled on VLANs.

Configuring DAI

NOTE
An index number is no longer needed to configure static ARP entries.

Follow the steps listed below to configure DAI.

1. Configure inspection of ARP entries for hosts on untrusted ports. Enable ARP Inspection on a VLAN to inspect ARP packets.
2. Configure the trust settings of the VLAN members. ARP packets received on *trusted* ports bypass the DAI validation process. ARP packets received on untrusted ports go through the DAI validation process.
3. Enable DHCP snooping to populate the DHCP snooping IP-to-MAC binding database. Refer to "DHCP binding database" on page 700 for more information.

The following shows the default settings of ARP Inspection.

Feature	Default
Dynamic ARP Inspection	Disabled
Trust setting for ports	Untrusted

Enabling dynamic ARP inspection on a VLAN

ARP and Dynamic inspection ARP entries need to be configured for hosts on untrusted ports. Otherwise, when Dynamic ARP Inspection checks ARP packets from these hosts against entries in the ARP table, it will not find any entries for them, and the device will not allow and learn ARP from an untrusted host.

Dynamic ARP Inspection is disabled by default. To enable Dynamic ARP Inspection on an existing VLAN or a range of VLANs, enter the following command.

```
NetIron(config)# ip arp-inspection vlan 18 to vlan 20
```

The command enables Dynamic ARP Inspection on VLAN 18 through VLAN 20. ARP packets from untrusted ports in VLAN 18 through VLAN 20 will undergo Dynamic ARP Inspection.

Syntax: [no] ip-arp inspection vlan <*vlan_id* > **to** <*vlan_id* >

The <*vlan_id*> variable specifies the ID of a configured VLAN or VLAN range. Valid VLAN ranges are 1-4090.

Configuring static ARP on a Vlan and port

In the PowerConnect configuration, the DHCP binding database is integrated with the ARP Inspection table. The ARP inspection table stores the DAI IP/MAC binding information, which is used to build the IP source guard ACL. The **static arp** command allows you to configure both the vlan id and port parameters on a layer 2 interface.

To configure a static arp entry for a vlan id, enter the following command.

```
NetIron(config)#arp 190.1.0.2 aabb.cc00.0100 vlan 10
```

Syntax: [no] arp <*ip*> <*mac*> **[vlan** <*vlan_id*>**]** [<*port*>]

The <*ip*> variable specifies the IP address for the static IP ARP entry.

The <*mac*> variable specifies the MAC address for the static IP ARP entry.

The <*vlan_id*> variable configures the static ARP entry for a vlan. The VLAN ID range is 1-4090.

The <*port*> variable configures the static ARP entry for a port.

If the vlan id is not configured when IP source guard is turned on, the IP address is assumed to be valid on all the vlans on the port.

If both the vlan id and the port are not configured when IP source guard is turned on, the IP address is assumed to be valid for all vlans.

Enabling trust on a port

The default trust setting for a port is untrusted. For ports that are connected to host ports, leave their trust settings as untrusted.

To enable trust on a port, enter commands such as the following.

```
NetIron(config)# interface ethernet 1/4
NetIron(config-if-e10000-1/4)# arp-inspection-trust
```

The commands change the CLI to the interface configuration level of port 1/4 and set the trust setting of port 1/4 to trusted.

Syntax: [no] arp-inspection-trust

Creating ARP entries

Static entries are useful in cases where you want to pre-configure an entry for a device that is not connected to the PowerConnect router, or you want to prevent a particular entry from aging out. The software removes a dynamic entry from the ARP cache if the ARP aging interval expires before the entry is refreshed. Static entries do not age out, regardless of whether the device receives an ARP request from the device that has the entry's address.

To create a static ARP entry for a static MAC entry, enter a command such as the following.

```
NetIron(config)# arp 192.53.4.2 1245.7654.2348 vlan 10
```

The command adds a static ARP entry that maps IP address 192.53.4.2 to MAC address 1245.7654.2348. The entry is for a MAC address connected to VLAN 10 of the PowerConnect.

Syntax: [no] arp <*ip-addr*> <*mac-addr*> **{ ethernet** <*slot/port*> **| vlan** <*vlan_id*> **}**

The <*ip-addr*> parameter specifies the IP address of the device that has the MAC address of the entry.

The <*mac-addr*> parameter specifies the MAC address of the entry.

The **ethernet** <*slot/port*> command specifies the port number attached to the device that has the MAC address of the entry.

The **vlan** <*vlan_id*> variable specifies the ID of a configured VLAN or VLAN range. Valid VLAN ranges are 1-4090.

Creating a floating static ARP entry

You can create a static ARP entry without port assignments.

When a floating static ARP entry (Static ARP Inspection entry without port defined) is added to ARP Inspection table, the mapping is checked against the current static ARP table. If ARP entry with a matching IP but mismatch MAC is found, it will be deleted and a re-arp on the IP will be issued.

When an ARP entry is deleted from ARP Inspection table, the corresponding entry in the static ARP table will also be deleted.

To create a floating static ARP entry for a static MAC entry, enter a command such as the following.

```
NetIron(config)# arp 192.53.4.2 1245.7654.2348
```

The command adds a floating static ARP entry that maps IP address 192.53.4.2 to MAC address 1245.7654.2348.

Syntax: [no] arp <*ip-add*> <*mac-addr*> **[ethernet** <*portnum*> **| vlan** <*vlan_id*>**]**

The <*ip-addr*> parameter specifies the IP address of the device that has the MAC address of the entry.

The <*mac-addr*> parameter specifies the MAC address of the entry.

The **ethernet** <*portnum*> parameter specifies the port number attached to the device that has the MAC address of the entry, and is only valid for original static ARP entries.

The **vlan** <*vlan_id*> parameter specifies the ID of a configured VLAN.

Configuring a Virtual Routing Instance (VRF)

To configure a virtual routing instance (VRF), enter a command such as the following.

```
NetIron(config)# ip vrf vpn1
```

Syntax: [no] ip vrf <*vrf-name*>

The **ip vrf** parameter specifies the virtual routing instance (VRF) specified by the variable <*vrf-name*>.

Adding an ARP entry for a VRF

IP Addresses can be uniquely determined by VRF. The VLAN number is not needed because the VLAN information is obtained through the ARP protocol. To define an ARP inspection entry for a specific VRF, enter commands such as the following.

```
NetIron(config)# ip vrf vpn1
NetIron(config-ip-vrf-vpn1))#arp 192.53.4.2 1245.7654.2348 e 3/5
```

This command creates an ARP entry for vrf with IP address 192.53.4.2 and MAC address of 1245.7654.2348 on ethernet 3/5.

Syntax: [no] arp <*ip-addr*> <*mac-addr*> **[ethernet** <*slot/port*>**]**

The <*vrf-name*> parameter specifies the VRF you are configuring a static ARP entry for.

The <*ip-addr*> parameter specifies the IP address of the device that has the MAC address of the entry.

The <*mac-addr*> parameter specifies the MAC address of the entry.

The e**thernet** <*slot/port*> variable specifies the port number attached to the device that has the MAC address of the entry.

Displaying ARP inspection information

You can display ARP inspection information using the **show ip arp-inspection** and the **show ip static-arp** commands as shown in the following.

Displaying ARP inspection status and ports

To display the ARP inspection status for a VLAN and the trusted/untrusted ports in the VLAN, enter the following command.

```
NetIron# show ip arp-inspection
ARP inspected VLANs:
1000

ARP inspection trusted ports:
ethe 2/1
```

Syntax: show ip arp-inspection [vlan <*vlan_id*>**]**

The **vlan** <*vlan_id*> parameter specifies the ID of a configured VLAN.

Displaying ARP inspection statistics

You can use the **show ip arp-statistics** command to display ARP inspection counters for all ports on the router, as shown in the following.

```
NetIron# show ip arp-inspection-statistics
Module 1:
Port     Arp Packets Captured      Arp Packets Failed Inspection
1/1         0                        0
1/2         0                        0
1/3         0                        0
1/4         0                        0
1/5         0                        0
1/6         0                        0
1/7         0                        0
1/8         0                        0
1/9         0                        0
1/10        0                        0
1/11        0                        0
1/12        0                        0
1/13        0                        0
1/14        0                        0
1/15        0                        0
1/16        0                        0
1/17        0                        0
1/18        0                        0
1/19        0                        0
1/20        0                        0
Module 3:
Port     Arp Packets Captured      Arp Packets Failed Inspection
3/1         0                        0
3/2         0                        0
3/3         0                        0
3/4         690                      153
```

Specifying a port number with the **show ip arp-statistics** command displays the statistics for that port only, along with details of the last five ARP packets that failed inspection, as shown in the following.

```
NetIron# show ip arp-inspection-statistics ethernet 3/4
Arp packets captured: 695
Arp packets failed inspection: 158
Last 5 packets failed inspection:
Time                 Op  Target IP Target Mac     Source IP Source Mac     Vlan
2007-10-24  18:53:28 2   145.1.1.1 000c.dbe2.9353 145.1.1.2 0000.0900.0005 1
2007-10-24  18:53:29 2   145.1.1.1 000c.dbe2.9353 145.1.1.2 0000.0900.0005 1
2007-10-24  18:53:30 2   145.1.1.1 000c.dbe2.9353 145.1.1.2 0000.0900.0005 1
2007-10-24  18:53:32 2   145.1.1.1 000c.dbe2.9353 145.1.1.2 0000.0900.0005 1
2007-10-24  18:53:33 2   145.1.1.1 000c.dbe2.9353 145.1.1.2 0000.0900.0005 1
```

Syntax: show ip arp-inspection-statistics [slot <*slot-num*> **| ethernet** <*slot/port*> **]**

The **slot** option allows you to limit the display of ARP inspection statistics to the Ethernet interface module in the slot specified by the <*slot-num*> variable.

The **ethernet** option allows you to limit the display of ARP inspection statistics to the port specified by the <*slot/port*> variable. It also provides details of the last five ARP packets received by the specified port that failed inspection.

This display shows the following information.

TABLE 108 Show ip arp-inspection-statistics

This field...	Displays...
Port	The slot/port number.
Arp packets captured	The number of ARP packets captured for the specified port.
Arp packets failed inspection	The number of captured ARP packets that failed inspection for the specified port.
The following fields apply to the first five packets that failed inspection on the specified port.	
Time	The date and time that the packet was received on the port.
Op	The ARP operation mode.
Target IP	The destination IP address of the ARP rejected packet.
Target MAC	The destination MAC address of the ARP rejected packet.
Source IP	The source IP address of the ARP rejected packet.
Source MAC	The source MAC address of the ARP rejected packet.
VLAN	The VLAN number of the ARP rejected packet.

Clearing ARP inspection counters

You can use the clear arp-inspection-statistics command to clear the ARP inspection statistics counters for all ports on the router or for a specified module or port as shown in the following.

```
clear arp-inspection-statistics ethernet 3/1
```

Syntax: clear ip arp-inspection-statistics [slot <*slot-num*> **| ethernet** <*slot/port*> **]**

The **slot** option allows you to clear ARP inspection statistics for a single Ethernet interface module in a slot specified by the <*slot-num*> variable.

The **ethernet** option allows you to clear ARP inspection statistics for a single port specified by the <*slot/port*> variable.

Displaying the ARP table

To display the ARP Inspection table, enter the following command.

```
NetIron# show ip static-arp

Total no. of entries: 4
  Index   IP Address          MAC Address         Port      VLAN  ESI
  1       1.1.1.1             0001.0001.0001      1/1
  2       6.6.6.2             0002.0002.0002      1/2
  3       6.6.6.7             1111.1111.1111      2/1...
          Ports  : ethe 2/1 to 2/7 ethe 3/1 to 3/2
  4       7.7.7.7             0100.5e42.7f40      3/3
```

The command displays all ARP entries in the system.

Syntax: show ip static-arp

DHCP snooping

NOTE
DHCP snooping only supports IPV4 traffic.

Dynamic Host Configuration Protocol (DHCP) snooping enables the device to filter untrusted DHCP packets in a subnet. DHCP snooping can ward off MiM attacks, such as a malicious user posing as a DHCP server sending false DHCP server reply packets with the intention of misdirecting other users. DHCP snooping can also stop unauthorized DHCP servers and prevent errors due to user mis-configuration of DHCP servers.

NOTE
DHCP Snooping will not dynamically build the ARP Inspection table.

How DHCP snooping works

When enabled on a VLAN, DHCP snooping stands between untrusted ports (those connected to host ports) and trusted ports (those connected to DHCP servers). A VLAN with DHCP snooping enabled forwards DHCP request packets from clients and discards DHCP server reply packets on untrusted ports, and it forwards DHCP server reply packets on trusted ports to DHCP clients, as shown in the following figures.

FIGURE 124 DHCP snooping at work - on untrusted port

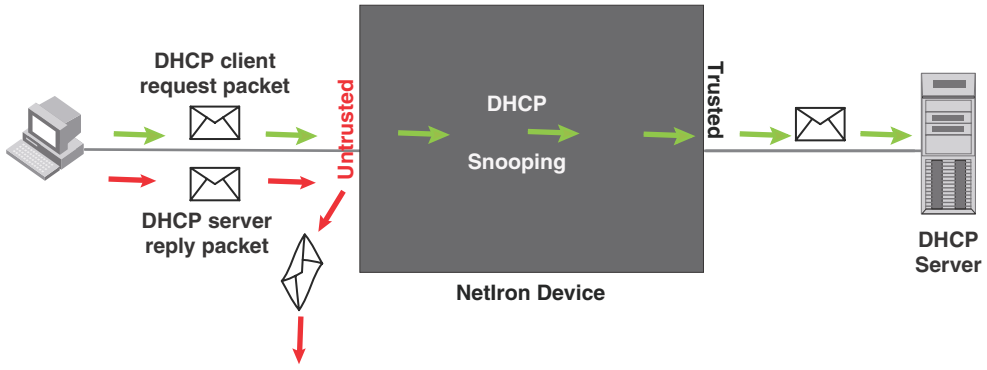


FIGURE 125 DHCP snooping at work - on trusted port

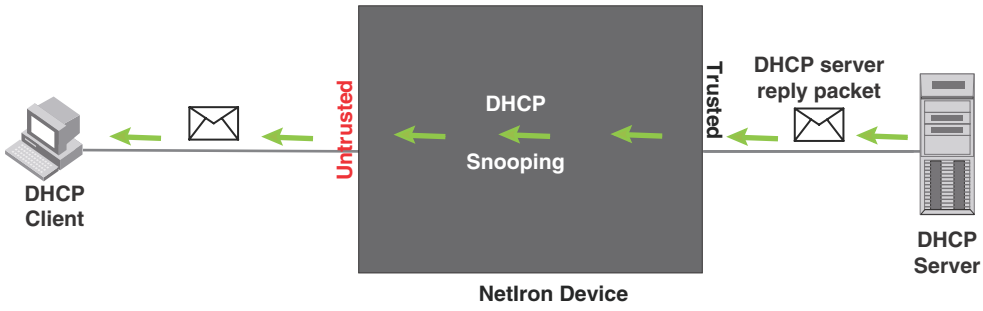

DHCP binding database

On trusted ports, DHCP server reply packets are forwarded to DHCP clients. The DHCP server reply packets collect client IP to MAC address binding information, which is saved in the DHCP binding database. This information includes MAC address, IP address, lease time, VLAN number, and port number.

In the PowerConnect configuration, the DHCP binding database is integrated with the enhanced ARP table, which is used by Dynamic ARP Inspection. For more information, refer to "ARP entries" on page 693.

The lease time will be refreshed when the client renews its IP address with the DHCP server; otherwise the router removes the entry when the lease time expires.

System reboot and the binding database

To allow DAI and DHCP snooping to work smoothly across a system reboot, the binding database is saved to a file in the system flash memory after the user issues the "reload" command. DHCP learned entries are written to the system flash memory before the router reboots. The flash file is written and read only if DHCP snooping is enabled.

Configuring DHCP snooping

Follow the steps listed below to configuring DHCP snooping.

1. Enable DHCP snooping on a VLAN.
2. For ports that are connected to a DHCP server, change their trust setting to trusted.

The following table shows the default settings of DHCP snooping:

Feature	Default
DHCP snooping	Disabled
Trust setting for ports	Untrusted

Enabling DHCP snooping on a VLAN

DHCP packets for a VLAN with DHCP snooping enabled are inspected.

DHCP snooping is disabled by default. This feature must be enabled on the client and the DHCP server VLANs. To enable DHCP snooping, enter the following global command for these VLANs.

```
NetIron(config)#ip dhcp-snooping vlan 2
```

The command enables DHCP snooping for a VLAN or a range of VLANS.

Syntax: [no] ip dhcp-snooping vlan <*vlan-number*> **[to** <*vlan_number*>**] [insert-relay-information]**

The <*vlan-number*> variable specifies the ID of a configured client or DHCP server VLAN.

If the [insert-relay-information] option is enabled, then DHCP option 82 is inserted in all the DHCP request packets. Refer to "DHCP binding database" on page 700 for more information.

Enabling trust on a port

The default trust setting for a port is untrusted. To enable trust on a port connected to a DHCP server, enter commands such as the following.

```
NetIron(config)#interface ethernet 1/1
NetIron(config-if-e10000-1/1)#dhcp-snooping-trust
```

Port 1/1 is connected to a DHCP server. The commands change the CLI to the interface configuration level of port 1/1 and set the trust setting of port 1/1 to trusted.

Syntax: [no] dhcp-snooping-trust

Clearing the DHCP binding database

You can clear the DHCP binding database using the **clear dhcp-binding** command. You can remove all entries in the database, or remove entries for a specific IP subnet, a VRF instance, or a VLAN id.

To remove all entries from the DHCP binding database, enter the following command.

```
NetIron#clear dhcp-binding
```

For example, to clear entries for a specific IP subnet, enter a command such as the following.

```
NetIron#clear dhcp 10.10.102.4
```

Syntax: clear dhcp [<*ip subnet*>] **[vlan** <*vlan_id*>] **[vrf** <*vrf_name*>]

The <*vlan_id*> variable specifies the ID of a configured VLAN.

The <*vrf_name*> variable specifies the VRF instance.

DHCP option 82 insertion

DHCP option 82 insertion can be used to assist DHCP servers to implement dynamic address policy. When DHCP option 82 is present in DHCP packets, DHCP servers gets additional information about the clients' identity.

The PowerConnect inserts DHCP option 82 when relaying DHCP request packets to DHCP servers. When DHCP server reply packets are forwarded back to DHCP clients, and sub-option 2 matches the local port MAC address, then DHCP option 82 is deleted. The vlan/port information is used to forward the DHCP reply. Refer to the following figures:

FIGURE 126 DHCP option 82 is added to the packet

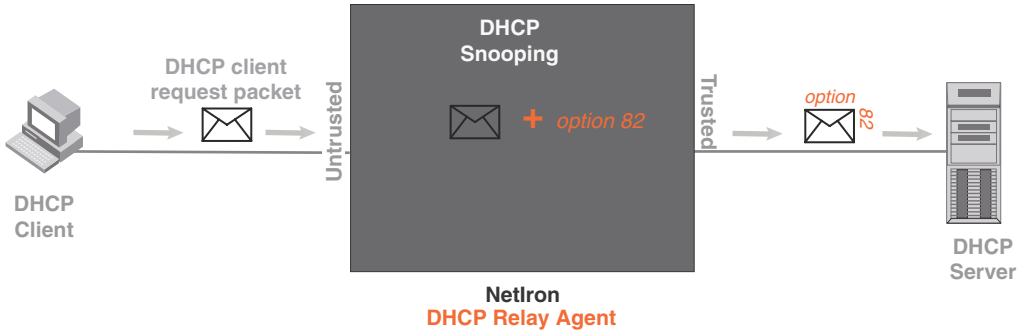

FIGURE 127 DHCP option 82 is removed from the packet

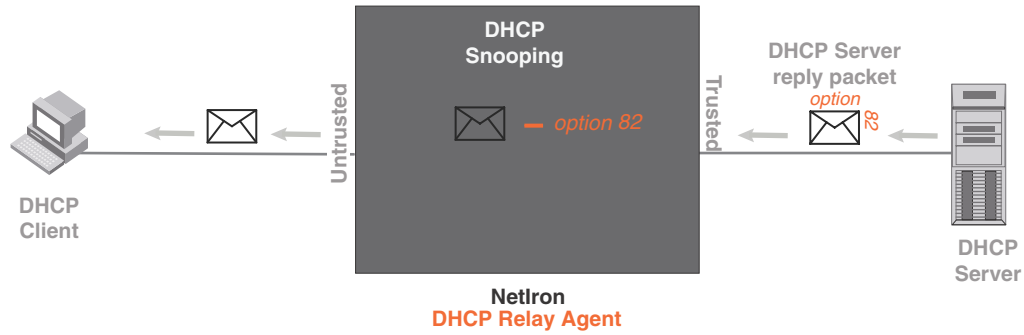

The option 82 insertion/deletion feature is available only when DHCP snooping is enabled for the client/server ports, and when the device is configured as a DHCP relay agent. By default, DHCP option 82 is off.

DHCP option 82 contains two sub-options; sub-option 1 (circuit ID) and sub-option 2 (remote ID).

Sub-option 1, relay agent circuit ID is in the following format.

VLAN id (2 bytes) / module id (1 byte) / port id (1 byte) (The module and port id will be 1 based).

The circuit ID identifies the location of the port, showing where the DHCP request comes from.

Typical address allocation is based on the gateway address of the relay agent.

Sub-option 2, Remote ID is in the following format.

MAC address (6 bytes)

Displaying DHCP snooping status and ports

To display the DHCP snooping status for a VLAN and the trusted and untrusted ports in the VLAN, enter the following command.

```
NetIron#show ip dhcp-snooping vlan 172
IP DHCP snooping VLAN 172: Enabled
  Trusted Ports : ethe 5/2 ethe 5/4
  Untrusted Ports : ethe 4/24 ethe 9/4 to 9/5 ethe 9/12 ethe 9/14
```

Syntax: show ip dhcp-snooping [vlan <*vlan-id*>**]**

Displaying DAI binding entries

To display all ARP inspection binding entries, including dhcp bindings specific to a VRF instance, enter the following command.

```
NetIron#(config)#show dai 201.1.1.0/24
Total no. of entries: 51
Idx Type IP Address      MAC Address       Port    Vlan Server IP    LTime
1   D    201.1.1.19      aabb.cc00.0012      10      200.1.1.2       3360
2   D    201.1.1.22      aabb.cc00.0007      10      200.1.1.2       3360
3   D    201.1.1.25      aabb.cc00.0030      10      200.1.1.2       3360
4   D    201.1.1.26      aabb.cc00.0004      10      200.1.1.2       3360
5   D    201.1.1.30      0030.488a.1c25      10      200.1.1.2       40200
6   D    201.1.1.32      aabb.cc00.0001      10      200.1.1.2       3360
7   D    201.1.1.34      aabb.cc00.0019      10      200.1.1.2       1560
8   D    201.1.1.39      aabb.cc00.000d      10      200.1.1.2       3360
9   D    201.1.1.44      aabb.cc00.0020      10      200.1.1.2       3360
10  D    201.1.1.46      aabb.cc00.0022          10       200.1.1.2       3360
```

Syntax: show dai [vrf <*vrf_name*>**] [vlan** <*vlan_id*>**] [**<*ip-subnet*>**]**

The <*vrf_name*> variable specifies the ARP entries that belong to a given VRF instance.

The <*vlan_id*> variable specifies the ID of a configured VLAN.

The <*ip subnet*> variable specifies the ARP entries that belong to specific IP-subnet address.

The following table describes the parameters of the **show dai** command:

TABLE 109 Display of show dai

This field...	Displays...
Index (Idx)	The row number of this entry in the IP route table.
Type	The ARP entry type, which can be any one of the following: Dynamic – The Layer 3 Switch learned the entry from an incoming packet. Static – The Layer 3 Switch loaded the entry from the static ARP table when the device for the entry was connected to the Layer 3 Switch. DHCP – The Layer 3 Switch learned the entry from the DHCP binding address table.
IP Address	The IP address of the device.
MAC Address	The MAC address of the device.
Port	The source port for the host vlan.
Vlan Server IP	The Vlan Server IP address of the server which assigns the IP/MAC mapping.
LTime	The lease time (aging timer for a DHCP entry).

Displaying DHCP snooping statistics counters

NOTE
The last five dropped packets are displayed through the CLI. Notifications and traps are not sent.

To display the DHCP snooping statistics counters, enter the following command.

```
NetIron#show ip dhcp-snooping-statistic slot 1
Module 1:
Port     DHCP Packets Captured      DHCP Packets dropped
1/1         0                        0
1/2         0                        0
1/3         0                        0
1/4         0                        0
1/5         0                        0
1/6         0                        0
1/7         0                        0
1/8         0                        0
1/9         0                        0
1/10        0                        0
1/11        0                        0
1/12        0                        0
1/13        0                        0
1/14        0                        0
1/15        0                        0
1/16        0                        0
1/17        0                        0
1/18        0                        0
1/19        9                        0
1/20        8                        6
```

The following table describes the output of the show ip dhcp snooping statisitc.

TABLE 110 Output from the show ip dhcp snooping statistic slot

This field...	Displays...
Module	Module number as positioned in the chassis.
Port	Port number in specified module.
DHCP Packets Captured	The number of DHCP packets captured on the port.
DHCP Packets Dropped	The number of DHCP packets dropped by DHCP snooping.

To display the DHCP snooping statistics counters for Ethernet ports, enter the following command.

```
NetIron#show ip dhcp-snooping-statistic eth 1/20
DHCP packets captured: 9
DHCP packets dropped by snooping: 7
Last 5 packets dropped by snooping:
Time                 DHCP type Source Mac/     Server IP/      Vlan
                               Source IP       Gateway IP

                               200.1.1.125     201.1.1.10
```

Syntax: show ip dhcp-snooping-statistic [slot <*slot*>**] | [ethernet** <*slot/port*>**]**

NOTE
If an Ethernet port is provided, the last five dropped packets are displayed

TABLE 111 Output from the show ip dhcp snooping statistic Ethernet port

This field...	Displays...
DHCP packets captured	The number of DHCP packets captured on port 20.
DHCP packets dropped by snooping	The number of DHCP packets dropped by DHCP snooping.
Last 5 packets dropped by snooping	The last 5 DHCP packets dropped per port.
Time	The time tracking system for collecting statistically information. Date and time are displayed.
DHCP Type	The DHCP Type displays the following: OFFER - When the server responds with a proposal of parameters. ACK- When the server assign an IP address. NAK- When the server rejects the request from the client.
Source MAC or Source IP	The Source MAC or Source IP address
Server IP or Gateway IP	The Serve IP or Gateway IP
Vlan	The VLAN number that DHCP Snooping was rejected on.

Clearing DHCP snooping counters

To clear the DHCP snooping statistic counters for a specific slot, enter the following command.

```
NetIron#clear dhcp-snooping-statistics slot 1
```

To clear the DHCP snooping statistic counters for a specific ethernet port, enter the following command.

```
NetIron#clear dhcp-snooping-statistics ethernet 1/20
```

Syntax: clear dhcp-snooping-statistics [slot <*slot*>] | [ethernet <*slot/port*>]

DHCP snooping configuration example

The following example configures VLAN 2 and VLAN 20, and changes the CLI to the global configuration level to enable DHCP snooping on the two VLANs. The commands are as follows.

```
NetIron(config)#vlan 2
NetIron(config-vlan-2)#untagged ethe 1/3 to 1/4
NetIron(config-vlan-2)#router-interface ve 2
NetIron(config-vlan-2)#exit
NetIron(config)# ip dhcp-snooping vlan 2

NetIron(config)#vlan 20
NetIron(config-vlan-20)#untagged ethe 1/1 to 1/2
NetIron(config-vlan-20)#router-interface ve 20
NetIron(config-vlan-20)#exit
NetIron(config)#ip dhcp-snooping vlan 20
```

On VLAN 2, client ports 1/3 and 1/4 are untrusted by default: all client ports are untrusted. Hence, only DHCP client request packets received on ports 1/3 and 1/4 are forwarded.

On VLAN 20, ports 1/1 and 1/2 are connected to a DHCP server. DHCP server ports are set to trusted.

```
NetIron(config)#interface ethernet 1/1
NetIron(config-if-e1000-1/1)#dhcp-snooping-trust
NetIron(config-if-e1000-1/1)#exit
NetIron(config)#interface ethernet 1/2
NetIron(config-if-e1000-1/2)#dhcp-snooping-trust
NetIron(config-if-e1000-1/2)#exit
```

Hence, DHCP sever reply packets received on ports 1/1 and 1/2 are forwarded, and client IP or MAC binding information is collected.

The example also sets the DHCP server address for the local relay agent.

```
NetIron(config)# interface ve 2
NetIron(config-vif-2)#ip address 20.20.20.1/24
NetIron(config-vif-2)#ip helper-address 30.30.30.4
NetIron(config-vif-2)#interface ve 20
NetIron(config-vif-20)#ip address 30.30.30.1/24
```

IP source guard

IP Source Guard permits traffic from only valid source IP addresses. IP source guard is used on client ports to prevent IP source address spoofing. Generally, IP source guard is used together with DHCP snooping and Dynamic ARP Inspection on untrusted ports. Refer to “DHCP snooping” on page 699 and “Dynamic ARP inspection” on page 691.

When IP Source Guard is first enabled, only DHCP packets are allowed and all other IP traffic is blocked. IP Source Guard uses IP or MAC bindings inside the ARP Inspection table to detect a valid IP address. When the system learns a valid IP address on the port, the client port then allows IP traffic to enter. If the source IP address of a packet does not match any of the IP addresses inside the ARP Inspection table, the packet is dropped. Only traffic with valid source IP addresses are permitted.

The system learns of a valid IP address from ARP. For information on how the ARP table is populated, Refer to“ARP entries” on page 693.

Enabling IP source guard

The **source-guard** command sets a port as an IP Source Guarded port. DHCP Snooping should be configured before you enable the IP Source Guard feature.

The default setting is disabled. To enable a port as an IP Source Guarded port, enter the following commands.

```
NetIron(config)# interface ethernet 2/2
NetIron(config-if-e10000-2/2)# source-guard
```

The commands change the CLI to the interface configuration level for port 2/2 and enable IP source guard on the port.

Syntax: [no] source-guard

NOTE
When IP Source Guard is enabled on a port it must have the same configuration as the primary port, otherwise it will not implemented as IP Source Guarded.

Enabling IP source inspection on a VLAN

IP Source Guard configuration is enabled on ports per vlan. When IP Source Guard is enabled on a vlan, by default all ports inside the vlan are set as “unguarded”. You can selectively turn on which ports inside the vlan to be set as “guarded”. Initially, when the vlan port is IP Source Guarded, only DHCP packets are allowed to get through. However, as IP or MAC binding is learned from DHCP snooping, or if it is manually configured, only packets with valid source IP address are allowed through.

There are two modes for IP Source Guard; strict mode and loose mode. You can configure either strict or loose mode during IP Source Guard vlan configuration. In a strict mode, the IP source address is bound to a particular port and vlan. Only packets with an IP address coming from a particular vlan port is considered valid. If the same source IP address is coming from a different port, then it is considered an attack and is dropped. The strict mode provides more security, but it does not allow for a layer 2 occurrence in a vlan. In a loose mode, the IP source address is bound to a vlan. Only packets with IP source addresses that come from ports within the vlan are considered valid.

To enable IP Source Inspection for a VLAN or a range of VLANs, enter the following command.

```
NetIron(config)# ip source-inspection vlan 2
```

Syntax: [no] ip source-inspection vlan <*vlan_number*> **[to** <*vlan_number*> **] [strict]**

The source IP addresses for VLAN IP packets are inspected for any port when IP Source Guard is enabled.

The <*vlan_number*> variable specifies the ID of a configured VLAN.

If the strict option is enabled, then valid IP source address is bound to a particular source port. This configuration can be learned from a DHCP reply, or manually configured.

NOTE
The strict mode requires DHCP relay-information insertion to be turned on.

Displaying IP source inspection status and ports

To display the IP Source Guard status for a VLAN, and the guarded or unguarded ports in the VLAN, enter the following command.

```
NetIron(config)#sh ip source-inspection vlan 10
IP Source Inspection configuration for VLAN 10:
Inspection mode: loose
un-guarded ports:
 ethe 1/4 ethe 1/18
guarded ports:
 ethe 1/20
```

The **show ip source-inspection vlan** command displays IP Source inspection configuration for VLAN 10 in loose mode.

Syntax: show ip source-inspection [vlan <*vlan_id*>**]**

The <*vlan_id*> variable specifies the ID of a configured vlan.

NOTE
This command is also available for debugging purposes on the Interface Module.

IP source guard CAM

The PowerConnect configuration uses a layer 4 ACL CAM to implement IP Source guard. When IP or MAC binding is learned or configured on an IP Source Guarded vlan-port, a layer 4 ACL CAM is programmed to allow valid source IP addresses.

When ACL is manually configured, a configuration conflict occurs with IP Source Guard, because it uses a layer 4 ACL CAM. The PowerConnect gives user ACL configuration a higher priority. When both IP Source Guard and user ACL is configured, the user ACL configuration takes precedence over IP Source Guard.

IP Source Guard uses layer 4 ACL CAM to check layer 2 switched traffic. When IP Source Guard is configured, the layer 3 port check flag is turned on. When IP Source Guard is configured, all traffic from the same physical port is subject to a layer 4 ACL check.

Configuring IP source guard CAM partition

IP Source Guard creates two CAM sub-partitions. The CAM sub-partitions include IP_SOURCE_GUARD_PERMIT and IP_SOURCE_GUARD_DENY. All CAM entries that are permitted, go to the IP_SOURCE_GUARD_PERMIT sub-partition. All CAM entries that are denied, go to the IP_SOURCE_GUARD_DENY sub-partition. The **system-max ip-source-guard-cam** command allows you to control the size of both IP_SOURCE_GUARD_PERMIT and IP_SOURCE_GUARD_DENY sub-partitions.

To specify a partition size of the IP Source Guard CAM, enter the following command.

```
NetIron(config)#system-max ip-source-guard-cam 1008
```

Syntax: [no] system-max [ip-source-guard-cam <*decimal*>**]**

By default, **no** system-max is configured.

The <*decimal*> variable specifies the range that is supported for configuring IP Source Guard CAM sub-partitions. The decimal range is from 0 to 131072. The default is 0.

Displaying IP source guard CAM partition

To display all IP Source Guard CAM partition on a layer 4 interface, enter the following command.

```
NetIron(config)# show cam l4 2/1
LP Index   Src  IP   SPort  Pro  Age IFL/ Out IF Group PRAM
   (Hex)(Dest IP         DPort)        VLAN Action       (Hex)
2  52000 0.0.0.0         0     17  Dis 0    CPU    31    00084
        (127.0.0.0       3784 )
```

Syntax: show cam <*interface*>

The following table describes the output of the **show cam** command.

TABLE 112 Display of show cam command

This field...	Displays...
Index (Hex)	The row number of this entry in the IP route table
Src IP/ Dest IP	The Source IP address or Destination IP address
SPort or DPort	The Source Port or Destination Port
Pro	The type of protocol (TCP, UDP) used.
Age	The Age is disabled.
IFL or VLAN	The VLAN that the port belongs to.
Action	The type of action: Pass or Drop.

Configuring forwarding parameters

The following configurable parameters control the forwarding behavior of the PowerConnect:

- Time-To-Live (TTL) threshold
- Forwarding of directed broadcasts
- Forwarding of source-routed packets
- Ones-based and zero-based broadcasts

All these parameters are global and thus affect all IP interfaces configured on the PowerConnect.

To configure these parameters, use the procedures in the following sections.

Changing the TTL threshold

The TTL threshold prevents routing loops by specifying the maximum number of router hops an IP packet originated by the PowerConnect can travel through. Each device capable of forwarding IP that receives the packet decreases the packet's TTL by one. If a device receives a packet with a TTL of 1 and reduces the TTL to zero, the device drops the packet.

The default TTL is 64. You can change the TTL to a value from 1– 255.

To modify the TTL threshold to 25, enter the following commands.

```
NetIron(config)# ip ttl 25
```

Syntax: [no] ip ttl <*1-255*>

Enabling forwarding of directed broadcasts

A directed broadcast is an IP broadcast to all devices within a single directly-attached network or subnet. A net-directed broadcast goes to all devices on a given network. A subnet-directed broadcast goes to all devices within a given subnet.

NOTE
A less common type, the all-subnets broadcast, goes to all directly-attached subnets. Forwarding for this broadcast type also is supported, but most networks use IP multicasting instead of all-subnet broadcasting.

Forwarding for all types of IP directed broadcasts is disabled by default. You can enable forwarding for all types if needed. You cannot enable forwarding for specific broadcast types.

To enable forwarding of IP directed broadcasts, enter the following command.

```
NetIron(config)# ip directed-broadcast
```

Syntax: [no] ip directed-broadcast

The software makes the forwarding decision based on the router's knowledge of the destination network prefix. Routers cannot determine that a message is unicast or directed broadcast apart from the destination network prefix. The decision to forward or not forward the message is by definition only possible in the last hop router.

To disable the directed broadcasts, enter the following command in the CONFIG mode.

```
NetIron(config)# no ip directed-broadcast
```

To enable directed broadcasts on an individual interface instead of globally for all interfaces, enter commands such as the following.

```
NetIron(config)# interface ethernet 1/1
NetIron(config-if-e10000-1/1)# ip directed-broadcast
```

Syntax: [no] ip directed-broadcast

Disabling forwarding of IP source-routed packets

A source-routed packet specifies the exact router path for the packet. The packet specifies the path by listing the IP addresses of the router interfaces through which the packet must pass on its way to the destination. The PowerConnect supports both types of IP source routing:

- **Strict source routing** – requires the packet to pass through only the listed routers. If the PowerConnect receives a strict source-routed packet but cannot reach the next hop interface specified by the packet, the PowerConnect discards the packet and sends an ICMP Source-Route-Failure message to the sender.

  NOTE
  The PowerConnect allows you to disable sending of the Source-Route-Failure messages. Refer to "Disabling ICMP messages" on page 712.

- **Loose source routing** – requires that the packet pass through all of the listed routers but also allows the packet to travel through other routers, which are not listed in the packet.

The PowerConnect forwards both types of source-routed packets by default. You cannot enable or disable strict or loose source routing separately.

To disable forwarding of IP source-routed packets, enter the following command.

```
NetIron(config)# no ip source-route
```

Syntax: [no] ip source-route

To re-enable forwarding of source-routed packets, enter the following command.

```
NetIron(config)# ip source-route
```

Enabling support for zero-based IP subnet broadcasts

By default, the PowerConnect treats IP packets with all ones in the host portion of the address as IP broadcast packets. For example, the PowerConnect treats IP packets with 209.157.22.255/24 as the destination IP address as IP broadcast packets and forwards the packets to all IP hosts within the 209.157.22.x subnet (except the host that sent the broadcast packet to the PowerConnect).

Most IP hosts are configured to receive IP subnet broadcast packets with all ones in the host portion of the address. However, some older IP hosts instead expect IP subnet broadcast packets that have all zeros instead of all ones in the host portion of the address. To accommodate this type of host, you can enable the PowerConnect to treat IP packets with all zeros in the host portion of the destination IP address as broadcast packets.

NOTE
When you enable the PowerConnect for zero-based subnet broadcasts, the PowerConnect still treats IP packets with all ones the host portion as IP subnet broadcasts too. Thus, the PowerConnect can be configured to support all ones only (the default) or all ones and all zeroes.

NOTE
This feature applies only to IP subnet broadcasts, not to local network broadcasts. The local network broadcast address is still expected to be all ones.

To enable the PowerConnect for zero-based IP subnet broadcasts in addition to ones-based IP subnet broadcasts, enter the following command.

```
NetIron(config)# ip broadcast-zero
```

Syntax: [no] ip broadcast-zero

Configuring the maximum ICMP error message rate

NOTE
The maximum ICMP error message rate configuration only supports IPv4 traffic.

The PowerConnect configuration allows 200 ICMP error messages per second per IP interface. You can now configure the maximum ICMP error message rate on all Interface Modules. The maximum configured value is increased to 5000 error messages per second. The maximum ICMP error message rate configuration uses an ICMP error metering mechanism. The process for the ICMP error metering mechanism is as follows:

- There is a meter counter for each interface. There is one total meter counter per Interface Module.
- The interface counter and the total counter will increment every time an icmp error message is sent out.
- The timer will rest all counters to 0 every second.
- Before an error message is sent out, it check the interface meter counter against the user configured icmp error limit (5000 max). The total counter will check against 10000. The error message is dropped if one any counter is larger the checked value.

The total error rate for all IP interfaces on an Interface Module is 10,000 errors per second. The ICMP error metering mechanism is per IP interface; this includes VRF IP interfaces.

Since the ICMP error metering code implementation is similar between the Management Module and Interface Module code, this change will also affect the Management Module ICMP error rate.

To configure the maximum ICMP error rate, enter the following command.

```
NetIron(config)# ip icmp max-err-msg-rate 600
```

Syntax: [no] ip icmp max-err-msg-rate *<error per second>*

The *<error per second>* variable specifies the maximum error rate in errors per second. The maximum configured value has a range from 0 (minimum) to 5000 (maximum) error message per second. The default value is 400.

Disabling ICMP messages

The PowerConnect is enabled to reply to ICMP echo messages and send ICMP Destination Unreachable messages by default.

You can selectively disable the following types of Internet Control Message Protocol (ICMP) messages:

- **Echo messages (ping messages)** – The PowerConnect replies to IP pings from other IP devices.
- **Destination Unreachable messages** – If the PowerConnect receives an IP packet that it cannot deliver to its destination, the PowerConnect discards the packet and sends a message back to the device that sent the packet. The message informfs the device that the destination cannot be reached by the PowerConnect.

Disabling replies to broadcast ping requests

By default, the PowerConnect is enabled to respond to broadcast ICMP echo packets, which are ping requests.

To disable response to broadcast ICMP echo packets (ping requests), enter the following command.

```
NetIron(config)# no ip icmp echo broadcast-request
```

Syntax: [no] ip icmp echo broadcast-request

If you need to re-enable response to ping requests, enter the following command.

```
NetIron(config)# ip icmp echo broadcast-request
```

Disabling ICMP destination unreachable messages

By default, when the PowerConnect receives an IP packet that the device cannot deliver, the device sends an ICMP Unreachable message back to the host that sent the packet. You can selectively disable a PowerConnect's response to the following types of ICMP Unreachable messages:

- **Administration** – The packet was dropped by the device due to a filter or ACL configured on the device.
- **Fragmentation-needed** – The packet has the Do not Fragment bit set in the IP Flag field, but the PowerConnect cannot forward the packet without fragmenting it.
- **Host** – The destination network or subnet of the packet is directly connected to the PowerConnect, but the host specified in the destination IP address of the packet is not on the network.
- **Network** – The PowerConnect cannot reach the network specified in the destination IP address of the packet.

- **Port** – The destination host does not have the destination TCP or UDP port specified in the packet. In this case, the host sends the ICMP Port Unreachable message to the PowerConnect, which in turn sends the message to the host that sent the packet.
- **Protocol** – The TCP or UDP protocol on the destination host is not running. This message is different from the Port Unreachable message, which indicates that the protocol is running on the host but the requested protocol port is unavailable.
- **Source-route-failure** – The device received a source-routed packet but cannot locate the next-hop IP address indicated in the packet's Source-Route option.

You can disable the PowerConnect from sending these types of ICMP messages on an individual basis.

NOTE
Disabling an ICMP Unreachable message type does not change the PowerConnect's ability to forward packets. Disabling ICMP Unreachable messages prevents the device from generating or forwarding the Unreachable messages.

To disable all ICMP Unreachable messages, enter the following command.

```
NetIron(config)# no ip icmp unreachable
```

Syntax: **[no] ip icmp unreachable [network | host | protocol | administration | fragmentation-needed | port | source-route-fail]**

- If you enter the command without specifying a message type (as in the example above), all types of ICMP Unreachable messages listed above are disabled. If you want to disable only specific types of ICMP Unreachable messages, you can specify the message type. To disable more than one type of ICMP message, enter the **no ip icmp unreachable** command for each messages type.
- The **network** parameter disables ICMP Network Unreachable messages.
- The **host** parameter disables ICMP Host Unreachable messages.
- The **protocol** parameter disables ICMP Protocol Unreachable messages.
- The **administration** parameter disables ICMP Unreachable (caused by Administration action) messages.
- The **fragmentation-needed** parameter disables ICMP Fragmentation-Needed But Do not-Fragment Bit Set messages.
- The **port** parameter disables ICMP Port Unreachable messages.
- The **source-route-fail** parameter disables ICMP Unreachable (caused by Source-Route-Failure) messages.

To disable ICMP Host Unreachable messages and ICMP Network Unreachable messages but leave the other types of ICMP Unreachable messages enabled, enter the following commands instead of the command shown above.

```
NetIron(config)# no ip icmp unreachable host
NetIron(config)# no ip icmp unreachable network
```

If you have disabled all ICMP Unreachable message types but want to re-enable certain types, you can do so by entering commands such as the following.

```
NetIron(config)# ip icmp unreachable host
NetIron(config)# ip icmp unreachable network
```

These commands re-enable ICMP Unreachable Host messages and ICMP Network Unreachable messages.

Disabling ICMP redirect messages

You can disable or re-enable ICMP redirect messages. By default, the PowerConnect sends an ICMP redirect message to the source of a misdirected packet in addition to forwarding the packet to the appropriate router. You can disable ICMP redirect messages on a global basis or on an individual port basis.

NOTE
An unusually high receipt of multiple Internet Control Message Protocol (ICMP) Redirect packets that are used to change routing table entries in a short period of time may cause high CPU utilization. However this can be avoided by configuring the maximum ICMP error message rate using **ip icmp max-err-msg-rate** command, 0 (minimum) to 5000 (maximum) error message per second. The default value is 400.The total error rate for all IP interfaces (SYSTEM) is 10,000 errors per second.

NOTE
The device forwards misdirected traffic to the appropriate router, even if you disable the redirect messages.

To disable ICMP redirect messages globally, enter the following command at the global CONFIG level of the CLI.

```
NetIron(config)# no ip icmp redirects
```

Syntax: [no] ip icmp redirects

To disable ICMP redirect messages on a specific interface, enter the following command at the configuration level for the interface.

```
NetIron(config)# int e 3/11
NetIron(config-if-e100-3/11)# no ip redirect
```

Syntax: [no] ip redirect

Configuring static routes

The IP route table can receive routes from the following sources:

- **Directly-connected networks** – When you add an IP interface, the PowerConnect automatically creates a route for the network the interface is in.
- **RIP** – If RIP is enabled, the PowerConnect can learn about routes from the advertisements other RIP routers send to the PowerConnect. If the route has a lower administrative distance than any other routes from different sources to the same destination, the PowerConnect places the route in the IP route table.
- **OSPF** – Refer to RIP, but substitute “OSPF” for “RIP”.
- **BGP4** – Refer to RIP, but substitute “BGP4” for “RIP”.
- **Default network route** – A statically configured default route that the PowerConnect uses if other default routes to the destination are not available. Refer to “Configuring a default network route” on page 730.
- **Statically configured route** – You can add routes directly to the route table. When you add a route to the IP route table, you are creating a static IP route. This section describes how to add static routes to the IP route table.

Static route types

You can configure the following types of static IP routes:

- **Standard** – the static route consists of the destination network address and network mask, and the IP address of the next-hop gateway. You can configure multiple standard static routes with the same metric for load sharing or with different metrics to provide a primary route and backup routes.
- **Interface-based** – the static route consists of the destination network address and network mask, and the PowerConnect interface through which you want the PowerConnect to send traffic for the route. Typically, this type of static route is for directly attached destination networks.
- **Null** – the static route consists of the destination network address and network mask, and the "null0" parameter. Typically, the null route is configured as a backup route for discarding traffic if the primary route is unavailable.

Static IP route parameters

When you configure a static IP route, you must specify the following parameters:

- The IP address and network mask for the route's destination network.
- The route's path, which can be one of the following:
  - The IP address of a next-hop gateway
  - An Ethernet port
  - A virtual interface (a routing interface used by VLANs for routing Layer 3 protocol traffic among one another)
  - A "null" interface. The PowerConnect drops traffic forwarded to the null interface.

The following parameters are optional:

- **The route's metric** – The value the PowerConnect uses when comparing this route to other routes in the IP route table to the same destination. The metric applies only to routes that the PowerConnect has already placed in the IP route table. The default metric for static IP routes is 1.
- **The route's administrative distance** – The value that the PowerConnect uses to compare this route with routes from other route sources to the same destination before placing a route in the IP route table. This parameter does not apply to routes that are already in the IP route table. The default administrative distance for static IP routes is 1.

The default metric and administrative distance values ensure that the PowerConnect always prefers static IP routes over routes from other sources to the same destination.

Multiple static routes to the same destination provide load sharing and redundancy

You can add multiple static routes for the same destination network to provide one or more of the following benefits:

- **IP load balancing** – When you add multiple IP static routes for the same destination to different next-hop gateways, and the routes each have the same metric and administrative distance, the PowerConnect can load balance traffic to the routes' destination. For information about IP load balancing, refer to "Configuring IP load sharing" on page 731.

- **Path redundancy** – When you add multiple static IP routes for the same destination, but give the routes different metrics or administrative distances, the PowerConnect uses the route with the lowest administrative distance by default, but uses another route to the same destination of the first route becomes unavailable.

Refer to the following sections for examples and configuration information:

- "Configuring load balancing and redundancy using multiple static routes to the same destination" on page 721
- "Configuring standard static IP routes and interface or null static routes to the same destination" on page 722

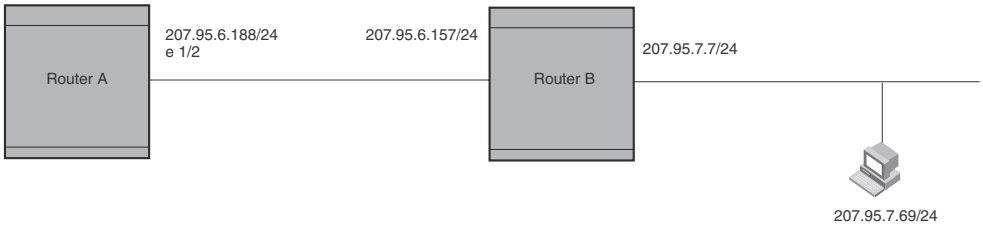
Static route states follow port states

IP static routes remain in the IP route table only so long as the port or virtual interface used by the route is available. If the port or virtual routing interface becomes unavailable, the software removes the static route from the IP route table. If the port or virtual routing interface becomes available again later, the software adds the route back to the route table.

This feature allows the PowerConnect to adjust to changes in network topology. The PowerConnect does not continue trying to use routes on unavailable paths but instead uses routes only when their paths are available.

Figure 128 shows a network containing a static route. The static route is configured on Router A, as shown in the CLI following the figure.

FIGURE 128 Example of a static route



The following command configures a static route to 207.95.7.0, using 207.95.6.157 as the next-hop gateway.

```
NetIron(config)# ip route 207.95.7.0/24 207.95.6.157
```

When you configure a static IP route, you specify the destination address for the route and the next-hop gateway or PowerConnect interface through which the PowerConnect can reach the route. The PowerConnect adds the route to the IP route table. In this case, Router A knows that 207.95.6.157 is reachable through port 1/2, and also assumes that local interfaces within that subnet are on the same port. Router A deduces that IP interface 207.95.7.188 is also on port 1/2.

The software automatically removes a static IP route from the IP route table if the port used by that route becomes unavailable. When the port becomes available again, the software automatically re-adds the route to the IP route table.

Configuring a static IP route

To configure an IP static route with a destination address of 192.0.0.0 255.0.0.0 and a next-hop router IP address of 195.1.1.1, enter the following.

```
NetIron(config)# ip route 192.0.0.0 255.0.0.0 195.1.1.1
```

To configure a default route, enter the following.

```
NetIron(config)# ip route 0.0.0.0  0.0.0.0
```

To configure a static IP route with an Ethernet port instead of a next-hop address, enter a command such as the following.

```
NetIron(config)# ip route 192.128.2.69 255.255.255.0 ethernet 4/1
```

The command configures a static IP route for destination network 192.128.2.69/24. Since an Ethernet port is specified instead of a gateway IP address as the next hop, the PowerConnect always forwards traffic for the 192.128.2.69/24 network to port 4/1.

To configure an IP static route that uses virtual interface 3 as its next hop, enter a command such as the following.

```
NetIron(config)# ip route 192.128.2.71 255.255.255.0 ve 3
```

Syntax: **ip route** <*dest-ip-addr*> <*dest-mask*> | <*dest-ip-addr*>/<*mask-bits*> <*next-hop-ip-addr*> | **ethernet** <*slot/port*> | **pos** <*slot/port*> | **ve** <*num*> *[*<*metric*>**]** **[tag** <*num*>**]** **[distance** <*num*>**]** **[name** <*string*>**]**

The <*dest-ip-addr*> is the route's destination. The <*dest-mask*> is the network mask for the route's destination IP address. Alternatively, you can specify the network mask information by entering / followed by the number of bits in the network mask. For example, you can enter 192.0.0.0 255.255.255.0 as 192.0.0.0/.24.

The <*next-hop-ip-addr*> is the IP address of the next-hop router (gateway) for the route.

For a default route, enter 0.0.0.0 0.0.0.0 xxx.xxx.xxx.xxx (use 0 for the <*mask-bits*> if you specify the address in CIDR format).

If you do not want to specify a next-hop IP address, you can instead specify a port or interface number on the PowerConnect. The <*num*> parameter is a virtual interface number. The <*slot/port*> is the port's number of the PowerConnect. If you specify an Ethernet port, the PowerConnect forwards packets destined for the static route's destination network to the specified interface. Conceptually, this feature makes the destination network like a directly connected network, associated with a PowerConnect interface.

NOTE
The port or virtual interface you use for the static route's next hop must have at least one IP address configured on it. The address does not need to be in the same subnet as the destination network.

The <*metric*> parameter specifies the cost of the route and can be a number from 1 – 16. The default is 1.

NOTE
If you specify 16, RIP considers the metric to be infinite and thus also considers the route to be unreachable.

The **tag** <*num*> parameter specifies the tag value of the route. Possible values: 0 - 4294967295. Default: 0.

The **distance** <*num*> parameter specifies the administrative distance of the route. When comparing otherwise equal routes to a destination, the PowerConnect prefers lower administrative distances over higher ones, so make sure you use a low value for your default route. Possible values: 1 - 255. Default: 1.

NOTE
The PowerConnect will replace the static route if it receives a route with a lower administrative distance.

The **name** <*string*> parameter specifies the name assigned to a route. The static route name is descriptive and an optional feature. It does not affect the selection of static routes.

Configuring a static IP route between VRFs

You can configure a static route next hop to be in a different VRF. This can be done for the following:

- From the default VRF to a non-default VRF
- From a non-default VRF to a non-default VRF
- From a non-default VRF to the default VRF
- From one VRF to an IP interface in a different VRF.

NOTE
RPF is not supported with the Static Route between VRFs feature.

NOTE
For information on disabling gratuitous ARP requests on a VRF IP interface, refer to "Disabling gratuitous ARP requests for local proxy ARP" on page 690.

Configuring a static route from the default VRF to a non-default VRF

To configure an IP static route with a destination address of 192.0.0.0/24 and a next-hop router with an IP address of 195.1.1.1 in the non-default VRF named "blue", enter the following at the general configuration prompt.

```
NetIron(config)# ip route 192.128.2.69/24 next-hop-vrf blue 195.1.1.1
```

Syntax: **[no] ip route** <*dest-ip-addr*> <*dest-mask*> | <*dest-ip-addr*>/<*mask-bits*> **next-hop-vrf** <*next-hop-vrf-name*> <*next-hop-ip-addr*>

The <*dest-ip-addr*> is the route's destination. The <*dest-mask*> is the network mask for the route's destination IP address. Alternatively, you can specify the network mask information by entering / followed by the number of bits in the network mask. For example, you can enter 192.0.0.0 255.255.255.0 as 192.0.0.0/.24.

The <*next-hop-vrf-name*> is the name of the VRF that contains the next-hop router (gateway) for the route.

The <*next-hop-ip-addr*> is the IP address of the next-hop router (gateway) for the route.

NOTE
The **next-hop-vrf** needs to be a valid VRF to be used in this command.

Configuring a static route from a non-default VRF to a non-default VRF

To configure an IP static route within the VRF named "red" with a destination address of 192.0.0.0/24 and a next-hop router with an IP address of 195.1.1.1 in the non-default VRF named "blue", enter the following from within the VRF "red" configuration context.

```
NetIron(config)# ip vrf red
NetIron(config-vrf-red)# ip route 192.128.2.69/24 next-hop-vrf blue 195.1.1.1
```

Syntax: [no] ip route <*dest-ip-addr*> <*dest-mask*> | <*dest-ip-addr*>/<*mask-bits*>
next-hop-vrf <*next-hop-vrf-name*> <*next-hop-ip-addr*>

The <*dest-ip-addr*> is the route's destination. The <*dest-mask*> is the network mask for the route's destination IP address. Alternatively, you can specify the network mask information by entering / followed by the number of bits in the network mask. For example, you can enter 192.0.0.0 255.255.255.0 as 192.0.0.0/.24.

The <*next-hop-vrf-name*> is the name of the VRF that contains the next-hop router (gateway) for the route.

The <*next-hop-ip-addr*> is the IP address of the next-hop router (gateway) for the route.

NOTE
The **next-hop-vrf** needs to be a valid VRF to be used in this command.

Configuring a static route from a non-default VRF to the default VRF

To configure an IP static route within the VRF named "red" with a destination address of 192.0.0.0/24 and a next-hop router in the default VRF and an IP address of 195.1.1.1, enter the following from within the VRF "red" configuration context.

```
NetIron(config)# ip vrf red
NetIron(config-vrf-red)# ip route 192.128.2.69/24 next-hop-vrf default-vrf
195.1.1.1
```

Syntax: [no] ip route <*dest-ip-addr*> <*dest-mask*> | <*dest-ip-addr*>/<*mask-bits*>
next-hop-vrf <*next-hop-vrf-name*> <*next-hop-ip-addr*>

The <*dest-ip-addr*> is the route's destination. The <*dest-mask*> is the network mask for the route's destination IP address. Alternatively, you can specify the network mask information by entering / followed by the number of bits in the network mask. For example, you can enter 192.0.0.0 255.255.255.0 as 192.0.0.0/.24.

The **default-vrf** option specifies that the next-hop router (gateway) for the route is in the default VRF.

The <*next-hop-ip-addr*> is the IP address of the next-hop router (gateway) for the route.

NOTE
The **next-hop-vrf** needs to be a valid VRF to be used in this command.

Configuring an IP static interface route across VRFs

You can configure an IP Static interface route from one VRF to an IP interface in a different VRF. This allows you to connect from one VRF to a host that is directly connected to a port in a different VRF. You can do this by configuring a static route to point to the interface that is directly connected to the device with the IP address you want to reach. The following example defines two VRFs as follows:

VRF A :

Route Distinguiser = 1:1

Interface: ethernet port 1/1

IP address: 10.0.0.1/24

VRF B :

Route Distinguiser = 2:2

Interface: ethernet port 1/2

IP address: 20.0.0.1/24

```
NetIron(config)# ip vrf A
NetIron(config-vrf-A)# rd 1:1
NetIron(config-vrf-A)# exit
NetIron(config)# interface ethernet 1/1
NetIron(config-if-e10000-1/1)# ip vrf forwarding A
NetIron(config-if-e10000-1/1)# ip address 10.0.0.1/24
NetIron(config-if-e10000-1/1)# exit
NetIron(config)# ip vrf B
NetIron(config-vrf-B)# rd 2:2
NetIron(config-vrf-B)# exit
NetIron(config)# interface ethernet 1/2
NetIron(config-if-e10000-1/2)# ip vrf forwarding B
NetIron(config-if-e10000-1/2)# ip address 20.0.0.1/24
```

The following example configures an IP Static interface route from VRF A to a network with IP address 20.0.0.0/24, which is directly connected to ethernet port 1/2 in VRF B:

```
NetIron(config)# ip vrf a
NetIron(config-vrf-a)# ip route 20.0.0.0/24 ethernet 1/2
```

Syntax: **[no] ip route** <*dest-ip-addr*>/<*mask-bits*> **[ethernet** <*slot/port*> **| ve** <*num*> **]**

The <*dest-ip-addr*> is the route's destination. The <*dest-mask*> is the network mask for the route's destination IP address. Alternatively, you can specify the network mask information by entering a forward slash followed by the number of bits in the network mask. For example, you can enter 192.0.0.0 255.255.255.0 as 192.0.0.0/.24. To configure a default route, enter 0.0.0.0 for <*dest-ip-addr*> and 0.0.0.0 for <*dest-mask*> (or 0 for the <*mask-bits*> if you specify the address in CIDR format). Specify the IP address of the default gateway using the <*next-hop-ipaddr*> parameter.

The <*slot/port*> or <*num*> is an interface in a different VRF that is directly connected to the device that you want to reach.

Configuring a "null" route

You can configure the PowerConnect to drop IP packets to a specific network or host address by configuring a "null" (sometimes called "null0") static route for the address. When the PowerConnect receives a packet destined for the address, the PowerConnect drops the packet instead of forwarding it.

To configure a null static route to drop packets destined for network 209.157.22.x, enter the following commands.

```
NetIron(config)# ip route 209.157.22.0 255.255.255.0 null0
NetIron(config)# write memory
```

Syntax: **[no] ip route** <*ip-addr*> <*ip-mask*> **|** <*dest-ip-addr*>/<*mask-bits*> **null0 [**<*metric*>*] [tag* <*num*>**] [distance** <*num*>**]**

To display the maximum value for your device, enter the **show default values** command. The maximum number of static IP routes the system can hold is listed in the ip-static-route row in the System Parameters section of the display. To change the maximum value, use the **system-max ip-static-route** <*num*> command at the global CONFIG level.

The <*ip-addr*> parameter specifies the network or host address. The PowerConnect will drop packets that contain this address in the destination field instead of forwarding them.

The <*ip-mask*> parameter specifies the network mask. Ones are significant bits and zeros allow any value. For example, the mask 255.255.255.0 matches on all hosts within the Class C subnet address specified by <*ip-addr*>. Alternatively, you can specify the number of bits in the network mask. For example, you can enter 209.157.22.0/24 instead of 209.157.22.0 255.255.255.0.

The **null0** parameter indicates that this is a null route. You must specify this parameter to make this a null route.

The <*metric*> parameter adds a cost to the route. You can specify from 1 – 16. The default is 1.

The **tag** <*num*> parameter specifies the tag value of the route. Possible values: 0 - 4294967295. Default: 0.

The **distance** <*num*> parameter configures the administrative distance for the route. You can specify a value from 1 – 255. The default is 1. The value 255 makes the route unusable.

NOTE
The last three parameters are optional and do not affect the null route, unless you configure the administrative distance to be 255. In this case, the route is not used and the traffic might be forwarded instead of dropped.

Dropping traffic sent to the null0 interface In hardware

Traffic sent to the null0 interface is done in hardware; that is, by programming the CAM to discard traffic sent to the null0 interface. This improves forwarding efficiency and reduces the burden on the PowerConnect's CPU.

Hardware dropping for IP traffic sent to the null0 interface is supported.

You can optionally configure the PowerConnect to drop traffic sent to the default IP route address in hardware. To do this, enter the following commands.

```
NetIron(config)# ip route 0.0.0.0 0.0.0.0 null0
NetIron(config)# ip hw-drop-on-def-route
```

Syntax: [no] ip hw-drop-on-def-route

CAM default route aggregation

Configuring the PowerConnect to drop traffic sent to the default IP route address in hardware causes the device to program 32-bit host CAM entries for each destination address using the default route, which could consume the CAM space. To prevent this from happening, you can enable the CAM Default Route Aggregation feature. To do this, enter the following command.

```
NetIron(config)# ip dr-aggregate
```

Syntax: [no] ip dr-aggregate

Configuring load balancing and redundancy using multiple static routes to the same destination

You can configure multiple static IP routes to the same destination, for the following benefits:

- **IP load sharing** – If you configure more than one static route to the same destination, and the routes have different next-hop gateways but have the same metrics, the PowerConnect load balances among the routes using basic round-robin. For example, if you configure two static routes with the same metrics but to different gateways, the PowerConnect alternates between the two routes. For information about IP load balancing, refer to "Configuring IP load sharing" on page 731.

- **Backup Routes** – If you configure multiple static IP routes to the same destination, but give the routes different next-hop gateways and different metrics, the PowerConnect will always use the route with the lowest metric. If this route becomes unavailable, the PowerConnect will fail over to the static route with the next-lowest metric, and so on.

NOTE
You also can bias the PowerConnect to select one of the routes by configuring them with different administrative distances. However, make sure you do not give a static route a higher administrative distance than other types of routes, unless you want those other types to be preferred over the static route.

The steps for configuring the static routes are the same as described in the previous section. The following sections provide examples.

To configure multiple static IP routes, enter commands such as the following.

```
NetIron(config)# ip route 192.128.2.69 255.255.255.0 209.157.22.1
NetIron(config)# ip route 192.128.2.69 255.255.255.0 192.111.10.1
```

The commands in the example above configure two static IP routes. The routes go to different next-hop gateways but have the same metrics. These commands use the default metric value (1), so the metric is not specified. These static routes are used for load sharing among the next-hop gateways.

The following commands configure static IP routes to the same destination, but with different metrics. The route with the lowest metric is used by default. The other routes are backups in case the first route becomes unavailable. The PowerConnect uses the route with the lowest metric if the route is available.

```
NetIron(config)# ip route 192.128.2.69 255.255.255.0 209.157.22.1
NetIron(config)# ip route 192.128.2.69 255.255.255.0 192.111.10.1 2
NetIron(config)# ip route 192.128.2.69 255.255.255.0 201.1.1.1 3
```

In this example, each static route has a different metric. The metric is not specified for the first route, so the default (1) is used. A metric is specified for the second and third static IP routes. The second route has a metric of two and the third route has a metric of 3. Thus, the second route is used only of the first route (which has a metric of 1) becomes unavailable. Likewise, the third route is used only if the first and second routes (which have lower metrics) are both unavailable.

For complete syntax information, refer to "Configuring a static IP route" on page 716.

Configuring standard static IP routes and interface or null static routes to the same destination

You can configure a null0 or interface-based static route to a destination and also configure a normal static route to the same destination, so long as the route metrics are different.

When the PowerConnect has multiple routes to the same destination, the PowerConnect always prefers the route with the lowest metric. Generally, when you configure a static route to a destination network, you assign the route a low metric so that the PowerConnect prefers the static route over other routes to the destination.

This feature is especially useful for the following configurations. These are not the only allowed configurations but they are typical uses of this enhancement:

- When you want to ensure that if a given destination network is unavailable, the PowerConnect drops (forwards to the null interface) traffic for that network instead of using alternate paths to route the traffic. In this case, assign the normal static route to the destination network a lower metric than the null route.
- When you want to use a specific interface by default to route traffic to a given destination network, but want to allow the PowerConnect to use other interfaces to reach the destination network if the path that uses the default interface becomes unavailable. In this case, give the interface route a lower metric than the normal static route.

NOTE
You cannot add a null or interface-based static route to a network if there is already a static route of any type with the same metric you specify for the null or interface-based route.

Figure 129 shows an example of two static routes configured for the same destination network. One of the routes is a standard static route and has a metric of 1. The other static route is a null route and has a higher metric than the standard static route. The PowerConnect always prefers the static route with the lower metric. In this example, the PowerConnect always uses the standard static route for traffic to destination network 192.168.7.0/24, unless that route becomes unavailable, in which case the PowerConnect sends traffic to the null route instead.

FIGURE 129 Standard and null static routes to the same destination network

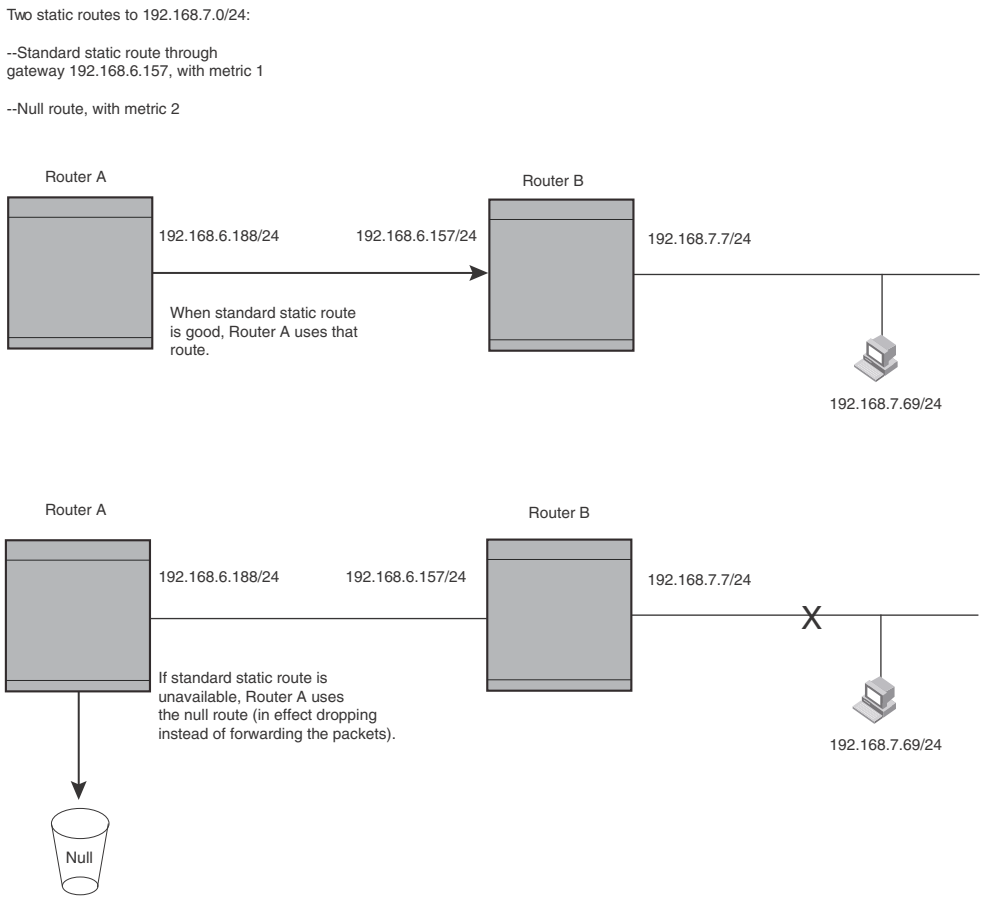


Figure 130 shows another example of two static routes. A standard static route and an interface-based static route are configured for destination network 192.168.6.0/24. The interface-based static route has a lower metric than the standard static route. As a result, the PowerConnect always prefers the interface-based route when the route is available. However, if the interface-based route becomes unavailable, the PowerConnect still forwards the traffic toward the destination using an alternate route through gateway 192.168.8.11/24.

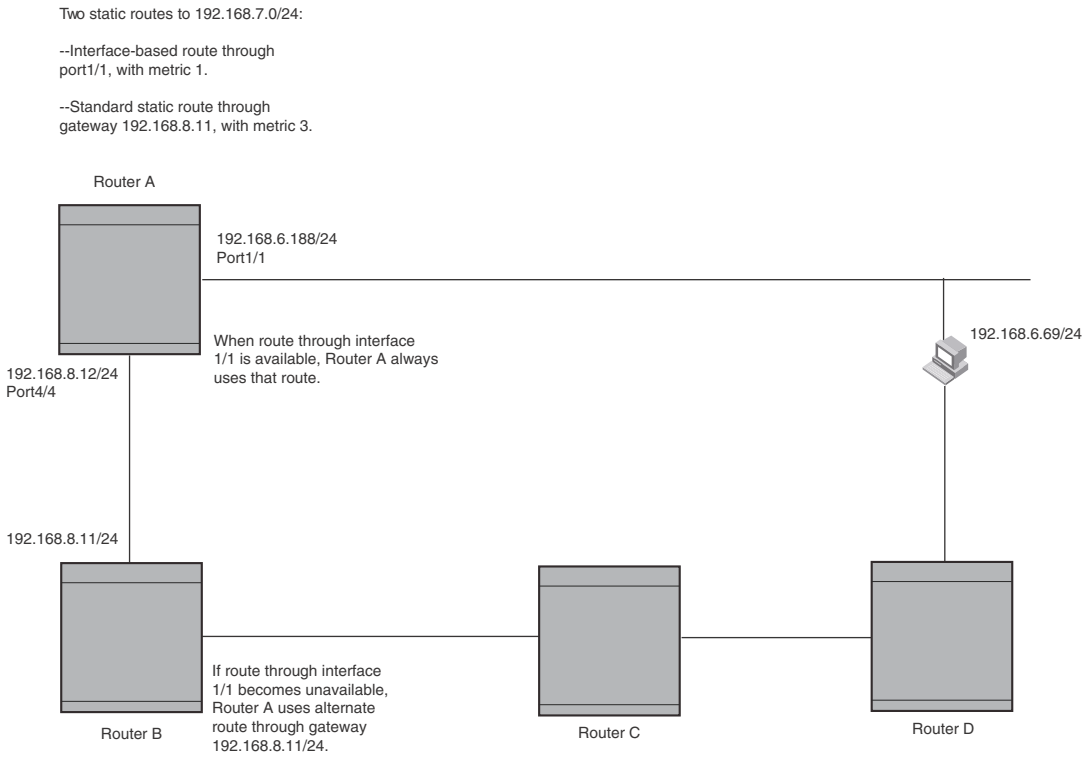
FIGURE 130 Standard and interface routes to the same destination network



To configure a standard static IP route and a null route to the same network as shown in Figure 129 on page 723, enter commands such as the following.

```
NetIron(config)# ip route 192.168.7.0/24 192.168.6.157/24 1
NetIron(config)# ip route 192.168.7.0/24 null0 3
```

The first command configures a standard static route, which includes specification of the next-hop gateway. The command also gives the standard static route a metric of 1, which causes the PowerConnect to always prefer this route when the route is available.

The second command configures another static route for the same destination network, but the second route is a null route. The metric for the null route is 3, which is higher than the metric for the standard static route. If the standard static route is unavailable, the software uses the null route.

For complete syntax information, refer torefer to “Configuring a static IP route” on page 716.

To configure a standard static route and an interface-based route to the same destination, enter commands such as the following.

```
NetIron(config)# ip route 192.168.6.0/24 ethernet 1/1 1
NetIron(config)# ip route 192.168.6.0/24 192.168.8.11/24 3
```

The first command configured an interface-based static route through Ethernet port 1/1. The command assigns a metric of 1 to this route, causing the PowerConnect to always prefer this route when it is available. If the route becomes unavailable, the PowerConnect uses an alternate route through the next-hop gateway 192.168.8.11/24.

Static route configuration

The following enhancements to static route configuration have been added:

- "Static route tagging" on page 725
- "Static route next hop resolution" on page 725
- "Static route recursive lookup" on page 726
- "Static route resolve by default route" on page 726

Static route tagging

Static routes can be configured with a tag value, which can be used to color routes and filter routes during a redistribution process. When tagged static routes are redistributed to OSPF or to a protocol that can carry tag information, they are redistributed with their tag values.

To add a tag value to a static route, enter commands such as the following.

```
NetIron(config)# ip route 192.122.12.1 255.255.255.0 192.122.1.1 tag 20
```

Syntax: [no] ip route <*dest-ip-addr*> <*dest-mask*> | <*dest-ip-addr*>/<*dest-mask*> <*next-hop-ip-address*> tag <*value*>

The <*dest-ip-addr*> is the route's destination. The <*dest-mask*> is the network mask for the route's destination IP address. Alternatively, you can specify the network mask information by entering a forward slash followed by the number of bits in the network mask. For example, you can enter 192.0.0.0 255.255.255.0 as 192.0.0.0/.24. You can enter multiple static routes for the same destination for load balancing or redundancy.

The <*next-hop-ip-address*> is the IP address of the next-hop router (gateway) for the route. In addition, the <*next-hop-ip-address*> can also be a virtual routing interface (for example. ve 100), or a physical port (for example, ethernet 1/1) that is connected to the next hop router.

Enter 0 – 4294967295 for **tag** <*value*>. The default is 0, meaning no tag.

Static route next hop resolution

This feature of the Multi-Service IronWare software enables the PowerConnect to use routes from a specified protocol to resolve a configured static route. By default this is disabled.

To configure static route next hop resolution with OSPF routes, use the following command.

```
NetIron(config)# ip route next-hop ospf
```

Syntax: [no] ip route next-hop [bgp | isis | ospf | rip]

NOTE
This command can be independently applied on a per-VRF basis.

This command causes the resolution of static route next hop using routes learned from one of the following protocols:

- bgp – both iBGP and eBGP routes are used to resolve static routes.
- isis
- ospf
- rip

NOTE
Connected routes are always used to resolve static routes.

Static route recursive lookup

This feature of the Multi-Service IronWare software enables the PowerConnect to use static routes to resolve another static route. The recursive static route nexthop lookup level can be configured. By default, this feature is disabled.

To configure static route next hop recursive lookup by other static routes, use the following command.

```
NetIron(config)# ip route next-hop-recursion 5
```

Syntax: [no] ip route next-hop-recursion <*level*>

The <*level*> available specifies the numbers of level of recursion allowed. Acceptable values are 1-10. The default value is 3.

NOTE
This command can be independently applied on a per-VRF basis.

Static route resolve by default route

This feature of the Multi-Service IronWare software enables the PowerConnect to use the default route (0.0.0.0/0) to resolve a static route. By default, this feature is disabled.

Use the following command to configure static route resolve by default route.

```
NetIron(config)# ip route next-hop-enable-default
```

Syntax: [no] ip route next-hop-enable-default

NOTE
This command can be independently applied on a per-VRF basis.

NOTE
This command works independently with the **ip route next-hop-recursion** and **ip route next-hop** commands. If the default route is a protocol route, that protocol needs to be enabled to resolve static routes using the **ip route next-hop [protocol-name]** command in order for static routes to resolve by this default route. If the default route itself is a static route, you must configure the **ip route next-hop-recursion** command to resolve other static routes by this default route.

Static route to an LSP tunnel interface

This feature allows you to set the next hop for a static route to the egress router of an LSP tunnel if the destination route is contained in the MPLS routing table. In this configuration, the static route is updated with the LSP routes and reverts to its original next hop outgoing interface when this feature is disabled or when the LSP goes down. This route can be used for the default route.

To enable the static route to an LSP tunnel interface feature, use the following command.

```
NetIron(config)# ip route next-hop-enable-mpls
```

Syntax: [no] ip route next-hop-enable-mpls

The static route can then be directed to the IP address of the egress router of the LSP. In the following example, a static route is configured to network 10.10.10.0/24 through 11.11.11.1, which is the IP address of the egress router of an LSP tunnel.

```
NetIron(config)# ip route 10.10.10.0/24 11.11.11.1
```

As previously stated, this feature works only if a route to the destination network is contained in the MPLS routing table. To verify that it is, you can use the **show ip route** command, as shown in the following example.

```
NetIron# show ip route
Total number of IP routes: 6
Type Codes - B:BGP D:Connected I:ISIS S:Static R:RIP O:OSPF; Cost - Dist/Metric
        Destination        Gateway         Port           Cost           Type
1       10.47.6.0/24       DIRECT          mgmt 1         0/0            D
2       11.11.11.11/32     DIRECT          loopback 1     0/0            D
3       12.12.12.12/32     40.1.0.1        eth 5/1        110/3          O
        12.12.12.12/32     12.12.12.12     lsp delll   110/3          O
                                           onglspfoundr
                                           ylonglspfoun
                                           drylonglspfo
                                           undrylonglsp
                                           fou
        12.12.12.12/32     12.12.12.12     lsp t11        110/3          O
4       13.13.13.13/32     40.1.0.1        eth 5/1        110/2          O
5       40.1.0.0/24        DIRECT          eth 5/1        0/0            D
6       50.1.0.0/24        40.1.0.1        eth 5/1        110/2          O
PE1-#
```

As shown in the example, route 2 has a destination network of 10.10.10.0/24 through the gateway at IP address 11.11.11.1 which is on LSP 12.

NOTE

The show commands are enhanced to include the full LSP name. Previously, the LSP name was truncated because it exceeded the character length. Now, the LSP name is text wrapped to display the full name. For example, see show ip route above.

To verify that an LSP is up and that MPLS has a route to it, you can use the **show mpls lsp** and **show mpls route** commands as shown in the following examples.

```
NetIron# show mpls lsp
Note: LSPs marked with * are taking a Secondary Path
                                Admin  Oper  Tunnel   Up/Dn  Retry   Active
Name            To              State State Intf     Times  No.     Path
t6              12.12.12.13     UP    DOWN    --      0      292     --
t5              12.12.12.12     UP    UP     tnl3     1      0       --
t2              12.12.12.12     UP    UP     tnl1     1      0       --
t7              12.12.12.12     UP    UP     tnl5     1      0       one
powerconnectlongl   12.12.12.12     UP    UP     tnl9     1      0       --
spverylongls
pveryverylon
glsp
t4              12.12.12.12     UP    UP     tnl2     1      0        --
t1              12.12.12.12     UP    UP     tnl0     1      0         --

NetIron(config-mpls-if-e100-1/3)#show mpls route
Total number of MPLS tunnel routes: 3
R:RSVP L:LDP S:Static O:Others
      Destination          Gateway           Tnnl    Port  Label  Sig Cost Use
1     2.2.2.2/32           2.2.2.2           tnl8    1/2   3      L   0    0
2     3.3.3.3/32           2.2.2.2           tnl9    1/1   1025   L   0    0
3     3.3.3.3/32           3.3.3.3           tnl1    1/2   1027   R   0    0
```

NOTE
The show commands have been enhanced to include the full MPLS tunnel name. Previously, the MPLS tunnel name was truncated because it exceeded the character length. Now, the MPLS tunnel name is text-wrapped to display the full name. For an illustration, see the output of the **show mpls lsp** and **show mpls route** commands in the preceding examples.

Naming a static IP route

You can assign a name to a static IP route. A static IP route name serves as a description of the route. The name can be used to more readily reference or identify the associated static route.

NOTE
The static route name is an optional feature. It does not affect the selection of static routes.

The Dell device does not check for the uniqueness of names assigned to static routes. Static routes that have the same or different next hop(s) can have the same or different name(s). Due to this, the same name can be assigned to multiple static routes to group them. The name is then used to reference or identify a group of static routes.

NOTE
This feature is supported on standard static IP routes and static IP routes between VRFs (both default and non-default).

The option to assign a name to a static route is displayed after you select either an outgoing interface type or configure the next hop address.

To assign a name to a static route, enter commands such as the following.

```
NetIron(config)# ip route 12.22.22.22 255.255.255.255 eth 1/1 name abc
```

OR

```
NetIron(config)# ip route 12.22.22.22 255.255.255.255 12.1.1.1 name abc
```

Syntax: [no] ip route <*dest-ip-addr*> <*dest-mask*> | <*dest-ip-addr*>/<*mask-bits*> <*next-hop-ip-addr*>| ethernet <*slot/port*>| pos <*slot/port*> | ve <num> [<metric>] [tag <num>] [distance <num>] [name <*string*>]

Enter the static route name for **name** <*string*>. The maximum length of the name is 128 bytes.

The output of the **show** commands displays the name of a static IP route if there is one assigned.

Show run displays the entire name of the static IP route. The **show ip static route** command displays an asterisk (*) after the first twelve characters if the assigned name is thirteen characters or more. The **show ipv6 static route** command displays an asterisk after the first two characters if the assigned name is three characters or more.

When displayed in **show run**, a static route name with a space in the name will appear within quotation marks (for example, “brcd route”).

Refer to “Displaying the IP static route table for a VRF” on page 1683.

Changing the name of a static IP route

To change the name of a static IP route, enter the static route as configured. Proceed to enter the new name instead of the previous name. See the example below.

Static IP route with the original name “abc”:

```
NetIron(config)# ip route 12.22.22.22 255.255.255.255 12.1.1.1 name abc
```

Change the name of “abc” to “xyz”:

```
NetIron(config)# ip route 12.22.22.22 255.255.255.255 12.1.1.1 name xyz
```

In this example, “xyz” is the set as the new name of the static IP route.

Deleting the name of a static IP route

To delete the name of a static IP route, use the **no** command. See the example below.

Static IP route with the name “xyz”:

```
NetIron(config)# ip route 12.22.22.22 255.255.255.255 12.1.1.1 name xyz
```

To remove the name “xyz” from the static IP route, specify both “name” and the string, in this case “xyz”.

```
NetIron(config)#no ip route 12.22.22.22 255.255.255.255 12.1.1.1 name xyz
```

The static route no longer has a name assigned to it.

Configuring a default network route

The PowerConnect enables you to specify a candidate default route without the need to specify the next hop gateway. If the IP route table does not contain an explicit default route (for example, 0.0.0.0/0) or propagate an explicit default route through routing protocols, the software can use the default network route as a default route instead.

When the software uses the default network route, it also uses the default network route's next hop gateway as the gateway of last resort.

This feature is especially useful in environments where network topology changes can make the next hop gateway unreachable. This feature allows the PowerConnect to perform default routing even if the default network route's default gateway changes.

The feature thus differs from standard default routes. When you configure a standard default route, you also specify the next hop gateway. If a topology change makes the gateway unreachable, the default route becomes unusable.

For example, if you configure 10.10.10.0/24 as a candidate default network route, if the IP route table does not contain an explicit default route (0.0.0.0/0), the software uses the default network route and automatically uses that route's next hop gateway as the default gateway. If a topology change occurs and as a result the default network route's next hop gateway changes, the software can still use the default network route.

If you configure more than one default network route, the PowerConnect uses the following algorithm to select one of the routes.

1. Use the route with the lowest administrative distance.
2. If the administrative distances are equal:
    - Are the routes from different routing protocols (RIP, OSPF, or BGP4)? If so, use the route with the lowest IP address.
    - If the routes are from the same routing protocol, use the route with the best metric. The meaning of “best” metric depends on the routing protocol:
    - **RIP** – The metric is the number of hops (additional routers) to the destination. The best route is the route with the fewest hops.
    - **OSPF** – The metric is the path cost associated with the route. The path cost does not indicate the number of hops but is instead a numeric value associated with each route. The best route is the route with the lowest path cost.
    - **BGP4** – The metric is the Multi-exit Discriminator (MED) associated with the route. The MED applies to routes that have multiple paths through the same AS. The best route is the route with the lowest MED.

NOTE
Currently the PowerConnect will *not* propagate a candidate default route, specified by the "**ip default-network** <>" command, into the routing protocols in spite of the **default-information-originate** command being configured under the routing protocols.

Configuring a default network route

You can configure up to four default network routes. To configure a default network route, enter commands such as the following.

```
NetIron(config)# ip default-network 209.157.22.0
NetIron(config)# write memory
```

Syntax: [no] ip default-network <*ip-addr*>

The <*ip-addr*> parameter specifies the network address.

To verify that the route is in the route table, enter the following command at any level of the CLI.

```
NetIron(config)# show ip route
Total number of IP routes: 2
Start index: 1  B:BGP D:Connected  R:RIP  S:Static  O:OSPF *:Candidate default
      Destination       Gateway          Port   Cost   Type
1     209.157.20.0      0.0.0.0          lb1    1      D
2     209.157.22.0      0.0.0.0          4/11   1      *D
```

This example shows two routes. Both of the routes are directly attached, as indicated in the Type column. However, one of the routes is shown as type "*D", with an asterisk (*). The asterisk indicates that this route is a candidate default network route.

Configuring IP load sharing

The IP route table can contain more than one path to a given destination. When this occurs, the PowerConnect selects the path with the lowest cost as the path for forwarding traffic to the destination. If the IP route table contains more than one path to a destination and the paths each have the lowest cost, then the PowerConnect uses ***IP load sharing*** to select a path to the destination.[1]

IP load sharing is based on the destination address of the traffic. PowerConnect supports load sharing based on individual host addresses or on network addresses.

You can enable a PowerConnect to load balance across up to eight equal-cost paths. The default maximum number of equal-cost load sharing paths is four.

NOTE
IP load sharing is not based on source routing, only on next-hop routing.

NOTE
The term "path" refers to the next-hop router to a destination, not to the entire route to a destination. Thus, when the software compares multiple equal-cost paths, the software is comparing paths that use different next-hop routers, with equal costs, to the same destination.

In many contexts, the terms "route" and "path" mean the same thing. Most of the user documentation uses the term "route" throughout. The term "path" is used in this section to refer to an individual next-hop router to a destination, while the term "route" refers collectively to the multiple paths to the destination. Load sharing applies when the IP route table contains multiple, equal-cost paths to a destination.

NOTE
The PowerConnect also performs load sharing among the ports in aggregate links.

1. IP load sharing is also called "Equal-Cost Multi-Path (ECMP)" load sharing or just "ECMP"

How multiple equal-cost paths enter the IP route table

IP load sharing applies to equal-cost paths in the IP route table. Routes eligible for load sharing can enter the table from the following sources:

- IP static routes
- Routes learned through RIP, OSPF, and BGP4

Administrative distance

The administrative distance is a unique value associated with each type (source) of IP route. Each path has an administrative distance. It is used when evaluating multiple equal-cost paths to the same destination from different sources, such as RIP, OSPF and so on, but not used when performing IP load sharing.

The value of the administrative distance is determined by the source of the route. The PowerConnect is configured with a unique administrative distance value for each IP route source.

When the software receives paths from different sources to the same destination, the software compares their administrative distances, selects the one with the lowest distance, and puts it in the IP route table. For example, if the PowerConnect has a path learned from OSPF and a path learned from RIP for a given destination, only the path with the lower administrative distance enters the IP route table.

Here are the default administrative distances on the PowerConnect:

- Directly connected – 0 (this value is not configurable)
- Static IP route – 1 (applies to all static routes, including default routes and default network routes)
- Exterior Border Gateway Protocol (EBGP) – 20
- OSPF – 110
- RIP – 120
- Interior Gateway Protocol (IBGP) – 200
- Local BGP – 200
- Unknown – 255 (the router will not use this route)

Lower administrative distances are preferred over higher distances. For example, if the router receives routes for the same network from OSPF and from RIP, the router will prefer the OSPF route by default.

NOTE
You can change the administrative distances individually. Refer to the configuration chapter for the route source for information.

Since the software selects only the path with the lowest administrative distance, and the administrative distance is determined by the path's source, IP load sharing does not apply to paths from different route sources. IP load sharing applies only when the IP route table contains paths from the same IP route source to the same destination.

Path cost

The cost parameter provides a basis of comparison for selecting among paths to a given destination. Each path in the IP route table has a cost. When the IP route table contains multiple paths to a destination, the PowerConnect chooses the path with the lowest cost. When the IP route table contains more than one path with the lowest cost to a destination, the PowerConnect uses IP load sharing to select one of the lowest-cost paths.

The source of a path's cost value depends on the source of the path:

- **IP static route** – The value you assign to the metric parameter when you configure the route. The default metric is 1. Refer to "Configuring load balancing and redundancy using multiple static routes to the same destination" on page 721.
- **RIP** – The number of next-hop routers to the destination.
- **OSPF** – The Path Cost associated with the path. The paths can come from any combination of inter-area, intra-area, and external Link State Advertisements (LSAs).
- **BGP4** – The path's Multi-Exit Discriminator (MED) value.

NOTE
If the path is redistributed between two or more of the above sources before entering the IP route table, the cost can increase during the redistribution due to settings in redistribution filters.

Static route, OSPF, and BGP4 load sharing

IP load sharing and load sharing for static routes, OSPF routes, and BGP4 routes are individually configured. Multiple equal-cost paths for a destination can enter the IP route table only if the source of the paths is configured to support multiple equal-cost paths. For example, if BGP4 allows only one path with a given cost for a given destination, the BGP4 route table cannot contain equal-cost paths to the destination. Consequently, the IP route table will not receive multiple equal-cost paths from BGP4.

Table 113 lists the default and configurable maximum numbers of paths for each IP route source that can provide equal-cost paths to the IP route table. The table also lists where to find configuration information for the route source's load sharing parameters.

The load sharing state for all the route sources is based on the state of IP load sharing. Since IP load sharing is enabled by default on the PowerConnect, load sharing for static IP routes, RIP routes, OSPF routes, and BGP4 routes also is enabled by default.

TABLE 113 Default load sharing parameters for route sources

Route source	Default maximum number of paths	Maximum number of paths	See...
Static IP route	4 **NOTE:** This value depends on the value for IP load sharing, and is not separately configurable.	8 **NOTE:** This value depends on the value for IP load sharing, and is not separately configurable.	page 737
RIP	4 **NOTE:** This value depends on the value for IP load sharing, and is not separately configurable.	8 **NOTE:** This value depends on the value for IP load sharing, and is not separately configurable.	page 737

TABLE 113 Default load sharing parameters for route sources (Continued)

Route source	Default maximum number of paths	Maximum number of paths	See...
OSPF	4	8	page 737
BGP4	1	4	page 1037

Options for IP load sharing and LAGs

The following options have been added to refine the hash calculations used for IP load sharing and LAGs. These include the following:

- **Speculate UDP or TCP Headers** – This option is applied to ECMP and LAG index hash calculations.
- **Mask Layer-3 and Layer-4 Information** – This option is applied to ECMP and LAG index hash calculations.
- **Mask Layer-2 Information** – This option is applied to ECMP and LAG index hash calculations.
- **Diversification** – This option is applied to ECMP and LAG index hash calculations.
- **Hash Rotate** – This option is applied to ECMP hash calculations and to LAG index calculations.

Speculate UDP or TCP packet headers

With this option set, the packet headers following IPv4 headers are used for the ECMP and LAG index hash calculations even if the packet is not a TCP or UDP packet. If the packet is a non-fragmented. no-IP options, true TCP or UDP packet, the TCP or UDP ports will be used for hash calculations unless the **load-balance mask ip** or **load-balance mask ipv6** commands are used. This behavior is off by default and can be enabled using the following command.

```
NetIron(config)# load-balance force-l4-hashing all
```

Syntax: **[no] load-balance force-l4-hashing [all |** <*slot-number*> **|** <*slot-number*> <*np-id*> **]**

The **all** option applies the command to all ports within the router.

Specifying a slot number using the <*slot-number*> variable limits the command to an individual module.

Specifying a slot number and a network processor ID using the <*slot-number*> and <*np-id*> variables limits the command to the ports supported by the specified network processor on the specified interface module.

NOTE
Problems can occur with the **Ping** and **Traceroute** functions when this option is enabled.

Masking layer-3 and layer-4 information

With this option set, the following values can be masked during ECMP and LAG index hash calculations: TCP or UDP source and destination port information, source and destination IP address, IPv4 protocol ID, and IPv6 next header. When used with the **load-balance force-l4-hashing** command, this command takes precedence. This option can be set using the following commands.

```
NetIron(config)# load-balance mask ip src-l4-port all
```

Syntax: **[no] load-balance mask ip [src-l4-port | dst-l4-port | src-ip | dst-ip | protocol] [all |** <*slot-number*> **|** <*slot-number*> <*np-id*> **]**

Use the **src-l4-port** option when you want to mask the Layer-4 source port.

Use the **dst-l4-port** option when you want to mask the Layer-4 destination port.

Use the **src-ip** option when you want to mask the IP source address.

Use the **dst-ip** option when you want to mask the IP destination address.

Use the **protocol** option when you want to mask the IPv4 protocol ID.

The **all** option applies the command to all ports within the router.

Specifying a slot number using the <*slot-number*> variable limits the command to an individual module.

Specifying a slot number and a network processor ID using the <*slot-number*> and <*np-id*> variables limits the command to the ports supported by the specified network processor on the specified interface module.

This command can be applied for IPv6 using the following command.

```
NetIron(config)# load-balance mask ipv6 src-l4-port all
```

Syntax: [no] load-balance mask ipv6 [src-l4-port | dst-l4-port | src-ip | dst-ip | next-hdr] [all | <*slot-number*> | <*slot-number*> <*np-id*>]

Except for the **next-hdr** option, the command options are the same as for the **load-balance mask ip** command as described previously. The **next-hdr** option is described in the following:

Use the **next-hdr** option when you want to mask the IPv6 next header.

These commands are disabled by default.

Masking layer-2 information

With the **load-balance mask ethernet** command set, the following Layer-2 values can be masked during ECMP and LAG index hash calculations: source and destination MAC address, VLAN, Ethertype, and Inner VLAN. To mask Layer-2 information, use the **load-balance mask ethernet** command, as shown in the following.

```
NetIron(config)# load-balance mask ethernet sa-mac all
```

Syntax: [no] load-balance mask ethernet [sa-mac | da-mac | vlan | etype | inner-vlan] [all | <*slot-number*> | <*slot-number*> <*np-id*>]

Use the **sa-mac** option when you want to mask the source MAC address.

Use the **da-mac** option when you want to mask the destination MAC address.

Use the **vlan** option when you want to mask the VLAN ID.

Use the **etype** option when you want to mask the Ethertype

Use the **inner-vlan** option when you want to mask the inner VLAN ID.

The **all** option applies the command to all ports within the router.

Specifying a slot number using the <*slot-number*> variable limits the command to an individual module.

Specifying a slot number and a network processor ID using the <*slot-number*> and <*np-id*> variables limits the command to the ports supported by the specified network processor on the specified interface module.

Masking MPLS information

With the **loadbalance mask mpls** command set, MPLS Labels 0, 1 or 2 can be masked during ECMP and LAG index hash calculation. To mask MPLS information, use the **load-balance mask mpls** command, as shown in the following.

```
NetIron(config)# load-balance mask mpls label0 all
```

Syntax: **[no] load-balance mask mpls [label0 | label1 | label2] [all |** <*slot-number*> **|** <*slot-number*> <*np-id*> **]**

Use the **label0** option when you want to mask MPLS Label 0 which is the outer-most MLS label in a packet.

Use the **label1** option when you want to mask MPLS Label 1 which is the next outer-most MLS label in a packet from MPLS Label 2.

Use the **label2** option when you want to mask MPLS Label 2 which is the inner-most MLS label in a packet.

The **all** option applies the command to all ports within the router.

Specifying a slot number using the <*slot-number*> variable limits the command to an individual module.

Specifying a slot number and a network processor ID using the <*slot-number*> and <*np-id*> variables limits the command to the ports supported by the specified network processor on the specified interface module.

Hash diversification for LAGs and IP load balancing

In a multi-stage network a traffic flow will normally use the same LAG port or same path (for IP load balancing) at each stage. The Hash Diversification feature works within an earlier stage of the hash calculation than the hash rotate feature. Using the **load-balance hash-diversify** command, you can provide a unique hash diversify value to a router, or a sub-set of ports on a router. This unique value is used in calculation of the ECMP and LAG index hash. Consequently, instead of a traffic flow always following the same port group or path, it will be distributed over different LAG or ECMP members. To apply hash diversification, use the following command.

```
NetIron(config)# load-balance hash-diversify random all
```

Syntax: **[no] load-balance hash-diversify [** <*number*> **| random | slot>] [all |** <*slot-number*> **|** <*slot-number*> <*np-id*> **]**

You can set the unique hash diversify value using one of the following options:

The <*number*> option allows you to specify a value from 0 - 255.

The **random** option directs the CPU to generate a random number for each packet processor and program it as the hash diversification value.

The **slot** option specifies the slot ID as the has diversification number.

The default value for the diversification number is 0 and the **no** version of the command resets the value to 0 regardless of any value previously set. Also, the most recent command added overrides any previous instances of the command. For example, if the **random** option is entered first and is then followed by the **slot** option, the value of the slot ID for the specified slot will be used.

The **all** option applies the command to all ports within the router.

Specifying a slot number using the <*slot-number*> variable limits the command to an individual module.

Specifying a slot number and a network processor ID using the <*slot-number*> and <*np-id*> variables limits the command to the ports supported by the specified network processor on the specified interface module.

This option can also be used in a multi-stage network to avoid the same traffic flow to always use one path of an ECMP or the same LAG member index at each stage. Using the hash rotate function the same set of traffic flows forwarded out of one LAG member or ECMP path to the next router can be distributed across different paths of the LAG member or ECMP path to the next router.

Hash rotate for LAGs and IP load balancing

The hash rotate function provides another option (in addition to hash diversification) for diversifying traffic flow in a multi-stage network. Using this feature, the ECMP hash index can be rotated by a specified number of bits after it has been calculated. This allows path selection within IP load balancing to be more diverse.

To configure hash rotate to LAG index calculations, enter a command such as the following.

```
NetIron(config)# load-balance hash-rotate 3 all
```

Syntax: **[no] load-balance hash-rotate** <*rotate-number*> **[all |** <*slot-number*> **|** <*slot-number*> <*np-id*> **]**

The <*rotate-number*> value specifies number of bits between 0 and 7 that you want to rotate the ECMP hash index value.

The **all** option applies the command to all ports within the router.

Specifying a slot number using the <*slot-number*> variable limits the command to an individual module.

Specifying a slot number and a network processor ID using the <*slot-number*> and <*np-id*> variables limits the command to the ports supported by the specified network processor on the specified interface module.

NOTE
The hash diversification and hash rotate features can be applied seperately or together. Depending on your network configuration, either or both of these features may need to be configured.

How IP load sharing works

On the PowerConnect, IP load sharing is done by the hardware. If there is more than one path to a given destination, a hash is calculated based on the source MAC address, destination MAC address, source IP address, destination IP address, VLAN-ID (if applicable), IPv4 protcol number, IPv6 next header and TCP/UDP source port and destination port if the packet is also a TCP/UDP packet. This hash is used to select one of the paths.

Changing the maximum number of load sharing paths

By default, IP load sharing allows IP traffic to be balanced across up to four equal path. You can change the maximum number of paths that the PowerConnect supports to a value of 2 – 8.

For optimal results, set the maximum number of paths to a value equal to or greater than the maximum number of equal-cost paths that your network typically contains. For example, if the PowerConnect has six next-hop routers, set the maximum paths value to six.

NOTE
If the setting for the maximum number of paths is lower than the actual number of equal-cost paths, the software does not use all the paths for load sharing.

To change the number of paths, enter a command such as the following.

```
NetIron(config)# ip load-sharing 8
```

Syntax: [no] ip load-sharing [<*number*>**]**

Enter a value from 2 – 8 for <*number*> to set the maximum number of paths.

NOTE
A new command was introduced (maximum-paths use-load-sharing) within the BGP configuration that allows support for BGP routes in IP Load Sharing while BGP Multipath Load sharing is not enable.

Response to path state changes

If one of the load-balanced paths becomes unavailable, the IP route table in hardware is modified to stop using the unavailable path. The traffic is load balanced between the available paths using the same hashing mechanism described above. (Refer to "How IP load sharing works" on page 737.)

Configuring IRDP

The PowerConnect uses ICMP Router Discovery Protocol (IRDP) to advertise the IP addresses of its router interfaces to directly attached hosts. IRDP is disabled by default. You can enable it globally or on individual ports.

Consider the following when you enable or disable IRDP globally:

- If you enable IRDP globally, all ports use the default values for the IRDP parameters.
- If you leave IRDP disabled globally but enable it on individual ports, you also can configure the IRDP parameters on an individual port basis.

  NOTE
  You can configure IRDP parameters only an individual port basis. To do so, IRDP must be disabled globally and enabled only on individual ports. You cannot configure IRDP parameters if the feature is globally enabled.

When IRDP is enabled, the PowerConnect periodically sends Router Advertisement messages out the IP interfaces on which the feature is enabled. The messages advertise the PowerConnect's IP addresses to directly attached hosts who listen for the messages. In addition, hosts can be configured to query the PowerConnect for the information by sending Router Solicitation messages.

Some types of hosts use the Router Solicitation messages to discover their default gateway. When IRDP is enabled, the PowerConnect responds to the Router Solicitation messages. Some clients interpret this response to mean that the PowerConnect is the default gateway. If another router is actually the default gateway for these clients, leave IRDP disabled on the PowerConnect.

IRDP uses the following parameters. If you enable IRDP on individual ports rather than globally, you can configure these parameters on an individual port basis. The IRDP parameters are as follows:

- **Packet type** – The PowerConnect can send Router Advertisement messages as IP broadcasts or as IP multicasts addressed to IP multicast group 224.0.0.1. The packet type is IP broadcast.
- **Maximum message interval and minimum message interval** – When IRDP is enabled, the PowerConnect sends the Router Advertisement messages every 450 – 600 seconds by default. The time within this interval that the PowerConnect selects is random for each message and is not affected by traffic loads or other network factors. The random interval minimizes the probability that a host will receive Router Advertisement messages from other routers at the same time. The interval on each IRDP-enabled PowerConnect interface is independent of the interval on other IRDP-enabled interfaces. The default maximum message interval is 600 seconds. The default minimum message interval is 450 seconds.
- **Hold time** – Each Router Advertisement message contains a hold time value. This value specifies the maximum amount of time the host should consider an advertisement to be valid until a newer advertisement arrives. When a new advertisement arrives, the hold time is reset. The hold time is always longer than the maximum advertisement interval. Therefore, if the hold time for an advertisement expires, the host can reasonably conclude that the router interface that sent the advertisement is no longer available. The default hold time is three times the maximum message interval.
- **Preference** – If a host receives multiple Router Advertisement messages from different routers, the host selects the router that sent the message with the highest preference as the default gateway. The preference can be a number from 4294967296 to 4294967295. The default is 0.

Enabling IRDP globally

To globally enable IRDP, enter the following command.

```
NetIron(config)# ip irdp
```

This command enables IRDP on the IP interfaces on all ports. Each port uses the default values for the IRDP parameters. The parameters are not configurable when IRDP is globally enabled.

Enabling IRDP on an individual port

To enable IRDP on an individual interface and change IRDP parameters, enter commands such as the following.

```
NetIron(config)# interface ethernet 1/3
NetIron(config-if-e10000-1/3)# ip irdp maxadvertinterval 400
```

This example shows how to enable IRDP on a specific port and change the maximum advertisement interval for Router Advertisement messages to 400 seconds.

NOTE
To enable IRDP on individual ports, you must leave the feature globally disabled.

Syntax: **[no] ip irdp [broadcast | multicast] [holdtime** <*seconds*>**] [maxadvertinterval** <*seconds*>**] [minadvertinterval** <*seconds*>**] [preference** <*number*>**]**

The **broadcast | multicast** parameter specifies the packet type the PowerConnect uses to send Router Advertisement.

- **broadcast** – The PowerConnect sends Router Advertisement as IP broadcasts. This is the default.

- **multicast** – The PowerConnect sends Router Advertisement as multicast packets addressed to IP multicast group 224.0.0.1.

The **holdtime** <*seconds*> parameter specifies how long a host that receives a Router Advertisement from the PowerConnect should consider the advertisement to be valid. When a host receives a new Router Advertisement message from the PowerConnect, the host resets the hold time for the PowerConnect to the hold time specified in the new advertisement. If the hold time of an advertisement expires, the host discards the advertisement, concluding that the router interface that sent the advertisement is no longer available. The value must be greater than the value of the **maxadvertinterval** parameter and cannot be greater than 9000. The default is three times the value of the **maxadvertinterval** parameter.

The **maxadvertinterval** parameter specifies the maximum amount of time the PowerConnect waits between sending Router Advertisements. You can specify a value from 1 to the current value of the **holdtime** parameter. The default is 600 seconds.

The **minadvertinterval** parameter specifies the minimum amount of time the PowerConnect can wait between sending Router Advertisements. The default is three-fourths (0.75) the value of the **maxadvertinterval** parameter. If you change the **maxadvertinterval** parameter, the software automatically adjusts the **minadvertinterval** parameter to be three-fourths the new value of the **maxadvertinterval** parameter. If you want to override the automatically configured value, you can specify an interval from 1 to the current value of the **maxadvertinterval** parameter.

The **preference** <*number*> parameter specifies the IRDP preference level of the PowerConnect. If a host receives Router Advertisements from multiple routers, the host selects the router interface that sent the message with the highest interval as the host's default gateway. The valid range is 4294967296 to 4294967295. The default is 0.

Configuring UDP broadcast and IP helper parameters

Some applications rely on client requests sent as limited IP broadcasts addressed to the UDP's application port. If a server for the application receives such a broadcast, the server can reply to the client. Routers do not forward subnet directed broadcasts, so the client and server must be on the same network for the broadcast to reach the server. If the client and server are on different networks (on opposite sides of a router), the client's request cannot reach the server.

To configure the PowerConnect to forward clients' requests to UDP application servers:

- Enable forwarding support for the UDP application port, if forwarding support is not already enabled.
- Configure a helper adders on the interface connected to the clients. Specify the helper address to be the IP address of the application server or the subnet directed broadcast address for the IP subnet the server is in. A helper address is associated with a specific interface and applies only to client requests received on that interface. The PowerConnect forwards client requests for any of the application ports the PowerConnect is enabled to forward to the helper address.

Forwarding support for the following application ports is enabled by default:

- bootps (port 67)
- dns (port 53)
- tftp (port 69)
- time (port 37)
- netbios-ns (port 137)

- netbios-dgm (port 138)
- tacacs (port 65)

NOTE
The application names are the names for these applications that the PowerConnect recognizes, and might not match the names for these applications on some third-party devices. The numbers listed in parentheses are the UDP port numbers for the applications. The numbers come from RFC 1340.

NOTE
As shown above, forwarding support for BootP or DHCP is enabled by default. If you are configuring the PowerConnect to forward BootP or DHCP requests, refer to "Configuring BootP or DHCP forwarding parameters" on page 742.

You can enable forwarding for other applications by specifying the application port number.

You also can disable forwarding for an application.

NOTE
If you disable forwarding for a UDP application, forwarding of client requests received as broadcasts to helper addresses is disabled. Disabling forwarding of an application does not disable other support for the application. For example, if you disable forwarding of Telnet requests to helper addresses, other Telnet support on the PowerConnect is not also disabled.

Enabling forwarding for a UDP application

If you want the PowerConnect to forward client requests for UDP applications that the PowerConnect does not forward by default, you can enable forwarding support for the port. To enable forwarding support for a UDP application, use either of the following methods. You also can disable forwarding for an application using these methods.

NOTE
You also must configure a helper address on the interface that is connected to the clients for the application. The PowerConnect cannot forward the requests unless you configure the helper address. Refer to "Configuring an IP helper address" on page 743.

To enable the forwarding of SNMP trap broadcasts, enter the following command.

```
NetIron(config)# ip forward-protocol udp snmp-trap
```

Syntax: [no] ip forward-protocol udp <*udp-port-name*> | <*udp-port-num*>

The <*udp-port-name*> parameter can have one of the following values. For reference, the corresponding port numbers from RFC 1340 are shown in parentheses. If you specify an application name, enter the name only, not the parentheses or the port number shown here:

- bootpc (port 68)
- bootps (port 67)
- discard (port 9)
- dns (port 53)
- dnsix (port 90)
- echo (port 7)
- mobile-ip (port 434)

- netbios-dgm (port 138)
- netbios-ns (port 137)
- ntp (port 123)
- tacacs (port 65)
- talk (port 517)
- time (port 37)
- tftp (port 69)

In addition, you can specify any UDP application by using the application's UDP port number.

The <*udp-port-num*> parameter specifies the UDP application port number. If the application you want to enable is not listed above, enter the application port number. You also can list the port number for any of the applications listed above.

To disable forwarding for an application, enter a command such as the following.

```
NetIron(config)# no ip forward-protocol udp snmp
```

This command disables forwarding of SNMP requests to the helper addresses configured on PowerConnect interfaces.

Configuring an IP helper address

To forward a client's broadcast request for a UDP application when the client and server are on different networks, you must configure a helper address on the interface connected to the client. Specify the server's IP address or the subnet directed broadcast address of the IP subnet the server is in as the helper address.

You can configure up to 16 helper addresses on each interface. You can configure a helper address on an Ethernet port or a virtual interface.

To configure a helper address on interface 2 on chassis module 1, enter the following commands.

```
NetIron(config)# interface e 1/2
NetIron(config-if-e1000-1/2)# ip helper-address 207.95.7.6
```

The commands in this example change the CLI to the configuration level for port 1/2, then add a helper address for server 207.95.7.6 to the port. If the port receives a client request for any of the applications that the PowerConnect is enabled to forward, the PowerConnect forwards the client's request to the server.

Syntax: [no] ip helper-address <*ip-addr*>

The <*ip-addr*> command specifies the server's IP address or the subnet directed broadcast address of the IP subnet the server is in.

Configuring BootP or DHCP forwarding parameters

A host on an IP network can use BootP or DHCP to obtain its IP address from a BootP or DHCP server. To obtain the address, the client sends a BootP or DHCP request. The request is a subnet directed broadcast and is addressed to UDP port 67. A limited IP broadcast is addressed to IP address 255.255.255.255 and is not forwarded by the PowerConnect or other IP routers.

When the BootP or DHCP client and server are on the same network, the server receives the broadcast request and replies to the client. However, when the client and server are on different networks, the server does not receive the client's request, because the PowerConnect does not forward the request.

You can configure the PowerConnect to forward BootP or DHCP requests. To do so, configure a helper address on the interface that receives the client requests, and specify the BootP or DHCP server's IP address as the address you are helping the BootP or DHCP requests to reach. Instead of the server's IP address, you can specify the subnet directed broadcast address of the IP subnet the server is in.

NOTE
The IP subnet configured on the port which is directly connected to the device sending a BootP or DHCP request, does not have to match the subnet of the IP address given by the DHCP server.

BootP or DHCP forwarding parameters

The following parameters control the PowerConnect's forwarding of BootP or DHCP requests:

- **Helper address** – The BootP or DHCP server's IP address. You must configure the helper address on the interface that receives the BootP or DHCP requests from the client. The PowerConnect cannot forward a request to the server unless you configure a helper address for the server.
- **Gateway address** – The PowerConnect places the IP address of the interface that received the BootP or DHCP request in the request packet's Gateway Address field (sometimes called the Router ID field). When the server responds to the request, the server sends the response as a unicast packet to the IP address in the Gateway Address field. (If the client and server are directly attached, the Gateway ID field is empty and the server replies to the client using a unicast or broadcast packet, depending on the server.)

  By default, the PowerConnect uses the lowest-numbered IP address on the interface that receives the request as the Gateway address. You can override the default by specifying the IP address you want the PowerConnect to use.
- **Hop Count** – Each router that forwards a BootP or DHCP packet increments the hop count by 1. Routers also discard a forwarded BootP or DHCP request instead of forwarding the request if the hop count is greater than the maximum number of BootP or DHCP hops allows by the router. By default, the PowerConnect forwards a BootP or DHCP request if its hop count is four or less, but discards the request if the hop count is greater than four. You can change the maximum number of hops the PowerConnect will allow to a value from 1 – 15.

  NOTE
  The BootP or DHCP hop count is not the TTL parameter.

Configuring an IP helper address

The procedure for configuring a helper address for BootP or DHCP requests is the same as the procedure for configuring a helper address for other types of UDP broadcasts. Refer to "Configuring an IP helper address" on page 742.

Changing the IP address used for stamping BootP or DHCP requests

When the PowerConnect forwards a BootP or DHCP request, the PowerConnect "stamps" the Gateway Address field. The default value the PowerConnect uses to stamp the packet is the lowest-numbered IP address configured on the interface that received the request.

The BootP or DHCP stamp address is an interface parameter. Change the parameter on the interface that is connected to the BootP or DHCP client.

To change the IP address used for stamping BootP or DHCP requests received on interface 1/1, enter commands such as the following.

```
NetIron(config)# int e 1/1
NetIron(config-if-e1000-1/1)# ip bootp-gateway 109.157.22.26
```

These commands change the CLI to the configuration level for port 1/1, then change the BootP or DHCP stamp address for requests received on port 1/1 to 192.157.22.26. The PowerConnect will place this IP address in the Gateway Address field of BootP or DHCP requests that the PowerConnect receives on port 1/1 and forwards to the BootP or DHCP server.

Syntax: [no] ip bootp-gateway <*ip-addr*>

Changing the maximum number of hops to a BootP relay server

Each BootP or DHCP request includes a field Hop Count field. The Hop Count field indicates how many routers the request has passed through. When the PowerConnect receives a BootP or DHCP request, the PowerConnect looks at the value in the Hop Count field:

- If the hop count value is equal to or less than the maximum hop count the PowerConnect allows, the PowerConnect increments the hop count by one and forwards the request.
- If the hop count is greater than the maximum hop count the PowerConnect allows, the PowerConnect discards the request.

NOTE
The BootP or DHCP hop count is not the TTL parameter.

To modify the maximum number of BootP or DHCP hops, enter the following command.

```
NetIron(config)# bootp-relay-max-hops 10
```

This command allows the PowerConnect to forward BootP or DHCP requests that have passed through up to ten previous hops before reaching the PowerConnect.

Syntax: [no] bootp-relay-max-hops <*1-15*>

Default: 4

Filtering Martian addresses

Martian addresses are obviously invalid host or network addresses. They commonly are sent by improperly configured systems on the network. Martian address filtering allows the system to automatically filter out those invalid addresses. When Martian address filtering is enabled, the BGP protocol applies the Martian address filters to all in-bound routes as received from all neighbors. Unlike BGP protocol, IGP protocols will rely on the RTM (routing table manager) to do the route filtering.

If no match is found, the route is accepted. This will be the case for almost all routes. If a match is found, the route is discarded (default action - deny), unless the action is set to permit. Martian address filtering is in addition to normal BGP in-bound route policies.

To enable Martian address filtering, enter the following command.

```
NetIron(config)#  ip martian filtering-on
```

Syntax: [no] ip martian [vrf <*name*> **] filtering-on**

The **vrf** <*name*> option applies martian filtering to a specified VRF.

NOTE
Martian address filtering is disabled by default.

When Martian address filtering is first enabled, the router will automatically load the following default Martian addresses:

* 0.0.0.0/8
* 10.0.0.0/8
* 127.0.0.0/8
* 172.16.0.0/12
* 192.168.0.0/16
* 224.0.0.0/4
* 240.0.0.0/4

Adding, deleting or modifying Martian addresses

As described previously, there are a set number of Martian addresses that are loaded by default when Martian addressing is enabled. You can add, subtract or modify addresses that are filtered by martian addressing. Although there is no limit of the number of martian address can be configured, it's expected the size of martian address list should be small, generally less than 100. If the user adds a new martian address after routes are already learnt, they will be taken out of the routing table. Likewise if the user removes a martian address after routes are deleted from the routing table, they should be put back into the routing table.

To add an address to the Martian filtering list, use a command such as the following.

```
NetIron(config)# ip martian 192.168.0.0/16
```

Syntax: [no] ip martian [vrf <*name*> **]** <*destination-prefix/prefix-length*> **[permit]**

The <*destination-prefix/prefix-length*> variable specifies the address and the prefix range to apply the martian filtering to. The matching rule is for prefix range match. It includes exact match, or with a longer prefix length match. For example, if the Martian address rule is 192.168.0.0/16, then routes 192.168.0.0/16, and 192.168.1.0/24 are matches. However route 192.0.0.0/8 is not a match.

The **vrf** <*name*> option applies the modification to the martian filtering list to a specified VRF.

The **[no]** option removes an address from the martian filtering list.

The **[permit]** option changes the default action of a martian address filter to permit. In this case, a route matches the "permit" martian address is accepted by the routing table manager. This option is only used if a user wants to allow a prefix "hole" in an otherwise denied martian address.

The default Martian addresses are described in: "Filtering Martian addresses" on page 744

Examples

To remove a user defined Martian address or a system default Martian address, use the "no" form of the command.

```
NetIron(config)# no ip martian 0.0.0.0/8
```

The following example configuration, creates a “hole” for 192.168.1.0/24 in the martian address 192.168.0.0/16.

```
NetIron(config)# ip martian 192.168.1.0/24 permit
NetIron(config)# ip martian 192.168.0.0/16
```

To display the currently configured Martian addresses refer to “Displaying martian addressing information” on page 774.

IPv6 Over IPv4 tunnels in hardware

To enable communication between the isolated IPv6 domains using the IPv4 infrastructure, you can configure IPv6 over IPv4 tunnels.

Dell supports the following IPv6 over IPv4 tunneling in hardware mechanisms:

- Manually configured tunnels
- Automatic 6to4 tunnels

In general, a manually configured tunnel establishes a permanent link between routers in IPv6 domains, while the automatic tunnels establish a transient link that is created and taken down on an as-needed basis. (Although the feature name and description may imply otherwise, some configuration is necessary to set up an automatic tunnel.) Also, a manually configured tunnel has explicitly configured IPv4 addresses for the tunnel source and destination, while the automatic tunnels have an explicitly configured IPv4 address for the tunnel source and an automatically generated address for the tunnel destination.

These tunneling mechanisms require that the router at each end of the tunnel run both IPv4 and IPv6 protocol stacks. The routers running both protocol stacks, or dual-stack routers, can interoperate directly with both IPv4 and IPv6 end systems and routers.

The following features are not supported for IPv6 tunnel configuration at this time:

- Keep-alive
- Hitless upgrade
- Tunnels over MPLS or GRE

Configuring a IPv6 IP tunnel

To configure a IPv6 IP Tunnel, configure the following parameters:

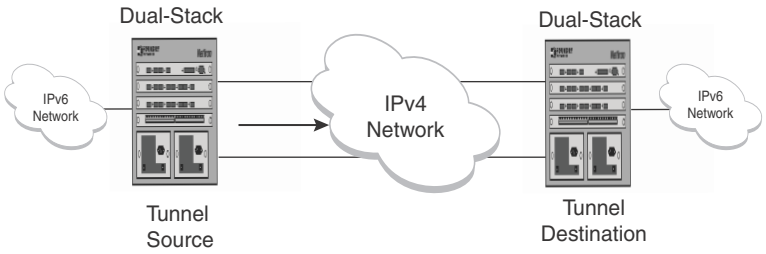
- CAM Restrictions
- Maximum Number of Tunnels (optional)
- Tunnel Interface
- Source Address or Source Interface for the Tunnel
- Destination address for the Tunnel

- IPv6 Encapsulation
- IP address for the Tunnel
- TTL Value (optional)
- TOS Value (optional)
- MTU Value (optional)

Configuring a manual IPv6 tunnel

You can use a manually configured tunnel to connect two isolated IPv6 domains. You should deploy this point-to-point tunnel mechanism if you need a permanent and stable connection.

FIGURE 131 Manually configured tunnel



Configuration notes on manual tunnels:

- The tunnel mode should be **ipv6ip** indicating that this is ipv6 manual tunnel.
- Both source and destination addresses needs to be configured on the tunnel.
- On the remote side you need to have exactly opposite source/destination pair.
- The tunnel destination should be reachable through the IPv4 backbone.
- The ipv6 address on the tunnel needs to be configured for the tunnel to come up.
- The tunnel source can be an IP address or interface name.
- Manual tunnels provide static point-point connectivity.
- Static routing on top of the tunnel is supported.
- IPv6 routing protocols including OSPFv3 and RIPng on top of the tunnel are supported.

NOTE
IPv6 IS-IS is not supported on top of the tunnel.

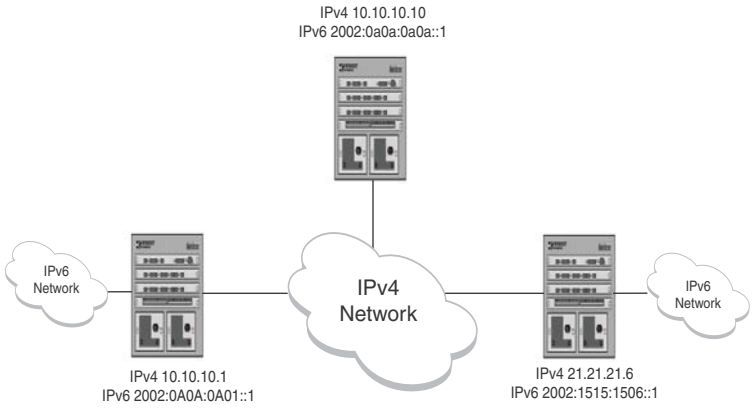
Configuring an automatic 6to4 tunnel

An automatic 6to4 tunnel establishes a transient link between IPv6 domains, which are connected by an IPv4 backbone. When needed, a device on which an automatic 6to4 tunnel is configured in one domain can establish a tunnel with another similarly configured device in another domain. When no longer needed, the devices take down the tunnel.

Instead of a manually configured tunnel destination, an automatic 6to4 tunnel constructs a globally unique 6to4 prefix, which determines the tunnel destination. The 6to4 prefix has the following format:

2002:<*ipv4-address*>::/48

When two domains need to communicate, a device creates a tunnel using the 6to4 prefix. The software automatically generates the 6to4 prefix by concatenating a configured static IPv6 prefix of 2002 with the destination device's globally unique IPv4 address. (Each device in an IPv6 domain that needs to communicate over an automatic 6to4 tunnel must have one globally unique IPv4 address, from which the globally unique 6to4 prefix is constructed.) After the communication ends, the tunnel is taken down.



Configuration notes on 6to4tunnels:

- This tunnel treats the IPv4 infrastructure as a virtual non-broadcast link and support multipoint connectivity.
- Tunnel mode must be configured as **ipv6ip 6to4.**
- Tunnel source must be configured.
- Tunnel destination is not configured on 6to4 tunnel explicitly, as the destination is specified as part of static nexthop or BGP nexthop.
- Static route with **2002::/16** MUST be configured.
- IPv6 address with **2002:A.B.C.D::/48** must be configured for the tunnel to come up (A.B.C.D is the tunnel source IP address).
- You can have 6to4 tunnel with multiple nexthops depending on the IPv6 nexthop used to forward the packets.
- With 6to4 tunnels, you can only use routing protocols (i.e. BGP+) that specify the nexthop in the configuration.
- OSPFv3, IPv6 IS-IS and RIPng are not supported on the 6to4 tunnels.
- Static routes can be used with 6to4 tunnels. If you use a static route to configure the nexthop, you MUST enable nexthop recursion in the system (ipv6 route next-hop-recursion).
- The 6to4 tunnel tries to resolve all the nexthops and programs the cam and pram entries needed. The IPv4 address in the nexthop should be reachable through the IPv4 network.

Example

In the below configuration:

- **10.10.10.1** is the tunnel source IP address
- **10.10.10.10** is the static nexthop
- **21.21.21.6** is I-BGP nexthop
- **22.22.22.6** is E-BGP nexthop

Static route Nexthop example:

- Create a static route pointing to the tunnel.

```
NetIron(config) #ipv6 route 2002::/16 tunnel 2 // Mandatory for 6to4 Configuration
NetIron(config) #ipv6 route next-hop-recursion // Mandatory with static nexthop
NetIron(config)# ipv6 route 3001::/64 2002:0a0a:0a0a::1 // Static Nexthop:
10.10.10.10
```

- Create a Source Interface - The remote node needs to have a similar route pointing to this node.

```
NetIron(config)# interface ethernet 1/1
NetIron(config-if-e10000-1 /1)ip address 10.10.10.1 255.255.255.0
```

- Create a 6to4 Tunnel configuration.

```
NetIron(config) interface tunnel 2
NetIron(config-tnif-2) tunnel mode ipv6ip 6to4
NetIron(config-tnif-1) tunnel source 10.10.10.1
NetIron(config-tnif-1) ipv6 address 2002:0a0a:0a01::1/64
```

Example : I-BGP Nexthop.

```
NetIron(config) router bgp
NetIron(config-bgp) local-as 100
NetIron(config-bgp) neighbor 2002:1515:1506::1 remote-as 100 // BGP Nexthop:
21.21.21.6
NetIron(config-bgp)# address-family ipv4 unicast
NetIron(config-bgp)# no neighbor 2002:1515:1506::1 activate
NetIron(config-bgp)# exit-address-family
NetIron(config-bgp)# address-family ipv4 multicast
NetIron(config-bgp)# exit-address-family
NetIron(config-bgp)# address-family ipv6 unicast
NetIron(config-bgp)# neighbor 2002:1515:1506::1 activate
NetIron(config-bgp)# exit-address-family
```

Example : E-BGP Nexthop.

```
NetIron(config)# router bgp
NetIron(config-bgp)# local-as 100
NetIron(config-bgp)# neighbor 2002:1616:1606::1 remote-as 101 // BGP Nexthop:
22.22.22.6
NetIron(config-bgp)# neighbor 2002:1616:1606::1 ebgp-multihop
NetIron(config-bgp)# address-family ipv4 unicast
NetIron(config-bgp)# no neighbor 2002:1515:1506::1 activate
NetIron(config-bgp)# exit-address-family
NetIron(config-bgp)# address-family ipv4 multicast
NetIron(config-bgp)# exit-address-family
NetIron(config-bgp)# address-family ipv6 unicast
NetIron(config-bgp)# neighbor 2002:1616:1606::1 activate
NetIron(config-bgp)# exit-address-family
```

Configuring the maximum number of tunnels supported

You can configure the routers to support a specified number of tunnels using the following command.

```
NetIron(config)# system-max ip-tunnels 512
NetIron(config)# write memory
```

Syntax: [no] system-max ip-tunnels <*number*>

The <*number*> variable specifies the number of IPv6 tunnels that can be supported on the PowerConnect router. The permissible range is 1 - 512. The default value is 256.

NOTE
You must write this command to memory and perform a system reload for this command to take effect.

Configuring a tunnel interface

To configure a tunnel interface, use a the following command.

```
NetIron(config)# interface tunnel 1
NetIron(config-tnif-1)
```

Syntax: [no] interface tunnel <*tunnel id*>

The <*tunnel-id*> variable is numerical value that identifies the tunnel being configured. Possible range is from 1 to the maximum configured tunnels in the system.

Configuring a source address or source interface for a tunnel interface

To configure a source address for a specific tunnel interface, enter the following command.

```
NetIron(config)# interface tunnel 1
NetIron(config-tnif-1)tunnel source 35.0.8.108
```

To configure a source interface for a specific tunnel interface, enter the following command.

```
NetIron(config)# interface tunnel 100
NetIron(config-tnif-100)tunnel source ethernet 3/1
```

Syntax: [no] tunnel source <*ip-address*> **|** <*port-no*>

You can specify either of the following:

The <*ip-address*> variable is the source IP address being configured for the specified tunnel.
The <*port-no*> variable is the source slot/port of the interface being configured for the specified tunnel. When you configure a source interface, there must be at least one IP address configured on that interface. Otherwise, the interface will not be added to the tunnel configuration and an error message like the following will be displayed: " Error - Tunnel source interface 3/1 has no configured ip address.

It can be a physical or virtual interface (ve).

Configuring a destination address for a tunnel interface

To configure a destination address for a specific tunnel interface, enter the following command.

```
NetIron(config)# interface tunnel 1
NetIron(config-tnif-1)tunnel destination 131.108.5.2
```

Syntax: [no] tunnel destination <*ip-address*>

The <*ip-address*> variable is destination IP address being configured for the specified tunnel.

Configuring a tunnel interface for IPv6 encapsulation

To configure a specified tunnel interface for IPv6 encapsulation, enter the following command.

```
NetIron(config)# interface tunnel 1
NetIron(config-tnif-1)tunnel mode ipv6ip
```

Syntax: [no] tunnel mode ipv6ip < 6to4 | auto-tunnel >

The **6to4** parameter specifies automatic tunneling using 6 to 4.

The **auto-tunnel** parameter specifies automatic tunnel using ipv4 compatible ipv6 address.

Configuring an IP address for a tunnel interface

To configure an IP address for a specified tunnel interface, enter the following command.

```
NetIron(config)# interface tunnel 1
NetIron(config-tnif-1)ipv6 address 1001:0a0a:0a01::1/64
```

Syntax: [no] ipv6 address <*ipv6-address*>

The <*ipv6-address*> variable is the IPv6 address being configured for the specified tunnel interface.

Configuring a TTL value

This is an optional parameter that allows you to set the Time-to-Live value for the outer IP header of the IPv6 tunnel packets.

To configure the TTL value, enter the following command.

```
NetIron(config)# interface tunnel 1
NetIron(config-tnif-1)tunnel ttl 100
```

Syntax: [no] tunnel ttl <*ttl-value*>

The <*ttl-value*> variable specifies a TTL value for the outer IP header. Possible values are 1 - 255. The default value is 255.

Configuring a TOS value

This is an optional parameter that allows you to set the TOS value for the outer IP header of the GRE tunnel packets.

To configure the TOS value, enter the following command.

```
NetIron(config)# interface tunnel 1
NetIron(config-tnif-1)tunnel tos 100
```

Syntax: [no] tunnel ttl <*tos-value*>

The <*tos-value*> variable specifies a TOS value for the outer IP header. Possible values are 1 - 255. The default value is 0.

Configuring IPv6 session enforce check

You can enable the IPv6 session enforce check by using the **ipv6-session-enforce-check** command. When an IPv6 packet arrives and this feature is enabled, the system tries to match the Ipv6 packet source and destination address pair with the tunnel configured destination and source pair. If the pairs do not match, the packet is dropped in hardware.

To configure the IPv6 session enforce check,go to the IP tunnel policy context and enter the **ipv6-session-enforce-check** command.

```
NetIron@MLXe1(config)#ip-tunnel-policy
NetIron@MLXe1(config-ip-tunnel-policy)#ipv6-session-enforce-check
```

Syntax: [no] ipv6-session-enforce-check

To disable the IPv6 session enforce check, use the **no** form of this command. This command is disabled by default. You might have to write the configuration to memory and reload the system when the configuration of this command is changed because a one-time creation of a source-ingress CAM partition is necessary. The system prompts you if the memory write and reload are required.

The first-time execution of certain commands necessitates the creation of a source-ingress CAM partition, after which you write to memory and reload. These commands are **gre-session-enforce-check**, **ipv6-session-enforce-check**, and **accounting-enable**. After this CAM partition is created, it is not necessary to follow either of the other two commands with a memory write and reload.

NOTE
The ipv6-sessions-enforce-check is not supported for 6to4 automatic tunnels.

Configuring a maximum MTU value for a tunnel interface

This command allows you to set an MTU value for packets entering the tunnel. Packets that exceed either the default MTU value of 1480 bytes or the value that you set using this command are sent back to the source.

The following command allows you to change the MTU value for packets transiting "tunnel 1".

```
NetIron(config)# interface tunnel 1
NetIron(config-tnif-1)tunnel mtu 1500
```

Syntax: [no] tunnel mtu <*packet-size*>

The <*packet-size*> variable specifies the maximum MTU size in bytes for the packets transiting the tunnel.

NOTE
To prevent packet loss after the 20 byte IP header is added, make sure that any physical interface that is carrying IPv6 tunnel traffic has an IP MTU setting at least 24 bytes greater than the tunnel MTU setting.

Displaying IPv6 tunneling information

You can display IPv6 Tunneling Information using the **show ip-tunnels**, **show ipv6 interface**, **show ipv6 route** and **show interface tunnel** commands as shown in the following:

Displaying tunnel information

For example, to tunnel information for tunnel 2, enter the following command at any level of the CLI.

```
NetIron# show ip-tunnels 2
IPv6 tnnl 2 UP   : src_ip 192.211.2.1, dst_ip 192.212.2.1
   TTL 255, TOS 0, NHT 0, MTU 1480
```

Syntax: show ip tunnels <*number*>

The <*number*> parameter indicates the tunnel interface number for which you want to display information.

This display shows the following information.

TABLE 114 Show IP tunnel display information

This field...	Displays...
Ipv6 tnnl <*UP* | *DOWN*>	The status of the tunnel interface can be one of the following: • up – The tunnel interface is functioning properly. • down – The tunnel interface is not functioning and is down.
src_ip	The tunnel source can an IPv4 address.
dst_ip	The tunnel destination can an IPv4 address.
TTL	The TTL value configured for the outer IP header. Possible values are 1 - 255.
TOS	The TOS value configured for the outer IP header. Possible values are 1 - 255.
NHT	The nextHop Table index value.
MTU	The setting of the IPv6 maximum transmission unit (MTU).

Displaying tunnel interface information

For example, to display status and configuration information for tunnel interface 1, enter the following command at any level of the CLI.

```
NetIron# show interfaces tunnel 1
Tunnel1 is up, line protocol is up
  Hardware is Tunnel
  Tunnel source ethernet 3/5
  Tunnel destination is not configured
  Tunnel mode ipv6ip auto-tunnel
  No port name
  MTU 1500 bytes
```

Syntax: show interfaces tunnel <*number*>

The <*number*> parameter indicates the tunnel interface number for which you want to display information.

This display shows the following information.

TABLE 115 IPv6 tunnel interface information

This field...	Displays...
Tunnel interface status	The status of the tunnel interface can be one of the following: • up – The tunnel interface is functioning properly. • down – The tunnel interface is not functioning and is down.
Line protocol status	The status of the line protocol can be one of the following: • up – The line protocol is functioning properly. • down – The line protocol is not functioning and is down.
Hardware is tunnel	The interface is a tunnel interface.
Tunnel source	The tunnel source can be one of the following: • An IPv4 address • The IPv4 address associated with an interface or port.
Tunnel destination	The tunnel destination can an IPv4 address.

TABLE 115 IPv6 tunnel interface information (Continued)

This field...	Displays...
Tunnel mode	The tunnel mode can be one the following: • ipv6ip auto-tunnel – Indicates an automatic IPv4-compatible tunnel. • ipv6ip 6to4 – Indicates an automatic 6to4 tunnel.
Port name	The port name configured for the tunnel interface.
MTU	The setting of the IPv6 maximum transmission unit (MTU).

Displaying interface level IPv6 settings

To display Interface level IPv6 settings for tunnel interface 1, enter the following command at any level of the CLI.

```
NetIron# show ipv6 inter tunnel 1
Interface Tunnel 1 is up, line protocol is up
  IPv6 is enabled, link-local address is fe80::3:4:2 [Preferred]
  Global unicast address(es):
    1001::1 [Preferred],  subnet is 1001::/64
    1011::1 [Preferred],  subnet is 1011::/64
  Joined group address(es):
    ff02::1:ff04:2
    ff02::5
    ff02::1:ff00:1
    ff02::2
    ff02::1
  MTU is 1480 bytes
  ICMP redirects are enabled
  No Inbound Access List Set
  No Outbound Access List Set
  OSPF enabled
```

The display command above reflects the following configuration.

```
NetIron# show running-config interface tunnel 1
!
interface tunnel 1
 port-name ManualTunnel1
 tunnel mode ipv6ip
 tunnel source loopback 1
 tunnel destination 2.1.1.1
 ipv6 address fe80::3:4:2 link-local
 ipv6 address 1011::1/64
 ipv6 address 1001::1/64
 ipv6 ospf area 0
```

Displaying IP information

You can display the following IP configuration information statistics:

- **Global IP parameter settings** – refer to "Displaying global IP configuration information" on page 755.
- **IP interfaces** – refer to "Displaying IP interface information" on page 756.
- **ARP entries** – refer to "Displaying ARP entries" on page 759.

- **Static ARP entries** – refer to "Displaying ARP entries" on page 759.
- **IP forwarding cache** – refer to "Displaying the forwarding cache" on page 761.
- **IP route table** – refer to "Displaying the IP route table" on page 763.
- **IP traffic statistics** – refer to "Displaying IP traffic statistics" on page 768.

The sections below describe how to display this information.

In addition to the information described below, you can display the following IP information:

- **RIP information** – refer to "Displaying RIP Information" on page 852.
- **OSPF information** – refer to "Displaying OSPF database information" on page 921.
- **BGP4 information** – refer to "Displaying BGP4 information" on page 1104.
- **PIM information** – refer to "Displaying PIM Sparse configuration information and statistics" on page 1174.

Displaying global IP configuration information

To display IP configuration information, enter the following command at any CLI level.

```
NetIron> show ip

Global Settings
  IP CAM Mode: dynamic IPVPN CAM Mode: static
  ttl: 64, arp-age: 10, bootp-relay-max-hops: 4, icmp-error-rate: 400
  IP Router-Id: 5.5.5.5
  enabled : UDP-Broadcast-Forwarding ICMP-Redirect Source-Route Load-Sharing
  RARP BGP4 OSPF
  disabled: Directed-Broadcast-Forwarding drop-arp-pending-packets IRDP Proxy
  -ARP RPF-Check RPF-Exclude-Default RIP IS-IS VRRP VRRP-Extended VSRP
Configured Static Routes: 31
Configured Static Mroutes: 30
```

Syntax: show ip

NOTE
This command has additional options, which are explained in other sections in this guide, including the sections below this one.

This display shows the following information.

TABLE 116 CLI display of global IP configuration information

This field...	Displays...
Global settings	
ttl	The Time-To-Live (TTL) for IP packets. The TTL specifies the maximum number of router hops a packet can travel before reaching the PowerConnect. If the packet's TTL value is higher than the value specified in this field, the router drops the packet. To change the maximum TTL, refer to "Changing the TTL threshold" on page 709.
arp-age	The ARP aging period. This parameter specifies how many minutes an inactive ARP entry remains in the ARP cache before the router ages out the entry. To change the ARP aging period, refer to "Changing the ARP aging period" on page 688.

TABLE 116 CLI display of global IP configuration information (Continued)

This field...	Displays...
bootp-relay-max-hops	The maximum number of hops away a BootP server can be located from the router and still be used by the router's clients for network booting. To change this value, refer to "Changing the maximum number of hops to a BootP relay server" on page 744.
router-id	The 32-bit number that uniquely identifies the router. By default, the router ID is the numerically lowest IP interface configured on the router. To change the router ID, refer to "Changing the router ID" on page 684.
enabled	The IP-related protocols that are enabled on the router.
disabled	The IP-related protocols that are disabled on the router.

Displaying IP interface information

To display IP interface information, enter the following command at any CLI level.

```
NetIron(config)# show ip interface

Interface       IP-Address      OK?  Method    Status                Protocol
Ethernet 1/1    207.95.6.173    YES  NVRAM     up                    up
Ethernet 1/2    3.3.3.3         YES  manual    up                    up
Loopback 1      1.2.3.4         YES  NVRAM     down                  down
```

Syntax: show ip interface [ethernet <*slot/port*>**] | [loopback** <*num*>**] | [ve** <*num*>**]**

This display shows the following information.

TABLE 117 CLI display of interface IP configuration information

This field...	Displays...
Interface	The type and the slot and port number of the interface.
IP-Address	The IP address of the interface. **NOTE:** If an "s" is listed following the address, this is a secondary address. When the address was configured, the interface already had an IP address in the same subnet, so the software required the "secondary" option before the software could add the interface.
OK?	Whether the IP address has been configured on the interface.
Method	Whether the IP address has been saved in NVRAM. If you have set the IP address for the interface in the CLI, but have not saved the configuration, the entry for the interface in the Method field is "manual".
Status	The link status of the interface. If you have disabled the interface with the **disable** command, the entry in the Status field will be "administratively down". Otherwise, the entry in the Status field will be either "up" or "down".
Protocol	Whether the interface can provide two-way communication. If the IP address is configured, and the link status of the interface is up, the entry in the protocol field will be "up". Otherwise the entry in the protocol field will be "down".

Displaying IP interface information for a specified interface

To display detailed IP information for a specific interface, enter a command such as the following.

```
NetIron# show ip interface ethernet e 3/1
Interface Ethernet 3/1 (80)
  port enabled
  port state: UP
  ip address: 13.1.1.2/24
  Port belongs to VRF: default
  encapsulation: ETHERNET, mtu: 1500
  MAC Address 0004.80a0.4050
  directed-broadcast-forwarding: disabled
  No inbound ip access-list is set
  No outbound ip access-list is set
  No Helper Addresses are configured.
  RPF mode: None  RPF Log: Disabled
  0 unicast RPF drop    0 unicast RPF suppressed drop
  RxPkts:  1200  TxPkts:  1200
  RxBytes: 60000 TxBytes: 60000
```

The PowerConnect software supports IPv4 and IPv6 packet and byte counters. The contents of these counters is displayed for a defined port as the result of the show ip interface ethernet command. In the above example, the fields in bold text display this content. Table 118 describes each of the fields that display interface counter statistics.

TABLE 118 Interface counter display statistics

This field...	Displays...
Interface	The interface that counter statistics are being displayed for.
RxPkts	The number of packets received at the specified port.
TxPkts	The number of packets transmitted from the specified port.
RxBytes	The number of bytes received at the specified port.
TxBytes	The number of bytes transmitted from the specified port.

Displaying interface counters for all ports

The PowerConnect supports IPv4 and IPv6 packet and byte counters. The contents of these counters can be displayed for all ports on a router or per-port. Output from the **show ip interface ethernet** command has been enhanced to include packet and byte counter information on a per-port basis. This is described in "Displaying interface counters for all ports" on page 757.

Commands have been added under IPv4 and IPv6 to display the interface counters for all ports on a router. The following example uses the **show ip interface counters** command to display to packet and byte counter information for all ports.

```
NetIron# show ip interface counters
Interface      RxPkts     TxPkts      RxBytes    TxBytes
eth 3/1         1200      1200        600000     60000
eth 3/2         500       500         25000      25000
```

Syntax: show ip interface counters

Default byte counters include the 20-byte per-packet Ethernet overhead. You can configure an PowerConnect router to exclude the 20-byte per-packet Ethernet overhead from byte accounting by configuring the **vlan-counter exclude-overhead** command.Table 118 describes each of the fields that display interface counter statistics.

TABLE 119 Interface counter display statistics

This field...	Displays...
Interface	The interface that counter statistics are being displayed for.
RxPkts	The number of packets received at the specified port.
TxPkts	The number of packets transmitted from the specified port.
RxBytes	The number of bytes received at the specified port.
TxBytes	The number of bytes transmitted from the specified port.

Clearing the interface counters

Use the following command to clear all interface counters on a router.

```
NetIron# clear ip interface counters
```

Syntax: clear ip interface counters

Use the following command to clear the interface counters for a specified port.

```
NetIron# clear ip interface ethernet 3/2
```

Syntax: clear ip interface ethernet <*port-number*>

The **port-number** variable specifies the slot and port number that you want to clear the interface counters for.

Displaying interface name in Syslog

By default an interface's slot number (if applicable) and port number are displayed when you display Syslog messages. You can display the name of the interface instead of its number by entering a command such as the following.

```
NetIron(config)# ip show-portname
```

This command is applied globally to all interfaces on the PowerConnect.

Syntax: [no] Ip show-portname

When you display the messages in the Syslog, you see the interface name under the Dynamic Log Buffer section. The actual interface number is appended to the interface name. For example, if the interface name is "lab" and its port number is "2", you see "lab2" displayed as in the example below.

```
NetIron># show logging
Syslog logging: enabled (0 messages dropped, 0 flushes, 0 overruns)
    Buffer logging: level ACDMEINW, 3 messages logged
    level code: A=alert C=critical D=debugging M=emergency E=error
         I=informational N=notification W=warning
Static Log Buffer:
Dec 15 19:04:14:A:Fan 1, fan on right connector, failed
Dynamic Log Buffer (50 entries):
Dec 15 18:46:17:I:Interface ethernet Lab2, state up
Dec 15 18:45:15:I:Warm start
```

Displaying ARP entries

You can display the ARP cache and the static ARP table. The ARP cache contains entries for devices attached to the PowerConnect. The static ARP table contains the user-configured ARP entries. An entry in the static ARP table enters the ARP cache when the entry's interface comes up.

The tables require separate display commands.

Displaying the ARP cache

To display the contents of the ARP cache, enter the following command at any CLI level.

```
NetIron# show arp

Total number of ARP entries: 5
     IP Address          MAC Address         Type        Age     Port
1     207.95.6.102        0800.5afc.ea21      Dynamic     0         6
2     207.95.6.18         00a0.24d2.04ed      Dynamic     3         6
3     207.95.6.54         00a0.24ab.cd2b      Dynamic     0         6
4     207.95.6.101        0800.207c.a7fa      Dynamic     0         6
5     207.95.6.211        00c0.2638.ac9c      Dynamic     0         6
6     30.30.30.15         none                Pending     0         v1
```

Syntax: **show arp** [**ethernet** <*slot/port*> | **mac-address** <*xxxx.xxxx.xxxx*> [<*mask*>] | <*ip-addr*> [<*ip-mask*>]] [<*num*>] [| **begin** <*expression*> | **exclude** <*expression*> | **include** <*expression*>]

The **ethernet** <*slot*>/<*portnum*> parameter lets you restrict the display to entries for a specific port.

The **mac-address** <*xxxx.xxxx.xxxx*> parameter lets you restrict the display to entries for a specific MAC address.

The <*mask*> parameter lets you specify a mask for the **mac-address** <*xxxx.xxxx.xxxx*> parameter to display entries for multiple MAC addresses. Specify the MAC address mask as fs and 0s, where fs are significant bits.

The <*ip-addr*> and <*ip-mask*> parameters let you restrict the display to entries for a specific IP address and network mask. Specify the IP address masks in standard decimal mask format (for example, 255.255.0.0).

NOTE
The <*ip-mask*> parameter and <*mask*> parameter perform different operations. The <*ip-mask*> parameter specifies the network mask for a specific IP address, whereas the <*mask*> parameter provides a filter for displaying multiple MAC addresses that have specific values in common.

The <*num*> parameter lets you display the table beginning with a specific entry number.

NOTE
The entry numbers in the ARP cache are not related to the entry numbers for static ARP table entries.

This display shows the following information. The number in the left column of the CLI display is the row number of the entry in the ARP cache. This number is not related to the number you assign to static MAC address entries in the static ARP table.

TABLE 120 CLI display of ARP cache

This field...	Displays...
IP Address	The IP address of the device.
MAC Address	The MAC address of the device.
Type	The type, which can be one of the following: • Dynamic – The PowerConnect router learned the entry from an incoming packet. • Static – The PowerConnect router loaded the entry from the static ARP table when the device for the entry was connected to the PowerConnect. • Pending – The PowerConnect router added the entry to the ARP table and is in the process of sending a series of ARP requests to determine if it is a valid entry.
Age	The number of minutes the entry has remained unused. If this value reaches the ARP aging period, the entry is removed from the table. To display the ARP aging period, refer to "Displaying global IP configuration information" on page 755. To change the ARP aging interval, refer to "Changing the ARP aging period" on page 688. **NOTE:** Static entries do not age out.
Port	The port on which the entry was learned.

Displaying the static ARP table

To display the static ARP table, enter the following command at any CLI level.

```
NetIron# show ip static-arp

Total no. of entries: 4
  Index   IP Address          MAC Address         Port      VLAN  ESI
  1       1.1.1.1             0001.0001.0001      1/1
  2       6.6.6.2             0002.0002.0002      1/2
```

Syntax: **show ip static-arp [ethernet** <*slot*>/<*portnum*> **| mac-address** <*xxxx.xxxx.xxxx*> [<*mask*>] **|** <*ip-addr*> [<*ip-mask*>]] [<*num*>] [**| begin** <*expression*> **| exclude** <*expression*> **| include** <*expression*> **]**

For information on the command syntax, see the syntax of the **show arp** command under "Displaying the ARP cache" on page 759.

TABLE 121 CLI display of static ARP table

This field...	Displays...
Index	The number of this entry in the table.
IP Address	The IP address of the device.
MAC Address	The MAC address of the device.

TABLE 121 CLI display of static ARP table (Continued)

This field...	Displays...
Port	The port attached to the device the entry is for. In the case of a multi-port static ARP, this will display a single port followed by an ellipsis, and the full list of ports will be displayed on the line below.
VLAN	VLAN associated with this entry, if any.
ESI	Ethernet Service Instance (ESI) associated with this entry, if any.

Displaying the forwarding cache

To display the IP Forwarding Cache for directly connected hosts, enter the following command.

```
NetIron> show ip cache
Cache Entry Usage on LPs:
Module    Host   Network      Free       Total
15         6      6           204788     204800
```

Syntax: **show ip cache** [<*ip-addr*>] [**| begin** <*expression*> **| exclude** <*expression*> **| include** <*expression*>]

The <*ip-addr*> parameter displays the cache entry for the specified IP address.

The **show ip cache** command shows the forwarding cache usage on each interface module CPU. The CPU on each interface module builds its own forwarding cache, depending on the traffic. To see the forwarding cache of a particular interface module, use the **rconsole**.

```
NetIron>rconsole 15
Connecting to slave CPU 15/1... (Press CTRL-Shift-6 X to exit)
rconsole-15/1@LP>show ip cache
Total number of host cache entries 3
D: Dynamic P:Permanent, F:Forward U:Us C:Conected Network
W:Wait ARP  I:ICMP Deny  K:Drop R:Frament S:Snap Encap  N:CAMInvalid
    IP Address    Next Hop     MAC              Type    Port    VLAN     Pri
1   30.1.0.0      DIRECT       0000.0000.0000    PU      2/5     n/a      0
2   20.1.0.0      DIRECT       0125.0a57.1c02    D       3/5     n/a      0
3   7.7.7.3       DIRECT       0000.0000.0000    PU      4/2     12       1
```

You also use the **rconsole** to display the IP Forwarding Cache for network entries.

```
NetIron>rconsole 15
Connecting to slave CPU 15/1... (Press CTRL-Shift-6 X to exit)
rconsole-15/1@LP>show ip network
Total number of host cache entries 3
D: Dynamic P:Permanent, F:Forward U:Us C:Conected Network
W:Wait ARP  I:ICMP Deny  K:Drop R:Frament S:Snap Encap  N:CAMInvalid
    IP Address       Next Hop     MAC              Type    Port    VLAN     Pri
1   0.0.0.0/0        DIRECT       0000.0000.0000    PK              n/a      0
2   20.1.1.0/24      DIRECT       0000.0000.0000    PC              n/a      0
3   40.40.40.0/24    30.1.1.10    0000.0000.0033    PF      15/14   154      1
```

The **show ip cache** and **show ip network** commands entered on the rconsole display the following information.

TABLE 122 CLI display of IP forwarding cache

This field...	Displays...
IP Address	The IP address of the destination.
Next Hop	The IP address of the next-hop router to the destination. This field contains either an IP address or the value DIRECT. DIRECT means the destination is either directly attached or the destination is an address on this device. For example, the next hop for loopback addresses and broadcast addresses is shown as DIRECT.
MAC	The MAC address of the destination. **NOTE:** If the entry is type U (indicating that the destination is this device), the address consists of zeroes.
Type	The type of host entry, which can be one or more of the following: • D – Dynamic • P – Permanent • F – Forward • U – Us • C – Complex Filter • W – Wait ARP • I – ICMP Deny • K – Drop • R – Fragment • S – Snap Encap
Port	The port through which this device reaches the destination. For destinations that are located on this device, the port number is shown as “n/a”.
VLAN	Indicates the VLANs the listed port is in.
Pri	The QoS priority of the port or VLAN.

Dual Active Console

The Dual Active Console command enables the standby terminal console to mirror the features of the active console, such that the standby console appears as active console itself. Hence, you can manage the system from either active or standby console and it will not be necessary to switch the console cable after the active-standby management module switchover.

To enable this feature, enter the following command,

```
NetIron(config)#dual-act
NetIron(config)#wr mem
Write startup-config done.
NetIron(config)#
```

To disable this feature, enter the following command,

```
NetIron(config)#no dual-act
NetIron(config)#wr mem
Write startup-config done.
NetIron(config)#
```

Displaying the IP route table

To display the IP route table, enter the **show ip route** command at any CLI level.

```
NetIron# show ip route
Total number of IP routes: 4
Type Codes - B:BGP D:Connected I:ISIS S:Static R:RIP O:OSPF; Cost - Dist/Metric
        Destination        Gateway         Port        Cost       Type Uptime
1       10.0.0.0/24        DIRECT          eth 1/1     0/0        D    45m18s
2       11.0.0.0/24        DIRECT          eth 1/2     0/0        D    1h0m
3       90.0.0.0/24        10.0.0.2        eth 1/1     1/1        S    13m18s
4       100.0.0.0/24       10.0.0.2        eth 1/1     1/1        S    2m42s
```

Syntax: **show ip route** <*num*> | [<*ip-addr*> [<*ip-mask*>] **[debug | detail | longer]**] | **connected | bgp | isis | ospf | rip | static | [summary] | nexthop** [<*nexthop_id*> **[ref-routes]] | [begin** <*expression*> **| exclude** <*expression*> **| include** <*expression*>]

The <*num*> option display the route table entry whose row number corresponds to the number you specify. For example, if you want to display the tenth row in the table, enter "10".

The <*ip-addr*> parameter displays the route to the specified IP address.

The <*ip-mask*> parameter lets you specify a network mask or, if you prefer CIDR format, the number of bits in the network mask. If you use CIDR format, enter a forward slash immediately after the IP address, then enter the number of mask bits (for example: 209.157.22.0/24 for 209.157.22.0 255.255.255.0).

The **longer | detail | debug** parameter applies only when you specify an IP address and mask. This option displays only the routes for the specified IP address and mask.

The **bgp** option displays the BGP4 routes.

The **connected** option displays only the IP routes that are directly attached to the PowerConnect.

The **ospf** option displays the OSPF routes.

The **rip** option displays the RIP routes.

The **isis** option displays the RIP routes.

The **static** option displays only the static IP routes.

The **nexthop** option displays next-hop information for all next hops in the routing table or for a specific entry.

Showing route details by IP address

You can display detailed information about a route by providing the IP address and using the **detail** option, as the following example illustrates.

```
NetIron@MLXe1>show ip route 41.1.1.2 detail
Type Codes - B:BGP D:Connected I:ISIS O:OSPF R:RIP S:Static; Cost - Dist/Metric
ISIS Codes - L1:Level-1 L2:Level-2
OSPF Codes - i:Inter Area 1:External Type 1 2:External Type 2 s:Sham Link
        Destination        Gateway         Port        Cost          Type Uptime
1       41.1.1.0/24        DIRECT          eth 1/15    0/0           D    7h11m
        Nexthop Entry ID:14, Paths: 1, Ref_Count:1/1
1       41.1.1.0/24        41.1.1.2        eth 1/15    115/20        IL2  7h11m
        41.1.1.0/24        129.0.0.18      eth 4/11    115/20        IL2  7h11m
        41.1.1.0/24        129.0.0.30      eth 4/7     115/20        IL2  7h11m
        41.1.1.0/24        129.0.0.34      eth 4/14    115/20        IL2  7h11m
        Nexthop Entry ID:68343, Paths: 4, Ref_Count:8/21
D:Dynamic  P:Permanent  F:Forward  U:Us  C:Connected Network
W:Wait ARP  I:ICMP Deny  K:Drop  R:Fragment  S:Snap Encap N:CamInvalid
Module S1:
      IP Address         Next Hop        MAC              Type  Port  Vlan  Pri
      41.1.1.0/24         DIRECT          0000.0000.0000     PC    n/a          0
      OutgoingIf  ArpIndex PPCR_ID   CamLevel   Parent  DontAge Index
       eth 1/15     65535    1:2        1              0    69203192   38
      U_flags   Entry_flags  Age   Cam:Index           Trunk_fid      Ecmp_count
       0000e220                0     0x1a8fc (L3, right)   0x00000(     0) 0
        CAM Entry Flag: 00000003H
        PPCR : 1:2 CIDX: 0x1a8fc (L3, right) (IP_NETWORK: 0x68703)
         PPCR : 1:1 CIDX: 0x1a8fc (L3, right) (IP_NETWORK: 0x68703)
```

Syntax: show ip route <*ip_addr*> **detail**

The IP address can be just the IP address but can also include shorthand for the mask: ip-address/prefix-length.

Using the summary option

The **summary** option displays a summary of the information in the IP route table. After the **summary** keyword, the pipe symbol (|) points to three options for modifying the presentation of the summary information, as follows:

- **begin** lets you start the display with the first matching line.
- **exclude** lets you exclude matching lines from the display.
- **include** lets you include matching lines in the display.

The default routes are displayed first.

Using the connected option

Here is an example of how to use the **connected** option. To display only the IP routes that go to devices directly attached to the PowerConnect.

```
NetIron(config)# show ip route connected
Type Codes - B:BGP D:Connected I:ISIS S:Static R:RIP O:OSPF; Cost - Dist/Metric
      Destination       Gateway          Port   Cost   Type   Uptime
1     209.157.22.0/24     0.0.0.0           4/11    1       D      1h0m
```

Notice that the route displayed in this example has “D” in the Type field, indicating the route is for a directly connected device.

Using the static option

Here is an example of how to use the **static** option. To display only the static IP routes.

```
NetIron(config)# show ip route static
Type Codes - B:BGP D:Connected I:ISIS S:Static R:RIP O:OSPF; Cost - Dist/Metric
      Destination       Gateway           Port   Cost   Type  Uptime
1     192.144.33.11/32  209.157.22.12     1/1    2      S     1h0m
```

Notice that the route displayed in this example has “S” in the Type field, indicating the route is static.

Using the longer option

Here is an example of how to use the **longer** option. To display only the routes for a specified IP address and mask, enter a command such as the following.

```
NetIron(config)# show ip route 209.159.0.0/16 longer
Type Codes - B:BGP D:Connected I:ISIS S:Static R:RIP O:OSPF; Cost - Dist/Metric
   Destination       Gateway           Port   Cost   Type  Uptime
52 209.159.38.0/24   207.95.6.101      1/1    1      S     45m18s
53 209.159.39.0/24   207.95.6.101      1/1    1      S     1h0m
54 209.159.40.0/24   207.95.6.101      1/1    1      S     45m18s
55 209.159.41.0/24   207.95.6.101      1/1    1      S     1h0m
56 209.159.42.0/24   207.95.6.101      1/1    1      S     13m18s
```

This example shows all the routes for networks beginning with 209.159. The mask value and **longer** parameter specify the range of network addresses to be displayed. In this example, all routes within the range 209.159.0.0 – 209.159.255.255 are listed.

Using the summary option

The **summary** option displays a summary of the information in the IP route table. The following is an example of the output from this command.

```
NetIron# show ip route summary

IP Routing Table - 35 entries:
  6 connected, 28 static, 0 RIP, 1 OSPF, 0 BGP, 0 ISIS, 0 MPLS
  Number of prefixes:
  /0: 1 /16: 27 /22: 1 /24: 5 /32: 1
```

Syntax: show ip route summary

In this example, the IP route table contains 35 entries. Of these entries, 6 are directly connected devices, 28 are static routes, and 1 route was calculated through OSPF. One of the routes has a zero-bit mask (this is the default route), 27 have a 22-bit mask, 5 have a 24-bit mask, and 1 has a 32-bit mask.

Using the nexthop option

You can display next-hop information for all next hops in the routing table or for a specific entry. For the first example, use the **show ip route nexthop** command to display all the next-hop entries, and then use the option to display the next hop for a specific table entry.

```
NetIron#show ip route nexthop
Total number of IP nexthop entries: 30; Forwarding Use: 24
       NextHopIp        Port             RefCount    ID      Age
1      0.0.0.0         mgmt 1         0/1        1536    80682
2      0.0.0.0         eth 1/15       1/1        14      80632
3      0.0.0.0         eth 1/16       1/1        15      16626
4      0.0.0.0         eth 1/18       1/1        17      16626
5      0.0.0.0         eth 1/43       1/1        42      35923
6      0.0.0.0         eth 1/47       1/1        46      80641
7      0.0.0.0         eth 2/2        1/1        49      16630
8      0.0.0.0         eth 2/4        1/1        51      16630
9      41.1.1.2        eth 1/15       0/2        68347   16620
       41.1.2.2        eth 1/18
       129.0.0.18      eth 4/11
       129.0.0.25      eth 4/9
10     41.1.1.2        eth 1/15       0/3        68352   16615
       129.0.0.6       eth 4/4
       129.0.0.10      eth 2/2
       129.0.0.21      eth 4/1
11     0.0.0.0         eth 4/1        1/1        144     16624
12     0.0.0.0         eth 4/3        1/1        146     16641
13     0.0.0.0         eth 4/4        1/1        147     16624
14     0.0.0.0         eth 4/6        1/1        149     16624
15     0.0.0.0         eth 4/7        1/1        150     16641
```

Syntax: show ip route nexthop [nexthop_id]

The <*nexthop_id*> is under the column labeled ID in the output of the **show ip route nexthop** command. For example, use nexthop ID 1536 from the first row of the preceding example to show only that entry.

```
NetIron#show ip route nexthop 1536
       NextHopIp        Port             RefCount      ID      Age
1      0.0.0.0          mgmt 1           0/1           1536    80685
```

Displaying IP routes with nexthop ID

By using the **nexthop** option with the **ref-routes** keyword, you can display IP routes in the forwarding table that refer to the specified nexthop entry, as the following example illustrates (using nexthop ID 65575).

```
NetIron#show ip route nexthop 65537 ref-routes
Type Codes - B:BGP D:Connected I:ISIS O:OSPF R:RIP S:Static; Cost - Dist/Metric
ISIS Codes - L1:Level-1 L2:Level-2
OSPF Codes - i:Inter Area 1:External Type 1 2:External Type 2 s:Sham Link
        Destination        Gateway         Port        Cost          Type Uptime
1       40.1.1.1/32        15.1.1.1        eth 1/11    115/10        IL2  7h51m
2       50.1.1.0/24        15.1.1.1        eth 1/11    115/10        IL2  7h51m
3       100.1.1.1/32       15.1.1.1        eth 1/11    115/40        IL2  7h51m
```

Syntax: show ip route nexthop [<*nexthop_id*> **[ref-routes]]**

Description of command output fields

The following table lists the information in the **show ip route** output when you use no optional arguments.

TABLE 123 CLI display of IP route table

This field...	Displays...
Destination	The destination network of the route.
NetMask	The network mask of the destination address.
Gateway	The next-hop router.
Port	The port through which this router sends packets to reach the route's destination.
Cost	The route's cost.
Type	The route type, which can be one of the following: • B – The route was learned from BGP. • D – The destination is directly connected to this PowerConnect. • R – The route was learned from RIP. • S – The route is a static route. • * – The route is a candidate default route. • O – The route is an OSPF route. Unless you use the ospf option to display the route table, "O" is used for all OSPF routes. If you do use the ospf option, the following type codes are used: • O – OSPF intra area route (within the same area). • IA – The route is an OSPF inter area route (a route that passes from one area into another). • E1 – The route is an OSPF external type 1 route. • E2 – The route is an OSPF external type 2 route.
Uptime	The amount of time since the route was last modified. The format of this display parameter may change depending upon the age of the route to include the seconds (s), minutes (m), hours (h), and days (d), as described in the following: 400d – Only days (d) displayed 20d23h – days (d) and hours (h) displayed 14h33m – hours (h) and minutes (m) displayed 10m59s – minutes (m) and seconds (s) displayed

Clearing IP routes

If needed, you can clear the entire route table or specific individual routes.

To clear all routes from the IP route table.

```
NetIron# clear ip route
```

To clear route 209.157.22.0/24 from the IP routing table.

```
NetIron# clear ip route 209.157.22.0/24
```

Syntax: clear ip route [*<ip-addr> <ip-mask>* | *<ip-addr>/<mask-bits>*]

Displaying IP traffic statistics

To display IP traffic statistics, enter the following command at any CLI level.

NOTE
In the PowerConnect, only those packets that are forwarded or generated by the CPU are included in the IP traffic statistics. Hardware forwarded packets are not included.

```
NetIron#show ip traffic
IP Statistics
  139 received, 145 sent, 0 forwarded
  0 filtered, 0 fragmented, 0 reassembled, 0 bad header
  0 no route, 0 unknown proto, 0 no buffer, 0 other errors

ICMP Statistics
Received:
  0 total, 0 errors, 0 unreachable, 0 time exceed
  0 parameter, 0 source quench, 0 redirect, 0 echo,
  0 echo reply, 0 timestamp, 0 timestamp reply, 0 addr mask
  0 addr mask reply, 0 irdp advertisement, 0 irdp solicitation
Sent:
  0 total, 0 errors, 0 unreachable, 0 time exceed
  0 parameter, 0 source quench, 0 redirect, 0 echo,
  0 echo reply, 0 timestamp, 0 timestamp reply, 0 addr mask
  0 addr mask reply, 0 irdp advertisement, 0 irdp solicitation

UDP Statistics
  1 received, 0 sent, 1 no port, 0 input errors

TCP Statistics
  0 active opens, 0 passive opens, 0 failed attempts
  0 active resets, 0 passive resets, 0 input errors
  138 in segments, 141 out segments, 4 retransmission
```

Syntax: show ip traffic

The **show ip traffic** command displays the following information.

TABLE 124 CLI display of IP traffic statistics

This field...	Displays...
IP statistics	
received	The total number of IP packets received by the device.
sent	The total number of IP packets originated and sent by the device.
forwarded	The total number of IP packets received by the device and forwarded to other devices.
filtered	The total number of IP packets filtered by the device.
fragmented	The total number of IP packets fragmented by this device to accommodate the IP MTU of this device or of another device.
reassembled	The total number of fragmented IP packets that this device re-assembled.
bad header	The number of IP packets dropped by the device due to a bad packet header.
no route	The number of packets dropped by the device because there was no route.
unknown proto	The number of packets dropped by the device because the value in the Protocol field of the packet header is unrecognized by this device.

TABLE 124 CLI display of IP traffic statistics (Continued)

This field...	Displays...
no buffer	This information is used by Dell customer support.
other errors	The number of packets that this device dropped due to error types other than the types listed above.
ICMP statistics The ICMP statistics are derived from RFC 792, "Internet Control Message Protocol", RFC 950, "Internet Standard Subnetting Procedure", and RFC 1256, "ICMP Router Discovery Messages". Statistics are organized into Sent and Received. The field descriptions below apply to each.	
total	The total number of ICMP messages sent or received by the device.
errors	This information is used by Dell customer support.
unreachable	The number of Destination Unreachable messages sent or received by the device.
time exceed	The number of Time Exceeded messages sent or received by the device.
parameter	The number of Parameter Problem messages sent or received by the device.
source quench	The number of Source Quench messages sent or received by the device.
redirect	The number of Redirect messages sent or received by the device.
echo	The number of Echo messages sent or received by the device.
echo reply	The number of Echo Reply messages sent or received by the device.
timestamp	The number of Timestamp messages sent or received by the device.
timestamp reply	The number of Timestamp Reply messages sent or received by the device.
addr mask	The number of Address Mask Request messages sent or received by the device.
addr mask reply	The number of Address Mask Replies messages sent or received by the device.
irdp advertisement	The number of ICMP Router Discovery Protocol (IRDP) Advertisement messages sent or received by the device.
irdp solicitation	The number of IRDP Solicitation messages sent or received by the device.
UDP statistics	
received	The number of UDP packets received by the device.
sent	The number of UDP packets sent by the device.
no port	The number of UDP packets dropped because the packet did not contain a valid UDP port number.
input errors	This information is used by Dell customer support.
TCP statistics The TCP statistics are derived from RFC 793, "Transmission Control Protocol".	
active opens	The number of TCP connections opened by this device by sending a TCP SYN to another device.
passive opens	The number of TCP connections opened by this device in response to connection requests (TCP SYNs) received from other devices.
failed attempts	This information is used by Dell customer support.
active resets	The number of TCP connections this device reset by sending a TCP RESET message to the device at the other end of the connection.
passive resets	The number of TCP connections this device reset because the device at the other end of the connection sent a TCP RESET message.

TABLE 124 CLI display of IP traffic statistics (Continued)

This field...	Displays...
input errors	This information is used by Dell customer support.
in segments	The number of TCP segments received by the device.
out segments	The number of TCP segments sent by the device.
retransmission	The number of segments that this device retransmitted because the retransmission timer for the segment had expired before the device at the other end of the connection had acknowledged receipt of the segment.

Displaying GRE tunnel information

To display information about all GRE tunnels configured on a router, enter the following command.

```
NetIron# show gre
Total Valid GRE Tunnels : 1, GRE Session Check Enforce: FALSE
GRE tnnl 1 UP : src_ip 25.25.25.4, dst_ip 15.15.15.3
   TTL 255, TOS 0, NHT 0, MTU 1476
```

Syntax: show gre <*tunnel-number*>

The <*tunnel-number*> option allows you to limit the display to information about a specified tunnel.

Displaying GRE and manual IPv6 tunnel statistics

This section contains examples of the following **show** commands for GRE tunnel and manual IPv6 tunnel statistics:

- **show ip-tunnels**
- **show ip-tunnel** <*tunnel ID*>
- **show statistics brief tunnel** [tunnel ID]
- **show statistics tunnel** [tunnel ID]
- **show interface tunnel** <*tunnel ID*>

To see a list of the configured tunnels with some details of each tunnel, use the **show ip-tunnels** command as the following example illustrates. This example shows that one tunnel exists; it has IP tunnel statistics collection enabled; and neither GRE nor IPv6 session enforce are enabled.

```
NetIron#show ip-tunnels
# of Valid Tunnels: 1, GRE Session Enforce: FALSE, IPv6 Session Enforce: FALSE
   IP Tunnel Statistics collection Enabled
GRE tnnl 1 UP src_ip 1.1.1.4, dst_ip 1.1.1.1
   TTL 255, TOS 0, NHT 0, MTU 1476
```

Syntax: show ip tunnel <*number*>

Syntax: show ip tunnels

The output of this command contains the following type of information:

TABLE 125 Show IP tunnel display information

This field...	Displays...
Ipv6 tnnl x <*UP* | *DOWN*>	The status of the interface for manual IPv6 tunnel interface x can be one of the following: • UP – The tunnel interface is functioning properly. • DOWN – The tunnel interface is not functioning and is down.
GRE tnnl x UP or DOWN	The status of the interface for GRE tunnel interface x can be one of the following: • UP – The tunnel interface is functioning properly. • DOWN – The tunnel interface is not functioning and is down.
GRE Session Enforce	Shows whether the global GRE session enforce feature is enabled. The output is one of the following: TRUE – the feature is enabled. FALSE – the feature is disabled.
IPv6 Session Enforce	Shows whether the global IPv6 session enforce feature is enabled. The output is one of the following: TRUE – the feature is enabled. FALSE – the feature is disabled.
IP Tunnel Statistics collection	Shows whether the collection of tunnel statistics is enabled. The enable or disable is a global setting that applies to both directions of GRE and manual IPv6 tunnels (unicast and multicast).
src_ip	The tunnel source can an IPv4 address.
dst_ip	The tunnel destination can an IPv4 address.
TTL	The TTL value configured for the outer IP header. The range for TTLs is 1 – 255.
TOS	The TOS value configured for the outer IP header. The range for TOS values is 1 – 255.
NHT	The nextHop Table index value.
MTU	The setting of the IPv6 maximum transmission unit (MTU).

Displaying brief tunnel statistics

Use the **show statistics brief tunnel** command to display the aggregate statistics for a specific tunnel or for all tunnels (in page mode). The feature combines both unicast and multicast statistics into one counter.

To display all of the brief statistics, run the **show statistics brief tunnel** command.

```
NetIron#show statistics brief tunnel
                                        Packets
Tunnel Id  Tunnel Type  [Rcv-from-tnnl    Xmit-to-tnnl]
1          GRE          586046            287497
2          GRE          0                 0
3         IPV6-Manual 0                0
```

Syntax: show statistics brief tunnel [tunnel-id]

To show the brief statistics for a particular tunnel, include the optional tunnel ID. The types of information in the output are as follows:

TABLE 126 Show IP tunnel display information

This field...	Displays...
Tunnel ID	For each tunnel displayed, the Tunnel ID indicates the tunnel for which the statistics are displayed.
Tunnel Type	The tunnel type is either GRE or manual IPv6.
Packets Rcv-from-tnnl	The number of packets that have arrived from the tunnel.
Packets Xmit-to-tnnl	The number of packets that have been sent to the tunnel.

Displaying tunnel statistics

Use the **show statistics tunnel** command to display the aggregate statistics (including unicast and multicast statistics) for a port-range for each packet processor (PPCR) for every LP module in the system. If you enter the command with no tunnel ID, the output displays statistics for all tunnels in page-mode. This command displays only the port ranges that have either unicast or multicast traffic and displays nothing if the LP does not have any non-zero counters. For this example, the LP2 is a four-port 10G card.

```
NetIron#show statistics tunnel 1
                                                    Packets
Tunnel Id  Tunnel Type  In-Port(s)     [Rcv-from-tnnl    Xmit-to-tnnl]
1          GRE          e2/1 - e2/2     586046           287497
                      e2/3 - e2/4    100340          150034
```

Syntax: show statistics tunnel [tunnel-ID]

The optional [tunnel-ID] parameter lets you specify a particular tunnel, otherwise all tunnel statistics are shown. The command output contains the following types of information.

TABLE 127 Show IP tunnel display information

This field...	Displays...
Tunnel ID	For each tunnel displayed, the Tunnel ID indicates the tunnel for which the statistics are displayed.
Tunnel Type	The tunnel type is either GRE or manual IPv6.
In-ports	The Ethernet ports traversed by the tunnel.
Packets Rcv-from-tnnl	The number of packets that have arrived from the tunnel.
Packets Xmit-to-tnnl	The number of packets that have been sent to the tunnel.

Displaying interface statistics for a tunnel

To see the interface statistics for a particular tunnel (GRE tunnel 1 in this case), use the **show interface tunnel** command, as the following illustrates.

```
NetIron#show interface tunnel 1
Tunnel 1 is up, line protocol is up
  Hardware is Tunnel
  Tunnel source  30.30.30.1
  Tunnel destination is 20.20.20.1
  Tunnel mode gre ip
  No port name
  Internet address is: 50.50.50.4/24
  Tunnel TOS 0, Tunnel TTL 255, Tunnel MTU 1476 bytes
  Keepalive is not Enabled
  Tunnel Packet Statistics:
               Unicast Packets       Multicast Packets
    In-Port(s)   [Rcv-from-tnnl  Xmit-to-tnnl]  [Rcv-from-tnnl    Xmit-to-tnnl]
    e5/1 - e5/20   0           16511754        0             0
    e6/1 - e6/20   0           14147748        0             20195730
    e7/1 - e7/24   21493545           0        40696309      0
    e16/1 - e16/2  0            3916998        0             0
    e16/3 - e16/4  0            13476342       0
```

Syntax: show interface tunnel <*tunnel ID*>

The <*tunnel ID*> is the ID of a particular tunnel. The output contains the following types of information:

TABLE 128 Show IP tunnel display information

This field...	Displays...
Tunnel status	The tunnel and the line protocol can be • UP – The tunnel or line protocol is up and functioning properly. • DOWN – The tunnel or line protocol is down.
Tunnel source	The source IP address of the hardware.
Tunnel destination	The destination IP address of the hardware.
Tunnel mode	The tunnel mode is either GRE or manual IPv6.
Port name	The port name is displayed, or if no name has been configured, this fact is stated.
Internet address	The IP address of the ingress.
TOS	The TOS value configured for the outer IP header. The range for TOS values is 1 – 255.
TTL	The TTL value configured for the outer IP header. The range for TTLs is 1 – 255.
MTU	The setting of the IPv6 maximum transmission unit (MTU).
Keepalive	Shows the number of seconds for the keepalive option if it has been configured, otherwise it states “not Enabled.”
In-ports	The Ethernet port numbers.

TABLE 128 Show IP tunnel display information (Continued)

This field...	Displays...
Unicast Packets	On a per port basis, this column shows the number of unicast packets that have arrived from the tunnel and the number of packets that have been transmitted to the tunnel. This count includes packets for both GRE tunnels and packets for manually configured IPv6 tunnels.
Multicast Packets	On a per port basis, this column shows the number of multicast packets that have arrived from the tunnel and the packets that have been transmitted to the tunnel. This count includes packets for both GRE tunnels and packets for manually configured IPv6 tunnels.

Displaying martian addressing information

To display Martian Addressing information, use the following command.

```
NetIron# show ip martian
ip martian filtering on
0.0.0.0/8 deny
10.0.0.0/8 deny
127.0.0.0/8 deny
191.255.0.0/16 deny
192.0.0.0/24 deny
223.255.255.0/24 deny
240.0.0.0/4 deny
```

Syntax: show [vrf <*name*>**] ip martian**

You can use the **vrf** option to display martian addresses for a specific VRF.

Layer 2 Access Control Lists 20

Tthe following Layer 2 ACLs features are supported by the NetIron MLX Series devices:

- Filtering Based on Ethertype
- Filtering Based on Ethertype IPv6
- Filtering and Priority Manipulation Based on 802.1p Priority
- Binding a Layer 2 ACL Table to an Interface
- VRF ACL
- Using the Priority Option
- Using the Priority Force Option
- Using the Priority Mapping Option
- ACL Accounting

Layer-2 Access Control Lists (ACLs) filter incoming traffic based on Layer-2 MAC header fields in the Ethernet IEEE 802.3 frame. Specifically, Layer-2 ACLs filter incoming traffic based on any of the following Layer-2 fields in the MAC header:

- Source MAC address and source MAC mask
- Destination MAC address and destination MAC mask
- VLAN ID
- Ethernet type
- 802.1p

Layer-2 ACLs filter traffic at line-rate speed.

Configuration rules and notes

General considerations

- You cannot bind a Layer-2 ACL to a virtual interface.
- The Layer-2 ACL feature cannot perform SNAP and LLC encapsulation type comparisons.
- PowerConnect processes ACLs in hardware.
- You cannot edit or modify an existing Layer-2 ACL clause. If you want to change the clause, you must delete it first, then re-enter the new clause.
- You cannot add remarks to a Layer-2 ACL clause.
- When you bind a Layer-2 ACL that is not defined, it implicitly denies all traffic.

- The behavior of Layer-2 ACLs for dynamic LAG creation and deletion is that before a LAG is formed all ports which will be parts of the LAG must have the same configuration. For example, all of the ports can have no ACL, or have ACL 401 on inbound and outbound ports. After the LAG is removed, all ACL bindings (if there are any) are propagated to all of the secondary ports.
- Layer-2 inbound ACLs and Layer-2 inbound ACL-based rate limiting are not supported on Layer-3 VPNs.
- You can bind multiple rate limiting policies to a single port. However, once a matching ACL clause is found for a packet, the device does not evaluate subsequent clauses in that rate limiting ACL and subsequent rate limiting ACLs.
- Only numbered ACLs support rate limiting.

Configuration considerations for VPLS, VLL, and VLL-Local endpoints

L2 ACLs are supported on VPLS, VLL, and VLL-local endpoints with the following configuration considerations:

- First configure the port as a VPLS, VLL, or VLL-local endpoint and then bind the Layer-2 ACL on it.
- First remove the Layer-2 ACL from a VPLS, VLL, or VLL-local endpoint before removing the port from the VPLS, VLL, or VLL-local instance or corresponding VLAN.
- First remove the Layer-2 ACL from a VPLS, VLL, or VLL-local endpoint(s) before deleting the VPLS, VLL, or VLL-local instance or corresponding VLAN.
- If the VPLS, VLL, or VLL-local endpoint is a LAG port, you must first remove the Layer-2 ACL from the primary LAG port before deleting the LAG. This restriction is applicable even if you are deleting the LAG using the **force** keyword.
- If a VLL or VLL-local endpoint is a LAG port with Layer-2 ACL, you have to first remove the Layer-2 ACL from the primary LAG port before dynamically removing a port from the LAG.
- Ensure that no VPLS, VLL, or VLL-local endpoint exists with an Layer-2 ACL before entering the command: **no router mpls**.

Types of Layer-2 ACLs

Layer-2 ACLs can be numbered or named. Numbered Layer-2 ACL table IDs range from 400 to 499 and for a maximum of 100 configurable numbered Layer-2 ACL tables.

Within each Layer-2 ACL table, you can configure from 64 (default) to 256 clauses. Each clause or entry can define a set of Layer-2 parameters for filtering. Once you completely define a Layer-2 ACL table, you must bind it to the interface for filtering to take effect.

There can be up to 500 named L2 ACLs. The maximum length of a named Layer-2 ACL is 255 characters. The Layer-2 ACL name cannot begin with digits 0 to 9 to avoid confusion with the numbered L2 ACLs.

The PowerConnect evaluates traffic coming into the port against each ACL clause. Once a matching entry is found, the device either forwards or drops the traffic, depending upon the action specified for the clause. Once a matching entry is found, the device does not evaluate the traffic against subsequent clauses.

By default, if the traffic does not match any of the clauses in the ACL table, the device drops the traffic. To override this behavior, specify a “permit any any...” clause at the end of the table to match and forward all traffic not matched by the previous clauses.

NOTE
Use precaution when placing entries within the ACL table. The Layer-2 ACL feature does not attempt to resolve conflicts conflicts across multiple ACL clauses.

Creating a numbered Layer-2 ACL table

You create a numbered Layer-2 ACL table by defining a Layer-2 ACL clause.

To create a numbered Layer-2 ACL table, enter commands (clauses) such as the following at the Global CONFIG level of the CLI. Note that you can add additional clauses to the ACL table at any time by entering the command with the same table ID and different MAC parameters.

```
NetIron(config)# access-list 400 deny any any any etype arp
NetIron(config)# access-list 400 deny any any any etype ipv6
NetIron(config)# access-list 400 permit any any 100
```

This configuration creates a Layer-2 ACL with an ID of 400. When applied to an interface, this Layer-2 ACL table will deny all ARP and IPv6 traffic, and permit all other traffic in VLAN 100.

For more examples of valid Layer-2 ACL clauses, see “Filtering and priority manipulation based on 802.1p priority” on page 778.

Syntax: [no] **access-list** <num> **permit** | **deny** <src-mac> <mask> | **any** <dest-mac> <mask> | **any** [<vlan-id> | **any**] [**etype** <etype-str>] [**priority** <queue-value> | **priority-force** <queue-value> | **priority-mapping** <queue-value>]

The <num> parameter specifies the Layer-2 ACL table that the clause belongs to. The table ID can range from 400 to 499. You can define a total of 100 Layer-2 ACL tables.

The **permit** | **deny** argument determines the action to be taken when a match occurs.

The <src-mac> <mask> | **any** parameter specifies the source MAC address. You can enter a specific address and a comparison mask or the keyword any to filter on all MAC addresses. Specify the mask using Fs and zeros. For example, to match on the first two bytes of the address aabb.ccdd.eeff, use the mask ffff.0000.0000. In this case, the clause matches all source MAC addresses that contain “aabb” as the first two bytes and any values in the remaining bytes of the MAC address. If you specify any, you don’t need to specify a mask and the clause matches on all MAC addresses.

The <dest-mac> <mask> | **any** parameter specifies the destination MAC address. The syntax rules are the same as those for the <src-mac> <mask> | **any** parameter.

The optional <vlan-id> | **any** parameter specifies the vlan-id to be matched against the VLAN IDof the incoming packet. You can specify **any** to ignore the vlan-id match.

The optional **etype** <etype-str> argument specifies the Ethernet type field of the incoming packet in order for a match to occur.

The <etype-str> variable can be one of the following keywords:

- IPv4-l5 (Etype=0x0800, IPv4, HeaderLen 20 bytes)
- ARP (Etype=0x0806, IP ARP)

- IPv6 (Etype=0x86dd, IP version 6)
- ANY – specify etype any to ignore Ethernet type field match.

NOTE
Filtering based on etype value is only supported for Layer-2 inbound ACLs. It is not supported for Layer-2 outbound ACLs.

Filtering and priority manipulation based on 802.1p priority

With the Multi-Service IronWare software, Layer-2 ACL support has been provided for filtering and priority manipulation based on a packet's 802.1p priority using the following keywords.

The following priority options can be configured following the etype argument .

NOTE
The keywords **priority** and **priority-force** cannot be used together in an ACL entry.

The **priority** option assigns traffic that matches the ACL to a hardware forwarding queue. In addition to changing the internal forwarding priority, if the outgoing interface is an 802.1q interface, this option maps the specified priority to its equivalent 802.1p (QoS) priority and marks the packet with the new 802.1p priority. This option is applicable for inbound ACLs only.

The **priority-force** option assigns packets of outgoing traffic that match the ACL to a specific hardware forwarding queue, even though the incoming packet may be assigned to another higher priority queue. This option is applicable for inbound ACLs only

The **priority-mapping** option matches on the packet's 802.1p value. This option does not change the packet's forwarding priority through the device or mark the packet. This keyword is applicable for both inbound and outbound ACLs.

The <queue value> variable specifies one of the following QoS queues for use with the priority, priority-force options

- 0 – qosp0
- 1 – qosp1
- 2 – qosp2
- 3 – qosp3
- 4 – qosp4
- 5 – qosp5
- 6 – qosp6
- 7 – qosp7

Use the **[no]** parameter to delete the Layer-2 ACL clause from the table. When all clauses are deleted from a table, the table is automatically deleted from the system.Example Numbered Layer-2 ACL Clauses

The following shows some examples of valid Layer-2 ACL clauses.

```
NetIron(config)# access-list 401 permit any any
NetIron(config)# access-list 402 permit any any 100
NetIron(config)# access-list 403 permit any any any
NetIron(config)# access-list 404 permit any any 100 etype ipv4
```

Inserting and deleting Layer-2 ACL clauses

You can make changes to the Layer-2 ACL table definitions without unbinding and rebinding the table from an interface. For example, you can add a new clause to the ACL table, delete a clause from the table, delete the ACL table, etc.

Increasing the maximum number of clauses per Layer-2 ACL table

You can increase the maximum number of clauses configurable within a Layer-2 ACL table.

To increase the maximum number of clauses per Layer-2 ACL table, enter a command such as the following at the Global CONFIG level of the CLI.

```
NetIron(config)# system-max l2-acl-table-entries 200
```

Syntax: [no] **system-max l2-acl-table-entries** <max>

NOTE
The **l2-acl-table-entries** controls the maximum number of filters supported on one Layer-2 ACL. The named Layer-2 ACL is also subject to the configuration of this **system-max** value.

The <max> parameter specifies the maximum number of clauses per Layer-2 ACL. The minimum, maximum and default values for this parameter are described in Table 4.6.

Binding a numbered Layer-2 ACL table to an interface

To enable Layer-2 ACL filtering, bind the Layer-2 ACL table to an interface. Enter a command such as the following at the Interface level of the CLI to bind an inbound Layer-2 ACL.

```
NetIron(config)# int e 4/12
NetIron(config-int-e100-4/12)# mac access-group 400 in
```

Enter a command such as the following at the Interface level of the CLI to bind an outbound Layer-2 ACL.

```
NetIron(config)# int e 4/12
NetIron(config-int-e100-4/12)# mac access-group 400 out
```

Syntax: [no] **mac access-group** <num> in | out

Filtering by MAC address

In the following example, an ACL is created that denies all traffic from the host with the MAC address 0012.3456.7890 being sent to the host with the MAC address 0011.2233.4455.

```
NetIron(config)# access-list 401 deny 0012.3456.7890 ffff.ffff.ffff
0011.2233.4455 ffff.ffff.ffff
NetIron(config)# access-list 401 permit any any
```

Using the mask, you can make the access list apply to a range of addresses. For instance if you changed the mask in the previous example from 0012.3456.7890 to ffff.ffff.fff0, all hosts with addresses from 0012.3456.7890 to 0012.3456.789f would be blocked. This configuration for this example is shown in the following.

```
NetIron(config)# access-list 401 deny 0012.3456.7890 ffff.ffff.fff0
0011.2233.4455 ffff.ffff.ffff
NetIron(config)# access-list 401 permit any any
```

The <num> parameter specifies the Layer-2 ACL table ID to bind to the interface.

Filtering broadcast traffic

To define an Layer-2 ACL that filters Broadcast traffic, enter commands such as the following.

```
NetIron(config)#access-list 401 deny any ffff.ffff.ffff ffff.ffff.ffff
NetIron(config)#access-list 401 permit any any any
```

To bind an Layer-2 ACL that filters Broadcast traffic, enter commands such as the following.

```
NetIron(config)#int eth 14/1
NetIron(config-if-e10000-14/1)#mac access-gr 401 in
```

Using the priority option

In the following example, access list 401 assigns ARP packets with any source and destination addresses from VLAN 10 to internal priority queue 5 and maps them to the 802.1p value 5 when outbound on an 802.1q interface.

```
NetIron(config)# access-list 401 permit any any 10 etype arp priority 5
```

Using the priority force option

In the following example, access list 401 assigns IPv4 packets with any source and destination addresses from VLAN 10 to the internal priority queue 6.

```
NetIron(config)# access-list 401 permit any any 10 etype ipv4-l5 priority-force 6
```

Using the priority mapping option

In the following example, access list 401 permits IPv6 packets with any source and destination addresses from VLAN 10 that have an 802.1p priority of 3.

```
NetIron(config)# access-list 401 permit any any 10 etype ipv6 priority-mapping 3
```

Creating a named Layer-2 ACL table

To create for example a named Layer-2 ACL called example_l2_acl , enter the following commands.

```
NetIron(config)#mac access-list example_l2_acl
NetIron(config-mac-nacl)#deny 0000.0000.0001 ffff.ffff.ffff any
NetIron(config-mac-nacl)#permit any 0000.0000.0002 ffff.ffff.ffff
NetIron(config-mac-nacl)#exit
```

Following is an example of how a named Layer-2 ACL “example_l2_acl” is displayed in the configuration file.

```
!
mac access-list example_l2_acl
 deny 0000.0000.0001 ffff.ffff.ffff any
 permit any 0000.0000.0002 ffff.ffff.ffff
!
```

Syntax: [no] **mac access-list** <acl_name>

Syntax: **[no] permit | deny** <src-mac> <mask> | any <dest-mac> <mask> | any [<vlan-id> | any] [etype <etype-str>] [priority <queue-value> | priority-force <queue-value> | priority-mapping <queue-value>]

Binding a named Layer-2 ACL table to an interface

Following is an example of the named Layer-2 ACL “example_l2_acl” applied to the inbound of port 2/2.

```
NetIron(config)# interface e 2/2
NetIron(config-if-e1000-2/2)#mac access-group example_l2_acl in
```

Syntax: [no] mac access-group <acl_name> <in|out>

If a Layer-2 ACL name is bound to an interface before the actual Layer-2 ACL filters are defined, the behavior will be implicit deny of all traffic. This is consistent with the behavior of other types of ACLs.

ACL accounting

Multi-Service devices monitor the number of times an ACL is used to filter incoming or outgoing traffic on an interface. The **show access-list accounting** command displays the number of “hits” or how many times ACL filters permitted or denied packets that matched the conditions of the filters. For more detailed information about ACL accounting, please refer to “ACL accounting” on page 828.

Enabling and disabling ACL accounting on NetIron MLX device

To enable ACL accounting, enter the following command in global configuration mode:

```
NetIron(config)# enable-acl-counter
```

Syntax: **[no] enable-acl-counter**

NOTE
Enabling or disabling ACL accounting affects the gathering of statistics from all ACL types (Layer-2, IPv4 and IPv6).

Displaying Layer-2 ACLs

Use the show access-list command to display Layer-2 ACL tables.

To display a Layer-2 numbered ACL table use the following command.

```
NetIron(config)#show access-list 401
```

Syntax: show access-list <number>

The <num> parameter specifies the Layer-2 ACL table ID.

To display a Layer-2 named ACL table use the following command.

```
NetIron(config)#show access-list example
```

Syntax: show access-list l2 <l2_acl_name>

The <l2_acl_name> parameter specifies the Layer-2 ACL name.

Displaying Layer-2 ACL statistics on NetIron MLX device

To display Layer 2 inbound ACL statistics on the NetIron MLX, enter commands such as the following.

```
(config-if-e10000-14/1)#show access-list acc eth 14/1 in l2
Collecting L2 ACL accounting for 400 on port 14/1  ...  Completed successfully.
L2 ACL Accounting Information:
Inbound: ACL 400
    0:   permit any any 100 etype ipv4-l5
       Hit count: (1 sec)                    0   (1 min)                    0
                  (5 min)                    0   (accum)                    0
    1:   deny any any any etype arp
       Hit count: (1 sec)                    0   (1 min)                    0
                  (5 min)                    0   (accum)                    0
```

To display Layer 2 outbound ACL statistics on the NetIron MLX, enter commands such as the following.

```
NetIron(config-if-e10000-14/1)#show access-list acc eth 14/1 out l2
Collecting L2 ACL accounting for 400 on port 14/1  ...  Completed successfully.
L2 ACL Accounting Information:
Outbound: ACL 400
    0:   permit any any 100 etype ipv4-l5
       Hit count: (1 sec)                    0   (1 min)                    0
                  (5 min)                    0   (accum)                    0
    1:   deny any any any etype arp
       Hit count: (1 sec)                    0   (1 min)                    0
                  (5 min)                    0   (accum)                    0
```

Syntax: show access-list accounting <int_type> <slot/port> <in | out> l2

Configuring ACL Deny Logging for Layer-2 inbound ACLs

Configuring ACL Deny Logging for Layer-2 ACLs requires the following:

- Enabling the Log Option

- Enabling ACL Deny Logging on an Interface

Enabling the log option

ACL Logging of Layer-2 ACLs requires that you add the **log** option to an ACL statement as shown.

```
NetIron(config)#access-list 401 deny any any any log
```

The **log** option enables logging for the Layer-2 ACL being defined.

Enabling ACL Deny Logging on an interface

The **mac access-group enable-deny-logging** command must be configured as shown on each interface that you want ACL Deny Logging for Layer-2 ACLs to function.

```
NetIron(config)# interface ethernet 5/1
NetIron(config-if-e1000-5/1)# mac access-group enable-deny-logging'
```

Syntax: [no] mac access-group enable-deny-logging [hw-drop]

The **hw-drop** option specifies that Layer-2 ACL Log packets be dropped in hardware. This is implemented to reduce the CPU load. In practice this means that the packet counts for denied traffic will only account for the first packet in each time cycle. The **no mac access-group enable-deny-logging hw-drop** command only removes the **hw-drop** keyword.

NOTE
Using this command, ACL logging can be enabled and disabled dynamically and does not require you to rebind the ACLs using the **ip rebind-acl** command

NOTE
When configuring the **mac access-group enable-deny-logging** command on VPLS, VLL, and VLL-Local endpoints, please refer to "Configuration considerations for VPLS, VLL, and VLL-Local endpoints" on page 776 for configuration guidelines.

Access Control List 21

The following ACL features are supported by the NetIron MLX Series devices.

- Access Control Lists (ACLs)
- Hardware Rule Based ACLs
- Named ACLs
- Numbered ACLs
- Standard ACLs
- Extended ACLs
- Modifying ACLs
- Deleting ACL Entries
- ACL Duplication Check
- ACL Conflict Check
- Binding IPv4 Inbound ACLs to a Management Port
- ACL CAM sharing for Inbound ACLs
- CAM sharing
- ACL Deny Logging
- ACL Accounting
- Receive ACL (RACL) Statistics
- Disabling Outbound ACLs for Switching Traffic
- Support for acl-frag-conservative
- Support for "priority" keyword in ACLs

This chapter discusses the IPv4 Access Control List (ACL) feature, which enables you to filter traffic based on the information in the IP packet header. For details on Layer 2 ACLs, refer to 20, "Layer 2 Access Control Lists". For details on IPv6 ACLs, refer to Chapter 40, "Configuring an IPv6 Access Control List".

You can use IPv4 ACLs to provide input to other features such as route maps, distribution lists, rate limiting, and BGP. When you use an ACL this way, use permit statements in the ACL to specify the traffic that you want to send to the other feature. If you use deny statements, the traffic specified by the deny statements is not supplied to the other feature. Refer to the chapters for a specific feature for information on using ACLs as input to those features.

How the PowerConnect processes ACLs

The PowerConnect processes traffic that ACLs filter in hardware. The PowerConnect creates an entry for each ACL in the Content Addressable Memory (CAM) at startup or when the ACL is created. The PowerConnect uses these CAM entries to permit or deny packets in the hardware, without sending the packets to the CPU for processing.

General configuration guidelines

Consider the following configuration guidelines:

- ACLs are supported on physical interfaces, LAG groups, and virtual routing interfaces.
- Both inbound and outbound ACLs are supported.
- You can create up to 4096 ACL entries in all the ACL configurations on the device.
- If you change the content of an ACL (add, change, or delete entries), you must remove and then reapply the ACL to all the ports that use it. Otherwise, the older version of the ACL remains in the CAM and continues to be used. You can easily re-apply ACLs using the **ip rebind-acl** <*num*> | <*name*> | **all** command. Refer to "Applying ACLs to interfaces" on page 808.
- You cannot enable any of the following features on the interface if an ACL is already applied to that interface:
  - ACL-based rate limiting
  - Policy-based routing (PBR)
  - VLAN ID Translation or Inner VLAN ID translation feature

  IP outbound and L2 outbound ACLs are mutually exclusive on NetIron MLX platform.
- Support for ACLs on MPLS VPN Endpoints – ACLs can be supported on the following endpoints:
  - IPv4 and IPv6 inbound ACLs are not supported on VPLS, VLL, or VLL-Local endpoints and vice-versa.
  - PBR route-map cannot be applied on VPLS, VLL, or VLL-Local endpoints and vice-versa.
  - The **ip access-group redirect-deny-to-inter** and **ip access-group enable-deny-logging** commands cannot be applied on VPLS, VLL, or VLL-local endpoints and vice versa.
  - IPv4 ACL-based rate limiting is not supported on VPLS and VLL endpoints.
  - Layer-2 ACLs and Layer-2 ACL-based rate limiting is not supported on Layer-3 VPNs.
  - TOS or DSCP marking using inbound ACLs is not supported on Layer-3 VPNs.
  - PBR policies are not supported on Layer-3 VPNs.

Configuration considerations for IPv4 outbound ACLs on VPLS, VLL, and VLL-Local endpoints

IPv4 outbound ACLs are supported on VPLS, VLL, and VLL-local endpoints with the following configuration considerations:

- First configure the port as a VPLS, VLL, or VLL-local endpoint and then bind the IPv4 outbound ACL on it.
- First remove the IPv4 outbound ACL from a VPLS, VLL, or VLL-local endpoint before removing the port from the VPLS, VLL, or VLL-local instance or corresponding VLAN.
- First remove the IPv4 outbound ACL from a VPLS, VLL, or VLL-local endpoint(s) before deleting the VPLS, VLL, or VLL-local instance or corresponding VLAN.
- If the VPLS, VLL, or VLL-local endpoint is a LAG port, you must first remove the IPv4 outbound ACL from the primary LAG port before deleting the LAG. This restriction is applicable even if you attempt to delete the lag using **force** keyword.

- If a VLL or VLL-local endpoint is a LAG port with a IPv4 outbound ACL, you have to first remove the IPv4 outbound ACL from the primary LAG port before dynamically removing a port from the LAG.
- Ensure that no VPLS, VLL, or VLL-local endpoint exists with an IPv4 outbound ACL before entering the command: **no router mpls**.

Disabling outbound ACLs for switching traffic

By default, when an outbound ACL is applied to a virtual interface, the PowerConnect router always filters traffic that is switched from one port to another within the same virtual routing interface. Additional commands have been added that allow you to exclude switched traffic from outbound ACL filtering. This exclusion can be configured globally or on per-port basis. This feature applies to IPv4 and IPv6 ACLs only.

All global and interface level command for disabling outbound ACLs for Switching Traffic are mutually exclusive. If the global command is configured, the interface command is not accepted. If the interface command has already been configured, configuring the global command will remove all individual port commands from the PowerConnect router's configuration.

NOTE
This feature is not recommended for MPLS interfaces.

Globally enabling outbound ACLS for switching traffic

Configuring the **acl-outbound exclude-switched-traffic** command at the general configuration level, allows you to globally exclude all switched traffic from outbound ACL filtering. This feature is configured as shown in the following.

```
NetIron(config)# acl-outbound exclude-switched-traffic ipv4
```

Syntax: [no] acl-outbound exclude-switched-traffic ipv6 | ipv4

The **ipv6** option limits the traffic excluded to IPv6 traffic only.

The **ipv4** option limits the traffic excluded to IPv4 traffic only.

The **ipv4** and **ipv6** options are mutually exclusive within the same command. If you want to configure this command to exclude both IPv4 and IPv6 traffic, you must use two separate commands.

Enabling outbound ACLS for switching traffic per port

Configuring the **if-acl-outbound exclude-switched-traffic** command at the interface configuration level, allows you to exclude all switched traffic from outbound ACL filtering on a per-port basis. With this command, one or more physical ports (for instance all ports within a VLAN) can be configured to exclude switched traffic from outbound ACL filtering.

This feature is configured as shown in the following.

```
NetIron(config)# interface ethernet 3/1
NetIron(config-if-e10000-3/1)# if-acl-outbound exclude-switched-traffic
```

Syntax: [no] it-acl-outbound exclude-switched-traffic [ipv6 | ipv4]

The **ipv6** option limits the traffic excluded to IPv6 traffic only.

The **ipv4** option limits the traffic excluded to IPv4 traffic only.

The **ipv4** and **ipv6** options are mutually exclusive within the same command. If you want to configure this command to exclude both IPv4 and IPv6 traffic, you must use two separate commands.

Default ACL action

The default action when no ACLs is configured on a PowerConnect is to permit all traffic. However, once you configure an ACL and apply it to a port, the default action for that port is to deny all traffic that is not explicitly permitted on the port:

- If you want to tightly control access, configure ACLs consisting of permit entries for the access you want to permit. The ACLs implicitly deny all other access.
- If you want to secure access in environments with many users, you might want to configure ACLs that consist of explicit deny entries, then add an entry to permit all access to the end of each ACL. The software permits packets that are not denied by the deny entries.

NOTE
Do not apply an empty ACL (an ACL ID without any corresponding entries) to an interface. If you accidentally do this, the software applies the default ACL action, deny all, to the interface and thus denies all traffic.

Types of IP ACLs

IP ACLs can be configured as standard or extended ACLs. A standard ACL permits or denies packets based on source IP address. An extended ACL permits or denies packets based on source and destination IP address and also based on IP protocol information.

Standard or extended ACLs can be numbered or named. Standard numbered ACLs have an ID of 1 – 99. Extended numbered ACLs are numbered 100 – 199. IDs for standard or extended ACLs can be a character string. In this document, an ACL with a string ID is called a named ACL.

ACL IDs and entries

ACLs consist of ACL IDs and ACL entries:

- **ACL ID** – An IPv4 ACL ID is a number from 1 – 99 (for a standard ACL) or 100 – 199 (for an extended ACL) or a character string. The ACL ID identifies a collection of individual ACL entries. When you apply ACL entries to an interface, you do so by applying the ACL ID that contains the ACL entries to the interface, instead of applying the individual entries to the interface. This makes applying large groups of access filters (ACL entries) to interfaces simple.
- **ACL entry** – An ACL entry are the filter commands associated with an ACL ID. These are also called “statements”. The maximum number of ACL entries you can configure is a system-wide parameter and depends on the PowerConnect you are configuring. You can configure up to the maximum number of entries in any combination in different ACLs. The total number of entries in all ACLs cannot exceed the system maximum.

You configure ACLs on a global basis, then apply them to the incoming or outgoing traffic on specific ports. You can apply only one ACL to a port's inbound traffic and only one ACL to a port's outbound traffic. The software applies the entries within an ACL in the order they appear in the ACL's configuration. As soon as a match is found, the software takes the action specified in the ACL entry (permit or deny the packet) and stops further comparison for that packet.

Enabling support for additional ACL statements

You can enable support for up to 40,960 ACL statements. To enable the PowerConnect to support 40,960 ACL entries, enter the following command at the Global CONFIG level of the CLI.

```
NetIron(config)# system-max ip-filter-sys 40960
```

Syntax: [no] system-max ip-filter-sys <*num*>

You can load ACLs dynamically by saving them in an external configuration file on flash card or TFTP server, then loading them using one of the following commands:

- **copy slot1 | slot2 running** <*from-name*>
- **ncopy slot1 | slot2** <*from-name*> **running**
- **copy tftp running-config** <*ip-addr*> <*filename*>
- **ncopy tftp** <*ip-addr*> <*from-name*> **running-config**

In this case, the ACLs are added to the existing configuration.

Configuring numbered and named ACLs

When you configure IPv4 ACLs, you can refer to the ACL by a numeric ID or by an alphanumeric name. The commands to configure numbered ACLs are different from the commands for named ACLs:

- If you refer to the ACL by a numeric ID, you can use 1 – 99 for a standard ACL or 100 – 199 for an extended ACL. This document refers to this ACL as *numbered ACL*.
- If you refer to the ACL by a name, you specify whether the ACL is a standard ACL or an extended ACL, then specify the name. This document refers to this ACL type as *named ACL*.

You can configure up to 99 standard numbered IP ACLs and 100 extended numbered IP ACLs. You also can configure up to 100 named ACLs and 500 extended named ACLs by number.

Configuring standard numbered ACLs

The following section describes how to configure standard numbered IPv4 ACLs with numeric IDs:

- For configuration information on named ACLs, refer to "Configuring standard or extended named ACLs" on page 800.
- For configuration information on extended ACLs, refer to "Configuring extended numbered ACLs" on page 791.

Standard ACLs permit or deny packets based on source IP address. You can configure up to 99 standard ACLs. There is no limit to the number of ACL entries an ACL can contain except for the system-wide limitation. For the number of ACL entries supported on a PowerConnect, refer to "ACL IDs and entries" on page 788.

To configure a standard ACL and apply it to inbound traffic on port 1/1, enter the following commands.

```
NetIron(config)# access-list 1 deny host 209.157.22.26
NetIron(config)# access-list 1 deny 209.157.29.12
NetIron(config)# access-list 1 deny host IPHost1
NetIron(config)# access-list 1 permit any
NetIron(config)# int eth 1/1
NetIron(config-if-e10000-1/1)# ip access-group 1 in
NetIron(config)# write memory
```

The commands in this example configure an ACL to deny incoming packets from three source IP addresses from being forwarded on port 1/1. The last ACL entry in this ACL permits all packets that are not explicitly denied by the first three ACL entries.

Standard ACL syntax

Syntax: [no] access-list <*num*> **deny | permit** <*source-ip*> **|** <*hostname*> <*wildcard*>

or

Syntax: [no] access-list <*num*> **deny | permit** <*source-ip*>/<*mask-bits*> **|** <*hostname*>

Syntax: [no] access-list <*num*> **deny | permit host** <*source-ip*> **|** <*hostname*>

Syntax: [no] access-list <*num*> **deny | permit any**

Syntax: [no] ip access-group <*num*> **in**

Parameters to configure standard ACL statements

<*num*>	Enter 1 – 99 for a standard ACL.
deny | permit	Enter **deny** if the packets that match the policy are to be dropped; **permit** if they are to be forwarded.
<*source-ip*> | <*hostname*>	Specify the source IP address for the policy. Alternatively, you can specify the host name. If you want the policy to match on all source addresses, enter **any**.

NOTE
To specify the host name instead of the IP address, the host name must be configured using the **ip dns server-address...** command at the global CONFIG level of the CLI.

<*wildcard*>	Specifies the portion of the source IP host address to match against. The <*wildcard*> is a four-part value in dotted-decimal notation (IP address format) consisting of ones and zeros. Zeros in the mask mean the packet's source address must match the <*source-ip*>. Ones mean any value matches. For example, the <*source-ip*> and <*wildcard*> values 209.157.22.26 0.0.0.255 mean that all hosts in the Class C subnet 209.157.22.x match the policy. If you prefer to specify the wildcard (mask value) in Classless Interdomain Routing (CIDR) format, you can enter a forward slash after the IP address, then enter the number of significant bits in the mask. For example, you can enter the CIDR equivalent of "209.157.22.26 0.0.0.255" as "209.157.22.26/24". The CLI automatically converts the CIDR number into the appropriate ACL mask (where zeros instead of ones are the significant bits) and changes the non-significant portion of the IP address into zeros. For example, if you specify 209.157.22.26/24 or 209.157.22.26 0.0.0.255, then save the changes to the startup-config file, the value appears as 209.157.22.0/24 (if you have enabled display of subnet lengths) or 209.157.22.0 0.0.0.255 in the startup-config file. If you enable the software to display IP subnet masks in CIDR format, the mask is saved in the file in "/<*mask-bits*>" format. You can use the CIDR format to configure the ACL entry regardless of whether the software is configured to display the masks in CIDR format. **NOTE** If you use the CIDR format, the ACL entries appear in this format in the running-config and startup-config files, but are shown with subnet mask in the display produced by the **show access-list** command.
host <*source-ip*> | <*hostname*>	Specify a host IP address or name. When you use this parameter, you do not need to specify the mask. A mask of all zeros (0.0.0.0) is implied.
any	Use this parameter to configure the policy to match on all host addresses.

Parameters to bind standard ACLs to an interface

Use the **ip access-group** command to bind the ACL to an inbound interface and enter the ACL number for <*num*>.

Configuring extended numbered ACLs

This section describes how to configure extended numbered IPv4 ACLs:

- For configuration information on named ACLs, refer to "Configuring numbered and named ACLs" on page 789.
- For configuration information on standard ACLs, refer to "Configuring standard numbered ACLs" on page 789.

Extended ACLs let you permit or deny packets based on the following information:

- IP protocol

- Source IP address or host name
- Destination IP address or host name
- Source TCP or UDP port (if the IP protocol is TCP or UDP)
- Destination TCP or UDP port (if the IP protocol is TCP or UDP)

The IP protocol can be one of the following well-known names or any IP protocol number from 0 – 255:

- Internet Control Message Protocol (ICMP)
- Internet Group Management Protocol (IGMP)
- Internet Gateway Routing Protocol (IGRP)
- Internet Protocol (IP)
- Open Shortest Path First (OSPF)
- Transmission Control Protocol (TCP)
- User Datagram Protocol (UDP)

For TCP and UDP, you also can specify a comparison operator and port name or number. For example, you can configure a policy to block web access to a specific website by denying all TCP port 80 (HTTP) packets from a specified source IP address to the website's IP address.

To configure an extended access list that blocks all Telnet traffic received on port 1/1 from IP host 209.157.22.26, create the ACL with permit and deny rules, then bind the ACL to port 1/1 using the **ip access-group** command. Enter the following commands.

```
NetIron(config)# access-list 101 deny tcp host 209.157.22.26 any eq telnet
NetIron(config)# access-list 101 permit ip any any
NetIron(config)# int eth 1/1
NetIron(config-if-e10000-1/1)# ip access-group 101 in
NetIron(config)# write memory
```

Here is another example of commands for configuring an extended ACL and applying it to an interface. These examples show many of the syntax choices.

```
NetIron(config)# access-list 102 perm icmp 209.157.22.0/24 209.157.21.0/24
NetIron(config)# access-list 102 deny igmp host rkwong 209.157.21.0/24
NetIron(config)# access-list 102 deny igrp 209.157.21.0/24 host rkwong
NetIron(config)# access-list 102 deny ip host 209.157.21.100 host 209.157.22.1
NetIron(config)# access-list 102 deny ospf any any
NetIron(config)# access-list 102 permit ip any any
```

The first entry permits ICMP traffic from hosts in the 209.157.22.x network to hosts in the 209.157.21.x network.

The second entry denies IGMP traffic from the host PowerConnect named "rkwong" to the 209.157.21.x network.

The third entry denies IGRP traffic from the 209.157.21.x network to the host PowerConnect named "**rkwong**".

The fourth entry denies all IP traffic from host 209.157.21.100 to host 209.157.22.1.

The fifth entry denies all OSPF traffic.

The sixth entry permits all packets that are not explicitly denied by the other entries. Without this entry, the ACL would deny all incoming or outgoing IP traffic on the ports to which you assign the ACL.

The following commands apply ACL 102 to the incoming traffic on port 1/2 and to the outgoing traffic on port 4/3.

```
NetIron(config)# int eth 1/2
NetIron(config-if-e10000-1/2)# ip access-group 102 in
NetIron(config-if-e10000-1/2)# exit
NetIron(config)# int eth 4/3
NetIron(config-if-e10000-4/3)# ip access-group 102 out
NetIron(config)# write memory
```

Here is another example of an extended ACL.

```
NetIron(config)# access-list 103 deny tcp 209.157.21.0/24 209.157.22.0/24
NetIron(config)# access-list 103 deny tcp 209.157.21.0/24 eq ftp 209.157.22.0/24
NetIron(config)# access-list 103 deny tcp 209.157.21.0/24 209.157.22.0/24 lt
telnet neq 5
NetIron(config)# access-list 103 deny udp any range 5 6 209.157.22.0/24 range 7 8
NetIron(config)# access-list 103 permit ip any any
```

The first entry in this ACL denies TCP traffic from the 209.157.21.x network to the 209.157.22.x network.

The second entry denies all FTP traffic from the 209.157.21.x network to the 209.157.22.x network.

The third entry denies TCP traffic from the 209.157.21.x network to the 209.157.22.x network, if the TCP port number of the traffic is less than the well-known TCP port number for Telnet (23), and if the TCP port is not equal to 5. Thus, TCP packets whose TCP port numbers are 5 or are greater than 23 are allowed.

The fourth entry denies UDP packets from any source to the 209.157.22.x network, if the UDP port number from the source network is 5 or 6 and the destination UDP port is 7 or 8.

The fifth entry permits all packets that are not explicitly denied by the other entries. Without this entry, the ACL would deny all incoming or outgoing IP traffic on the ports to which you assign the ACL.

The following commands apply ACL 103 to the incoming and outgoing traffic on ports 2/1 and 2/2.

```
NetIron(config)# int eth 2/1
NetIron(config-if-e10000-2/1)# ip access-group 103 in
NetIron(config-if-e10000-2/1)# ip access-group 103 out
NetIron(config-if-e10000-2/1)# exit
NetIron(config)# int eth 2/2
NetIron(config-if-e10000-2/2)# ip access-group 103 in
NetIron(config-if-e10000-2/2)# ip access-group 103 out
NetIron(config)# write memory
```

Extended ACL syntax

This section presents the syntax for creating an extended IPv4 ACL and for binding the ACL to an interface. Use the **ip access-group** command in the interface level to bind the ACL to an interface.

Syntax: [no] **access-list** <*num*> **deny | permit** <*ip-protocol*>
<*source-ip*> **|** <*hostname*> <*wildcard*>
[<*operator*> <*source-tcp/udp-port*>]
<*destination-ip*> **|** <*hostname*> <*wildcard*>
[<*operator*> <*destination-tcp/udp-port*>]
[<*icmp-type*>] [**established**] [**precedence** <*name*> **|** <*num*>]

[**tos** <*number*>] [**dscp-mapping** <*number*>]
[**dscp-marking** <*number*>] | [**fragment**] [**non-fragment**]
[**option value | name | keyword**] [**priority** <*priority-value*> | **priority-force** <*priority-value*> | **priority-mapping** <*priority-value*>] [**mirror**]

Syntax: [**no**] **access-list** <*num*> **deny | permit host** <*ip-protocol*> **any any**

Syntax: [**no**] **ip access-group** <*num*> **in | out**

General parameters for extended ACLs

The following parameters apply to any extended ACL you are creating.

<*num*>	Enter 100 – 199 for an extended ACL.
deny | permit	Enter **deny** if the packets that match the policy are to be dropped; **permit** if they are to be forwarded.
<*ip-protocol*>	Indicate the type of IP packet you are filtering. You can specify a well-known name for any protocol whose number is less than 255. For other protocols, you must enter the number. Enter "?" instead of a protocol to list the well-known names recognized by the CLI.
<*source-ip*> | <*hostname*>	Specify the source IP host for the policy. If you want the policy to match on all source addresses, enter **any**.
<*wildcard*>	Specifies the portion of the source IP host address to match against. The <*wildcard*> is a four-part value in dotted-decimal notation (IP address format) consisting of ones and zeros. Zeros in the mask mean the packet's source address must match the <*source-ip*>. Ones mean any value matches. For example, the <*source-ip*> and <*wildcard*> values 209.157.22.26 0.0.0.255 mean that all hosts in the Class C subnet 209.157.22.x match the policy. If you prefer to specify the wildcard (mask value) in Classless Interdomain Routing (CIDR) format, you can enter a forward slash after the IP address, then enter the number of significant bits in the mask. For example, you can enter the CIDR equivalent of "209.157.22.26 0.0.0.255" as "209.157.22.26/24". The CLI automatically converts the CIDR number into the appropriate ACL mask (where zeros instead of ones are the significant bits) and changes the non-significant portion of the IP address into zeros. For example, if you specify 209.157.22.26/24 or 209.157.22.26 0.0.0.255, then save the changes to the startup-config file, the value appears as 209.157.22.0/24 (if you have enabled display of subnet lengths) or 209.157.22.0 0.0.0.255 in the startup-config file. The IP subnet masks in CIDR format is saved in the file in "/<*mask-bits*>" format. If you use the CIDR format, the ACL entries appear in this format in the running-config and startup-config files, but are shown with subnet mask in the display produced by the **show access-list** command.
<*destination-ip*> | <*hostname*>	Specify the destination IP host for the policy. If you want the policy to match on all destination addresses, enter **any.**

fragment	Enter this keyword if you want to filter fragmented packets. Refer to "Enabling ACL filtering of fragmented or non-fragmented packets" on page 810.
	NOTE The **fragmented** and **non-fragmented** parameters cannot be used together in an ACL entry.
non-fragment	Enter this keyword if you want to filter non-fragmented packets. Refer to "Enabling ACL filtering of fragmented or non-fragmented packets" on page 810.
	NOTE The **fragmented** and **non-fragmented** parameters cannot be used together in an ACL entry.
priority | priority-force | priority-mapping	• The **Priority** option assigns internal priority to traffic that matches the ACL. In addition to changing the internal forwarding priority, if the outgoing interface is an 802.1q interface, this option maps the specified priority to its equivalent 802.1p (QoS) priority and marks the packet with the new 802.1p priority. This option is applicable for inbound ACLs only. • The **Priority-force** option assigns internal priority to packets of traffic that match the ACL, even though the incoming packet may be assigned a higher priority. This option is applicable for inbound ACLs only. • The **priority-mapping** option matches on the packet's 802.1p value. This option does not change the packet's forwarding priority through the device or mark the packet. This keyword is applicable for both inbound and outbound ACLs.
<*priority-value*>	The <*priority-value*> variable specifies one of the following QoS queues for use with the **priority, priority-force** or **priority-mapping** options: • 0 – qosp0 • 1 – qosp1 • 2 – qosp2 • 3 – qosp3 • 4 – qosp4 • 5 – qosp5 • 6 – qosp6 • 7 – qosp7
mirror	Specifies mirror packets matching ACL permit clause. For more information on configuring the **acl-mirror-port** command, refer to "ACL-based inbound mirroring" on page 148.

Parameters to filter TCP or UDP packets

Use the parameters below if you want to filter traffic with the TCP or UDP packets. These parameters apply only if you entered **tcp** or **udp** for the <*ip-protocol*> parameter. For example, if you are configuring an entry for HTTP, specify **tcp eq http**.

<operator> Specifies a comparison operator for the TCP or UDP port number. You can enter one of the following operators:

- **eq** – The policy applies to the TCP or UDP port name or number you enter after **eq**.
- **gt** – The policy applies to TCP or UDP port numbers greater than the port number or the numeric equivalent of the port name you enter after **gt**.
- **lt** – The policy applies to TCP or UDP port numbers that are less than the port number or the numeric equivalent of the port name you enter after **lt**.
- **neq** – The policy applies to all TCP or UDP port numbers except the port number or port name you enter after **neq**.
- **range** – The policy applies to all TCP or UDP port numbers that are between the first TCP or UDP port name or number and the second one you enter following the **range** parameter. The range includes the port names or numbers you enter. For example, to apply the policy to all ports between and including 23 (Telnet) and 53 (DNS), enter the following: **range 23 53**. The first port number in the range must be lower than the last number in the range.
- **established** – This operator applies only to TCP packets. If you use this operator, the policy applies to TCP packets that have the ACK (Acknowledgment) or RST (Reset) bits set on (set to "1") in the Control Bits field of the TCP packet header. Thus, the policy applies only to established TCP sessions, not to new sessions. Refer to Section 3.1, "Header Format", in RFC 793 for information about this field.

NOTE
This operator applies only to destination TCP ports, not source TCP ports.

<source-tcp/udp-port> Enter the source TCP or UDP port number.

<destination-tcp/udp-port> Enter the destination TCP or UDP port number.

Filtering traffic with ICMP packets

Use the following parameters if you want to filter traffic that contains ICMP packets. These parameters apply only if you specified **icmp** as the *<ip-protocol>* value.

<icmp-type> Enter one of the following values, depending on the software version the PowerConnect is running:

- any-icmp-type
- echo
- echo-reply
- information-request
- mask-reply
- mask-request
- parameter-problem
- redirect
- source-quench
- time-exceeded
- timestamp-reply
- timestamp-request
- unreachable
- *<num>*

NOTE
If the ACL is for the inbound traffic direction on a virtual routing interface, you also can specify a subset of ports within the VLAN containing that interface when assigning an ACL to the interface. Refer to "Configuring numbered and named ACLs" on page 789.

precedence <*name*> | <*num*>

The precedence option for of an IP packet is set in a three-bit field following the four-bit header-length field of the packet's header.

NOTE

You can specify one of the following name or number:

- **critical** or **5** – The ACL matches packets that have the critical precedence. If you specify the option number instead of the name, specify number 5.
- **flash** or **3** – The ACL matches packets that have the flash precedence. If you specify the option number instead of the name, specify number 3.
- **flash-override** or **4** – The ACL matches packets that have the flash override precedence. If you specify the option number instead of the name, specify number 4.
- **immediate** or **2** – The ACL matches packets that have the immediate precedence. If you specify the option number instead of the name, specify number 2.
- **internet** or **6** – The ACL matches packets that have the internetwork control precedence. If you specify the option number instead of the name, specify number 6.
- **network** or **7** – The ACL matches packets that have the network control precedence. If you specify the option number instead of the name, specify number 7.
- **priority** or **1** – The ACL matches packets that have the priority precedence. If you specify the option number instead of the name, specify number 1.
- **routine** or **0** – The ACL matches packets that have the routine precedence. If you specify the option number instead of the name, specify number 0.

Using ACL QoS options to filter packets

You can filter packets based on their QoS values by entering values for the following parameters:

tos <*name*> | <*num*> Specify the IP ToS name or number.

You can specify one of the following:

- **max-reliability** or **2** – The ACL matches packets that have the maximum reliability ToS. The decimal value for this option is 2.
- **max-throughput** or **4** – The ACL matches packets that have the maximum throughput ToS. The decimal value for this option is 4.
- **min-delay** or **8** – The ACL matches packets that have the minimum delay ToS. The decimal value for this option is 8.
- **normal** or **0** – The ACL matches packets that have the normal ToS. The decimal value for this option is 0.
- <*num*> – A number from 0 – 15 that is the sum of the numeric values of the options you want. The ToS field is a four-bit field following the Precedence field in the IP header. You can specify one or more of the following. To select more than one option, enter the decimal value that is equivalent to the sum of the numeric values of all the ToS options you want to select. For example, to select the **max-reliability** and **min-delay** options, enter number 10. To select all options, select 15.

dscp-mapping <*number*> The ACL matches packets on the DSCP value. This option does not change the packet's forwarding priority through the device or mark the packet.

Parameters to mark the DSCP value in a packet

Specify the DSCP value to a packet by entering the following parameter:

Use **dscp-marking** <*number*> to mark the DSCP value in the incoming packet with the value you specify. **Dscp-marking** is not supported on outbound ACLs.

Parameters to bind standard ACLs to an interface

Use the **ip access-group** command to bind the ACL to an interface and enter the ACL number for <*num*>.

Parameters to filter IP option packets

You can filter IP Option traffic based upon the content of the IP option field in the IP header.

<*value*> You can match based upon a specified IP Option value. Values between 1 - 255 can be used.

<*keyword*> You can use the **any** keyword to match packets with IP Options or use the **ignore** keyword to match packets with or without IP Options.

NOTE
If you are configuring a filter to permit/deny rsvp or igmp packets, it will ignore IP options within the packet by default.

<*name*> You can match by using any of the following well-known options by name:

eol – Matches IP Option packets that contain the eol option.

extended-security – Matches IP Option packets that contain the extended security option.

loose-source-route – Matches IP Option packets that contain the loose source route option.

no-op – Matches IP Option packets that contain the no-op option.

record-route – Matches IP Option packets that contain the record route option.

router-alert – Matches IP Option packets that contain the router alert option.

security – Matches IP Option packets that contain the security option.

streamid – Matches IP Option packets that contain the stream id option.

strict-source-route – Matches IP Option packets that contain the strict source route option.

timestamp – Matches IP Option packets that contain the timestamp option.

Please note, the behavior of an implicit **deny ip any any** ACL filter is different than that of an explicit **deny ip any any** filter as described in the following:

- Explicit **deny ip any any** will only apply to non-option packets.
- Explicit **deny ip any any option ignore** will apply to both option and non-option packets
- Implicit **deny ip any any** will apply to both option and non-option packets

Configuring standard or extended named ACLs

The commands for configuring named ACL entries are different from the commands for configuring numbered ACL entries. The command to configure a numbered ACL is **access-list**. The command for configuring a named ACL is **ip access-list**. In addition, when you configure a numbered ACL entry, you specify all the command parameters on the same command. When you configure a named ACL, you specify the ACL type (standard or extended) and the ACL name with one command, which places you in the configuration level for that ACL. Once you enter the configuration level for the ACL, the command syntax is the same as the syntax for numbered ACLs.

The following examples show how to configure a named standard ACL entry and a named extended ACL entry.

Configuration example for standard ACL

To configure a named standard ACL entry, enter commands such as the following.

```
NetIron(config)# ip access-list standard Net1
NetIron(config-std-nacl)# deny host 209.157.22.26
NetIron(config-std-nacl)# deny 209.157.29.12
NetIron(config-std-nacl)# deny host IPHost1
NetIron(config-std-nacl)# permit any
NetIron(config-std-nacl)# exit
NetIron(config)# int eth 1/1
NetIron(config-if-e10000-1/1)# ip access-group Net1 in
```

The commands in this example configure a standard ACL named "Net1". The entries in this ACL deny packets from three source IP addresses from being forwarded on port 1/1. Since the implicit action for an ACL is "deny", the last ACL entry in this ACL permits all packets that are not explicitly denied by the first three ACL entries. For an example of how to configure the same entries in a numbered ACL, refer to "Configuring standard numbered ACLs" on page 789.

Notice that the command prompt changes after you enter the ACL type and name. The "std" in the command prompt indicates that you are configuring entries for a standard ACL. For an extended ACL, this part of the command prompt is "ext". The "nacl" indicates that are configuring a named ACL.

Syntax: **[no] ip access-list standard** <*string*> **|** <*num*>

Syntax: **[no] ip access-list standard** <*string*> **|** <*num*> **deny | permit** <*source-ip*> **|** <*hostname*> <*wildcard*>

or

Syntax: **[no] ip access-list standard** <*string*> **|** <*num*> **deny | permit** <*source-ip*>**/**<*mask-bits*> **|** <*hostname*>

Syntax: **[no] ip access-list standard** <*string*> **|** <*num*> **deny | permit host** <*source-ip*> **|** <*hostname*>

Syntax: **[no] ip access-list standard** <*string*> **|** <*num*> **deny | permit any**

Syntax: **[no] ip access-group** <*num*> **in**

The **standard** parameter indicates the ACL type.

The <*string*> parameter is the ACL name. You can specify a string of up to 256 alphanumeric characters. You can use blanks in the ACL name if you enclose the name in quotation marks (for example, "ACL for Net1"). The <*num*> parameter allows you to specify an ACL number if you prefer. If you specify a number, you can specify from 1 – 99 for standard ACLs or 100 – 199 for extended ACLs.

NOTE

For convenience, the software allows you to configure numbered ACLs using the syntax for named ACLs. The software also still supports the older syntax for numbered ACLs. Although the software allows both methods for configuring numbered ACLs, numbered ACLs are always formatted in the startup-config and running-config files in using the older syntax, as follows.

```
access-list 1 deny host 209.157.22.26
access-list 1 deny 209.157.22.0 0.0.0.255
access-list 1 permit any
access-list 101 deny tcp any any eq http
```

The options at the ACL configuration level and the syntax for the **ip access-group** command are the same for numbered and named ACLs and are described in "Configuring standard numbered ACLs" on page 789.

Configuration example for extended ACL

To configure a named extended ACL entry, enter commands such as the following.

```
NetIron(config)# ip access-list extended "block Telnet"
NetIron(config-ext-nacl)# deny tcp host 209.157.22.26 any eq telnet
NetIron(config-ext-nacl)# permit ip any any
NetIron(config-ext-nacl)# exit
NetIron(config)# int eth 1/1
NetIron(config-if-e10000-1/1)# ip access-group "block Telnet" in
```

NOTE

The command prompt changes after you enter the ACL type and name. The "ext" in the command prompt indicates that you are configuring entries for an extended ACL. The "nacl" indicates that are configuring a named ACL.

Syntax: **[no] ip access-list extended** <*string*> **|** <*num*>

Syntax: **[no] deny | permit** <*ip-protocol*>
<*source-ip*> **|** <*hostname*> <*wildcard*>
[<*operator*> <*source-tcp/udp-port*>]
<*destination-ip*> **|** <*hostname*> <*wildcard*>
[<*operator*> <*destination-tcp/udp-port*>]
[<*icmp-type*>] **[established] [precedence** <*name*> **|** <*num*>]
[tos <*number*>] **[dscp-mapping** <*number*>]
[fragment] [non-fragment]

Syntax: **[no] ip access-list extended** <*string*> **|** <*num*>

Syntax: **[no] deny | permit host** <*ip-protocol*> **any any**

Syntax: **[no] ip access-group** <*string*> **|** <*num*> **in I out**

The options at the ACL configuration level and the syntax for the **ip access-group** command are the same for numbered and named ACLs and are described in "Configuring extended numbered ACLs" on page 791.

Displaying ACL definitions

To display the ACLs configured on a PowerConnect, use the **show access-list** command.

Numbered ACL

For a numbered ACL, you can enter a command such as the following.

```
NetIron(config)#show access-list 99
ACL configuration:
!
Standard IP access list 10
access-list 99 deny host 10.10.10.1
access-list 99 permit any
```

Syntax: **show access-list** <*number*> **| all**

Enter the ACL's number for the <*number*> parameter:

- 1 – 99 for standard ACLs
- 100 – 199 for extended ACLs

Enter **all** if you want to display all the ACLs configured on the device.

Named ACL

For a named ACL, enter a command such as the following.

```
NetIron(config)#show access-list name entry

Standard IP access list entry
deny host 5.6.7.8
deny host 192.168.12.3
permit any
```

Syntax: show access-list name <*acl-name*>

The ACL's name for the <*acl-name*> parameter or the ACL's number for <*acl-number*>.

Modifying ACLs

When you configure any ACL, the software places the ACL entries in the ACL in the order you enter them. For example, if you enter the following entries in the order shown below, the software always applies the entries to traffic in the same order.

```
NetIron(config)#access-list 1 deny 209.157.22.0/24
NetIron(config)#access-list 1 permit 209.157.22.26
```

Thus, if a packet matches the first ACL entry in this ACL and is therefore denied, the software does not compare the packet to the remaining ACL entries. In this example, packets from host 209.157.22.26 will always be dropped, even though packets from this host match the second entry.

You can use the CLI to reorder entries within an ACL by individually removing the ACL entries and then re-adding them. To use this method, enter "**no**" followed by the command for an ACL entry, and repeat this for each ACL entry in the ACL you want to edit. After removing all the ACL entries from the ACL, re-add them.

This method works well for small ACLs such as the example above, but can be impractical for ACLs containing many entries. Therefore, the PowerConnect provides an alternative method. The alternative method lets you upload an ACL list from a TFTP server and replace the ACLs in the PowerConnect's running-config file with the uploaded list. Thus, to change an ACL, you can edit the ACL on the file server, then upload the edited ACL to the PowerConnect. You then can save the changed ACL to the PowerConnect's startup-config file.

ACL lists contain only the ACL entries themselves, not the assignments of ACLs to interfaces. You must assign the ACLs on the PowerConnect itself.

NOTE
The only commands that are valid in the ACL list are the **access-list** and **end** commands; other commands are ignored.

Modify an ACL by configuring an ACL list on a file server.

1. Use a text editor to create a new text file. When you name the file, use 8.3 format (up to eight characters in the name and up to three characters in the extension).

NOTE
Make sure the PowerConnect has network access to the TFTP server.

2. Optionally, clear the ACL entries from the ACLs you are changing by placing commands such as the following at the top of the file.

```
NetIron(config)#no access-list 1
NetIron(config)#no access-list 101
```

When you load the ACL list into the PowerConnect, the software adds the ACL entries in the file after any entries that already exist in the same ACLs. Thus, if you intend to entirely replace an ACL, you must use the **no access-list** <*num*> command to clear the entries from the ACL before the new ones are added.

3. Place the commands to create the ACL entries into the file. The order of the separate ACLs does not matter, but the order of the entries within each ACL is important. The software applies the entries in an ACL in the order they are listed within the ACL. Here is an example of some ACL entries.

```
NetIron(config)#access-list 1 deny host 209.157.22.26
NetIron(config)#access-list 1 deny 209.157.22.0 0.0.0.255
NetIron(config)#access-list 1 permit any
NetIron(config)#access-list 101 deny tcp any any eq http
```

The software will apply the entries in ACL 1 in the order shown and stop at the first match. Thus, if a packet is denied by one of the first three entries, the packet will not be permitted by the fourth entry, even if the packet matches the comparison values in this entry.

4. Enter the command "**end**" on a separate line at the end of the file. This command indicates to the software that the entire ACL list has been read from the file.
5. Save the text file.
6. On the PowerConnect, enter the following command at the Privileged EXEC level of the CLI:

copy tftp running-config <*tftp-ip-addr*> <*filename*>

NOTE
This command will be unsuccessful if you place any commands other than **access-list** and **end** (at the end only) in the file. These are the only commands that are valid in a file you load using the **copy tftp running-config...** command.

7. To save the changes to the PowerConnect's startup-config file, enter the following command at the Privileged EXEC level of the CLI:

write memory

NOTE
Do not place other commands in the file. The PowerConnect reads only the ACL information in the file and ignores other commands, including **ip access-group** commands. To assign ACLs to interfaces, use the CLI.

Adding or deleting a comment

You can add or delete comments to an IP ACL entry.

Numbered ACLs: Adding a comment

To add a comment to an ACL entry in a numbered IPv4 ACL, perform the tasks listed below.

1. Use the **show access-list** to display the entries in an ACL.

   Example

   ```
   NetIron(config-std-nacl)# show access-list 99
   Standard IP access-list 99
   deny host 1.2.4.5
   permit host 5.6.7.8
   ```

2. To add the comment "Permit all users" to filter “permit any” (the ACL remark is attached to the filter “permit any” as instructed in Step 4). Enter a command such as the following.

   ```
   NetIron(config)# access-list 99 remark Permit all users
   ```

3. Entering a **show access-list** command displays the following:

   ```
   NetIron(config-std-nacl)# show access-list 99
   Standard IP access-list 99
   deny host 1.2.4.5
   permit host 5.6.7.8

   ACL Remarks: Permit all users
   ```

4. Enter the filter “permit any”.

   Example

   ```
   NetIron (config-std-nacl)# permit any
   ```

5. Entering a **show access-list** command displays the following.

   ```
   NetIron(config-std-nacl)# show access-list 99
   Standard IP access-list 99
   deny host 1.2.4.5
   permit host 5.6.7.8
   ACL Remarks: Permit all users
   permit any
   ```

Syntax: [no] access-list <*acl-num*> **remark** <*comment-text*>

Simply entering **access-list** <*acl-num*> **remark** <*comment-text*> adds a remark to the next ACL entry you create.

The **remark** <*comment-text*> adds a comment to the ACL entry. The remark can have up to 128 characters in length. The comment must be entered separately from the actual ACL entry; that is, you cannot enter the ACL entry and the ACL comment with the same command. Also, in order for the remark to be displayed correctly in the output of **show** commands, the comment must be entered immediately before the ACL entry it describes.

NOTE
An ACL remark is attached to each individual filter only, not to the entire ACL (ACL 199).

Complete the syntax by specifying any options you want for the ACL entry. Options you can use to configure standard or extended numbered ACLs are discussed in "Configuring standard or extended named ACLs" on page 800.

Numbered ACLs: deleting a comment

For example, if the remark "Permit all users" has been defined for ACL 99, remove the remark by entering the following command.

```
NetIron(config)# no access-list 99 remark Permit all users
```

Syntax: [no] access-list <*number*> **remark** <*comment-text*>

Named ACLs: adding a comment to a new ACL

You can add a comment to an ACL by performing the tasks listed below.

1. Use the **show access-list** command to display the contents of the ACL. For example, you may have an ACL named "entry" and a **show access-list** command shows that it has only one entry.

```
NetIron(config)# show access-list name entry
Standard IP access-list 99
deny host 1.2.4.5
```

2. Add a new entry with a remark to this named ACL by entering commands such as the following:

```
NetIron(config)#ip access-list standard entry
NetIron(config-std-nacl)# remark Deny traffic from Marketing
NetIron(config-std-nacl)# deny 5.6.7.8
```

3. Enter a **show access-list** command displays the new ACL entry with its remark.

```
NetIron(config)# show access-list name entry
Standard IP access-list entry
deny host 1.2.4.5
ACL remark: Deny traffic from Marketing
deny host 5.6.7.8
```

Syntax: [no] ip access-list standard | extended <*acl-name*>

Syntax: [no] remark <*string*>

Syntax: [no] deny <*options*> **| permit** <*options*>

The **standard | extended** parameter indicates the ACL type.

The <*acl-name*> parameter is the IPv4 ACL name. You can specify a string of up to 256 alphanumeric characters. You can use blanks in the ACL name if you enclose the name in quotation marks (for example, "ACL for Net1"). The <*acl-num*> parameter allows you to specify an ACL number if you prefer. If you specify a number, enter a number from 1 – 99 for standard ACLs or 100 – 199 for extended ACLs.

The **remark** <*string*> adds a comment to the ACL entry that you are about to create. The comment can have up to 128 characters in length. The comment must be entered separately from the actual ACL entry; that is, you cannot enter the ACL entry and the ACL comment with the same command. Also, in order for the remark to be displayed correctly in the output of show commands, the comment must be entered immediately before the ACL entry it describes.

Enter **deny** to deny the specified traffic or **permit** to allow the specified traffic. Complete the configuration by specifying <*options*> for the standard or extended ACL entry. Options you can use to configure standard or extended named ACLs are discussed in the section "Configuring standard or extended named ACLs" on page 800.

Named ACLs: deleting a comment

To delete a remark from a named ACL, enter the following command.

```
NetIron(config)#ip access-list standard entry
NetIron(config-std-nacl)#no remark Deny traffic from Marketing
```

Syntax: no remark <*string*>

Deleting ACL entries

Newly created ACL entries are appended to the end of the ACL list. Since ACL entries are applied to data packets in the order they appear in a list, you needed to create ACLs in the order you want them applied.

Deleting entries from numbered ACLs

If you want to delete the second entry from a numbered ACL such as ACL 99, perform the tasks listed below.

1. Display the contents of the list.

```
NetIron(config)#show access-list 99
Standard IP access-list 99
deny host 1.2.4.5
deny host 5.6.7.8
permit any
```

2. Enter the following command.

```
NetIron(config)#no access-list 99 deny host 5.6.7.8
```

3. Display the contents of the updated list.

```
NetIron(config)# show ip access-list 99
Standard IP access-list 99
deny host 1.2.4.5
permit any
```

Syntax: no access-list <*acl-number*> **<***entire-deny-or-permit-statement***>**

The <*acl-num*> parameter allows you to specify an ACL number from 1 – 99 for standard ACLs or 100 – 199 for extended ACLs.

You must enter the complete deny or permit statement for the <entire-deny-or-permit-statement> variable.

Complete the configuration by specifying options for the ACL entry. Options you can use to configure standard or extended numbered ACLs are discussed in "Configuring standard numbered ACLs" on page 789 and "Configuring extended numbered ACLs" on page 791.

Deleting entries from named ACLs

To delete an ACL entry from an ACL named "entry", perform the tasks listed below.

1. Enter the following command to display the contents of the ACL list.

```
NetIron#show access-list name entry
Standard IP access list entry
deny host 1.2.4.5
deny host 10.1.1.1
deny host 5.6.7.8
permit any
```

2. To delete the second ACL entry from the list, enter a command such as the following.

```
NetIron(config)#ip access-list standard entry
NetIron(config-std-nacl)#no deny host 10.1.1.1
```

3. Enter the **show access-list name entry** command to display the updated list.

```
NetIron(config)# ip show access entry all
Standard IP access list entry
deny host1.2.4.5
deny host 5.6.7.8
permit any
```

Syntax: [no] ip access-list standard | extended <*acl-name*> **|** <*acl-number*>

Syntax: no <*entire-deny-or-permit-statement***>**

The **extended | standard** parameter indicates the ACL type.

The <*acl-name*> parameter is the IPv4 ACL name. You can specify a string of up to 256 alphanumeric characters. You can use blanks in the ACL name if you enclose the name in quotation marks (for example, “ACL for Net1”). The <*acl-num*> parameter allows you to specify an ACL number if you prefer. If you specify a number, enter a number from 1 – 99 for standard ACLs or 100 – 199 for extended ACLs.

You must enter the complete deny or permit statement for the <entire-deny-or-permit-statement> variable.

Applying ACLs to interfaces

Configuration examples in the section “Configuring numbered and named ACLs” on page 789 show that you apply ACLs to interfaces using the **ip access-group** command. This section present additional information about applying ACLs to interfaces.

Reapplying modified ACLs

If you make an ACL configuration change, you must reapply the ACLs to their interfaces to place the change into effect.

An ACL configuration change includes any of the following:

- Adding, changing, or removing an ACL or an entry in an ACL
- Changing a PBR policy
- Changing ToS-based QoS mappings

To reapply ACLs following an ACL configuration change, enter the following command at the global CONFIG level of the CLI.

```
NetIron(config)# ip rebind-acl all
```

Syntax: [no] ip rebind-acl <*num*> | <*name*> **| all**

Applying ACLs to a virtual routing interface

You can apply an ACL to a virtual routing interface for both inbound and outbound traffic direction on PowerConnect. The virtual interface is used for routing between VLANs and contains all the ports within the VLAN. If the ACL is for the inbound traffic direction, you also can specify a subset of ports within the VLAN containing a specified virtual interface when assigning an ACL to that virtual interface.

Use this feature when you do not want the ACLs to apply to all the ports in the virtual interface's VLAN or when you want to streamline ACL performance for the VLAN.

To apply an ACL to a subset of ports within a virtual interface, enter commands such as the following.

```
NetIron(config)# vlan 10 name IP-subnet-vlan
NetIron(config-vlan-10)# untag ethernet 1/1 to 1/20 ethernet 2/1 to 2/12
NetIron(config-vlan-10)# router-interface ve 1
NetIron(config-vlan-10)# exit
NetIron(config)# access-list 1 deny host 209.157.22.26
NetIron(config)# access-list 1 deny 209.157.29.12
NetIron(config)# access-list 1 deny host IPHost1
NetIron(config)# access-list 1 permit any
NetIron(config)# interface ve 1
NetIron(config-vif-1)# ip access-group 1 in ethernet 1/1 ethernet 1/3 ethernet 2/1
to 2/4
```

The commands in this example configure port-based VLAN 10, add ports 1/1 – 2/12 to the VLAN, and add virtual routing interface 1 to the VLAN. The commands following the VLAN configuration commands configure ACL 1. Finally, the last two commands apply ACL 1 to a subset of the ports associated with virtual interface 1.

Syntax: [no] ip access-group <*num*> **in [ethernet** <*slot*>/<*portnum*> **| pos** <*slot*>/<*portnum*>] [<*slot*>/<*portnum*>**...] to** <*slot*>/<*portnum*>

The **ethernet** <*slot*>/<*portnum*> **| pos** <*slot*>/<*portnum*> options allow you to limit the ACL to a subset of ports within the virtual interface. You can also use the **to** <*slot*>/<*portnum*> option to specify a range of ports. A maximum of 4 port ranges are supported.

Enabling ACL duplication check

If desired, you can enable software checking for duplicate ACL entries. To do so, enter the following command at the Global CONFIG level of the CLI.

```
NetIron(config)# acl-duplication-check
```

Syntax: [no] acl-duplication-check

Enabling ACL conflict check

If desired, you can enable software checking for conflicting ACL entries. To do so, enter the following command at the Global CONFIG level of the CLI.

```
NetIron(config)# acl-conflict-check
```

Syntax: [no] acl-conflict-check

NOTE
This command only checks for conflict between ACL filters that are the same except for the permit/deny keyword.

Enabling ACL filtering of fragmented or non-fragmented packets

To define an extended IPv4 ACL to deny or permit traffic with fragmented or unfragmented packets, enter a command such as those shown in one of the methods below.

Numbered ACLs

```
NetIron(config)# access-list 111 deny ip any any fragment
NetIron(config)# int eth 1/1
NetIron(config-if-e10000-1/1)# ip access-group 111 in
NetIron(config)# write memory
```

The first line in the example defines ACL 111 to deny any fragmented packets. Other packets will be denied or permitted, based on the next filter condition.

Next, after assigning the ACL to Access Group 111, the access group is bound to port 1/1. It will be used to filter incoming traffic.

Refer to "Extended ACL syntax" on page 793 for the complete syntax for extended ACLs.

Named ACLs

```
NetIron(config)# ip access-list extended entry
NetIron(config-ext-nacl)# deny ip any any fragment

NetIron(config)# int eth 1/1
NetIron(config-if-e10000-1/1)# ip access-group entry in
NetIron(config)# write memory
```

The first line in the example defines ACL entry to deny any fragmented packets. Other packets will be denied or permitted, based on the next filter condition.

Next, after assigning the ACL to Access Group entry, the access group is bound to port 1/1. It will be used to filter incoming traffic.

Syntax: **ip access-list extended** <*acl-name*> | <*acl-num*> **deny | permit** <*ip-protocol*> <*source-ip*> | <*hostname*> <*wildcard*> [<*operator*> <*source-tcp/udp-port*>] <*destination-ip*> | <*hostname*> [<*icmp-type*> | <*num*>] <*wildcard*> [<*operator*> <*destination-tcp/udp-port*>] **[precedence** <*name*> | <*num*>] **[tos** <*name*> | <*num*>] **[fragment] | [non-fragmented]**

Enter **extended** to indicate the named ACL is an extended ACL.

The <*acl-name*> | <*acl-num*> parameter allows you to specify an IPv4 ACL name or number. If using a name, specify a string of up to 256 alphanumeric characters. You can use blanks in the ACL name, if you enclose the name in quotation marks (for example, "ACL for Net1"). The <*acl-num*> parameter allows you to specify an ACL number if you prefer. If you specify a number, enter a number from 100 – 199 for extended ACLs.

Enter the **fragment** keyword to allow the ACL to filter fragmented packets. Use the **non-fragmented** keyword to filter non-fragmented packets.

NOTE
The **fragmented** and **non-fragmented** parameters cannot be used together in an ACL entry.

Complete the configuration by specifying options for the ACL entry. Options you can use are discussed in the appropriate sections for configuring ACLs in this chapter.

Configuring the conservative ACL fragment mode

The **acl-frag-conservative** command allows you to change the operation of ACLs on fragmented packets.

When a a packet exceeds the maximum packet size, the packet is fragmented into a number of smaller packets that contain portions of the contents of the original packet. This packet flow begins with an initial packet that contains all of the Layer-3 and Layer-4 header information contained in the original packet and is following by a number of packets that contain only the Layer-3 header information. This packet flow contains all of the information contained in the original packet distributed through the packet flow into packets that are small enough to avoid the maximum packet size limit. This provides a particular problem for ACL processing. If the ACL is filtering based on Layer-4 information, the non-initial packets within the fragmented packet flow will not match the Layer-4 information even if the original packet that was fragmented would have matched the filter. Consequently, packets that the ACL was designed to filter for are not processed by the ACL.

This can be a particular problem for Deny ACLs because packets can be dropped that should be forwarded. For this reason, the conservative ACL fragment mode has been created to treat fragmented packets differently both when the **fragmented** keyword is and is not used. While under normal operation, fragmented packets are treated the same as all other packets, when the **acl-frag-conservative** command is enabled, the router only applies Layer-4 information within an ACL to non-fragmented packets and to the initial packet within a fragmented packet flow.

Layer-4 information in an ACL

An ACL entry with one or more of the following keywords is consider to have Layer-4 information:

- TCP or UDP source or destination port. (In the case of ICMP, matching based on ICMP type or code values)
- TCP SYN flag
- TCP Established flag

ACL operation with the router configured in conservative ACL fragment mode

Operation of ACLs with Fragmented packets when the router is configured in Conservative ACL Fragment mode, through use of the **acl-frag-conservative** command, can be described to follow one these four procedures:

- ACL entries with Layer-3 Information only that do not contain the **fragment** keyword
- ACL entries with Layer-3 Information only that do contain the **fragment** keyword
- ACL entries with Layer-3 and Layer-4 Information that do not contain the **fragment** keyword
- ACL entries with Layer-3 and Layer-4 Information that do contain the **fragment** keyword

Detailed operation of ACLs under each of these conditions are described as follows.

ACL entries with Layer-3 information only that do not contain the fragment keyword

In this situation, the operation of the ACL is exactly like it is during normal operation (**acl-frag-conservative** command not configured). Any packet or fragment that matches the Layer-3 information specified in the ACL will be matched as described in Table 129

TABLE 129 ACL entry with Layer-3 information only and no fragment keyword

	Packet matches AND is either a non-fragmented or the 1st packet within a fragmented packet flow	Packet matches AND is a non-initial packet within a fragmented packet flow
permit	Yes – Matches because the packet matches the Layer-3 Information in the ACL	Yes – Matches because the packet matches the Layer-3 Information in the ACL
deny	Yes – Matches because the packet matches the Layer-3 Information in the ACL	Yes – Matches because the packet matches the Layer-3 Information in the ACL

ACL entries with Layer-3 information only that do contain the fragment keyword

In this situation, any packet that is not fragmented will not match because the fragment keyword is configured in the ACL. Non-initial packets within a fragmented packet flow that contain the Layer-3 information specified in the ACL will be matched as described in Table 130.

TABLE 130 ACL entry with Layer-3 information only and fragment keyword in ACL

	Packet matches AND is either a non-fragmented or the 1st packet within a fragmented packet flow	Packet matches AND is a non-initial packet within a fragmented packet flow
permit	No – Does not match because fragment keyword is in ACL and packet is either non-fragmented or the 1st packet within a fragmented packet flow	Yes – Matches because fragment keyword is in ACL and packet is a non-initial packet within a fragmented packet flow and the packet matches the Layer-3 information in the ACL.
deny	No – Does not match because fragment keyword is in ACL and packet is either non-fragmented or the 1st packet within a fragmented packet flow	Yes – Matches because fragment keyword is in ACL and packet is a non-initial packet within a fragmented packet flow and the packet matches the Layer-3 information in the ACL.

ACL entries with Layer-3 and Layer-4 information that do not contain the fragment keyword

In this situation, any packet that is not fragmented or is the 1st packet within a fragmented packet flow and also contains the Layer-3 and Layer-4 information specified in the ACL will be matched. Packets that are non-initial packets within a fragmented packet flow and match the Layer-3 information will be matched for the permit clause because in conservative ACL fragment mode,

Layer-4 information is disregarded for non-initial packets. Also, non-initial packets within a fragmented packet flow will not be matched for the deny clause because in conservative ACL fragment mode, the deny clause is not invoked for non-initial packets within a fragmented packet flow. Refer to Table 131 for operation in this scenario

TABLE 131 ACL entry with Layer-3 and Layer-4 information and no fragment keyword in ACL

	Packet matches AND is either a non-fragmented or the 1st packet within a fragmented packet flow	Packet matches AND is a non-initial packet within a fragmented packet flow
permit	Yes – Matches because the packet matches the Layer-3 and Layer-4 Information in the ACL	Yes – Matches because the packet matches the Layer-3 Information in the ACL and in conservative mode, Layer-4 information is disregarded for non-initial packets within a fragmented packet flow
deny	Yes – Matches because the packet matches the Layer-3 and Layer-4 Information in the ACL	No – Does not match because in conservative mode, the deny clause is not invoked for non-initial packets within a fragmented packet flow.

ACL entries with Layer-3 and Layer-4 information that contains the fragment keyword

In this situation, any packet that is not fragmented or is the 1st packet within a fragmented packet flow will not be matched because the fragment keyword is specified in the ACL. Packets that are non-initial packets within a fragmented packet flow, match the **fragment** keyword and match the Layer-3 information will be matched for the permit clause because in conservative ACL fragment mode, Layer-4 information is disregarded for non-initial packets. Also, non-initial packets within a fragmented packet flow will not be matched for the deny clause because in conservative ACL fragment mode, the **deny** clause is not invoked for non-initial packets within a fragmented packet flow. Refer to Table 132 for operation in this scenario.

TABLE 132 ACL entry with Layer-3 and Layer-4 information and fragment keyword in ACL

	Packet matches AND is either a non-fragmented or the 1st packet within a fragmented packet flow	Packet matches AND is a non-initial packet within a fragmented packet flow
permit	No – Does not match because fragment keyword is in ACL and packet is either non-fragmented or the 1st packet within a fragmented packet flow	Yes – Matches because the packet matches the Layer-3 Information in the ACL and in conservative mode, Layer-4 information is disregarded for non-initial packets within a fragmented packet flow
deny	No – Does not match because fragment keyword is in ACL and packet is either non-fragmented or the 1st packet within a fragmented packet flow	No – Does not match because in conservative mode, the deny clause is not invoked for non-initial packets within a fragmented packet flow.

Configuring the conservative ACL fragment mode

The Conservative ACL Fragment Mode is configured using the **acl-frag-conservative** command as shown in the following.

```
NetIron(config)# acl-frag-conservative
```

Syntax: [no] acl-frag-conservative

Examples of ACL filtering in normal and conservative ACL fragment modes

The following examples illustrate how an ACL with the fragment keyword operates for filtering applications in both the normal and conservative mode:

- ACL Configuration Example with Fragment Keyword and Permit Clause

- ACL Configuration Example with Fragment Keyword and Deny Clause

ACL configuration example with fragment keyword and permit clause

In the following example, ACL 100 is configured to process fragmented IP packets in Normal and Conservative ACL modes as described.

```
NetIron(config)# access-list 100 permit tcp 150.1.0.0.0.0.0.255 any fragment
NetIron(config)# access-list 100 deny ip any any
```

Behavior In Normal ACL Fragment Mode – In the normal PowerConnect router mode, fragmented and non-fragmented packets will be dropped or forwarded as described in the following:

All TCP fragments (both initial and subsequent fragments) from the specified IP address, will match the first ACL entry. Because this is a **permit** ACL entry, the matching packets are forwarded.

Non-fragmented packets will not match the first ACL entry because the **fragment** keyword is present. The packet will then match the second (**deny**) ACL entry and consequently will be dropped.

Behavior In Conservative ACL Fragment Mode – If the PowerConnect router is configured for Conservative ACL Fragment mode using the **acl-frag-conservative** command, fragmented and non-fragmented packets will be dropped or forwarded as described in the following:

The initial fragment will not match the first ACL entry because the **fragment** keyword is present. The packet will then match the second (**deny**) ACL entry and consequently will be dropped.

Non-initial TCP fragments from the specified IP address, will match the first ACL entry based on Layer-3 information. Because this is a **permit** ACL entry, the matching packets are forwarded.

Non-fragmented packets will not match the first ACL entry because the **fragment** keyword is present. The packet will then match the second (**deny**) ACL entry and consequently will be dropped.

ACL configuration example with fragment keyword and deny clause

In the following example, ACL 101 is configured to process fragmented IP packets in Normal and Conservative ACL modes as described.

```
NetIron(config)# access-list 101 deny tcp 150.1.0.0.0.0.0.255 any fragment
NetIron(config)# access-list 101 permit ip any any
```

Behavior In Normal ACL Fragment Mode – In the normal PowerConnect router mode, fragmented and non-fragmented packets will be dropped or forwarded as described in the following:

All TCP fragments (both initial and subsequent fragments) from the specified IP address will match the first ACL entry. Because this is a **deny** ACL entry, the matching packets are dropped.

Non-fragmented packets will not match the first ACL entry because the **fragment** keyword is present. The packet will then match the second (**permit**) ACL entry and consequently will be forwarded.

Behavior In Conservative ACL Fragment Mode – If the PowerConnect router is configured for Conservative ACL Fragment mode using the **acl-frag-conservative** command, fragmented and non-fragmented packets will be dropped or forwarded as described in the following:

The initial fragment will not match the first ACL entry because the **fragment** keyword is present. The packet will then match the second (**permit**) ACL entry and consequently will be forwarded.

Non-initial TCP fragments will match the first ACL entry based on Layer-3 information. Because this is a **deny** ACL entry with Layer-3 information only, the matching packets are dropped.

Non-fragmented packets will not match the first ACL entry because the **fragment** keyword is present. The packet will then match the second (**permit**) ACL entry and consequently will be forwarded.

Examples of ACL-based rate limiting in normal and conservative ACL fragment modes

The following examples illustrate how an ACL with the fragment keyword operates for rate limiting applications in both the normal and conservative mode:

- ACL-based Rate Limiting Configuration Example with Fragment Keyword and Deny Clause
- ACL-based Rate Limiting Configuration Example with Fragment Keyword and Permit Clause

ACL-based rate limiting configuration example with fragment keyword and deny clause

In the following example, ACL 102 is configured to process fragmented IP packets in Normal and Conservative ACL modes as described.

```
NetIron(config)# interface ethernet 3/1
NetIron(config-if-e1000-3/1)# enable
NetIron(config-if-e1000-3/1)# rate-limit strict-acl
NetIron(config-if-e1000-3/1)# rate-limit input access-group 102 499992736
750000000
NetIron(config-if-e1000-3/1)# no spanning-tree
NetIron(config-if-e1000-3/1)# exit
NetIron(config)# access-list 102 deny ip any any fragment
NetIron(config)# access-list 102 permit ip any any
```

Behavior In Normal ACL Fragment Mode – In the normal PowerConnect router mode, fragmented and non-fragmented packets will be dropped or forwarded as described in the following:

All IP fragments (both initial and subsequent fragments) will match the first ACL entry. Because this is a **deny** ACL entry, and **rate-limit strict-acl** is configured, the matching packets are dropped.

Non-fragmented packets will not match the first ACL entry because the **fragment** keyword is present. The packet will then match the second (**permit**) ACL entry and consequently will be forwarded and rate-limited.

Behavior In Conservative ACL Fragment Mode – If the PowerConnect router is configured for Conservative ACL Fragment mode using the **acl-frag-conservative** command, fragmented and non-fragmented packets will be dropped or forwarded as described in the following:

The initial fragment will not match the first ACL entry because the **fragment** keyword is present. The packet will then match the second (**permit**) ACL entry and consequently will be forwarded and rate-limited.

Non-initial IP fragments will match the first ACL entry based on Layer-3 information. Because this is a **deny** ACL entry with Layer-3 information only, and **rate-limit strict-acl** is configured, the matching packets are dropped.

Non-fragmented packets will not match the first ACL entry because the **fragment** keyword is present. The packet will then match the second (**permit**) ACL entry and consequently will be forwarded and rate-limited.

ACL-based rate limiting configuration example with fragment keyword and permit clause

In the following example, ACL 103 is configured to process fragmented IP packets in Normal and Conservative ACL modes as described.

```
NetIron(config)# interface ethernet 3/1
NetIron(config-if-e1000-3/1)# enable
NetIron(config-if-e1000-3/1)# rate-limit strict-acl
NetIron(config-if-e1000-3/1)# rate-limit input access-group 103 499992736
750000000
NetIron(config-if-e1000-3/1)# no spanning-tree
NetIron(config-if-e1000-3/1)# exit
NetIron(config)# access-list 103 permit ip any any fragment
NetIron(config)# access-list 102 deny ip any any
```

Behavior In Normal ACL Fragment Mode – In the normal PowerConnect router mode, fragmented and non-fragmented packets will be dropped or forwarded as described in the following:

All IP fragments (both initial and subsequent fragments) will match the first ACL entry. Because this is a **permit** ACL entry, the matching packets are forwarded and rate-limited.

Non-fragmented packets will not match the first ACL entry because the **fragment** keyword is present. The packet will then match the second (**deny**) ACL entry and consequently will be dropped.

Behavior In Conservative ACL Fragment Mode – If the PowerConnect router is configured for Conservative ACL Fragment mode using the **acl-frag-conservative** commad, fragmented and non-fragmented packets will be dropped or forwarded as described in the following:

The initial fragment will not match the first ACL entry because the **fragment** keyword is present. The packet will then match the second (**deny**) ACL entry and consequently will be dropped.

Non-initial IP fragments will match the first ACL entry based on L3 information. Because this is a **permit** ACL entry, the matching packets are forwarded and rate-limited.

Non-fragmented packets will not match the first ACL entry because the **fragment** keyword is present. The packet will then match the second (**deny**) ACL entry and consequently will be dropped.

ACL filtering for traffic switched within a virtual routing interface

By default, a PowerConnect does not filter traffic that is switched from one port to another within the same virtual routing interface, even if an ACL is applied to the interface. You can enable the PowerConnect to filter switched traffic within a virtual routing interface. When you enable the filtering, the PowerConnect uses the ACLs applied to inbound traffic to filter traffic received by a port from another port in the same virtual routing interface. This feature does not apply to ACLs applied to outbound traffic.

To enable filtering of traffic switched within a virtual routing interface, enter the following command at the configuration level for the interface.

```
NetIron(config-vif-1)# ip access-group ve-traffic
```

Syntax: [no] ip access-group ve-traffic

Filtering and priority manipulation based on 802.1p priority

Filtering and priority manipulation based on a packet's 801.1p priority is supported in the PowerConnect devices through the following QoS options:

- **priority** – Assigns traffic that matches the ACL to a hardware forwarding queue. In addition to changing the internal forwarding priority, if the outgoing interface is an 802.1q interface, this option maps the specified priority to its equivalent 802.1p (QoS) priority and marks the packet with the new 802.1p priority.
- **priority-force** – Assigns packets of outgoing traffic that match the ACL to a specific hardware forwarding queue, even though the incoming packet may be assigned to another queue. Specify one of the following QoS queues:
  - 0 – qosp0
  - 1 – qosp1
  - 2 – qosp2
  - 3 – qosp3
  - 4 – qosp4
  - 5 – qosp5
  - 6 – qosp6
  - 7 – qosp7

  If a packet's 802.1p value is forced to another value by its assignment to a lower value queue, it will retain that value when it is sent out through the outbound port.

  The default behavior on previous revisions of this feature was to send the packet out with the higher of two possible values: the initial 802.1p value that the packet arrived with or the new (higher) priority that the packet has been "forced" to.
- **priority-mapping** – Matches on the packet's 802.1p value. This option does not change the packet's forwarding priority through the device or mark the packet.
- **drop-precedence** – Assigns traffic that matches the ACL to a drop precedence value between 0 -3.

drop-precedence-force – This keyword applies in situations where there are conflicting priority values for packets on an Ingress port, that conflict can be resolved by performing a priority merge (the default) or by using a **force** command to direct the router to use a particular value above other values. The **drop-precedence-force** keyword specifies that if a drop precedence is applied on the port the ACL keyword will override existing or default mappings, however, if forced at the ingress port, the port value will prevail over the acl value. Assigns traffic that matches the ACL to a drop precedence value between 0 -3.

Example using the priority option (IPv4)

In the following IPv4 example, access list 100 assigns tcp packets with the source and destination addresses specified to internal priority 2 and maps them to the 802.1p value 2 when outbound.

```
NetIron(config)#access-list 100 permit tcp 100.1.1.0/24 105.23.45.0/24 priority 2
```

The **priority** parameter specifies one of the 8 internal priorities of the PowerConnect Router. Possible values are between 0 and 7. If the outgoing interface is an 802.1q interface, the packet will have its 802.1p (QoS) priority marked with the new priority defined in this ACL.

Example using the priority force option

In the following IPv4 ACL example, access list 100 assigns udp packets with the source and destination addresses specified to the internal priority 3.

```
NetIron(config)#access-list 100 permit udp 100.1.1.0/24 105.23.45.0/24
priority-force 3
```

The **priority-force** parameter specifies one of the 8 internal priorities of the PowerConnect Router. Possible values are between 0 and 7.

For limitations when using the **priority-force** parameter, please see "Configuration considerations for IPv4 outbound ACLs on VPLS, VLL, and VLL-Local endpoints" on page 786.

Example using the priority mapping option

In the following IPv4 ACL example, access list 100 permits udp packets with the source and destination addresses specified and the 802.1p priority 7.

```
NetIron(config)# access-list 100 permit udp 175.1.1.0/24 145.75.34.0/24
priority-mapping 7
```

The **priority-mapping** parameter specifies one of the eight possible 802.1p priority values. Possible values are between 0 and 7.

NOTE
When the priority configured for a physical port and the 802.1p priority of an arriving packet differ, the higher of the two priorities is used.

ICMP filtering for extended ACLs

Extended IPv4 ACL policies can be created to filter traffic based on its ICMP message type. You can either enter the description of the message type or enter its type and code IDs. All packets matching the defined ICMP message type or type number and code number are processed in hardware.

Numbered ACLs

For example, to deny the echo message type in a numbered, extended ACL, enter commands such as the following when configuring a numbered ACL.

```
NetIron(config)# access-list 109 deny icmp any any echo
```

or

```
NetIron(config)# access-list 109 deny icmp any any 8 0
```

Syntax: [no] **access-list** <*num*> **deny | permit icmp any any** <*icmp-type*> **|** <*type-number*> <*code-number*>

The **deny | permit** parameter indicates whether packets that match the policy are dropped or forwarded.

You can either enter the name of the message type for <*icmp-type*> or the message's <*type number*> and <*code number*> of the message type. Refer to Table 133 on page 819 for valid values.

Named ACLs

For example, to deny the administratively-prohibited message type in a named ACL, enter commands such as the following.

```
NetIron(config)# ip access-list extended entry
NetIron(config-ext-nacl)# deny ICMP any any administratively-prohibited
```

or

```
NetIron(config)# ip access-list extended entry
NetIron(config-ext-nacl)#deny ICMP any any 3 13
```

Syntax: [no] ip access-list extended <*acl-name*>
deny | permit host icmp any any <*icmp-type*> **|** <*type-number*> <*code-number*>

The **extended** parameter indicates the ACL entry is an extended ACL.

The <*acl-name*> | <*acl-num*> parameter allows you to specify an ACL name or number. If using a name, specify a string of up to 256 alphanumeric characters. You can use blanks in the ACL name if you enclose the name in quotation marks (for example, "ACL for Net1"). The <*acl-num*> parameter allows you to specify an ACL number if you prefer. If you specify a number, enter a number from 100 – 199 for extended ACLs.

The **deny | permit** parameter indicates whether packets that match the policy are dropped or forwarded.

You can either use the <*icmp-type*> and enter the name of the message type or use the <*type-number*> <*code-number*> parameter to enter the type number and code number of the message. Refer to Table 133 on page 819 for valid values

TABLE 133 ICMP message types and codes

Binding IPv4 inbound ACLs to a management port

You can bind a small number of IPv4 inbound ACLs to the Ethernet port on the Management Module for filtering IP traffic sent to the Management module's CPU. These ACLs are processed in software only and are not programmed in CAM. Outbound IPv4 ACLs are not supported on the Management module's Ethernet port.

The default size of IPv4 Inbound ACLs on a management port is 20 filters. This number can be set from 1 to 100 using the following command.

```
NetIron(config)# system-max mgmt-port-acl-size 100
```

Syntax: system mgmt-port-acl-size *<acls-supported>*

The *<acls-supported>* variable allows you set a maximum number of filters that are supported for the IPv4 ACL bound to the Management Module's Ethernet port.

The possible values are 1 - 100 .

The default value is 20.

NOTE
For IPv4 inbound ACL applied to management port, the user can log traffic matching both "permit" and "deny" ACL filters that have the log keyword. The command **ip access-group enable-deny-logging** is not be required to turn on logging on a management port.

IP receive ACLs

The IP receive access-control list feature (rACL) provides hardware-based filtering capability for IPv4 traffic destined for the CPU in the default VRF such as management traffic. Its purpose is to protect the management module's CPU from overloading due to large amounts of traffic sent to one of the PowerConnect router's IP interfaces. Using the rACL command, the specified ACL is applied to every interface on the PowerConnect router. This eliminates the need to add an ACL to each interface on a PowerConnect router.

The rACL feature is configured by creating an ACL to filter traffic and then specifying that ACL in the rACL command. This applies the ACL to all interfaces on the router. The destination IP address in an ACL specified by the rACL command is interpreted to apply to all interfaces in the default VRF of the router. This is implemented by programming an ACL entry in CAM that applies the ACL clause for each interface.

For example there are the following three interfaces defined on a router:

- loopback 1 = 2.2.2.2;
- ethernet 4/1 = 10.10.10.1
- virtual ethernet interface 1 = 10.10.20.1

The access list defined in the following command will act to deny ICMP traffic to each of the defined interfaces.

```
NetIron(config)# access-list 170 deny icmp host 1.1.1.1 any
```

The ACL CAM would then be programmed with the following three entries:

- deny icmp host 1.1.1.1 host 2.2.2.2
- deny icmp host 1.1.1.1 host 10.10.10.1

- deny icmp host 1.1.1.1 host 10.10.20.1

NOTE
You must rebind an rACL whenever it is changed, as described in "Rebinding an rACL definition or policy-map" on page 824, otherwise now invalid entries will still be in CAM.

NOTE
For more information on configuring the **acl-mirror-port** command for IP Receive ACLs, refer to "Specifying the destination mirror port for IP Receive ACLs" on page 152.

Configuration guidelines for IP receive ACLs

Use the following considerations when configuring IP Receive ACLs:

- **For interface level inbound IPv4 ACL or RL-ACLs**: Traffic matching rACLs will not be subject to interface-level ACL or RL-ACLs. You must take care to configure an rACL such that only management traffic matches the rACL clauses.
- **For interface level inbound L2 ACLs or RL-ACLs**: On an interface, we support either launching an IPv4 inbound or L2 inbound ACL CAM lookup, but not both. For interfaces with L2 inbound ACLs, rACL filtering will be performed by software. Therefore, only traffic permitted by L2 inbound ACL will be processed by rACLs. Note that rate-limiting using rACLs will not be applicable for such traffic.
- **VLAN ID translation or Inner VLAN ID translation**: This feature programs L2 inbound ACL CAM entries, and hence, for ports in VLAN or Inner VLAN translation group, rACL filtering is performed in software. Note that rate limiting using rACLs will not be applicable for traffic incoming on such interfaces.
- **Global DOS attack policies**: These are supported in software. The order of precedence is:
  - rACL filtering (either in hardware or software)
  - Global DOS attack policies (only in software)

NOTE
IP Receive ACLs are applicable only for line card interfaces. IP Receive ACLs are not applicable for management ethernet interfaces.

Configuring rACLs

Configuring rACLs requires the following steps:

- Configuring an rACL and Establishing the Sequence of rACL Commands
- Applying Rate Limiting on rACLs Defined Traffic
- Specifying the Maximum Number of rACL Entries
- Rebinding an rACL Definition or Policy map

You can bind multiple rACLs, up to a maximum of 199. You must however ensure that there is no explicit **permit ip any any** or **deny ip any any** clause in any of the rACLs except the last one.

NOTE
An implicit deny ip any any will be programmed at the end, after all other rACLs. This implicit clause will always be programmed to drop the matching traffic.

Configuring rACL to apply a defined ACL and establishing the sequence of rACL commands

To configure rACL to apply ACL number 101 with a sequence number of 15 to all interfaces within the default VRF for all CPU-bound traffic, enter the following command:

```
NetIron(config)# ip receive access-list 101 sequence 15
```

Syntax: [no] ip receive access-list <*acl-num*> **sequence** <*seq-num*>

The <*acl-num*> variable identifies the ACL (standard or extended) that you want to apply to all interfaces within the default VRF for all CPU-bound traffic.

The sequence <*seq-num*> option defines the sequence in which the rACL commands will be applied. Commands are applied in order of the lowest to highest sequence numbers. For example, if the following rACL commands are entered.

```
NetIron(config)# ip receive access-list 100 sequence 10
NetIron(config)# ip receive access-list 101 sequence 25
NetIron(config)# ip receive access-list 102 sequence 15
```

The effective binding of the commands will be in the following order.

```
ip receive access-list 100 sequence 10
ip receive access-list 102 sequence 15
ip receive access-list 101 sequence 25
```

Using the **[no]** option removes the rACL access list defined in the command.

Applying rate limiting on rACL defined traffic

The rACL feature allows you to apply rate limiting to CPU-bound traffic using the **policy-map** and **strict-acl** options of the **ip receive access-list** command as described in the following:

Syntax: [no] ip receive access-list <*acl-num*> **sequence** <*seq-num*> **policy-map** <*policy-map-name*>

By default, traffic matching the "permit" clause in the specified ACL is permitted and traffic matching the "deny" clause in the ACL is dropped.

When the **policy-map** option is used, traffic matching the permit clause of the specified ACL is rate-limited as defined in the policy map specified by the **<*policy-map-name*>** variable and traffic matching the "deny" clause in the ACL is permitted but not rate limited. Using the **[no]** option removes the policy map defined in the command.

When the **policy-map** option is used with the **strict-acl** option, traffic matching the permit clause of the specified ACL is rate-limited as defined in the policy map specified by the **<*policy-map-name*>** variable and traffic matching the "deny" clause in the ACL is dropped. Using the **[no]** option removes the **strict-acl** option for the rACL command defined in the command.

Specifying the maximum number of rACLs supported in CAM

You can configure the number of software ACL CAM entries available for rACLs. This is done using the following command.

```
NetIron(config)# system-max receive-cam 2048
```

Syntax: [no] system-max receive-cam <*number*>

The <*number*> variable is the maximum number of ACL CAM entries that are allowed.

Acceptable values are powers of 2 between 512 and 8192

The default value is 1024.

NOTE
You must reload the device for this command to take effect.

Rebinding an rACL definition or policy-map

If a change is made to the definition of an IP rACL or to a rate-limiting, policy map that is specified for an rACL, you must perform a rebind as shown in the following.

```
NetIron(config)# ip rebind-receive all
```

Syntax: [no] ip rebind-receive all

NOTE
If you add or delete an IP address to or from a router interface, you need to rebind the IP Receive ACLs.

Displaying accounting information for rACL statistics

To display rACL accounting information for a specific ACL, use the following command.

```
NetIron# show access-list receive accounting 102
```

Syntax: show access-list receive accounting <*acl-id*>

The <*acl-id*> variable specifies the ACL that you want to display rACL statistics for.

To clear rACL accounting information for a specific ACL, use the following command.

```
NetIron# clear access-list receive 102
```

Syntax: clear access-list receive <*acl-id*>

The <*acl-id*> variable specifies the ACL that you want to clear rACL statistics for.

Example

If you are using loopback interfaces for all BGP peering sessions, you can define an ACL that only permits BGP traffic from a specified source IP address. Where the peer source has an IP address of 1.1.1.1 and the loopback IP address on the router is 2.2.2.2, the access list command is configured as shown in the following.

```
NetIron(config)# access-list 106 permit tcp host 1.1.1.1 host 2.2.2.2 eq bgp
```

The rACL command that implements ACL 106 is configured as shown in the following.

```
NetIron(config)# ip receive access-list 106 sequence 10
```

Matching on TCP header flags for IPv4 ACLs

In this release, you can match packets for one additional TCP header flag using IPv4 ACLs. The following command implements the additional tcp parameter for IPv4 ACLs.

Syntax: [no] access-list <*num*> **permit | deny tcp any any syn**

The <*num*> parameter indicates the ACL number and must be from 1 - 99 for a standard ACL or from 100 - 199 for and extended ACL

The **tcp** parameter indicates that you are filtering the TCP header.

The **syn** parameter directs the ACL to permit or deny based upon the status of the syn flag in the TCP header. If the contents of the flag is "1" the condition is met.

ACL deny logging

The ACL Deny Logging feature records traffic flows that are denied by an ACL bound to a port. When a packet is denied by an ACL, a Syslog entry is generated and a timer is started to keep track of the packets from this packet flow. After the timer expires (default: 5 minutes), another Syslog entry is generated if there is any packet from the tracked packet flow that was denied.

ACL Deny Logging is supported for the following:

- IPv4 Inbound ACLs
- IP Receive ACLs

ACL Deny Logging is not supported for the following:

- ACL-based Rate Limiting
- Policy Based Routing
- IPv6 ACLs

Configuration notes

Carefully consider each of the following statements before configuring the ACL Deny Logging feature on your router:

- The ACL Deny Logging feature cannot be used in conjunction with the deny traffic redirection feature (command: **ip access-group redirect-deny-to-interf**). The **ip access-group redirect-deny-to-interf** command cannot be applied on VPLS, VLL, or VLL-local endpoints and vice versa. When configuring the **ip access-group redirect-deny-to-interf** command on VPLS, VLL, and VLL-Local endpoints, please refer to "Configuration considerations for IPv4 outbound ACLs on VPLS, VLL, and VLL-Local endpoints" on page 786. If you configure both features on the same interface, the ACL deny logging feature will take precedence and the deny traffic redirection will be disabled. Although disabled, deny traffic redirection will still be shown in the running configuration.
- ACL Deny Logging is a CPU-based feature. Consequently, to maintain maximum performance we recommend that you selectively enable the logging option only on the deny filters where you are interested in seeing the logs.
- ACL Deny Logging generates Syslog entries only. No SNMP traps are issued.
- The ACL Deny Logging feature is supported for inbound ACLs only.
- You can configure the maximum number of ACL session entries using the **system-max session-limit** command as described in the *Brocade MLXe and NetIron Family Configuration Guide*.
- ACL logging is applicable only for traffic matching ACL deny clauses. It is not applicable for traffic matching ACL permit clauses.

Configuring ACL deny logging for IPv4 ACLs

Configuring ACL Deny Logging for IPv4 ACLs requires the following:

- Enabling the Log Option
- Enabling ACL Deny Logging on a Interface

Enabling the log option

ACL Logging requires that you add the **log** option to an ACL statement as shown.

```
NetIron(config)#access-list 101 deny ip any any log
```

The **log** option enables logging for the ACL being defined.

The ACL or RPF logging mechanism on the Interface modules log a maximum of 256 messages per minute, and send these messages to the Management module. A rate-limiting mechanism has been added to rate-limit the number of log messages from the Interface module CPU to the Management module CPU to 5 messages per second. Because this delays the delivery of messages to the Management module, in the worst case scenario with all 256 packets arriving at the same time on the Interface module, the time values stamped by the Management module on the messages will vary by as much as 60 seconds.

Enabling ACL deny logging on an interface

The **ip access-group enable-deny-logging** command must be configured as shown on each interface that you want ACL Deny Logging to function.

```
NetIron(config)# interface ethernet 5/1
NetIron(config-if-e1000-5/1)# ip access-group enable-deny-logging
```

Syntax: [no] ip access-group enable-deny-logging [hw-drop]

NOTE
The **ip access-group enable-deny-logging** command cannot be applied on VPLS, VLL, or VLL-local endpoints and vice versa. When configuring the **ip access-group enable-deny-logging** command on VPLS, VLL, and VLL-Local endpoints, please refer to "Configuration considerations for IPv4 outbound ACLs on VPLS, VLL, and VLL-Local endpoints" on page 786.

NOTE
The command **ip access-gr enable-deny-logging** is not be required to turn on logging on management port.

The **hw-drop** option specifies that ACL Log packets be dropped in hardware. This is implemented to reduce the CPU load. In practice this means that the packet counts for denied traffic will only account for the first packet in each time cycle. The **no ip access-group enable-deny-logging hw-drop** command only removes the **hw-drop** keyword.

NOTE
Using this command, ACL logging can be enabled and disabled dynamically and does not require you to rebind the ACLs using the **ip rebind-acl** command

Configuring ACL Deny Logging for IP receive ACLs

Since ACL Logging for IP Receive ACLs applies to all CPU bound traffic it is only required that you configure the following command globally as shown.

```
NetIron(config)#ip receive access-list enable-deny-logging
```

Syntax: [no] ip receive access-list enable-deny-logging [hw-drop]

The **hw-drop** option specifies that IP Receive ACL Log packets be dropped in hardware. This is implemented to reduce the CPU load. In practice this means that the packet counts for denied traffic will only account for the first packet in each time cycle. The **no ip receive access-list enable-deny-logging hw-drop** command only removes the **hw-drop** keyword.

NOTE
Using this command, ACL logging can be enabled and disabled dynamically and does not require you to rebind the ACLs using the **ip rebind-receive-acl** command

Configuring the log timer

You can specify how long the system waits before it sends a message in the Syslog by entering a command such as the following.

```
NetIron(config)# ip access-list logging-age 2
```

Syntax: ip access-list logging-age <*minutes*>

Enter 1 – 10 minutes. The default is 5 minutes.

Support for ACL CAM sharing

For ports sharing a PPCR that have the same ACL binded to them, ACL CAM sharing only applies if all or none of the ports have ACL Deny Logging configured.

The

In the following example, ports 4/1 and 4/2 in same packet processor (PPCR) are binded with inbound ACL 101 but only port 4/2 has the **ip access-group enable-deny-logging** command configured.

```
NetIron(config)# enable-acl-cam-sharing
NetIron(config)# interface ethernet 4/1
NetIron(config-if-e1000-4/1)# ip access group 101 in
NetIron(config)# interface ethernet 4/2
NetIron(config-if-e1000-4/2)# ip access group 101 in
NetIron(config-if-e1000-4/2)# ip access-group enable-deny-logging
```

Because they do not have the same ACL Deny Logging configuration, a separate set of ACL CAM entries are programmed for ports 4/1 and 4/2.

Log example

The following examples display typical log entries where the ACL Deny Logging feature is configured.

```
[IPv4 Inbound ACL]
Dec 16 12:12:29:I:list 102 denied tcp 10.10.10.1(1024)(Ethernet 3/1
0000.0000.0010) -> 20.20.20.1(1025), 27298224 event(s)
[L2 MAC ACL]
Dec 16 12:12:29:I: MAC ACL 400 denied 1 packets on port 3/16 [SA:0000.0000.0020,
DA:0000.0000.0010, Type:IPV4-L5, VLAN:1]
```

NOTE
Log entries generated by the ACL Logging feature for POS ports do not display the source MAC address.

ACL accounting

Multi-Service devices monitor the number of times an ACL is used to filter incoming or outgoing traffic on an interface. The **show access-list accounting** command displays the number of "hits" or how many times ACL filters permitted or denied packets that matched the conditions of the filters.

NOTE
ACL accounting does not tabulate nor display the number of implicit denials by an ACL.

Counters, stored in hardware, keep track of the number of times an ACL filter is used.

The counters that are displayed on the ACL accounting report are:

- 1s – Number of hits during the last second. This counter is updated every second.
- 1m – Number of hits during the last minute. This counter is updated every one minute.
- 5m – Number of hits during the last five minutes. This counter is updated every five minutes.
- ac – Accumulated total number of hits. This counter begins when an ACL is bound to an interface and is updated every one minute. This total is updated until it is cleared.

  The accumulated total is updated every minute. For example, a minute after an ACL is bound to a port, it receives 10 hits per second and continues to receive 10 hits per second. After one minute, the accumulated total hits is 600. After 10 minutes, there will be 6000 hits.

The counters can be cleared when the device is rebooted, when an ACL is bound to or unbound from an interface, or by entering a **clear access-list** command.

ACL rate-limiting and ACL accounting

To check the availability of ACL accounting and ACL rate-limiting resources, use the **show resource** command.

```
NetIron# show resource
< . . . >
[I cntr/mtrs(1)]  2048(size),  1982(free), 03.22%(used), 0(failed)
[O cntr/mtrs(1)]  2048(size),  1984(free), 03.12%(used), 0(failed)
< . . . >
```

The above example shows only the output related to ACL rate-limiting and ACL accounting resources, and indicates that 3.22% of input resources and 3.12% of output resources have been used.

ACL Accounting interactions between L2 ACLs and IP ACLs

Dell recommends enabling ACL accounting in only one of the ACLs bound to the same port. Including ACL-accounting-enabled clauses in both ACLs can result in anomalous reporting of filtering results.

Displaying accounting statistics for all ACLs

To display a summary of the number of hits in all ACLs on a Multi-Service device, enter the following command.

```
NetIron (config)#show access-list accounting brief
Collecting ACL accounting summary for VE 1 ...  Completed successfully.
ACL Accounting Summary: (ac = accumulated since accounting started)
    Int    In ACL              Total In Hit   Out ACL             Total Out Hit
    VE 1    111                473963(1s)
                               25540391(1m)
                               87014178(5m)
                               112554569(ac)
```

The display shows the following information:

This field...	Displays...
Collecting ACL accounting summary for <*interface*>	Shows for which interfaces the ACL accounting information was collected and whether or not the collection was successful.
Int	The ID of the interface for which the statistics are being reported.
In ACL	The ID of the ACL used to filter the incoming traffic on the interface.
Total In Hit*	The number of hits from incoming traffic processed by all ACL entries (filters) in the ACL. A number is shown for each counter.
Out ACL	ID of the ACL used to filter the outgoing traffic on the interface.
Total Out Hit*	The number of hits from incoming traffic processed by all ACL entries (filters) in the ACL. A number is shown for each counter.

* The Total In Hit and Total Out Hit displays the total number of hits for all the ACL entries (or filters) in an ACL. For example, if an ACL has five entries and each entry processed matching conditions three times during the last minute, then the total Hits for the 1m counter is 15.

Syntax: show access-list accounting brief [l2 | policy-based-routing | rate-limit]

The **l2** parameter limits the display to Layer 2 ACL accounting information.

The **policy-based-routing** parameter limits the display to policy based routing accounting information.

The **rate-limit** parameter limits the display to rate limiting ACL accounting information.

IPv4 ACL accounting statistics are displayed if no option is specified.

Displaying statistics for an interface

To display statistics for an interface, enter commands such as the following.

```
NetIron (config)#show access-list accounting ve 1 in
Collecting ACL accounting for VE 1  ...  Completed successfully.
ACL Accounting Information:
Inbound: ACL 111
    1: deny tcp any any
       Hit count: (1 sec)              237000   (1 min)12502822
                  (5 min)            87014178   (accum) 99517000
    3: permit ip any any
       Hit count: (1 sec)              236961   (1 min) 13037569
                  (5 min)                   0   (accum) 13037569
    0: deny tcp 1.1.1.0 0.0.0.255 2.2.2.0 0.0.0.255
       Hit count: (1 sec)                   0   (1 min) 0
                  (5 min)                   0   (accum) 0
    2: deny udp any any
       Hit count: (1 sec)                   0   (1 min) 0
                  (5 min)                   0   (accum) 0
```

The display shows the following information:

This field...	Displays...
The IP multicast traffic snooping state	The first line of the display indicates whether IP multicast traffic snooping is enabled or disabled. If enabled, it indicates if the feature is configured as passive or active.
Collecting ACL accounting summary for <*interface*>	Shows the interface included in the report and whether or not the collection was successful.
Outbound or Inbound ACL ID	Shows the direction of the traffic on the interface and the ID of the ACL used.
#	Shows the index of the ACL entry, starting with 0, followed by the permit or deny condition defined for that ACL entry. (The first entry created for an ACL is assigned the index 0. The next one created is indexed as 1, and so on.) ACL entries are arranged beginning with the entry with the highest number of hits for IPv4 ACLs. For all other options, ACL entries are displayed in order of ascending ACL filter IDs.
Hit count	Shows the number of hits for each counter.

Syntax: show access-list accounting ethernet [<*slot*>/<*port*> | **ve** <*ve-number*> | **pos** <*slot*>/<*portnum*>] **in | out [l2 | policy-based-routing | rate-limit]**

Use **ethernet** <*slot*>/<*port*> to display a report for a physical interface.

Use **ve** <*ve-number*> to display a report for the ports that are included in a virtual routing interface. For example, if ports 1/2, 1/4, and 1/6 are all members of ve 2, the report includes information for all three ports.

Use the **in** parameter to display statistics for incoming traffic; **out** for outgoing traffic.

The **l2** parameter limits the display to Layer 2 ACL accounting information.

The **policy-based-routing** parameter limits the display to policy based routing accounting information. This option is only available for incoming traffic.

The **rate-limit** parameter limits the display to rate limiting ACL accounting information.

Clearing the ACL statistics

Statistics on the ACL account report can be cleared:

- When a software reload occurs
- When the ACL is bound to or unbound from an interface
- When you enter the **clear access-list** command, as in the following example.

```
NetIron(config)# clear access-list all
```

Syntax: **clear access-list all** | **ethernet** <*slot*>/<*port*> | **ve** <*ve-num*> | **pos** <*slot*>/<*portnum*>

Enter **all** to clear all statistics for all ACLs.

Use **pos** <*slot*>/<*port*> to clear statistics for ACLs bound to a POS port.

Use **ethernet** <*slot*>/<*port*> to clear statistics for ACLs bound to a physical port.

Use **ve** <*ve-number*> to clear statistics for all ACLs bound to ports that are members of a virtual routing interface.

Policy-Based Routing 22

Overview

The following Policy-Based Routing features are supported on the NetIron MLX Series devices.

- Policy-Based Routing (PBR)
- Next Hop VLAN Flooding
- Policy-Based Routing over a GRE Tunnel
- Setting the Output Interface to the Null Interface
- Selectively Applying Normal Routing to Packets
- Configure the Route Map

Policy-Based Routing (PBR) allows you to use ACLs and route maps to selectively modify and route IP packets in hardware. The ACLs classify the traffic. Route maps that match on the ACLs set routing attributes for the traffic.

A PBR policy specifies the next hop for traffic that matches the policy. Using standard ACLs with PBR, you can route IP packets based on their source IP address. With extended ACLs, you can route IP packets based on all of the match criteria in the extended ACL.

You can configure the PowerConnect to perform the following types of PBR based on a packet's Layer 3 and Layer 4 information:

- Select the next-hop gateway.
- Send the packet to the null interface (null0).

When a PBR policy has multiple next hops to a destination, PBR selects the first live next hop specified in the policy that is up. If none of the policy's direct routes or next hops is available, the packets are forwarded as per the routing table.

Configuration considerations

The configuration considerations are as follows:

- A PBR policy on an interface takes precedence over a global PBR policy.
- You cannot apply PBR on a port if that port already has inbound ACLs, inbound ACL-based rate limiting, or TOS-based QoS.
- The number of route maps that you can define is limited by the system memory. When a route map is used in a PBR policy, the PBR policy uses up to 64 instances of a route map, up to 5 ACLs in a matching policy of each route map instance.
- ACLs with the **log** option configured should not be used for PBR purposes.

- PBR ignores implicit **deny ip any any** ACL entries, to ensure that for route maps that use multiple ACLs, the traffic is compared to all the ACLs. However, if an explicit **deny ip any any** is configured, traffic matching this clause will be routed normally using Layer 3 paths and will not be compared to any ACL clauses that follow this clause.
- PBR always selects the first next hop from the next hop list that is up. If a PBR policy's next hop goes down, the policy uses another next hop if available. If no next hops are available, the device routes the traffic in the normal way.
- When you change route maps or ACL definitions you must explicitly rebind the PBR policy to an interface using the **ip rebind-acl** command.
- If a PBR policy is applied globally, inbound ACLs, inbound ACL-based rate-limiting or TOS-based QoS cannot be applied to any port on the router.
- If an IPv4 option packet matches a **deny** ACL filter with the **option** keyword, the packet will be forwarded based on Layer-3 destination. If the **ignore-options** command is configured on the incoming physical port, the packet will be forwarded based on its Layer-3 destination in hardware, otherwise the packet will be sent to the CPU for software forwarding.
- If an IPv4 option packet matches a **permit** ACL filter with the option keyword, it is hardware-forwarded based on its PBR next-hop (if available). If no PBR next-hop is available, the packet is either software or hardware-forwarded (depending on whether **ignore-options** is configured), based on an IP forwarding decision.
- Policy Based Routing (PBR) currently does not support the IPv4 and IPv6 features for changing the MTU.
- Where the next hop is a GRE tunnel:
  - Packets that are larger than the tunnel's MTU are subject to IP fragmentation and PBR processing of the fragmented packets.
  - For route changes of the tunnel destination, the appropriate information is automatically propagated to the PBR feature. Depending on the configuration of the route map, a route change can change the active next hop of the PBR if it leads to the active next hop going down which triggers a new next hop selection process.

Configuring a PBR policy

To configure PBR, you define the policies using IP ACLs and route maps, then enable PBR globally or on individual interfaces. The device programs the ACLs into the Layer 4 CAM on the interfaces and routes traffic that matches the ACLs according to the instructions in the route maps.

To configure a PBR policy:

- Configure ACLs that contain the source IP addresses for the IP traffic you want to route using PBR. Refer to the section 21, "Access Control List" for details on how to configure ACLs.
- Configure a route map that matches on the ACLs and sets the route information.
- Apply the route map to an interface.

Configure the route map

After you configure the ACLs, you can configure a PBR route map that matches based on the ACLs and sets routing information in the IP traffic.

NOTE
The match and set statements described in this section are the only route-map statements supported for PBR. Other route-map statements described in the documentation apply only to the protocols with which they are described.

To configure a PBR route map, enter commands such as the following.

```
NetIron(config)# route-map test-route permit 99
NetIron(config-routemap test-route)# match ip address 99
NetIron(config-routemap test-route)# set ip next-hop 192.168.2.1
NetIron(config-routemap test-route)# exit
```

The commands in this example configure an entry in a route map named “test-route”. The **match** statement matches on IP information in ACL 99. The **set** statement changes the next-hop IP address for packets that match to 192.168.2.1.

Syntax: [no] route-map <*map-name*> **permit | deny** <*num*>

The <*map-name*> is a string of characters that names the map. Map names can be up to 32 characters in length. You can define an unlimited number of route maps on the PowerConnect, as long as system memory is available.

The **permit | deny** parameter specifies the action the PowerConnect will take if a route matches a match statement:

- If you specify a **deny** routemap instance, it is ignored and not programmed in Layer- 4 CAM.
- If you specify **permit**, the PowerConnect applies the match and set statements associated with this route map instance.

The <*num*> parameter specifies the instance of the route map you are defining. Routes are compared to the instances in ascending numerical order. For example, a route is compared to instance 1, then instance 2, and so on.

PBR uses up to 64 route map instances for comparison and ignores the rest.

Syntax: [no] match ip address <*ACL-num-or-name*>

The <*ACL-num*> parameter specifies a standard or extended ACL number or name.

Setting the next hop

Traffic that matches a match statement in the route map is forwarded as defined by **set** commands. Multiple **set** commands can be configured and when a match condition is met, the router works sequentially through the list of **set** commands until it finds the first “next hop” that is operational and uses it. If that “next hop” goes down, the next hop as defined in a **set** command is chosen and if all next hop interfaces in the list are down, the packet is routed as determined in the IP Route Table. If a next hop interface that was down comes back up, the next hop selection process begins again and restarts its selection process from the top of the list.

Options for setting the next hop are described in the following:

- Setting the Next Hop to an IP Address
- Setting the Next Hop to a GRE Tunnel
- Setting the Next Hop to a Null Interface
- Setting the Next Hop to an LSP
- Setting the Next Hop to VLAN Flooding

Setting the next hop to an IP address

You can set the next hop to an IP address as shown in the following.

```
NetIron(config)# route-map net10web permit 101
NetIron(config-routemap net10web)# match ip address 101
NetIron(config-routemap net10web)# set ip next-hop 1.1.1.1
```

Syntax: [no] set ip next-hop <*ip-address*>

The <*ip-address*> variable specifies the IP address of the next-hop IP address for traffic that matches a match statement in the route map.

NOTE
If the IP address used in this command is the IP address of a configured GRE tunnel, the configuration will still be accepted but the next-hop slection will never choose this next-hop so it will not become active. If you want to set the next hop using a GRE tunnel, you must use the **set next-hop-ip-tunnel** command.

Setting the next hop to a GRE tunnel

You can set the next hop to a GRE Tunnel as shown in the following:

Syntax: [no] set next-hop-ip-tunnel <*tunnel-id*>

This command sets the next hop to the GRE tunnel identifed by the <*tunnel-id*> variable. Only GRE tunnels are supported by this command. The system will verify if a valid GRE tunnel with the specifed <*tunnel-id*> variable exists. If the <*tunnel-id*> variable points to a tunnel other than a GRE tunnel or to a non-existent tunnel, the configuration will be rejected.

Values for the <*tunnel-id*> variable can be from 1 to the maximum number of allowed Tunnel IDs in the system, The maximum number of Tunnel IDs allowed is set using the **system-max ip-tunnels** command.

For an example of a configuration using this command, refer to "Setting the next hop to a GRE tunnel" on page 840.

Setting the next hop to a Null0 interface

Sending traffic to a Null0 Interface drops the traffic. You can set the next hop to a Null0 interface as shown in the following.

```
NetIron(config)# route-map file-13 permit 56
NetIron(config-routemap file-13)# match ip address 56
NetIron(config-routemap file-13)# set interface null0
```

Syntax: [no] set interface null0

Setting the next hop to an LSP

You can set the next hop to an LSP as shown in the following.

```
NetIron(config)# route-map pbrmap permit 10
NetIron(config-routemap pbrmap)# match ip address 101
NetIron(config-routemap pbrmap)# set next-hop-lsp t3
```

Syntax: [no] set next-hop-lsp <*lsp-name*>

This command allows you to forward matching traffic to an RSVP -signalled LSP that is specified by the <*lsp-name*> variable.

Setting next hop VLAN flooding

This feature supports the ability to use PBR to forward traffic to a VLAN through use of a new "set" command. Using this feature, matched traffic can be flooded on all ports of the VLAN except the incoming physical port. Any PBR policy that contains the **set next-flood-vlan** statement applies to both routed and switched traffic. This means that if any instance in a PBR route-map contains the **set next-flood-vlan** statement, all instances of that route-map will be applied to both routed and switched traffic.

The following example floods all traffic matched from ACL 101 on all ports of VLAN 10 except the incoming physical port.

```
NetIron(config)# access-list 101 permit ip any any
NetIron(config)# route-map calea permit 10
NetIron(config-routemap calea)# match ip address 101
NetIron(config-routemap calea)# set next-flood-vlan 10
NetIron(config-routemap calea)# exit
```

Syntax: [no] set next-flood-vlan <*vlan-id*> **[outgoing da** <*mac-address*> **]**

If the VLAN specified by the <*vlan-id*> variable is not configured, the PBR route-map set statement will fall through to the next configured set statement. If no valid next-hop is available, the packet is forwarded as per L2/L3 forwarding decision. If the VLAN specified by the <*vlan-id*> variable has no valid outgoing ports, (such as when all ports in the VLAN are down or when the VLAN is empty) matching packets will be dropped.

The **outgoing da** option directs the router to send packets flooded to the ports on the VLAN to carry the destination MAC address specified in the <*mac-address*> variable.

If the destination MAC address is not set using the **outgoing da** option, the destination address is set as described in Table 134.

TABLE 134 Destination address on VLAN flooded packets

Incoming port	Outgoing port	Routed traffic	Switched traffic
Ethernet	Ethernet	Replaced Destination Address	Original Destination Address from Incoming Packet
POS	Ethernet	Replaced Destination Address	N/A

The **no set next-hop-flood-vlan** <*vlan-id*> **outgoing-da** <*mac-address*> command deletes only the outgoing-da option from the set statement. It does not delete the set statement itself. To delete the set statement, the user would have to specify the **no set next-hop-flood-vlan** <*vlan-id*> command .

In the case of traffic incoming on MPLS uplink, PBR to VLAN flooding is only supported for IPv4 traffic, and not for MPLS traffic.

Enabling PBR

After you configure the ACLs and route map entries, you can enable PBR globally, on individual interfaces, or both as described in this section. To enable PBR, you apply a route map you have configured for PBR globally or locally.

Enabling PBR globally

To enable PBR globally, enter a command such as the following at the global CONFIG level.

```
NetIron(config)# ip policy route-map test-route
```

This command applies a route map named “test-route” to all interfaces on the device for PBR.

Syntax: [no] ip policy route-map <*map-name*>

Enabling PBR locally

To enable PBR locally, enter commands such as the following.

```
NetIron(config)# interface ve 1
NetIron(config-vif-1)# ip policy route-map test-route
```

The commands in this example change the CLI to the Interface level for virtual interface 1, then apply the “test-route” route map to the interface. You can apply a PBR route map to Ethernet ports, POS ports, or virtual interfaces.

Syntax: [no] ip policy route-map <*map-name*>

Enter the name of the route map you want to use for the route-map <*map-name*> parameter.

Configuration examples

This section presents configuration examples for:

Basic example

The following commands configure and apply a PBR policy that routes HTTP traffic received on virtual routing interface 1 from the 10.10.10.x/24 network to 5.5.5.x/24 through next-hop IP address 1.1.1.1 or, if 1.1.1.x is unavailable, through 2.2.2.1.

```
NetIron(config)# access-list 101 permit tcp 10.10.10.0 0.0.0.255 eq http 5.5.5.0
NetIron(config)# route-map net10web permit 101
NetIron(config-routemap net10web)# match ip address 101
NetIron(config-routemap net10web)# set ip next-hop 1.1.1.1
NetIron(config-routemap net10web)# set ip next-hop 2.2.2.1
NetIron(config-routemap net10web)# exit
NetIron(config)# vlan 10
NetIron(config-vlan-10)# tagged ethernet 1/1 to 1/4

NetIron(config-vlan-10)# router-interface ve 1
NetIron(config)# interface ve 1
NetIron(config-vif-1)# ip policy route-map net10web
```

Setting the next hop

The following commands configure the PowerConnect to apply PBR to traffic from IP subnets 209.157.23.x, 209.157.24.x, and 209.157.25.x. In this example, route maps specify the next-hop gateway for packets from each of these subnets:

- Packets from 209.157.23.x are sent to 192.168.2.1.

- Packets from 209.157.24.x are sent to 192.168.2.2.
- Packets from 209.157.25.x are sent to 192.168.2.3.

The following commands configure three standard ACLs. Each ACL contains one of the ACLs listed above. Make sure you specify **permit** instead of deny in the ACLs, so that the PowerConnect permits the traffic that matches the ACLs to be further evaluated by the route map. If you specify **deny**, the traffic that matches the **deny** statements are routed normally. Notice that these ACLs specify **any** for the destination address.

```
NetIron(config)# access-list 50 permit 209.157.23.0 0.0.0.255
NetIron(config)# access-list 51 permit 209.157.24.0 0.0.0.255
NetIron(config)# access-list 52 permit 209.157.25.0 0.0.0.255
```

The following commands set an RSVP-signalled LSP as the next hop.

```
NetIron(config)# access-list 101 permit tcp any any
NetIron(config)# access-list 101 deny ip any any
NetIron(config)# router mpls
NetIron(config-mpls)# mpls-interface ethernet 6/1
NetIron(config-mpls)# lsp t3
NetIron(config-mpls-lsp-t3)# to 30.1.1.1
NetIron(config-mpls-lsp-t3)# enable
NetIron(config)# route-map pbrmap permit 10
NetIron(config-routemap pbrmap)# match ip address 101
NetIron(config-routemap pbrmap)# set next-hop-lsp t3
```

The following commands configure three entries in a route map called “test-route”. The first entry (permit 50) matches on the IP address information in ACL 50 above. For IP traffic from subnet 209.157.23.0/24, this route map entry sets the next-hop IP address to 192.168.2.1.

```
NetIron(config)# route-map test-route permit 50
NetIron(config-routemap test-route)# match ip address 50
NetIron(config-routemap test-route)# set ip next-hop 192.168.2.1
NetIron(config-routemap test-route)# exit
```

The following commands configure the second entry in the route map. This entry (permit 51) matches on the IP address information in ACL 51 above. For IP traffic from subnet 209.157.24.0/24, this route map entry sets the next-hop IP address to 192.168.2.2.

```
NetIron(config)# route-map test-route permit 51
NetIron(config-routemap test-route)# match ip address 51
NetIron(config-routemap test-route)# set ip next-hop 192.168.2.2
NetIron(config-routemap test-route)# exit
```

The following commands configure the third entry in the test-route route map. This entry (permit 52) matches on the IP address information in ACL 52 above. For IP traffic from subnet 209.157.25.0/24, this route map entry sets the next-hop IP address to 192.168.2.3.

```
NetIron(config)# route-map test-route permit 52
NetIron(config-routemap test-route)# match ip address 52
NetIron(config-routemap test-route)# set ip next-hop 192.168.2.3
NetIron(config-routemap test-route)# exit
```

The following command enables PBR by globally applying the test-route route map to all interfaces.

```
NetIron(config)# ip policy route-map test-route
```

Alternatively, you can enable PBR on specific interfaces, as shown in the following example. The commands in this example configure IP addresses in the three source subnets identified in ACLs 50, 51, and 52, then apply route map test-route the interface.

```
NetIron(config)# interface ve 1
NetIron(config-vif-1)# ip address 209.157.23.1/24
NetIron(config-vif-1)# ip address 209.157.24.1/24
NetIron(config-vif-1)# ip address 209.157.25.1/24
NetIron(config-vif-1)# ip policy route-map test-route
```

Setting the next hop to a GRE tunnel

This section describes how to configure a PowerConnect to apply PBR to traffic on port 1/4 from subnets 11.12.13.x and 14.15.16.x. Packets from these subnets are then sent to a next hop that is a GRE tunnel. In this configuration, two GRE tunnels are configured to provide redundancy. If the first tunnel in the configuration (Tunnel 1) is down, traffic will be routed to the second tunnel (Tunnel 2). In situations where both tunnels are down, traffic from the subnets will be routed as directed from the IP route table.

```
NetIron(config)# interface ethernet 1/4
NetIron(config-if-e1000-1/1)# ip policy route-map test1
NetIron(config-if-e1000-1/1)# exit
NetIron(config)# interface tunnel 1
NetIron(config-tnif-1)# tunnel mode gre ip
NetIron(config-tnif-1)# tunnel source ethernet 1/2
NetIron(config-tnif-1)# tunnel destination 36.0.8.108
NetIron(config-tnif-1)# ip address 10.10.3.2/24
NetIron(config-tnif-1)# exit

NetIron(config)# interface tunnel 2
NetIron(config-tnif-2)# tunnel mode gre ip
NetIron(config-tnif-2)# tunnel source ethernet 2/2
NetIron(config-tnif-2)# tunnel destination 36.0.9.108
NetIron(config-tnif-2)# ip address 10.10.4.2/24
NetIron(config-tnif-2)# exit
NetIron(config)# access-list 99 permit 11.12.13.0 0.0.0.255
NetIron(config)# access-list 99 permit 14.15.16.0 0.0.0.255

NetIron(config)# route-map test1 permit 5
NetIron(config-routemap test1)# match ip address 99
NetIron(config-routemap test1)# set next-hop-ip-tunnel 1
NetIron(config-routemap test1)# set next-hop-ip-tunnel 2
```

Setting the output interface to the null interface

The following commands configure a PBR to send all traffic from 209.168.1.204 to the null interface, thus dropping the traffic instead of forwarding it.

```
NetIron(config)# access-list 56 permit 209.168.1.204 0.0.0.0
```

The following commands configure an entry in a route map called “file-13”. The first entry (permit 56) matches on the IP address information in ACL 56 above. For IP traffic from the host 209.168.1.204/32, this route map entry sends the traffic to the null interface instead of forwarding it, thus sparing the rest of the network the unwanted traffic.

```
NetIron(config)# route-map file-13 permit 56
NetIron(config-routemap file-13)# match ip address 56
NetIron(config-routemap file-13)# set interface null0
NetIron(config-routemap file-13)# exit
```

The following command enables PBR by globally applying the route map to all interfaces.

```
NetIron(config)# ip policy route-map file-13
```

Alternatively, you can enable the PBR on specific interfaces, as shown in the following example. The commands in this example configure IP addresses in the source subnet identified in ACL 56, then apply route map file-13 to the interface.

```
NetIron(config)# interface ethernet 3/11
NetIron(config-if-e10000-3/11)# ip address 192.168.1.204/32
NetIron(config-if-e10000-3/11)# ip policy route-map file-13
```

Selectively applying normal routing to packets

This example demonstrates how to configure PBR to route all TCP traffic from a host normally while routing all other traffic from the same host through the PBR next hop. In this example, the IP address of the host is 192.168.2.2.

To route TCP traffic from 192.168.2.2 normally, configure a **deny** ACL clause and define it as a **permit route-map** entry as shown in the following.

```
NetIron(config)# access-list 112 deny tcp host 192.168.2.2 any
NetIron(config)# access-list 112 permit ip host 192.168.2.2 any
NetIron(config)# route-map mymap2 permit 10
NetIron(config-routemap mymap2)# match ip address 112
NetIron(config-routemap mymap2)# set ip next-hop 11.1.1.2
```

LAG formation

When a LAG is formed, all ports must have the same PBR configuration before deployment, during deployment the configuration on the primary port is replicated to all ports and on undeployment each port inherits the same PBR configuration.

Configuring RIP 23

Overview

The following displays the RIP features supported by Brocade NetIron XMR Series.

- RIP V1
- RIP V1 compatible with V2
- RIP Version 2 (the default)
- Administrative Distances
- Redistribution
- Route Learning and Advertising Parameters
- Changing the Route Loop Prevention Method
- Suppressing RIP Route Advertisement on a VRRP or VRRPE Backup Interface
- RIP Timers
- RIP Filters

Routing Information Protocol (RIP) is an IP route exchange protocol that uses a ***distance vector*** (a number representing distance) to measure the cost of a given route. The ***cost*** is a distance vector because the cost often is equivalent to the number of router hops between the device and the destination network.

A device can receive multiple paths to a destination. The software evaluates the paths, selects the best path, and saves the path in the IP route table as the route to the destination. Typically, the best path is the path with the fewest hops. A hop is another router through which packets must travel to reach the destination. If the device receives a RIP update from another router that contains a path with fewer hops than the path stored in the device's route table, the device replaces the older route with the newer one. The device then includes the new path in the updates it sends to other RIP routers, including device.

RIP routers, including the PowerConnect, also can modify a route's cost, generally by adding to it, to bias the selection of a route for a given destination. In this case, the actual number of router hops may be the same, but the route has an administratively higher cost and is thus less likely to be used than other, lower-cost routes.

A RIP route can have a maximum cost of 15. Any destination with a higher cost is considered unreachable. Although limiting to larger networks, the low maximum hop count prevents endless loops in the network.

The device supports the following RIP versions:

- Version 1
- V1 compatible with V2
- Version 2 (the default)

RIP parameters and defaults

The following tables list the RIP parameters, their default values, and where to find configuration information.

RIP global parameters

Table 135 lists the global RIP parameters and their default values, and indicates where you can find configuration information.

TABLE 135 RIP global parameters

Parameter	Description	Default	See page...
RIP state	The global state of the protocol **NOTE:** You also must enable the protocol on individual interfaces. Globally enabling the protocol does not allow interfaces to send and receive RIP information. Refer to Table 136 on page 845.	Disabled	page 845
Administrative distance	The administrative distance is a numeric value assigned to each type of route on the router. When the router is selecting from among multiple routes (sometimes of different origins) to the same destination, the router compares the administrative distances of the routes and selects the route with the lowest administrative distance.	120	page 846
Redistribution	RIP can redistribute routes from other routing protocols such as OSPF and BGP4 into RIP. A redistributed route is one that a router learns through another protocol, then distributes into RIP.	Disabled	page 847
Redistribution metric	RIP assigns a RIP metric (cost) to each external route redistributed from another routing protocol into RIP. This parameter applies to routes that are redistributed from other protocols into RIP.	1 (one)	page 848
Learning default routes	The router can learn default routes from its RIP neighbors. **NOTE:** You also can enable or disable this parameter on an individual interface basis. Refer to Table 136 on page 845.	Disabled	page 849
Advertising and learning with specific neighbors	The device learns and advertises RIP routes with all its neighbors by default. You can prevent the device from advertising routes to specific neighbors or learning routes from specific neighbors.	Learning and advertising permitted for all neighbors	page 849

RIP interface parameters

Table 136 lists the interface-level RIP parameters and their default values, and indicates where you can find configuration information.

TABLE 136 RIP interface parameters

Parameter	Description	Default	See page...
RIP state and version	The state of the protocol and the version that is supported on the interface. The version can be one of the following: • Version 1 only • Version 2 only • Version 1, but also compatible with version 2 **NOTE:** : You also must enable RIP globally.	Disabled	page 845
Metric	A numeric cost the router adds to RIP routes learned on the interface. This parameter applies only to RIP routes.	1 (one)	page 846
Learning default routes	Locally overrides the global setting. Refer to Table 135 on page 844.	Disabled	page 849
Loop prevention	The method a router uses to prevent routing loops caused by advertising a route on the same interface as the one on which the router learned the route. • Split horizon – The router does not advertise a route on the same interface as the one on which the router learned the route. • Poison reverse – The router assigns a cost of 16 ("infinite" or "unreachable") to a route before advertising it on the same interface as the one on which the router learned the route.	Split Horizon **NOTE:** Disabling poison reverse enables split horizon on the interface.	page 849
Advertising and learning specific routes	You can control the routes that a device learns or advertises.	The device learns and advertises all RIP routes on all interfaces.	page 850

Configuring RIP parameters

Use the following procedures to configure RIP parameters on a system-wide and individual interface basis.

Enabling RIP

RIP is disabled by default. To enable RIP, you must enable it globally and also on individual interfaces on which you want to advertise RIP. Globally enabling the protocol does not enable it on individual interfaces. You can enable the protocol on physical interfaces as well as virtual routing interfaces. When you enable RIP on a port, you also must specify the version (version 1 only, version 2 only, or version 1 compatible with version 2).

To enable RIP globally, enter the following command.

```
NetIron(config)# router rip
```

Syntax: [no] router rip

After globally enabling the protocol, you must enable it on individual interfaces. To enable RIP on an interface, enter commands such as the following.

```
NetIron(config)# interface ethernet 1/1
NetIron(config-if-e1000-1/1)# ip rip v1-only
```

Syntax: [no] ip rip v1-only | v1-compatible-v2 | v2-only

Configuring metric parameters

By default, a PowerConnect port increases the cost of a RIP route that is learned or advertised on the port by one. You can configure individual ports to add more than one to a learned or advertised route's cost.

Changing the cost of routes learned or advertised on a port

By default, a PowerConnect port increases the cost of a RIP route that is learned on the port. The PowerConnect increases the cost by adding one to the route's metric before storing the route.

You can change the amount that an individual port adds to the metric of RIP routes learned on the port.

To increase the metric for learned routes, enter commands such as the following.

```
NetIron(config-if-e1000-1/1)# ip rip metric-offset 5 in
```

The command configures port 1/1 to add 5 to the cost of each route it learns.

Syntax: [no] ip rip metric-offset <*num*> **in | out**

The number is 1-16. A route with a metric of 16 is unreachable. Use 16 only if you do not want the route to be used. In fact, you can prevent the device from using a specific port for routes learned though that port by setting its metric to 16.

In applies to routes the port learns from RIP neighbors.

Out applies to routes the port advertises to its RIP neighbors.

Changing the administrative distance

By default, the device assigns the default RIP administrative distance (120) to RIP routes. When comparing routes based on administrative distance, the device selects the route with the lower distance. You can change the administrative distance for RIP routes.

NOTE
Refer to "Changing administrative distances" on page 1030 for a list of the default distances for all route sources.

To change the administrative distance for RIP routes, enter a command such as the following.

```
NetIron(config-rip-router)# distance 140
```

The command changes the administrative distance to 140 for all RIP routes.

Syntax: [no] distance <*number*>

The number is 1 - 255.

Configuring redistribution

You can configure the device to redistribute routes learned through OSPF or BGP4, connected into RIP, or static routes. When you redistribute a route from one of these other protocols into RIP, the device can use RIP to advertise the route to its RIP neighbors.

To configure redistribution, perform the following tasks:

- Configure redistribution filters. You can configure filters to permit or deny redistribution for a route based on its origin (OSPF, BGP4, and so on), the destination network address, and the route's metric. You also can configure a filter to set the metric based on these criteria.
- Change the default redistribution metric (optional). The device assigns a RIP metric of one to each redistributed route by default. You can change the default metric to a value up to 16.

Configuring redistribution filters

RIP redistribution filters apply to all interfaces. You use route maps to define how you want to deny or permit redistribution.

NOTE
The default redistribution action is permit, even after you configure and apply redistribution filters to the virtual routing interface. If you want to tightly control redistribution, apply a filter to deny all routes as the last filter (the filter with the highest ID), then apply filters to allow specific routes.

A ***route map*** is a named set of match conditions and parameter settings that the router can use to modify route attributes and to control redistribution of the routes into other protocols. A route map consists of a sequence of up to 50 ***instances***. If you think of a route map as a table, an instance is a row in that table. The router evaluates a route according to a route map's instances in ascending numerical order. The route is first compared against instance 1, then against instance 2, and so on. As soon as a match is found, the router stops evaluating the route against the route map instances.

Route maps can contain ***match*** statements and ***set*** statements. Each route map contains a "permit" or "deny" action for routes that match the match statements:

- If the route map contains a permit action, a route that matches a match statement is permitted; otherwise, the route is denied.
- If the route map contains a deny action, a route that matches a match statement is denied.
- If a route does not match any match statements in the route map, the route is denied. This is the default action. To change the default action, configure the last match statement in the last instance of the route map to "permit any any".
- If there is no match statement, the software considers the route to be a match.
- For route maps that contain address filters, AS-path filters, or community filters, if the action specified by a filter conflicts with the action specified by the route map, the route map's action takes precedence over the individual filter's action.

If the route map contains set statements, routes that are permitted by the route map's match statements are modified according to the set statements.

In RIP, the match statements are based on prefix lists and access control lists. Set statements are based on tag values and metric values.

To configure redistribution filters, enter a command such as the following.

```
NetIron(config-rip-router)#redistribute bgp route-map longroute
```

Syntax: [no] redistribute connected | bgp | ospf | static [metric <*value*> | route-map <*name*>]

The **connected** parameter applies redistribution to connected types.

The **bgp** parameter applies redistribution to BGP4 routes.

The **ospf** parameter applies redistribution to OSPF routes.

The **static** parameter applies redistribution to IP static routes.

The **metric** <*value*> parameter sets the RIP metric value 1- 15 that will be applied to the routes imported into RIP.

The **route-map** <*name*> parameter indicates the route map's name.

Matching based on RIP protocol type

The **match** option has been added to the **route-map** command that allows statically configured routes or the routes learned from the IGP protocol RIP.

To configure the route map to match to RIP, enter a command such as the following.

```
NetIron(config-routemap test)# match protocol rip
```

Syntax: [no] match protocol rip

Changing the default redistribution metric

When the device redistributes a route into RIP, the software assigns a RIP metric (cost) to the route. By default, the software assigns a metric of one to each route that is redistributed into RIP. You can increase the metric that the device assigns, up to 15.

To change the RIP metric the device assigns to redistributed routes, enter a command such as the following.

```
NetIron(config-rip-router)# default-metric 10
```

This command assigns a RIP metric of 10 to each route that is redistributed into RIP.

Syntax: [no] default-metric <*1-15*>

Configuring route learning and advertising parameters

By default, a device learns routes from all its RIP neighbors and advertises RIP routes to those neighbors.

You can configure the following learning and advertising parameters:

- **Learning and advertising of RIP default routes** – The device learns and advertises RIP default routes by default. You can disable learning and advertising of default routes on a global or individual interface basis.
- **Learning of standard RIP routes** – By default, the device can learn RIP routes from all its RIP neighbors. You can configure RIP neighbor filters to explicitly permit or deny learning from specific neighbors.

Enabling learning of RIP default routes

By default, the device does not learn default RIP routes. You can enable learning of RIP default routes on a global or interface basis.

To enable learning of default RIP routes on a global basis, enter the following command.

```
NetIron(config-rip-router)# learn-default
```

Syntax: [no] learn-default

To enable learning of default RIP routes on an interface, enter commands such as the following.

```
NetIron(config)# interface ethernet 1/1
NetIron(config-if-e10000-1/1)# ip rip learn-default
```

Syntax: [no] ip rip learn-default

Configuring a RIP neighbor filter

By default, a device learns RIP routes from all its RIP neighbors. Neighbor filters allow you to specify the neighbor routers from which the device can receive RIP routes. Neighbor filters apply globally to all ports.

To configure a RIP neighbor filters, enter a command such as the following.

```
NetIron(config-rip-router)# neighbor 1 deny any
```

Syntax: [no] neighbor <*filter-num*> **permit | deny** <*source-ip-address*> **| any**

This command configures the NetIron so that the device does not learn any RIP routes from any RIP neighbors.

The following commands configure the device to learn routes from all neighbors except 192.168.1.170. Once you define a RIP neighbor filter, the default action changes from learning all routes from all neighbors to denying all routes from all neighbors except the ones you explicitly permit. Thus, to deny learning from a specific neighbor but allow all other neighbors, you must add a filter that allows learning from all neighbors. Make sure you add the filter to permit all neighbors as the last filter (the one with the highest filter number). Otherwise, the software can match on the permit all filter before a filter that denies a specific neighbor, and learn routes from that neighbor.

```
NetIron(config-rip-router)# neighbor 2 deny 192.16.1.170
NetIron(config-rip-router)# neighbor 1024 permit any
```

Changing the route loop prevention method

RIP uses the following methods to prevent routing loops:

- **Split horizon** – The device does not advertise a route on the same interface as the one on which the router learned the route. This is the default.
- **Poison reverse** – The device assigns a cost of 16 (“infinite” or “unreachable”) to a route before advertising it on the same interface as the one on which the router learned the route.

These loop prevention methods are configurable on a global basis as well as on an individual interface basis. One of the methods is always in effect on an interface enabled for RIP. Thus, if you disable one method, the other method is enabled.

NOTE
These methods are in addition to RIP’s maximum valid route cost of 15.

To disable poison reverse and enable split horizon on a global basis, enter the following command.

```
NetIron(config-rip-router)# no poison-reverse
```

Syntax: [no] poison-reverse

To disable poison reverse and enable split horizon on an interface, enter commands such as the following.

```
NetIron(config-if-e10000-1/1)# no ip rip poison-reverse
```

Syntax: [no] ip rip poison-reverse

To disable split horizon and enable poison reverse on an interface, enter the command such as the following.

```
NetIron(config-if-e10000-1/1)# ip rip poison-reverse
```

You can configure the device to avoid routing loops by advertising local RIP routes with a cost of 16 ("infinite" or "unreachable") when these routes go down.

```
NetIron(config-rip-router)# poison-local-routes
```

Syntax: [no] poison-local-routes

Suppressing RIP route advertisement on a VRRP or VRRPE backup interface

NOTE
This section applies only if you configure the device for Virtual Router Redundancy Protocol (VRRP) or VRRP Extended (VRRPE). Refer to 17, “Configuring VRRP and VRRP-E”.

Normally, a VRRP or VRRPE Backup includes route information for the virtual IP address (the backed up interface) in RIP advertisements. As a result, other routers receive multiple paths for the backed up interface and might sometimes unsuccessfully use the path to the Backup rather than the path to the Master.

You can prevent the Backups from advertising route information for the backed up interface by enabling suppression of the advertisements.

To suppress RIP advertisements for the backed up interface in Router2, enter the following commands.

```
Router2(config)# router rip
Router2(config-rip-router)# use-vrrp-path
```

Syntax: [no] use-vrrp-path

The syntax is the same for VRRP and VRRPE.

Using prefix lists and route maps as route filters

You can configure prefix lists to permit or deny specific routes, then apply them globally or to individual interfaces and specify whether the lists apply to learned routes (in) or advertised routes (out).

You can configure route maps to permit or deny specific routes, then apply a route map to an interface, and specify whether the map applies to learned routes (in) or advertised routes (out).

NOTE
A route is defined by the destination's IP address and network mask.

NOTE
By default, routes that do not match a prefix list are learned or advertised. To prevent a route from being learned or advertised, you must configure a prefix list to deny the route.

To configure a prefix list, enter commands such as the following.

```
NetIron(config)# ip prefix-list list1  permit 192.53.4.1 255.255.255.0
NetIron(config)# ip prefix-list list2  permit 192.53.5.1 255.255.255.0
NetIron(config)# ip prefix-list list3  permit 192.53.6.1 255.255.255.0
NetIron(config)# ip prefix-list list4 deny 192.53.7.1 255.255.255.0
```

The prefix lists permit routes to three networks, and deny the route to one network.

Since the default action is permit, all other routes (routes not explicitly permitted or denied by the filters) can be learned or advertised.

Syntax: [no] ip prefix-list <*name*> **permit | deny** <*source-ip-address*> **| any** <*source-mask*> **| any**

To apply a prefix list at the global level of RIP, enter commands such as the following.

```
NetIron(config-rip-router)# prefix-list list1 in
```

Syntax: [no] prefix-list <*name*> **in | out**

To apply prefix lists to a RIP interface, enter commands such as the following.

```
NetIron(config-if-e1000-1/2)# ip rip prefix-list list2 in
NetIron(config-if-e1000-1/2)# ip rip prefix-list list3 out
```

Syntax: [no] ip rip prefix-list <*name*> **in | out**

In applies the prefix list to routes the device learns from its neighbor on the interface.

Out applies the prefix list to routes the device advertises to its neighbor on the interface.

The commands apply RIP list2 route filters to all routes learned from the RIP neighbor on port 1/2 and applies the lists to all routes advertised on port 1/2.

To apply a route map to a RIP interface, enter commands such as the following.

```
NetIron(config-if-e1000-1/2)# ip rip route-map map1 in
```

Syntax: [no] ip rip route-map <*name*> **in | out**

The **route-map** <*name*> can be a prefix list or an ACL. Setting this command can change the metric.

In applies the route map to routes the device learns from its neighbor on the interface.

Out applies the route map to routes the device advertises to its neighbor on the interface.

The commands apply route map map1 as route filters to routes learned from the RIP neighbor on port 1/2.

Setting RIP timers

You can set basic update timers for the RIP protocol. The protocol must be enabled in order to set the timers.

To set the timers.

```
NetIron(config) router rip
NetIron(config-rip-router)# timers 50
```

Syntax: [no] timers <*seconds*>

Possible values: 3 - 21845 seconds

Default: 30 seconds

The command specifies how often RIP update messages are sent.

Displaying RIP Information

To display RIP filters, enter the following command at any CLI level.

```
NetIron#> show ip rip
  RIP Summary
  Default port 520
      Administrative distance is 120
      Updates every 30 seconds, expire after 180
      Holddown lasts 180 seconds, garbage collect after 120
      Last broadcast 2, Next Update 26
      Need trigger update 0, Next trigger broadcast 3
      Minimum update interval 25, Max update Offset 5
      Split horizon is on; poison reverse is off
      Import metric 1
      Prefix List, Inbound : Not set
      Prefix List, Outbound : Not set
      Route-map, Inbound : Not set
      Route-map, Outbound : Not set
      Redistribute:
  No Neighbors are configured in RIP Neighbor Filter Table
```

Syntax: show ip rip

See Table 137 on page 853 for display information.

To display RIP filters for a specific interface, enter the following command.

```
NetIron#show ip rip interface
Interface eth 1/20
 Rip Mode : Version 2 Running: TRUE
 Route summarization disabled
 Split horizon is on; poison reverse is off
 Default routes not accepted
 Metric-offset, Inbound 1
 Metric-offset, Outbound 0
 Prefix List, Inbound : Not set
      Prefix List, Outbound : Not set
 Route-map, Inbound : Not set
Interface ve 10
 RIP Mode : Compatible Running: TRUE
 Route summarization disabled
 Split horizon is off; poison reverse is on
 Default routes not accepted
 Metric-offset, Inbound 1
 Metric-offset, Outbound 0
 Prefix List, Inbound : Not set
      Prefix List, Outbound : Not set
 Route-map, Inbound : Not set
 Route-map, Outbound : Not set
Interface ve 20
 RIP Mode : Version1 Running: TRUE
 Route summarization enabled
 Split horizon is off; poison reverse is on
 Default routes not accepted
 Metric-offset, Inbound 1
 Metric-offset, Outbound 0
 Prefix List, Inbound : Not set
      Prefix List, Outbound : Not set
 Route-map, Inbound : Not set
 Route-map, Outbound : Not set
```

Syntax: show ip rip interface <ifName>

This display shows the following information.

TABLE 137 CLI display of neighbor filter information

This field...	Displays...
RIP Summary area	Shows the current configuration of RIP on the device.
Statis metric	Shows the static metric configuration. ".not defined" means the route map has not been distributed.
OSPF metric	Shows what OSPF route map has been applied.
Neighbor Filter Table area	
Index	The filter number. You assign this number when you configure the filter.

TABLE 137 CLI display of neighbor filter information (Continued)

This field...	Displays...
Action	The action the router takes for RIP route packets to or from the specified neighbor: • deny – If the filter is applied to an interface's outbound filter group, the filter prevents the router from advertising RIP routes to the specified neighbor on that interface. If the filter is applied to an interface's inbound filter group, the filter prevents the router from receiving RIP updates from the specified neighbor. • permit – If the filter is applied to an interface's outbound filter group, the filter allows the router to advertise RIP routes to the specified neighbor on that interface. If the filter is applied to an interface's inbound filter group, the filter allows the router to receive RIP updates from the specified neighbor.
Neighbor IP Address	The IP address of the RIP neighbor.

To display RIP route information, enter the following command.

```
PowerConnect#show ip rip route
RIP Routing Table - 35 entries:
 1.0.0.0/8, from 51.1.0.2, ve 10 (2)
          RIP, metric 4, tag 0, timers: aging 17 holddown -163
 12.0.0.0/8, from 51.1.0.2, ve 10 (6)
          RIP, metric 16, tag 0, timers: holddown 19 garbage 19
 12.1.1.0/24, from 0.0.0.0, eth 1/20 (34)
          MCAST, metric 1, tag 0, timers: none
 51.1.0.0/24, from 0.0.0.0, ve 10 (1)
          MCAST, metric 1, tag 0, timers: none
```

Syntax: show ip rip route

To display current running configuration for interface 1/20, enter the following command.

```
NetIron#show running-config interface ethernet 1/20
interface ethernet 1/20
 enable
 ip ospf area 0
 ip ospf priority 0
 ip rip v2-only
 ip address 12.1.1.2/24
 ipv6 address 2000::1/32
 ipv6 enable
!
```

To display current running configuration for ve 10, enter the following command.

```
NetIron#show running-config interface ve 10
interface ve 10
 bfd interval 50 min-rx 50 multiplier 3
 ip ospf area 2
 ip rip v1-compatible-v2
 ip rip poison-reverse
 ip address 51.1.0.1/24
 ipv6 address 51:1:1::14/64
!
```

To display current running configuration for ve 20, enter the following command.

```
NetIron#show running-config interface ve 20
interface ve 20
 ip ospf area 1
 ip rip v1-only
 ip rip poison-reverse
 ip address 51.2.0.1/24
!
```

Configuring OSPF Version 2 24

Overview

The following list displays the OSPF features supported by PowerConnect B-MLXe:

- OSPF
- OSPF Graceful Restart
- OSPF Graceful Restart helper-mode
- OSPF Dynamic Metric Calculation for LAGs/VE
- OSPF Point-to-Point Links
- OSPF Non-Broadcast
- Router LSAs (Type 1)
- Network LSAs (Type 2)
- Interarea prefix LSAs for ABRs (Type 3)
- Interarearouter LSAs for ASBRs (Type 4)
- Autonomous system external LSAs (Type 5)
- Link LSAs (Type 8)
- Intra-area prefix LSAs (Type 9)
- OSPF Distribute List
- OSPF Administrative Distance Control Using Route Maps
- OSPF Non-stop routing (NSR)
- OSPFv3 Virtual-Link Enhancement:Dynamic Tunnel Calculation
- New encryption code for passwords, authentication keys, and community strings
- Support for the **show ip ospf interface** command with interface filters
- OSPF VRF-Lite for CE routers

OSPF is a link-state routing protocol. The protocol uses link-state advertisements (LSA) to update neighboring routers regarding its interfaces and information on those interfaces. The router floods these LSAs to all neighboring routers to update them regarding the interfaces. Each router maintains an identical database that describes its area topology to help a router determine the shortest path between it and any neighboring router.

The PowerConnect supports the following types of LSAs, which are described in RFC 2328 and 3101:

- Router link
- Network link
- Summary link
- Autonomous system (AS) summary link

- AS external link
- Not-So-Stubby Area (NSSA) external link

OSPF is built upon a hierarchy of network components. The highest level of the hierarchy is the ***Autonomous System (AS)***. An autonomous system is defined as a number of networks, all of which share the same routing and administration characteristics.

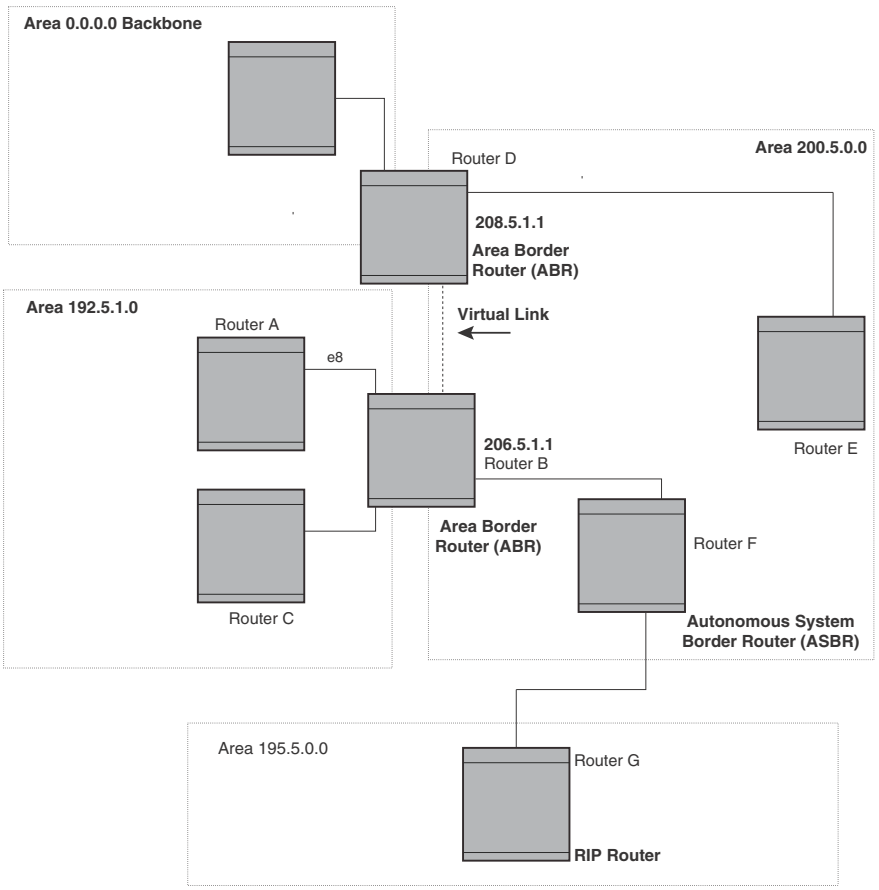
An AS can be divided into multiple ***areas*** as shown in Figure 132 on page 859. Each area represents a collection of contiguous networks and hosts. Areas limit the area to which link-state advertisements are broadcast, thereby limiting the amount of flooding that occurs within the network. An area is represented in OSPF by either an IP address or a number.

You can further limit the broadcast area of flooding by defining an area range. The area range allows you to assign an aggregate value to a range of IP addresses. This aggregate value becomes the address that is advertised instead all of the individual addresses it represents being advertised. You can assign up to 32 ranges in an OSPF area.

An OSPF router can be a member of multiple areas. Routers with membership in multiple areas are known as ***Area Border Routers (ABRs)***. Each ABR maintains a separate topological database for each area the router is in. Each topological database contains all of the LSA databases for each router within a given area. The routers within the same area have identical topological databases. The ABR is responsible for forwarding routing information or changes between its border areas.

An ***Autonomous System Boundary Router (ASBR)*** is a router that is running multiple protocols and serves as a gateway to routers outside an area and those operating with different protocols. The ASBR is able to import and translate different protocol routes into OSPF through a process known as ***redistribution***. For more details on redistribution and configuration examples, refer to "Enable route redistribution" on page 886

FIGURE 132 .OSPF operating in a network



OSPF point-to-point links

In an OSPF point-to-point network, where a direct Layer 3 connection exists between a single pair of OSPF routers, there is no need for Designated and Backup Designated Routers, as is the case in OSPF multi-access networks. Without the need for Designated and Backup Designated routers, a point-to-point network establishes adjacency and converges faster. The neighboring routers become adjacent whenever they can communicate directly. In contrast, in broadcast and non-broadcast multi-access (NBMA) networks, the Designated Router and Backup Designated Router become adjacent to all other routers attached to the network.

To configure an OSPF point-to-point link, refer to "Configuring an OSPF network type" on page 904.

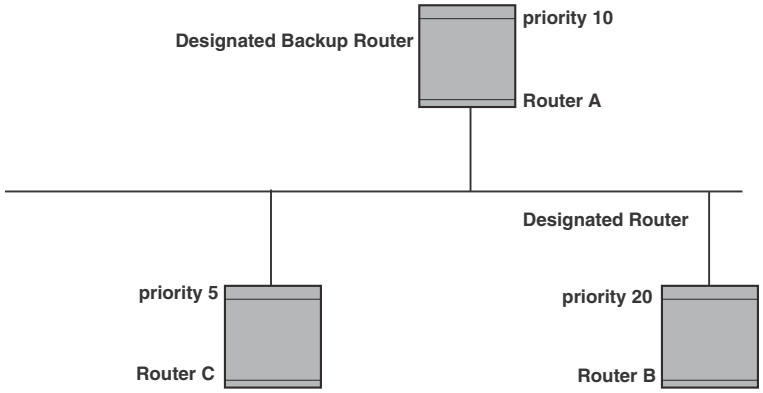
Designated routers in multi-access networks

In a network that has multiple routers attached, OSPF elects one router to serve as the designated router (DR) and another router on the segment to act as the backup designated router (BDR). This arrangement minimizes the amount of repetitive information that is forwarded on the network by forwarding all messages to the designated router and backup designated routers responsible for forwarding the updates throughout the network.

Designated router election in multi-access networks

In a network with no designated router and no backup designated router, the neighboring router with the highest priority is elected as the DR, and the router with the next largest priority is elected as the BDR, as shown in Figure 133

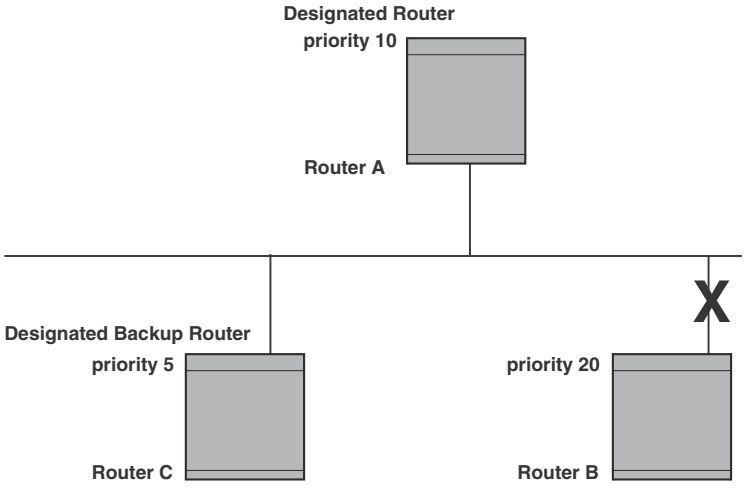
FIGURE 133 Designated and backup router election



If the DR goes off-line, the BDR automatically becomes the DR. The router with the next highest priority becomes the new BDR. This process is shown in Figure 134.

NOTE
Priority is a configurable option at the interface level. You can use this parameter to help bias one router as the DR.

FIGURE 134 Backup designated router becomes designated router



If two neighbors share the same priority, the router with the highest router ID is designated as the DR. The router with the next highest router ID is designated as the BDR.

NOTE
By default, the Dell router ID is the IP address configured on the lowest numbered loopback interface. If the device does not have a loopback interface, the default router ID is the lowest numbered IP address configured on the device.

When multiple routers on the same network are declaring themselves as DRs, then both priority and router ID are used to select the designated router and backup designated routers.

When only one router on the network claims the DR role despite neighboring routers with higher priorities or router IDs, this router remains the DR. This is also true for BDRs.

The DR and BDR election process is performed when one of the following events occurs:

- an interface is in a waiting state and the wait time expires
- an interface is in a waiting state and a hello packet is received that addresses the BDR
- a change in the neighbor state occurs, such as:
  - a neighbor state transitions from ATTEMPT state to a higher state
  - communication to a neighbor is lost
  - a neighbor declares itself to be the DR or BDR for the first time

OSPF RFC 1583 and 2328 compliance

Dell routers are configured, by default, to be compliant with the RFC 1583 OSPF V2 specification. Dell routers can also be configured to operate with the latest OSPF standard, RFC 2328.

NOTE
For details on how to configure the system to operate with the RFC 2328, refer to "Modify OSPF standard compliance setting" on page 903.

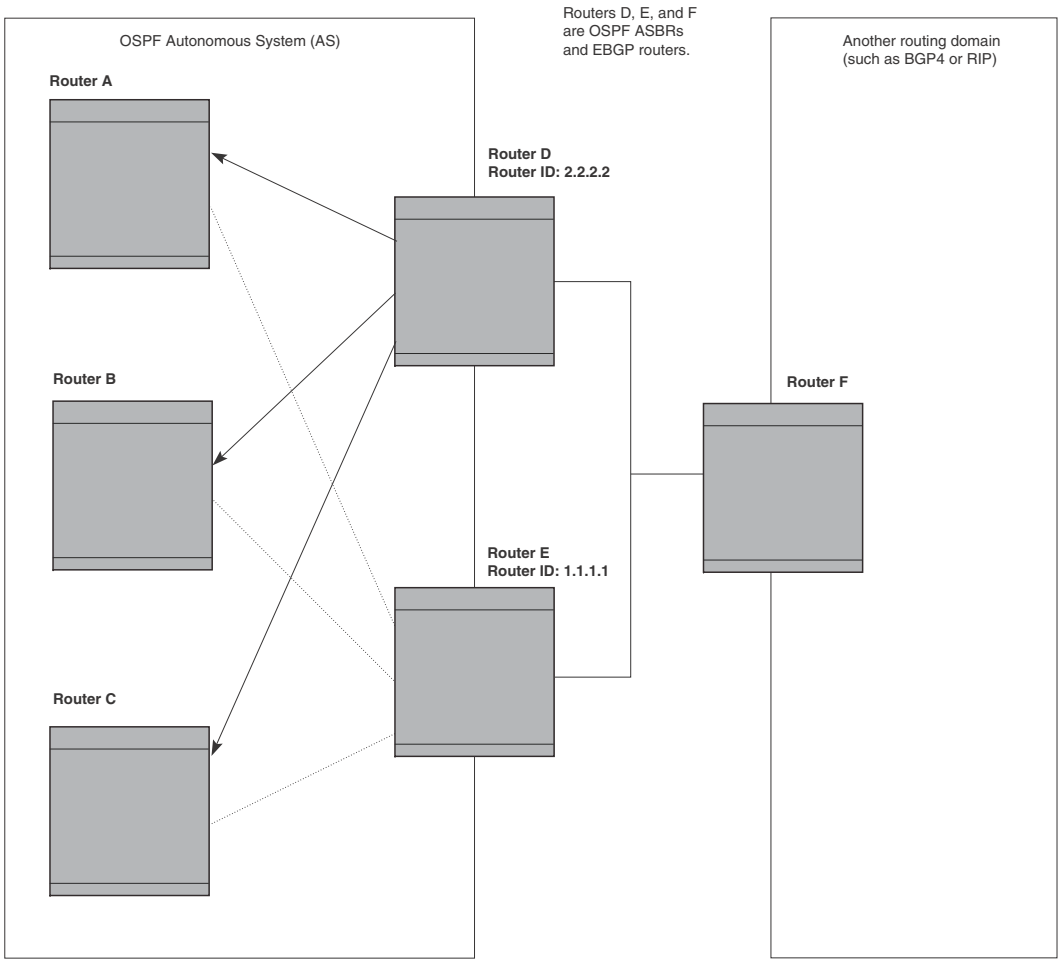
Reduction of equivalent AS external LSAs

An OSPF ASBR uses AS External link advertisements (AS External LSAs) to originate advertisements of a route learned from another routing domain, such as a BGP4 or RIP domain. The ASBR advertises the route to the external domain by flooding AS External LSAs to all the other OSPF routers (except those inside stub networks) within the local OSPF Autonomous System (AS).

In some cases, multiple ASBRs in an AS can originate equivalent LSAs. The LSAs are equivalent when they have the same cost, the same next hop, and the same destination. The device optimizes OSPF by eliminating duplicate AS External LSAs in this case. The device with the lower router ID flushes the duplicate External LSAs from its database and thus does not flood the duplicate External LSAs into the OSPF AS. AS External LSA reduction therefore reduces the size of the link state database on the device. The AS External LSA reduction is described in RFC 2328

Figure 135 shows an example of the AS External LSA reduction feature. In this example, Routers D and E are OSPF ASBRs, and thus communicate route information between the OSPF AS, which contains Routers A, B, and C, and another routing domain, which contains Router F. The other routing domain is running another routing protocol, such as BGP4 or RIP. Routers D, E, and F, therefore, are each running both OSPF and either BGP4 or RIP.

FIGURE 135 AS External LSA reduction



Notice that both Router D and Router E have a route to the other routing domain through Router F.

OSPF eliminates the duplicate AS External LSAs. When two or more devices are configured as ASBRs have equal-cost routes to the same next-hop router in an external routing domain, the ASBR with the highest router ID floods the AS External LSAs for the external domain into the OSPF AS, while the other ASBRs flush the equivalent AS External LSAs from their databases. As a result, the overall volume of route advertisement traffic within the AS is reduced and the devices that flush the duplicate AS External LSAs have more memory for other OSPF data. In Figure 135, since Router D has a higher router ID than Router E, Router D floods the AS External LSAs for Router F to Routers A, B, and C. Router E flushes the equivalent AS External LSAs from its database.

Algorithm for AS external LSA reduction

Figure 135 shows an example in which the normal AS External LSA reduction feature is in effect. The behavior changes under the following conditions:

- There is one ASBR advertising (originating) a route to the external destination, but one of the following happens:
  - A second ASBR comes on-line

- A second ASBR that is already on-line begins advertising an equivalent route to the same destination.

In either case above, the router with the higher router ID floods the AS External LSAs and the other router flushes its equivalent AS External LSAs. For example, if Router D is offline, Router E is the only source for a route to the external routing domain. When Router D comes on-line, it takes over flooding of the AS External LSAs to Router F, while Router E flushes its equivalent AS External LSAs to Router F.

- One of the ASBRs starts advertising a route that is no longer equivalent to the route the other ASBR is advertising. In this case, the ASBRs each flood AS External LSAs. Since the LSAs either no longer have the same cost or no longer have the same next-hop router, the LSAs are no longer equivalent, and the LSA reduction feature no longer applies.
- The ASBR with the higher router ID becomes unavailable or is reconfigured so that it is no longer an ASBR. In this case, the other ASBR floods the AS External LSAs. For example, if Router D goes off-line, then Router E starts flooding the AS with AS External LSAs for the route to Router F.

Support for OSPF RFC 2328 Appendix E

Dell devices support Appendix E in OSPF RFC 2328. Appendix E describes a method to ensure that an OSPF router generates unique link state IDs for type-5 (External) link state advertisements (LSAs) in cases where two networks have the same network address but different network masks.

NOTE
Support for Appendix E of RFC 2328 is enabled automatically and cannot be disabled. No user configuration is required.

Normally, an OSPF router uses the network address alone for the link state ID of the link state advertisement (LSA) for the network. For example, if the router needs to generate an LSA for network 10.1.2.3 255.0.0.0, the router generates ID 10.1.2.3 for the LSA.

However, suppose that an OSPF router needs to generate LSAs for all the following networks:

- 10.0.0.0 255.0.0.0
- 10.0.0.0 255.255.0.0
- 10.0.0.0 255.255.255.0

All three networks have the same network address, 10.0.0.0. Without support for RFC 2328 Appendix E, an OSPF router uses the same link state ID, 10.0.0.0, for the LSAs for all three networks. For example, if the router generates an LSA with ID 10.0.0.0 for network 10.0.0.0 255.0.0.0, this LSA conflicts with the LSA generated for network 10.0.0.0 255.255.0.0 or 10.0.0.0 255.255.255.0. The result is multiple LSAs that have the same ID but that contain different route information.

When appendix E is supported, the router generates the link state ID for a network as the following steps.

1. Does an LSA with the network address as its ID already exist?
   - No – Use the network address as the ID.
   - Yes – Go to step 2.

2. Compare the networks that have the same network address, to determine which network is more specific. The more specific network is the one that has more contiguous one bits in its network mask. For example, network 10.0.0.0 255.255.0.0 is more specific than network 10.0.0.0 255.0.0.0, because the first network has 16 ones bits (255.255.0.0) whereas the second network has only 8 ones bits (255.0.0.0).
   - For the less specific network, use the networks address as the ID.
   - For the more specific network, use the network's broadcast address as the ID. The broadcast address is the network address, with all ones bits in the host portion of the address. For example, the broadcast address for network 10.0.0.0 255.255.0.0 is 10.0.255.255.

   If this comparison results in a change to the ID of an LSA that has already been generated, the router generates a new LSA to replace the previous one. For example, if the router has already generated an LSA for network with ID 10.0.0.0 for network 10.0.0.0 255.255.255.0, the router must generate a new LSA for the network, if the router needs to generate an LSA for network 10.0.0.0 255.255.0.0 or 10.0.0.0 255.0.0.0.

OSPF graceful restart

The OSPF Graceful Restart feature provides support for high-availability routing. With this feature enabled, disruptions in forwarding are minimized and route flapping diminished to provide continuous service during times when a router experiences a restart.

With OSPF graceful restart enabled, a restarting router sends special LSAs to its neighbors called grace LSAs. These LSAs are sent to neighbors either before a planned OSPF restart or immediately after an unplanned restart. The grace LSA specifies a grace period for the neighbors of the restarting router to continue using the existing routes to and through the router after a restart. The restarting router comes up, it continues to use its existing OSPF routes as if nothing has occurred. In the background, the router re-acquires its neighbors prior to the restart and recalculates its OSPF routes and replaces them with new routes as necessary. Once the grace period has passed, the adjacent routers return to normal operation.

OSPF Graceful Restart can be enabled in the following configurations:

- **Configuring OSPF Graceful Restart for the Global Instance** – In this configuration all OSPF neighbors other than those used by VRFs are made subject to the Graceful Restart capability. The restart timer set globally does not apply to Graceful Restart on a configured VRF.
- **Configuring OSPF Graceful Restart per VRF** – In this configuration all OSPF neighbors for the specified VRF are made subject to the Graceful Restart capability. The restart timer set for a specific VRF only applies to that VRF.

Hitless upgrade support for OSPF graceful restart

OSPF graceful restart experiences minimal packet loss during hitless upgrade on a non-default VRF. On a default VRF, there is no packet loss during hitless upgrade.

OSPF Stub Router Advertisement

OSPFv2 Stub Router Advertisement is an open standard based feature and it is specified in RFC 3137. This feature provides a user with the ability to gracefully introduce and remove an OSPFv2 router from the network by controlling when the data traffic can start and stop flowing through the router in case where there are other OSPFv2 routers present on the network providing alternative paths for the traffic. This feature does not work if there is no alternative for the traffic through other OSPFv2 routers. The router can control the data traffic flowing through it by changing the cost of the paths passing through the configured router. By setting the path cost high the traffic will be redirected to other OSPFv2 routers providing a lower cost path. This change in path cost is accomplished by setting the metric of the links advertised in the Router LSA to a maximum value. When the OSPFv2 router is ready to forward the traffic the links are advertised with the real metric value instead of the maximum value.

The feature is useful for avoiding a loss of traffic during short periods when adjacency failures are detected and traffic is rerouted. Using this feature, traffic can be rerouted before an adjacency failure occurs due to common services interruptions such as a router being shutdown for maintenance.

The feature is also useful during router startup because it gives the router enough time to build up its routing table before forwarding traffic. This can be useful where BGP is enabled on the router because it takes time for the BGP routing table to converge.

Multi-Service IronWare software introduced an enhancement that allows you to configure and set a metric value for the following LSA types:

- Summary (type 3 and type 4)
- External (type 5 and type 7)
- Opaque (type 10, TE link)

Configuration of this feature is described in "Configuring OSPF router advertisement" on page 907.

OSPF Shortest Path First throttling

Multi-Service IronWare software introduced rapid triggering of SPF calculations with exponential back-off to offer the advantages of rapid convergence without sacrificing stability. As the delay increases, multiple topology changes can occur within a single SPF. This dampens network activity due to frequent topology changes.

This scheduling method starts with an initial value after which a configured delay time is followed. If a topology change event occurs the SPF is schedule after the time specified by the initial value, the router starts a timer for the time period specified by a configured hold time value. If no topology events occur during this hold time, the router returns to using the initial delay time.

If a topology event occurs during the hold time period, the next hold time period is recalculated to a value that is double the initial value. If no topology events occur during this extended hold time, the router resets to its initial value. If an event occurs during this extended hold time, the next hold time is doubled again. The doubling occurs as long as topology events occur during the calculated hold times until a configured maximum delay time value is reached or no event occurs (which resets the router to the initial hold time). The maximum value is then held until the hold time expires without a topology change event occurring. At any time that a hold time expires without a topology change event occurring, the router reverts to the initial hold value and begins the process all over again.

For example if you set the initial delay timer to 100 milliseconds, the hold timer to 300 and the maximum hold timer to 2000 milliseconds, the following would occur:

If a topology change occurs the initial delay of 100 milliseconds will be observed. If a topology change occurs during the hold time of 300 milliseconds the hold time is doubled to 600 milliseconds. If a topology change event occurs during the 600 millisecond period, the hold time is doubled again to 1200 milliseconds. If a topology change event occurs during the 1200 millisecond period, the hold time is doubled to 2400 milliseconds. Because the maximum hold time is specified as 2000, the value will be held at 2000. This 2000 millisecond period will then repeat as long as topology events occur within the maximum 2000 millisecond hold time. When a maximum hold time expires without a topology event occurring, the router reverts to the initial delay time and the cycle repeats as described.

The purpose of this feature is to use longer SPF scheduling values during network topology instability.

Configuration of this feature is described in "Configuring OSPF shortest path first throttling" on page 909.

IETF RFC and internet draft support

The implementation of OSPF Graceful Restart supports the following IETF RFC:

- RFC 3623: Graceful OSPF Restart

NOTE
A secondary management module must be installed for the device to function as a graceful restart device. If the device functions as a graceful restart helper device only, there is no requirement for a secondary management module.

For details on how to configure OSPF Graceful Restart, refer to "Configuring OSPF Graceful Restart" on page 905.

Dynamic OSPF activation and configuration

OSPF is automatically activated when you enable it. The protocol does not require a software reload.

You can configure and save the following OSPF changes without resetting the system:

- All OSPF interface-related parameters (for example: area, hello timer, router dead time cost, priority, re-transmission time, transit delay)
- All area parameters
- All area range parameters
- All virtual-link parameters
- All global parameters
- creation and deletion of an area, interface or virtual link
- Changes to address ranges
- Changes to global values for redistribution
- Addition of new virtual links

OSPF VRF-Lite for customer-edge routers

When a type 3, 5, or 7 LSA is sent from a provider edge (PE) router to a customer edge (CE) router, the DN (down) bit in the LSA options field must be set. This prevents any type 3, 5, or 7 LSA messages sent from the CE router to the PE router from being distributed any farther. The PE router ignores messages with the DN bit set and does not add these routes to the VRF routing table.

When you enable VRF-Lite on the CE router, the DN setting is ignored, allowing the CE router to add these routes to the VRF routing table.

To enable VRF-Lite, enter commands such as the following:

```
NetIron(config)# router ospf vrf 1
NetIron(config-ospf-router-vrf-1)# vrf-lite-capability
```

Syntax: [no] vrf-lite-capability

Use the no form of the command to disable VRF-Lite. This applies to the VRF instance only. It does not apply to the default VRF.

NOTE
For vpn4 external routes to be installed on CE routers, the domain-tags on PE routers must be different that the domain-tags on CE routers.

NOTE
This command applies to CE routers only. This command does not apply to PE routers.

Configuring OSPF

To begin using OSPF on the router, perform the steps outlined below.

1. Enable OSPF on the router.
2. Assign the areas to which the router will be attached.
3. Assign individual interfaces to the OSPF areas.
4. Configure route map for route redistribution, if desired.
5. Enable redistribution, if desired.
6. Modify default global and port parameters as required.
7. Modify OSPF standard compliance, if desired.

Configuration rules

The configuration rules are as follows:

- If a router is to operate as an ASBR, you must enable the ASBR capability at the system level.
- Redistribution must be enabled on routers configured to operate as ASBRs.
- All router ports must be assigned to one of the defined areas on an OSPF router. When a port is assigned to an area, all corresponding subnets on that port are automatically included in the assignment.

OSPF parameters

You can modify or set the following global and interface OSPF parameters.

Global parameters

The global OSPF parameters are as follows:

- Modify OSPF standard compliance setting.
- Assign an area.
- Define an area range.
- Define the area virtual link.
- Set global default metric for OSPF.
- Change the reference bandwidth for the default cost of OSPF interfaces.
- Disable or re-enable load sharing.
- Enable or disable default-information-originate.
- Modify Shortest Path First (SPF) timers
- Define external route summarization
- Define redistribution metric type.
- Define redistribution route maps.
- Enable redistribution.
- Change the LSA pacing interval.
- Modify OSPF Traps generated.
- Modify database overflow interval.
- Stub Router advertisement

Interface parameters

The interface OSPF parameters are as follows:

- Assign interfaces to an area.
- Define the authentication key for the interface.
- Change the authentication-change interval
- Modify the cost for a link.
- Modify the dead interval.
- Modify MD5 authentication key parameters.
- Modify the priority of the interface.
- Modify the retransmit interval for the interface.
- Modify the transit delay of the interface.

NOTE
You set global level parameters at the OSPF CONFIG Level of the CLI. To reach that level, enter **router ospf...** at the global CONFIG Level. Interface parameters for OSPF are set at the interface CONFIG Level using the CLI command, **ip ospf...**

Enable OSPF on the router

When you enable OSPF on the router, the protocol is automatically activated. To enable OSPF on the router, use the following method.

```
NetIron(config)# router ospf
NetIron(config-ospf-router)#
```

This command launches you into the OSPF router level where you can assign areas and modify OSPF global parameters.

Note regarding disabling OSPF

If you disable OSPF, the device removes all the configuration information for the disabled protocol from the running configuration. Moreover, when you save the configuration to the startup configuration file after disabling one of these protocols, all the configuration information for the disabled protocol is removed from the startup configuration file.

The CLI displays a warning message such as the following.

```
NetIron(config-ospf-router)# no router ospf
router ospf mode now disabled. All ospf config data will be lost when writing to
flash!
```

If you have disabled the protocol but have not yet saved the configuration to the startup configuration file and reloaded the software, you can restore the configuration information by re-entering the **router ospf** command to enable the protocol. If you have already saved the configuration to the startup configuration file and reloaded the software, the information is gone.

If you are testing an OSPF configuration and are likely to disable and re-enable the protocol, you might want to make a backup copy of the startup configuration file containing the protocol's configuration information. This way, if you remove the configuration information by saving the configuration after disabling the protocol, you can restore the configuration by copying the backup copy of the startup configuration file onto the flash memory.

Assign OSPF areas

Once OSPF is enabled on the system, you can assign areas. Assign an IP address or number as the ***area ID*** for each area. The area ID is representative of all IP addresses (subnets) on a router port. Each port on a router can support one area.

An area can be ***normal***, a ***stub***, or a ***Not-So-Stubby Area (NSSA)***:

- **Normal** – OSPF routers within a normal area can send and receive External Link State Advertisements (LSAs).
- **Stub** – OSPF routers within a stub area cannot send or receive External LSAs. In addition, OSPF routers in a stub area must use a default route to the area's Area Border Router (ABR) or Autonomous System Boundary Router (ASBR) to send traffic out of the area.
- **NSSA** – The ASBR of an NSSA can import external route information into the area.
  - ASBRs redistribute (import) external routes into the NSSA as type 7 LSAs. Type-7 External LSAs are a special type of LSA generated only by ASBRs within an NSSA, and are flooded to all the routers within only that NSSA.
  - ABRs translate type 7 LSAs into type 5 External LSAs, which can then be flooded throughout the AS. You can configure address ranges on the ABR of an NSSA so that the ABR converts multiple type-7 External LSAs received from the NSSA into a single type-5 External LSA.

    When an NSSA contains more than one ABR, OSPF elects one of the ABRs to perform the LSA translation for NSSA. OSPF elects the ABR with the highest router ID. If the elected ABR becomes unavailable, OSPF automatically elects the ABR with the next highest router ID to take over translation of LSAs for the NSSA. The election process for NSSA ABRs is automatic.

Example

To set up the OSPF areas shown in Figure 132 on page 859, use the following method.

```
NetIron(config-ospf-router)# area 192.5.1.0
NetIron(config-ospf-router)# area 200.5.0.0
NetIron(config-ospf-router)# area 195.5.0.0
NetIron(config-ospf-router)# area 0.0.0.0
NetIron(config-ospf-router)# write memory
```

Syntax: [**no**] **area** <*num*> | <*ip-addr*>

The <*num*> | <*ip-addr*> parameters speciy the area number, which can be a number or in IP address format. If you specify a number, the number can be from 0 – 2,147,483,647.

Multi-Service IronWare software support up to 200 OSPF areas

Assign a totally stubby area

By default, the device sends summary LSAs (LSA type 3) into stub areas. You can further reduce the number of link state advertisements (LSA) sent into a stub area by configuring the device to stop sending summary LSAs (type 3 LSAs) into the area. You can disable the summary LSAs when you are configuring the stub area or later after you have configured the area.

This feature disables origination of summary LSAs, but the device still accepts summary LSAs from OSPF neighbors and floods them to other neighbors. The device can form adjacencies with other routers regardless of whether summarization is enabled or disabled for areas on each router.

When you enter a command to disable the summary LSAs, the change takes effect immediately. If you apply the option to a previously configured area, the device flushes all of the summary LSAs it has generated (as an ABR) from the area.

NOTE
This feature applies only when the device is configured as an Area Border Router (ABR) for the area. To completely prevent summary LSAs from being sent to the area, disable the summary LSAs on each OSPF router that is an ABR for the area.

To disable summary LSAs for a stub area, enter commands such as the following.

```
NetIron(config-ospf-router)# area 40 stub 99 no-summary
```

Syntax: [no] area <*num*> **|** <*ip-addr*> **stub** <*cost*> **[no-summary]**

The <*num*> | <*ip-addr*> parameter specifies the area number, which can be a number or in IP address format. If you specify a number, the number can be from 0 – 2,147,483,647.

The **stub** <*cost*> parameter specifies an additional cost for using a route to or from this area and can be from 1 – 16777215. There is no default. Normal areas do not use the cost parameter.

The **no-summary** parameter applies only to stub areas and disables summary LSAs from being sent into the area.

Assign a Not-So-Stubby Area (NSSA)

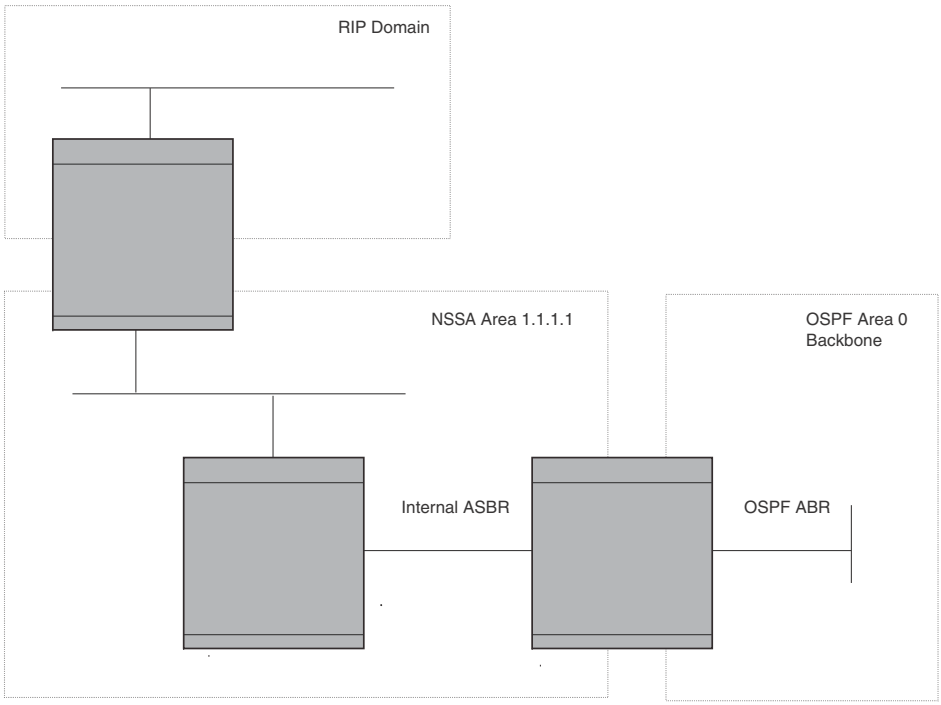
The OSPF Not So Stubby Area (NSSA) feature enables you to configure OSPF areas that provide the benefits of stub areas, but that also are capable of importing external route information. OSPF does not flood external routes from other areas into an NSSA, but does translate and flood route information from the NSSA into other areas such as the backbone.

NSSAs are especially useful when you want to summarize Type-5 External LSAs (external routes) before forwarding them into an OSPF area. The OSPF specification (RFC 2328) prohibits summarization of Type-5 LSAs and requires OSPF to flood Type-5 LSAs throughout a routing domain. When you configure an NSSA, you can specify an address range for aggregating the external routes that the NSSA's ABR exports into other areas.

The implementation of NSSA is based on RFC 1587.

Figure 136 shows an example of an OSPF network containing an NSSA.

FIGURE 136 OSPF network containing an NSSA



This example shows two routing domains, a RIP domain and an OSPF domain. The ASBR inside the NSSA imports external routes from RIP into the NSSA as Type-7 LSAs, which the ASBR floods throughout the NSSA.

The ABR translates the Type-7 LSAs into Type-5 LSAs. If an area range is configured for the NSSA, the ABR also summarizes the LSAs into an aggregate LSA before flooding the Type-5 LSAs into the backbone.

Since the NSSA is partially "stubby" the ABR does not flood external LSAs from the backbone into the NSSA. To provide access to the rest of the Autonomous System (AS), the ABR generates a default Type-7 LSA into the NSSA.

Configuring an NSSA

To configure OSPF area 1.1.1.1 as an NSSA, enter the following commands.

```
NetIron(config)# router ospf
NetIron(config-ospf-router)# area 1.1.1.1 nssa 1
NetIron(config-ospf-router)# write memory
```

Syntax: [no] area <*num*> **|** <*ip-addr*> **nssa** <*cost*> **[no-summary] | default-information-originate**

The <*num*> | <*ip-addr*> parameter specifies the area number, which can be a number or in IP address format. If you specify a number, the number can be from 0 – 2,147,483,647.

The **nssa** <*cost*> | **default-information-originate** parameter specifies that this is a Not-So-Stubby-Area (NSSA). The <*cost*> specifies an additional cost for using a route to or from this NSSA and can be from 1 – 16777215. There is no default. Normal areas do not use the cost parameter. Alternatively, you can use the **default-information-originate** parameter causes the device to inject the default route into the NSSA.

Specifying the **no-summary** option directs the router to not import type 3 summary LSAs into the NSSA area. The default operation is to import summary LSAs into an NSSA area.

NOTE
The device does not inject the default route into an NSSA by default.

To configure additional parameters for OSPF interfaces in the NSSA, use the **ip ospf area...** command at the interface level of the CLI.

Disabling the router to perform translations for NSSA LSAs

This command allows you to disable the router to perform translations for NSSA LSAs. When this command is used, type 7 NSSA external LSAs are not translated into type 5 external LSAs. This command is useful when the router is an area border router with many NSSA areas, and does not need to export the NSSA external routes into the backbone.

The following command enables this feature.

```
NetIron(config)# router ospf
NetIron(config-ospf-router)# no nssa-translator
```

Syntax: [no] nssa-translator

Configuring an address range for the NSSA

If you want the ABR that connects the NSSA to other areas to summarize the routes in the NSSA before translating them into Type-5 LSAs and flooding them into the other areas, configure an address range. The ABR creates an aggregate value based on the address range. The aggregate value becomes the address that the ABR advertises instead of advertising the individual addresses represented by the aggregate. You can configure up to 32 ranges in an OSPF area.

To configure an address range in NSSA 1.1.1.1, enter the following commands. This example assumes that you have already configured NSSA 1.1.1.1.

```
NetIron(config)# router ospf
NetIron(config-ospf-router)# area 1.1.1.1 range 209.157.22.1 255.255.0.0
NetIron(config-ospf-router)# write memory
```

Syntax: [no] area <*num*> **|** <*ip-addr*> **range** <*ip-addr*> <*ip-mask*> **[advertise | not-advertise]**

The <*num*> | <*ip-addr*> parameter specifies the area number, which can be in IP address format. If you specify a number, the number can be from 0 – 2,147,483,647.

The **range** <*ip-addr*> parameter specifies the IP address portion of the range. The software compares the address with the significant bits in the mask. All network addresses that match this comparison are summarized in a single route advertised by the router.

The <*ip-mask*> parameter specifies the portions of the IP address that a route must contain to be summarized in the summary route. In the example above, all networks that begin with 209.157 are summarized into a single route.

The **advertise | not-advertise** parameter specifies whether you want the device to send type 3 LSAs for the specified range in this area. The default is **advertise**.

Assigning an area range (optional)

You can assign a ***range*** for an area, but it is not required. Ranges allow a specific IP address and mask to represent a range of IP addresses within an area, so that only that reference range address is advertised to the network, instead of all the addresses within that range. Each area can have up to 32 range addresses.

Example

To define an area range for subnets on 193.45.5.1 and 193.45.6.2, enter the following command.

```
NetIron(config)# router ospf
NetIron(config-ospf-router)# area 192.45.5.1 range 193.45.0.0 255.255.0.0
NetIron(config-ospf-router)# area 193.45.6.2 range 193.45.0.0 255.255.0.0
```

Syntax: [no] area <*num*> **|** <*ip-addr*> **range** <*ip-addr*> <*ip-mask*>

The <*num*> | <*ip-addr*> parameter specifies the area number, which can be in IP address format.

The **range** <*ip-addr*> parameter specifies the IP address portion of the range. The software compares the address with the significant bits in the mask. All network addresses that match this comparison are summarized in a single route advertised by the router.

The <*ip-mask*> parameter specifies the portions of the IP address that a route must contain to be summarized in the summary route. In the example above, all networks that begin with 193.45 are summarized into a single route.

Assigning interfaces to an area

Once you define OSPF areas, you can assign interfaces to the areas. All router ports must be assigned to one of the defined areas on an OSPF router. When a port is assigned to an area, all corresponding subnets on that port are automatically included in the assignment.

To assign interface 1/8 of Router A to area 192.5.0.0 and then save the changes, enter the following commands.

```
RouterA(config)# interface e 1/8
RouterA(config-if-e10000-1/8)# ip ospf area 192.5.0.0
RouterA(config-if-e10000-1/8)# write memory
```

Modify interface defaults

OSPF has interface parameters that you can configure. For simplicity, each of these parameters has a default value. No change to these default values is required except as needed for specific network configurations.

Port default values can be modified using the following CLI commands at the interface configuration level of the CLI:

- ip ospf area <*ip-addr*>
- ip ospf auth-change-wait-time <*secs*>
- ip ospf authentication-key <*string*>
- ip ospf cost <*num*>
- ip ospf database-filter all out
- ip ospf dead-interval <*value*>

- ip ospf hello-interval <*value*>
- ip ospf md5-authentication key-activation-wait-time <*num*> | key-id <*num*> key <*string*>
- ip ospf mtu-ignore
- ip ospf passive
- ip ospf priority <*value*>
- ip ospf retransmit-interval <*value*>
- ip ospf transmit-delay <*value*>

For a complete description of these parameters, see the summary of OSPF port parameters in the next section.

OSPF interface parameters

The following parameters apply to OSPF interfaces

area	Assigns an interface to a specific area. You can assign either an IP address or number to represent an OSPF Area ID. If you assign a number, it can be any value from 0 – 2,147,483,647.
auth-change-wait-time	OSPF gracefully implements authentication changes to allow all routers to implement the change and thus prevent disruption to neighbor adjacencies. During the authentication-change interval, both the old and new authentication information is supported. The default authentication-change interval is 300 seconds (5 minutes). You change the interval to a value from 0 – 14400 seconds.

authentication-key <*string*>	By default, the authentication key is encrypted. If you want the authentication key to be in clear text, insert a **0** between **key** and <*string*>. For example,
	`NetIron(config-if-e10000-1/8)# ip ospf authentication-key 0 morningadmin`
	The software adds a prefix to the authentication key string in the configuration. For example, the following portion of the code has the encrypted code “2”.
	`ip ospf authentication-key 2 $on-o`
	The prefix can be one of the following:
	• 0 = the key string is not encrypted and is in clear text
	• 1 = the key string uses proprietary simple crytographic 2-way algorithm
	• 2 = the key string uses proprietary base64 crytographic 2-way algorithm

cost	Indicates the overhead required to send a packet across an interface. You can modify the cost to differentiate between 100 Mbps, 1Gbps, and 10 Gbps. The default cost is calculated by dividing 100 million by the bandwidth. For 10 Mbps links, the cost is 10. The cost for 100 Mbps, 1Gbps, and 10 Gbps links is 1, because the speed of 100 Mbps and 10Gbps was not in use at the time the OSPF cost formula was devised.
database-filter	Blocks all outbound LSAs on the OSPF interface.
dead-interval:	Indicates the number of seconds that a neighbor router waits for a hello packet from the current router before declaring the router down. The value can be from 1 – 65535 seconds. The default is 40 seconds. The rules described in “Rules for OSPF dead interval and hello interval timers” on page 877 apply regarding this timer.

hello-interval	Represents the length of time between the transmission of hello packets. The value can be from 1 – 65535 seconds. The default is 10 seconds. The rules described in "Rules for OSPF dead interval and hello interval timers" on page 877 apply regarding this timer.
MD5-authentication activation wait time	The number of seconds the device waits until placing a new MD5 key into effect. The wait time provides a way to gracefully transition from one MD5 key to another without disturbing the network. The wait time can be from 0 – 14400 seconds. The default is 300 seconds (5 minutes).
MD5-authentication key <*string*>	The MD5 **key** is a number from 1 – 255 and identifies the MD5 key that is being used. This parameter is required to differentiate among multiple keys defined on a router. By default, the authentication key is encrypted. If you want the authentication key to be in clear text, insert a **0** between **key** and <*string*>. For example, NetIron`(config-if-e10000-1/8)# ip ospf 1 md-5-authentication key-id 5 key` **`2`** `morningadmin` The software adds a prefix to the authentication key string in the configuration. For example, the following portion of the code has the encrypted code "2". `ip ospf 1 md-5-authentication key-id 5 key` **`2`** `$on-o` The prefix can be one of the following: • 0 = the key string is not encrypted and is in clear text • 1 = the key string uses proprietary simple crytographic 2-way algorithm. • 2 = the key string uses proprietary base64 crytographic 2-way algorithm
mtu-ignore	A database description packet is rejected if the interface MTU specified in the DBD packet is greater than the MTU of the interface shared between the neighbors. To disable the mismatch condition set "mtu-ignore". By default, the mismatch detection is enabled
passive	When you configure an OSPF interface to be passive, that interface does not send or receive OSPF route updates. By default, all OSPF interfaces are active and thus can send and receive OSPF route information. Since a passive interface does not send or receive route information, the interface is in effect a stub network. OSPF interfaces are active by default. **Note:** This option affects all IP subnets configured on the interface. If you want to disable OSPF updates only on some of the IP subnets on the interface, use the **ospf-ignore** or **ospf-passive** parameter with the **ip address** command.
priority	Allows you to modify the priority of an OSPF router. The priority is used when selecting the designated router (DR) and backup designated routers (BDRs). The value can be from 0 – 255. The default is 1. If you set the priority to 0, the device does not participate in DR and BDR election.
retransmit-interval	The time between retransmissions of link-state advertisements (LSAs) to adjacent routers for this interface. The value can be from 0 – 3600 seconds. The default is 5 seconds.
transit-delay	The time it takes to transmit Link State Update packets on this interface. The value can be from 0 – 3600 seconds. The default is 1 second.

Rules for OSPF dead interval and hello interval timers

The following rules apply regarding these timers:

- If both the **hello-interval** and **dead-interval** parameters are configured, they will each be set to the values that you have configured.
- If the **hello-interval** parameter is configured, but not the **dead-interval** parameter, the **dead-interval** parameter will be set to a value that is 4 times the value set for the **hello-interval.**
- If the **dead-interval** parameter is configured, but not the **hello-interval** parameter, the **hello-interval.** parameter will be set to a value that is 1/4 the value set for the **dead-interval.** The minimum value for the **hello-interval** is 1.

Change the timer for OSPF authentication changes

When you make an OSPF authentication change, the software uses the authentication-change timer to gracefully implement the change. The software implements the change in the following ways:

- **Outgoing OSPF packets** – After you make the change, the software continues to use the old authentication to send packets, during the remainder of the current authentication-change interval. After this, the software uses the new authentication for sending packets.
- **Inbound OSPF packets** – The software accepts packets containing the new authentication and continues to accept packets containing the older authentication for two authentication-change intervals. After the second interval ends, the software accepts packets only if they contain the new authentication key.

The default authentication-change interval is 300 seconds (5 minutes). You change the interval to a value from 0 – 14400 seconds.

OSPF provides graceful authentication change for all the following types of authentication changes in OSPF:

- Changing authentication methods from one of the following to another of the following:
  - Simple text password
  - MD5 authentication
  - No authentication
- Configuring a new simple text password or MD5 authentication key
- Changing an existing simple text password or MD5 authentication key

To change the authentication-change interval, enter a command such as the following at the interface configuration level of the CLI.

```
NetIron(config-if-e10000-2/5)# ip ospf auth-change-wait-time 400
```

Syntax: [no] ip ospf auth-change-wait-time <*secs*>

The <*secs*> parameter specifies the interval and can be from 0 – 14400 seconds. The default is 300 seconds (5 minutes).

NOTE
For backward compatibility, the **ip ospf md5-authentication key-activation-wait-time** <*seconds*> command is still supported.

Block flooding of outbound LSAs on specific OSPF interfaces

By default, the device floods all outbound LSAs on all the OSPF interfaces within an area. You can configure a filter to block outbound LSAs on an OSPF interface. This feature is particularly useful when you want to block LSAs from some, but not all, of the interfaces attached to the area.

This command blocks all outbound LSAs. The command has been enhanced to provide options for selective blocking of LSAs.

After you apply filters to block the outbound LSAs, the filtering occurs during the database synchronization and flooding. When a filtering configuration is changed on a interface, all adjacencies on the interface are set to the Extstart state to restart the database exchange process. In cases where an LSA has already been flooded on an interface prior to application of the LSA filter, the LSA will not be flushed out from the remote neighbors. In this situation the user must clear the link state database and the adjacencies on all remote neighbors to flush out the leaked LSAs or wait for the LSAs to be aged out.

If you remove the filters, the blocked LSAs are automatically re-flooded. You do not need to reset OSPF to re-flood the LSAs.

NOTE
You cannot block LSAs on virtual links, and LSA filtering is not supported on sham links.

To apply a filter to an OSPF interface to block flooding of outbound LSAs on the interface, enter the following command at the Interface configuration level for that interface.

```
NetIron(config-if-e10000-1/1)# ip ospf database-filter all out
```

The command in this example blocks all outbound LSAs on the OSPF interface configured on port 1/1.

Syntax: [no] ip ospf database-filter {all | all-external [allow-default | allow-default-and-type4] | all-summary-external [allow-default | allow-default-and-type4] out

The **all** parameter directs the router to block all outbound LSAs on the OSPF interface.

The **all-external** option directs the router to allow the following LSAs: Router, Network, Opq-Area-TE, Opq-Link-Graceful and Type-3 Summary while it blocks all Type-4 and Type-5 LSAs unless directed by one of the following keywords:

allow-default – allows only Type-5 default LSAs .

allow-default-and-type4 – allows Type-5 default LSAs and all Type 4 LSAs.

The **all-summary-external** option directs the router to allow the following LSAs: Router, Network, Opq-Area-TE and Opq-Link-Graceful while it blocks all Type-3, Type-4 and Type-5 LSAs unless directed by one of the following keywords:

allow-default – allows only Type-3 or Type-5 default LSAs .

allow-default-and-type4 – allows Type-3 or Type-5 default LSAs and all Type 4 LSAs.

All Type-7 LSAs are always filtered if the **ip ospf database-filter** command is enabled.

By default, OSPF LSA filtering is disabled on all interfaces.

To remove the filter, enter a command such as the following.

```
NetIron(config-if-e10000-1/1)# no ip ospf database-filter all out
```

Assign virtual links

All ABRs (area border routers) must have either a direct or indirect link to the OSPF backbone area (0.0.0.0 or 0). If an ABR does not have a physical link to the area backbone, the ABR can configure a ***virtual link*** to another router within the same area, which has a physical connection to the area backbone.

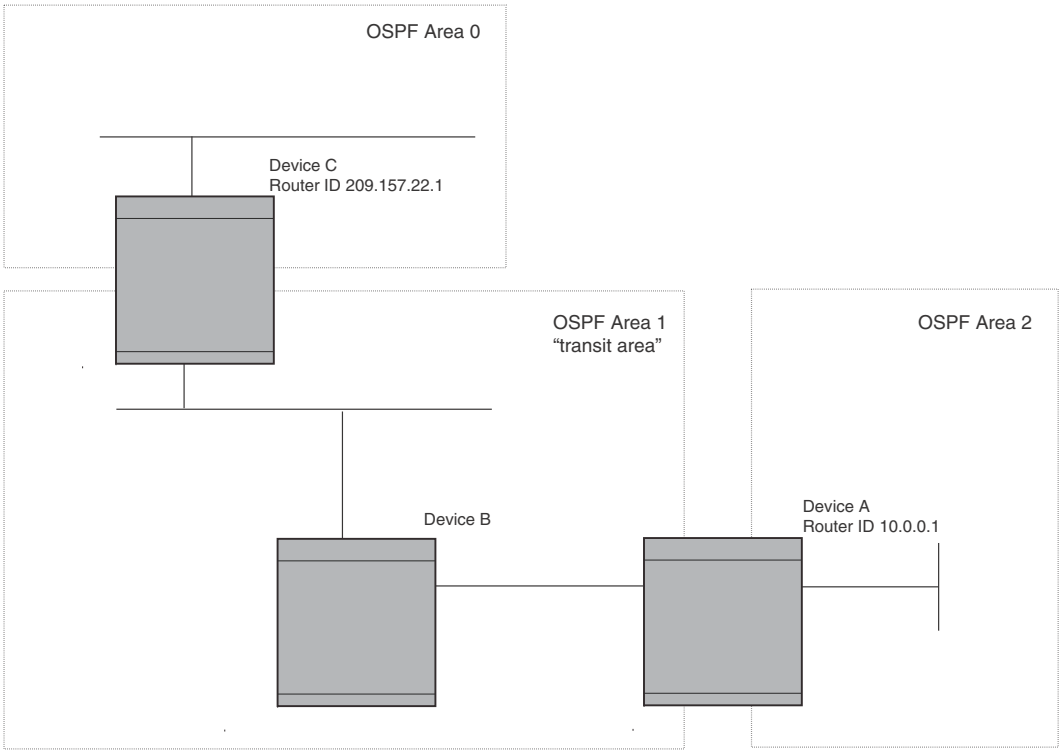
The path for a virtual link is through an area shared by the neighbor ABR (router with a physical backbone connection), and the ABR requiring a logical connection to the backbone.

Two parameters fields must be defined for all virtual links—transit area ID and neighbor router:

- The ***transit area ID*** represents the shared area of the two ABRs and serves as the connection point between the two routers. This number should match the area ID value.
- The ***neighbor router*** field is the router ID (IP address) of the router that is physically connected to the backbone, when assigned from the router interface requiring a logical connection. When assigning the parameters from the router with the physical connection, the router ID is the IP address of the router requiring a logical connection to the backbone.

NOTE
By default, the Dell router ID is the IP address configured on the lowest numbered loopback interface. If the device does not have a loopback interface, the default router ID is the lowest numbered IP address configured on the device. When you establish an area virtual link, you must configure it on both of the routers (both ends of the virtual link).

FIGURE 137 Defining OSPF virtual links within a network



Example

Figure 137 shows an OSPF area border router, Device A, that is cut off from the backbone area (area 0). To provide backbone access to Device A, you can add a virtual link between Device A and Device C using area 1 as a transit area. To configure the virtual link, you define the link on the router that is at each end of the link. No configuration for the virtual link is required on the routers in the transit area.

To define the virtual link on Device A, enter the following commands.

```
NetIron A(config)# router ospf
NetIron A(config-ospf-router)# area 2
NetIron A(config-ospf-router)# area 1
NetIron A(config-ospf-router)# area 1 virtual-link 209.157.22.1
NetIron A(config-ospf-router)# write memory
```

Enter the following commands to configure the virtual link on Device C.

```
NetIron C(config)# router ospf
NetIron C(config-ospf-router)# area 0
NetIron C(config-ospf-router)# area 1
NetIron C(config-ospf-router)# area 1 virtual-link 10.0.0.1
```

Syntax: [**no**] **area** <*ip-addr*> | <*num*> **virtual-link** <*router-id*>
[**authentication-key** <*string*> | **dead-interval** <*num*> | **hello-interval** <*num*> | **retransmit-interval** <*num*> | **transmit-delay** <*num*> | **md5-authentication key-activation-wait-time** <*num*> | **md5-authentication key-id** <*num*> **key** [**0**|**1**] <*string*>]

The **area** <*ip-addr*> | <*num*> parameters specify the transit area.

The **virtual-link** <*router-id*> parameter specifies the router ID of the OSPF router at the remote end of the virtual link. To display the router ID on a device, enter the **show ip** command.

Refer to "Modify virtual link parameters" on page 881 for descriptions of the optional parameters.

Modify virtual link parameters

OSPF has some parameters that you can modify for virtual links. Notice that these are the same parameters as the ones you can modify for physical interfaces.

You can modify default values for virtual links using the following CLI command at the ***OSPF router level*** of the CLI, as shown in the following syntax:

Syntax: **[no] area** <*ip-addr*> **|** <*num*> **virtual-link** <*router-id*>
dead-interval <*num*> **| hello-interval** <*num*> **| retransmit-interval** <*num*> **|**
transmit-delay <*num*> **|**
authentication-key <*string*> **|**
md5-authentication key <*key-string*> **|**
md5-authentication key-activation-wait-time <*num*>

The parameters are described in the following table.

Virtual link parameter descriptions

You can modify the following virtual link interface parameters:

area <*ip-addr*> | <*num*>	The IP address or number of the transit area.
virutal-link <*router-id*>	The router ID of the OSPF router at the remote end of the virtual link.
dead-interval <*num*>	The number of seconds that a neighbor router waits for a hello packet from the current router before declaring the router down. The value can be from 1 – 65535 seconds. The default is 40 seconds. Refer to "Rules for OSPF dead interval and hello interval timers" on page 877 for more information about this timer.
hello-interval <*num*>	The length of time between the transmission of hello packets. The range is 1 – 65535 seconds. The default is 10 seconds.
retransmit-interval <*num*>	The interval between the re-transmission of link state advertisements to router adjacencies for this interface. The range is 0 – 3600 seconds. The default is 5 seconds.

transmit-delay <*num*>	The period of time it takes to transmit Link State Update packets on the interface. The range is 0 – 3600 seconds. The default is 1 second.

authentication-key <*string*>	This parameter allows you to assign different authentication encryption methods on a port-by-port basis. OSPF supports three methods of authentication for each interface: none, simple encryption, and base 64 encryption. Only one encryption method can be active on an interface at a time.
	The simple encryption and base 64 encryption methods requires you to configure an alphanumeric password on an interface. The password can be up to eight characters long. All OSPF packets transmitted on the interface contain this password. All OSPF packets received on the interface are checked for this password. If the password is not present, then the packet is dropped.
	By default, the authentication key is encrypted. If you want the authentication key to be in clear text, insert a **0** between **key** and <*string*>. For example,
	`NetIron C(config-ospf-router)# area 1 virtual-link 10.0.0.1 authentication-key 0 afternoon`
	The software adds a prefix to the authentication key string in the configuration. For example, the following portion of the code has the encrypted code “2”.
	`area 1 virtual-link 12.12.12.25 authentication-key 2 $on-o`
	The prefix can be one of the following:
	• 0 = the key string is not encrypted and is in clear text
	• 1 = the key string uses proprietary simple crytographic 2-way algorithm
	• 2 = the key string uses proprietray base64 crytographic 2-way algorithm

md5-authentication key <*string*>	The MD5 **key** is a number from 1 – 255 and identifies the MD5 key that is being used. This parameter is required to differentiate among multiple keys defined on a router. When MD5 is enabled, the key-string is an alphanumeric password of up to 16 characters that is later encrypted and included in each OSPF packet transmitted. You must enter a password in this field when the system is configured to operate with either simple or MD5 authentication. By default, the MD5 authentication key is encrypted. If you want the authentication key to be in clear text, insert a **0** between **key** and <*string*>. For example, `NetIron C(config-ospf-router)# area 1 virtual-link 10.0.0.1 md-5-authentication key-id 5 key evening` The software adds a prefix to the authentication key string in the configuration. For example, the following portion of the code has the encrypted code “2”. area 1 virtual-link 12.12.12.25 md-5-authentication key-id 5 key **2** $on-o The prefix can be one of the following: • 0 = the key string is not encrypted and is in clear text • 1 = the key string uses proprietary simple crytographic 2-way algorithm • 2 = the key string uses proprietary base64 crytographic 2-way algorithm
md5-authentication wait time	This parameter determines when a newly configured MD5 authentication key is valid. This parameter provides a graceful transition from one MD5 key to another without disturbing the network. All new packets transmitted after the key activation wait time interval use the newly configured MD5 Key. OSPF packets that contain the old MD5 key are accepted for up to five minutes after the new MD5 key is in operation. The range for the key activation wait time is from 0 – 14400 seconds. The default value is 300 seconds.

Changing the reference bandwidth for the cost on OSPF interfaces

Each interface on which OSPF is enabled has a cost associated with it. The device advertises its interfaces and their costs to OSPF neighbors. For example, if an interface has an OSPF cost of ten, the device advertises the interface with a cost of ten to other OSPF routers.

By default, an interface's OSPF cost is based on the port speed of the interface. The cost is calculated by dividing the reference bandwidth by the port speed. The default reference bandwidth is 100 Mbps, which results in the following default costs:

- 10 Mbps port – 10
- All other port speeds – 1

You can change the reference bandwidth, to change the costs calculated by the software.

The software uses the following formula to calculate the cost:

Cost = reference-bandwidth/interface-speed

If the resulting cost is less than 1, the software rounds the cost up to 1. The default reference bandwidth results in the following costs:

- 10 Mbps port's cost = 100/10 = 10
- 100 Mbps port's cost = 100/100 = 1
- 1000 Mbps port's cost = 100/1000 = 0.10, which is rounded up to 1
- 10 Gbps port's cost = 100/10000 = 0.01, which is rounded up to 1

The bandwidth for interfaces that consist of more than one physical port is calculated as follows:

- LAG group – The combined bandwidth of all the ports.
- Virtual interface – The combined bandwidth of all the ports in the port-based VLAN that contains the virtual interface.

The default reference bandwidth is 100 Mbps. You can change the reference bandwidth to a value from 1 – 4294967.

If a change to the reference bandwidth results in a cost change to an interface, the device sends a link-state update to update the costs of interfaces advertised by the device.

NOTE
If you specify the cost for an individual interface, the cost you specify overrides the cost calculated by the software.

Interface types to which the reference bandwidth does not apply

Some interface types are not affected by the reference bandwidth and always have the same cost regardless of the reference bandwidth in use:

- The cost of a loopback interface is always 1.
- The cost of a virtual link is calculated using the Shortest Path First (SPF) algorithm and is not affected by the auto-cost feature.
- The bandwidth for tunnel interfaces is 9 Kbps and is also subject to the auto-cost reference bandwidth setting.

Changing the reference bandwidth

To change the reference bandwidth, enter a command such as the following at the OSPF configuration level of the CLI.

```
NetIron(config)# router ospf
NetIron(config-ospf-router)# auto-cost reference-bandwidth 500
```

The reference bandwidth specified in this example results in the following costs:

- 10 Mbps port's cost = 500/10 = 50
- 100 Mbps port's cost = 500/100 = 5
- 1000 Mbps port's cost = 500/1000 = 0.5, which is rounded up to 1

The costs for 10 Mbps and 100 Mbps ports change as a result of the changed reference bandwidth. Costs for higher-speed interfaces remain the same.

Syntax: [no] auto-cost reference-bandwidth <*num*> **| use-active-ports**

The <*num*> parameter specifies the reference bandwidth and can be a value from 1 – 4294967. The default is 100.

To restore the reference bandwidth to its default value and thus restore the default costs of interfaces to their default values, enter the following command.

```
NetIron(config-ospf-router)# no auto-cost reference-bandwidth
```

Determining cost calculation for active ports only on LAG and VE interfaces

The default operation is for cost calculation of OSPF interfaces to be based upon all configured ports. There is also an option for the **auto-cost reference-bandwidth** command for the calculation of OSPF costs on active ports of LAG and VE interfaces. This option allows you to calculate cost based on the ports that are currently active. The following example enables cost calculation for currently active ports.

```
NetIron(config-ospf-router)# auto-cost use-active-ports
```

The **use-active-ports** option enables cost calculation for currently active ports only. This option does not have any effect on non-VE or non-LAG interfaces. The default operation is for costs to be based on configured ports.

Define redistribution filters

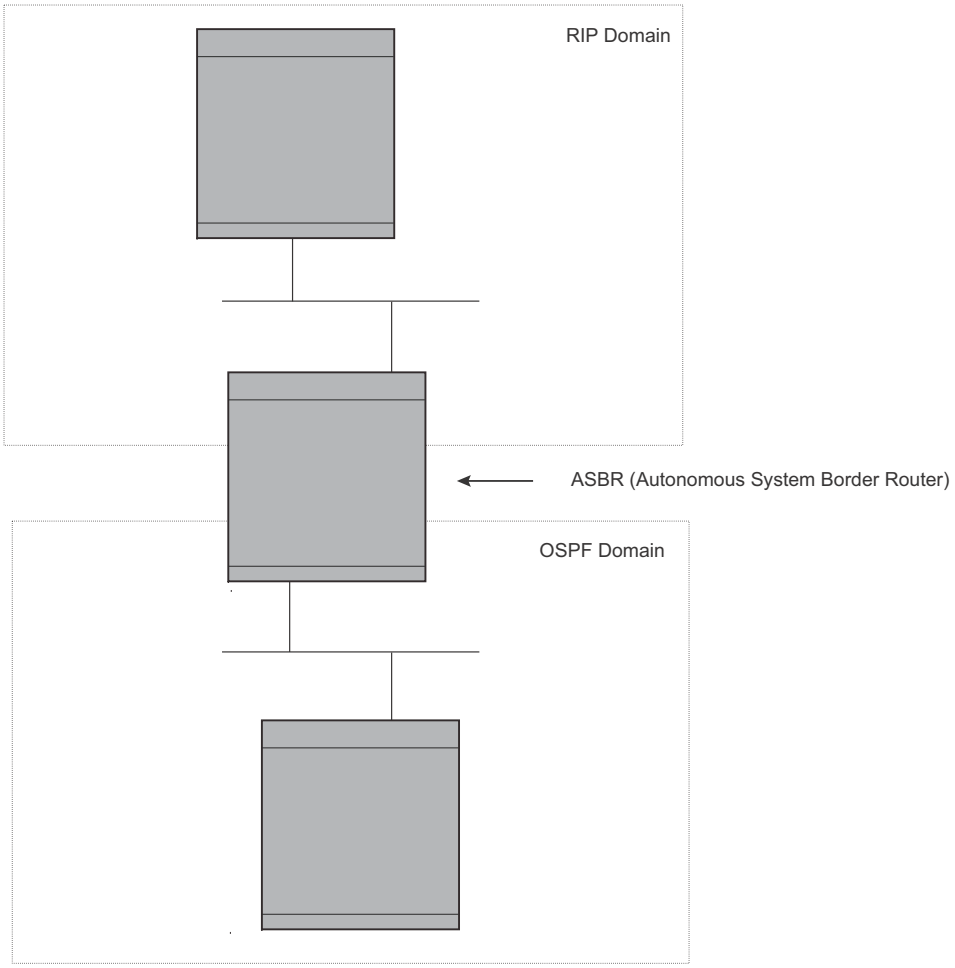
Route redistribution imports and translates different protocol routes into a specified protocol type. On the device, redistribution is supported for static routes, ISIS, OSPF, RIP, and BGP4. OSPF redistribution supports the import of static, ISIS, RIP, and BGP4 routes into OSPF routes.

NOTE
The device advertises the default route into OSPF even if redistribution is not enabled, and even if the default route is learned through an IBGP neighbor. IBGP routes (including the default route) are not redistributed into OSPF by OSPF redistribution (for example, by the OSPF **redistribute** command).

In Figure 138 on page 885, an administrator wants to configure the device acting as the ASBR (Autonomous System Boundary Router) between the RIP domain and the OSPF domain to redistribute routes between the two domains.

NOTE
The ASBR must be running both RIP and OSPF protocols to support this activity.

FIGURE 138 Redistributing OSPF and static routes to RIP routes



You also have the option of specifying import of just ISIS, RIP, OSPF, BGP4, or static routes, as well as specifying that only routes for a specific network or with a specific cost (metric) be imported, as shown in the command syntax below.

Syntax: [no] redistribute bgp | connected | rip | static [route-map <*map-name*>**]**

For example, to enable redistribution of RIP and static IP routes into OSPF, enter the following commands.

```
NetIron(config)# router ospf
NetIron(config-ospf-router)# redistribute rip
NetIron(config-ospf-router)# redistribute static
NetIron(config-ospf-router)# write memory
```

Modify default metric for redistribution

The default metric is a global parameter that specifies the cost applied to all OSPF routes by default. The default value is 10. You can assign a cost from 1 – 65535.

NOTE
You also can define the cost on individual interfaces. The interface cost overrides the default cost.

To assign a default metric of 4 to all routes imported into OSPF, enter the following commands.

```
NetIron(config)# router ospf
NetIron(config-ospf-router)# default-metric 4
```

Syntax: default-metric <*value*>

The <*value*> can be from 1 – 15. The default is 10.

Enable route redistribution

NOTE
Do not enable redistribution until you have configured the redistribution route map. Otherwise, you might accidentally overload the network with routes you did not intend to redistribute.

To enable redistribution of RIP and static IP routes into OSPF, enter the following commands.

```
NetIron(config)# router ospf
NetIron(config-ospf-router)# redistribute rip
NetIron(config-ospf-router)# redistribute static
NetIron(config-ospf-router)# write memory
```

Example using a route map

To configure a route map and use it for redistribution of routes into OSPF, enter commands such as the following.

```
NetIron(config)# ip route 1.1.0.0 255.255.0.0 207.95.7.30
NetIron(config)# ip route 1.2.0.0 255.255.0.0 207.95.7.30
NetIron(config)# ip route 1.3.0.0 255.255.0.0 207.95.7.30
NetIron(config)# ip route 4.1.0.0 255.255.0.0 207.95.6.30
NetIron(config)# ip route 4.2.0.0 255.255.0.0 207.95.6.30
NetIron(config)# ip route 4.3.0.0 255.255.0.0 207.95.6.30
NetIron(config)# ip route 4.4.0.0 255.255.0.0 207.95.6.30 5
NetIron(config)# route-map abc permit 1
NetIron(config-routemap abc)# match metric 5
NetIron(config-routemap abc)# set metric 8
NetIron(config-routemap abc)# router ospf
NetIron(config-ospf-router)# redistribute static route-map abc
```

The commands in this example configure some static IP routes, then configure a route map and use the route map for redistributing static IP routes into OSPF.

The **ip route** commands configure the static IP routes. The **route-map** command begins configuration of a route map called “abc”. The number indicates the route map entry (called the “instance”) you are configuring. A route map can contain multiple entries. The software compares routes to the route map entries in ascending numerical order and stops the comparison once a match is found.

The **match** command in the route map matches on routes that have 5 for their metric value (cost). The **set** command changes the metric in routes that match the route map to 8.

The **redistribute static** command enables redistribution of static IP routes into OSPF, and uses route map “abc“ to control the routes that are redistributed. In this example, the route map allows a static IP route to be redistributed into OSPF only if the route has a metric of 5, and changes the metric to 8 before placing the route into the OSPF route table.

The following command shows the result of the redistribution. Since only one of the static IP routes configured above matches the route map, only one route is redistributed. Notice that the route’s metric is 5 before redistribution but is 8 after redistribution.

```
NetIron# show ip ospf database external

Index Aging  LS ID           Router          Netmask  Metric    Flag
1     2      4.4.0.0         10.10.10.60     ffff0000 80000008  0000
```

Syntax: **[no] redistribute bgp | connected | rip | isis [level-1| level-1-2| level-2] | static [route-map** *<map-name>***]**

The **bgp | connected | rip | isis | static** parameter specifies the route source.

The **route-map** *<map-name>* parameter specifies the route map name. The following match parameters are valid for OSPF redistribution:

- **match ip address | next-hop** *<acl-num>*
- **match metric** *<num>*
- **match tag** *<tag-value>*

NOTE
A match tag can take up to 16 tags. During the execution of a route-map a match on any tag value in the list is considered a succesful match.

The following set parameters are valid for OSPF redistribution:

- **set ip next hop** *<ip-addr>*
- **set metric [+ | -]***<num>* **| none**
- **set metric-type type-1 | type-2**
- **set tag** *<tag-value>*

NOTE
You must configure the route map before you configure a redistribution that uses the route map.

NOTE
When you use a route map for route redistribution, the software disregards the permit or deny action of the route map.

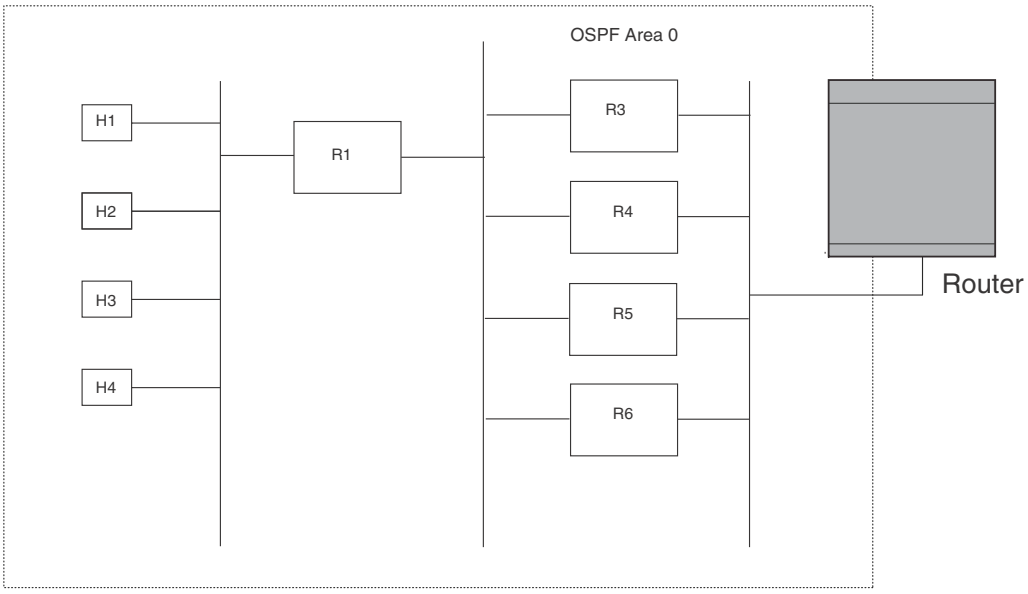
NOTE
For an external route that is redistributed into OSPF through a route map, the metric value of the route remains the same unless the metric is set by a **set metric** command inside the route map. The **default-metric** <*num*> command has no effect on the route. This behavior is different from a route that is redistributed without using a route map. For a route redistributed without using a route map, the metric is set by the default-metric <*num*> command.

Disable or re-enable load sharing

Dell routers can load share among up to eight equal-cost IP routes to a destination. By default, IP load sharing is enabled. The default is 4 equal-cost paths but you can specify from 2 – 8 paths.

The router software can use the route information it learns through OSPF to determine the paths and costs. Figure 139 shows an example of an OSPF network containing multiple paths to a destination (in this case, R1).

FIGURE 139 Example OSPF network with four equal-cost paths



In the example in Figure 139, the device has four paths to R1:

- Router ->R3
- Router ->R4
- Router ->R5
- Router ->R6

Normally, the device will choose the path to the R1 with the lower metric. For example, if the metric for R3 is 1400 and the metric for R4 is 600, the device will always choose R4.

However, suppose the metric is the same for all four routers in this example. If the costs are the same, the router now has four equal-cost paths to R1. To allow the router to load share among the equal cost routes, enable IP load sharing. The software supports four equal-cost OSPF paths by default when you enable load sharing. You can specify from 2 – 8 paths.

NOTE
The device is not source routing in these examples. The device is concerned only with the paths to the next-hop routers, not the entire paths to the destination hosts.

OSPF load sharing is enabled by default when IP load sharing is enabled.

Configure external route summarization

When the device is an OSPF Autonomous System Boundary Router (ASBR), you can configure it to advertise one external route as an aggregate for all redistributed routes that are covered by a specified address range.

When you configure an address range, the range takes effect immediately. All the imported routes are summarized according to the configured address range. Imported routes that have already been advertised and that fall within the range are flushed out of the AS and a single route corresponding to the range is advertised.

If a route that falls within a configured address range is imported by the device, no action is taken if the device has already advertised the aggregate route; otherwise the device advertises the aggregate route. If an imported route that falls with in a configured address range is removed by the device, no action is taken if there are other imported routes that fall with in the same address range; otherwise the aggregate route is flushed.

You can configure up to 32 address ranges. The device sets the forwarding address of the aggregate route to zero and sets the tag to zero.

If you delete an address range, the advertised aggregate route is flushed and all imported routes that fall within the range are advertised individually.

If an external LSDB overflow condition occurs, all aggregate routes are flushed out of the AS, along with other external routes. When the device exits the external LSDB overflow condition, all the imported routes are summarized according to the configured address ranges.

NOTE
If you use redistribution filters in addition to address ranges, the device applies the redistribution filters to routes first, then applies them to the address ranges.

NOTE
If you disable redistribution, all the aggregate routes are flushed, along with other imported routes.

NOTE
This option affects only imported, type 5 external routes. A single type 5 LSA is generated and flooded throughout the AS for multiple external routes. Type 7-route redistribution is not affected by this feature. All type 7 routes will be imported (if redistribution is enabled). To summarize type 7 LSAs or exported routes, use NSSA address range summarization.

To configure a summary address for OSPF routes, enter commands such as the following.

```
NetIron(config-ospf-router)# summary-address 10.1.0.0 255.255.0.0
```

The command in this example configures summary address 10.1.0.0, which includes addresses 10.1.1.0, 10.1.2.0, 10.1.3.0, and so on. For all of these networks, only the address 10.1.0.0 is advertised in external LSAs.

Syntax: **summary-address** <*ip-addr*> <*ip-mask*>

The <*ip-addr*> parameter specifies the network address.

The <*ip-mask*> parameter specifies the network mask.

To display the configured summary addresses, enter the following command at any level of the CLI.

```
NetIron)# show ip ospf config
OSPF Redistribution Address Ranges currently defined:
Range-Address    Subnetmask
1.0.0.0          255.0.0.0
1.0.1.0          255.255.255.0
1.0.2.0          255.255.255.0
```

Syntax: show ip ospf config

Configure default route origination

When the device is an OSPF Autonomous System Boundary Router (ASBR), you can configure it to automatically generate a default external route into an OSPF routing domain. This feature is called "default route origination" or "default information origination".

By default, the device does not advertise the default route into the OSPF domain. If you want the device to advertise the OSPF default route, you must explicitly enable default route origination.

When you enable OSPF default route origination, the device advertises a type 5 default route that is flooded throughout the AS (except stub areas and NSSAs). In addition, internal NSSA ASBRs advertise their default routes as translatable type 7 default routes.

The device advertises the default route into OSPF even if OSPF route redistribution is not enabled, and even if the default route is learned through an IBGP neighbor.

NOTE
The device never advertises the OSPF default route, regardless of other configuration parameters, unless you explicitly enable default route origination using the following method.

If the device is an ASBR, you can use the "always" option when you enable the default route origination. The always option causes the ASBR to create and advertise a default route if it does not already have one configured.

If default route origination is enabled and you disable it, the default route originated by the device is flushed. Default routes generated by other OSPF routers are not affected. If you re-enable the feature, the feature takes effect immediately and thus does not require you to reload the software.

NOTE
The ABR (device) will not inject the default route into an NSSA by default and the command described in this section will not cause the device to inject the default route into the NSSA. To inject the default route into an NSSA, use the **area** <*num*> | <*ip-addr*> **nssa default-information-originate** command. Refer to "Assign a Not-So-Stubby Area (NSSA)" on page 871.

To enable default route origination, enter the following command.

```
NetIron(config-ospf-router)# default-information-originate
```

To disable the feature, enter the following command.

```
NetIron(config-ospf-router)# no default-information-originate
```

Syntax: [no] default-information-originate [always] [metric <*value*>**] [metric-type** <*type*>**]**

The **always** parameter advertises the default route regardless of whether the router has a default route. This option is disabled by default.

The **metric** <*value*> parameter specifies a metric for the default route. If this option is not used, the default metric is used for the route.

The **metric-type** <*type*> parameter specifies the external link type associated with the default route advertised into the OSPF routing domain. The <*type*> can be one of the following:

- type1 – Type 1 external route
- type2 – Type 2 external route

If you do not use this option, the default redistribution metric type is used for the route type.

NOTE
If you specify a metric and metric type, the values you specify are used even if you do not use the **always** option.

The **route-map** parameter overrides other options. If **set** commands for **metric** and **metric-type** are specified in the route-map, the command-line values of metric and metric-type if specified, are ignored" for clarification.

The **route-map** <rmap> parameter specifies the route map reference.

The corresponding route-map should be created before configuring the **route-map** option along with the **default-information-originate**. If the corresponding route-map was not been created beforehand, then the an error message will be displayed stating that the route-map must be created.

NOTE
The route-map option cannot be used with a non-default address in the match conditions. The default-route LSA shall not be generated if a default route is not present in the routing table and a **match ip address** condition for an existing non-default route is configured in the route-map. The **match ip-address** command in the route-map is a no-op operation for the default information originate command.

Supported match and set conditions

Table 138 and Table 139 list the supported **match** and **set** conditions of a normal route-map configuration:

TABLE 138 Match Conditions

Match Conditions	
ip nexthop prefix-list	<prefixList>
ip nexthop	<accessList>
interface	<interfaceName>
metric	<metricValue>
tag	<routeTagValue>
protocol-type	<protocol route type and (or) sub-type value>
route-type	<route type (IS-IS sub-type values)>

TABLE 139 Set Conditions

Set Conditions:	
metric	<metricValue>
metric-type	<type1/type2>
tag	<routeTagValue>

OSPF non-stop routing

The graceful restart feature supported by open shortest path first (OSPF) maintains area topology and dataflow. Though the network requires neighboring routers to support graceful restart and perform hitless failover, the graceful restart feature may not be supported by all routers in the network. NSR does not require support from neighboring routers to perform hitless failover.

If the active management module fails, the standby management module takes over and maintains the current OSPF routes, link-state advertisements (LSAs), and neighbor adjacencies, so that there is no loss of existing traffic to the OSPF destination.

Synchronization of critical OSPF elements

All types of LSAs and the neighbor information are synchronized to the standby module using the NSR synchronization library and IPC mechanism to transmit and receive packets.

Link state database synchronization

When the active management module fails, the standby management module takes over from the active management module with the identical OSPF link state database it had before the failure to ensure non-stop routing. The next shortest path firtst (SPF) run after switchover yieds the same result in routes as the active module had before the failure and OSPF protocol requires that all routers in the network to have identical databases.

LSA delayed acknowledging

When an OSPF router receives LSAs from its neighbor, it acknowledges the LSAs. After the acknowledgement is received, the neighbor removes this router from its retransmission list and stops resending the LSAs.

In the case of NSR, the router fails after receiving the LSA from its neighbor and has acknowledged that neighbor upon receipt of an LSA, and the LSA synchronization to the standby module is completed. In this case, the standby module when taking over from the active module does not have that LSA in its database and the already acknowledged neighbor does not retransmit that LSA. For this reason, the NSR-capable router waits for LSA synchronization of the standby module to complete (Sync-Ack) and then acknowledges the neighbor that sent the LSA.

LSA synching and packing

When the LSA processing is completed on the active management module and the decision is made to install the LSA in its link state database (LSDB), OSPF synchronizes that LSA to the standby module. OSPF checks the current state of the database entry whether or not it is marked for deletion. After checking the database state, OSPF packs the LSA status and other necessary information needed for direct installation in the standby OSPF LSDB along with the LSA portion. When the LSA reaches the standby module, OSPF checks the database entry state in the buffer and takes appropriate action, such as adding, overwriting, updating, or deleting the LSA from the LSDB.

Neighbor router synchronization

When the neighbor router is added in the active management module, it is synchronized and added to the standby module. When the neighbor is deleted in the active module, it is synchronized to the standby and deleted in the standby. When the neighbor router state becomes 2WAY or FULL, the neighbor router is synchronized to the standby module.The following attributes of the neighbor router is synchronized to the standby module:

- Neighbor router id
- Neighbor router ip address
- Destination router or backup destination router information
- Neighbor state 2WAY or FULL
- MD5 information
- Neighbor priority

Limitations

- If a neighbor router is inactive for 30 seconds, and if the standby module takes over in another 10 seconds, the neighbor router cannot be dropped. The inactivity timer starts again and takes another 40 seconds to drop the neighbor router.
- In standby module, the valid neighbor states are LOADING, DOWN, 2WAY, and FULL. If the active management processor (MP) fails when the neighbor state is LOADING, the standby module cannot continue from LOADING, but the standby can continue from 2WAY and tries to establish adjacency between the neighboring routers.

Interface synchronization

Interface information is synchronized for interfaces such as PTPT, broadcast, and non-broadcast. Interface wait time is not synchronized to the standby module. If an interface waits for 30 seconds to determine the identity of designated router (DR) or backup designated router (BDR), and if the standby module takes over, the wait timer starts again and takes another 40 seconds for the interface state to change from waiting to BDR, DR, or DROther.

BFD with OSPF NSR

Bidirectional forwarding detection (BFD) supports MP switchover and all BFD sessions for OSPF with graceful OSPF NSR, which are in the up state after the switchover. The BFD sessions for OSPF that do not use OSPF NSR are cleared before the switchover and then re-established on the new active MP after the MP switchover.

In case the active MP learns an OSPF neighbor and then restarts before a new BFD session is established, the standby module will not have a BFD session for the new OSPF neighbor. To overcome this and to support OSPF NSR with BFD, the following functions are supported when the active MP restarts:

- During MP switchover, BFD checks whether OSPF NSR is enabled. If OSPF NSR is enabled, the existing BFD sessions for OSPF is maintained during the switchover.
- OSPF sets up or clears the BFD sessions after OSPF neighbor transition.
- After the switchover, BFD sessions correspond with the active OSPF neighbor.

Standby module operations

The standby management module with OSPF configuration performs the following functions.

Neighbor database

Neighbor information is updated in the standby module based on updates from the active module. Certain neighbor state and interface transitions are synchronized to the standby module. By default, the neighbor timers on the standby module are disabled.

LSA database

The standby module processes LSA synchronization events from the active module and unpacks the LSA synchronization information to directly install it in its LSDB as the LSA has already been processed on the active module. The information required to install all types of LSAs (and special LSAs such as Grace LSAs) is packed by OSPF on the active module in the synchronization buffer, so that you can directly install LSAs on the standby module without extra processing.

The standby module is not allowed to originate any LSAs of its own. This is to maintain all information consistently from the active module. The active module synchronizes self-originated LSAs to the standby module.

LSA aging is not applicable on the standby module. During synchronization from the active, the current LSA age is recorded and the new database timestamp is created on the standby to later derive the LSA age as needed.

When the active module sends the LSAs to the standby module, based on the message, the standby module deletes or updates its link state database with the latest information.

LSA acknowledging or flooding are not done on the standby module. When the LSA synchronization update arrives from the active module, it will be directly installed into the LSDB.

Enabling and disabling NSR

To enable NSR for OSPF, enter the following command.

```
NetIron(config)# router ospf
PowerConnect(config-ospf-router)# nonstop-routing
```

To disable NSR for OSPF, enter the following command.

```
PowerConnect(config)# router ospf
```

`PowerConnect` (config-ospf-router)# no nonstop-routing

Syntax: [no] nonstop-routing

If you enter the **graceful-restart** command when NSR is already enabled, the command is rejected with the following message: “Error - Please disable NSR before enabling Graceful Restart”.

Similarly, if you enter the **nonstop-routing** command when graceful restart is already enabled, the command is rejected and the following message is displayed: “Error - Please disable Graceful Restart before enabling NSR”.

Limitations of NSR

Following are the limitations of NSR:

- Configurations that occur before the switchover are lost due to the CLI synchronization.
- Sham links are not supported.
- GRE tunnels are not supported.
- Changes in the neighbor state or interface state before or during a switchover do not take effect.
- Traffic counters are not synchronized because the neighbor and LSA database counters are recalculated on the standby module during synchronization.
- LSA acknowledging is delayed because it has to wait until standby acknowledging occurs.
- Depending on the sequence of redistribution or new LSAs (from neighbors), the LSAs accepted within the limits of the database may change after switchover.
- In NSR hitless failover, after switchover, additional flooding-related protocol traffic is generated to the directly connected neighbors.
- OSPF startup timers, database overflow, and max-metric, are not applied during NSR switchover.

Adding additional parameters

Previously, to add new parmeters, the old configuration had to be undone and the newer configuration had to be recreated. In release 04.1.00 however, to add new parmeters, the existing configuration need not be undone or removed. Any successive configuration changes with new parameters is appended to the existing configuration. If the same parmeter is entered again with a different value, then the corresponding parmeter value is updated.

Example

```
NetIron(config-ospf-router)#default-information-originate route-map defaultToOspf
NetIron(config-ospf-router)#default-information-originate always
NetIron(config-ospf-router)#default-information-originate metric 200
```

In the above example, **default-information-originate**' is enabled with the **route-map** parameter for the first CLI and then the **always** and **metric** is appended to the existing configuration. The running configuration of the above three split commands would be as follows:

```
NetIron(config-ospf-router)#default-information-originate always metric 200
route-map defaultToOspf
```

Disabling configuration

To disable the **route-map** parameter from the configuration, enter the following command:

```
NetIron(config-ospf-router)# no default-information-originate route-map
defaultToOspf
```

The above CLI would retain the configuration with **default-information-originate** alone and **route-map** option would get reset or removed.

The following commands with any or all of the options will remove the options from the **default-information-originate** command if any of the options are configured:

```
NetIron(config-ospf-router)#no default-information-originate always
```

```
NetIron(config-ospf-router)#no default-information-originate always route-map
test
```

```
NetIron(config-ospf-router)#no default-information-originate always route-map
test metric 200
```

```
NetIron(config-ospf-router)#no default-information-originate always route-map
test metric 200 metric-type type1
```

In the following example, the parameters of the **default-information-originate** command are reset if they are configured and if none of the parmeters are configured then, these commands will have no effect.

To disable the origination of default route, issue the command with "**no**" option and without any other options. This would remove the configuration of the **default information origination** even if any of the above mentioned options are configured.

Syntax: [no] default-information-originate [always] [metric <metric value>] [metric-type <metric-type>] [route-map <rmap-name>]

The **always** parameter advertises the default route regardless of whether the router has a default route. This option is disabled by default.

The **metric** <*value*> parameter specifies a metric for the default route. If this option is not used, the default metric is used for the route.

The **metric-type** <*type*> parameter specifies the external link type associated with the default route advertised into the OSPF routing domain. The <*type*> can be one of the following:

- type1 – Type 1 external route
- type2 – Type 2 external route

If you do not use this option, the default redistribution metric type is used for the route type.

NOTE
If you specify a metric and metric type, the values you specify are used even if you do not use the **always** option.

The **route-map** parameter overrides other options. If **set** commands for **metric** and **metric-type** are specified in the route-map, the command-line values of metric and metric-type if specified, are ignored" for clarification.

The **route-map** <rmap> parameter specifies the route map reference.

The corresponding route-map should be created before configuring the **route-map** option along with the **default-information-originate**. If the corresponding route-map was not been created beforehand, then the an error message will be displayed stating that the route-map must be created.

OSPF distribute list

This feature of PowerConnect Multi-Service IronWare configures a distribution list to explicitly deny specific routes from being eligible for installation in the IP route table. By default, all OSPF routes in the OSPF route table are eligible for installation in the IP route table. This feature does not block receipt of LSAs for the denied routes. The Layer 3 Switch still receives the routes and installs them in the OSPF database. The feature only prevents the software from installing the denied OSPF routes into the IP route table.

The OSPF distribution list can be managed using ACLs or Route Maps to identify routes to be denied as described in the following sections:

- Configuring an OSPF Distribution List using ACLs
- Configuring an OSPF Distribution List using Route Maps

Configuring an OSPF distribution list using ACLs

To configure an OSPF distribution list using ACLs:

- Configure an ACL that identifies the routes you want to deny. Using a standard ACL lets you deny routes based on the destination network, but does not filter based on the network mask. To also filter based on the destination network's network mask, use an extended ACL.
- Configure an OSPF distribution list that uses the ACL as input

Examples

In the following example, the first three commands configure a standard ACL that denies routes to any 78.x.x.x destination network and allows all other routes for eligibility to be installed in the IP route table. The last three commands change the CLI to the OSPF configuration level and configure an OSPF distribution list that uses the ACL as input. The distribution list prevents routes to any 78.x.x.x destination network from entering the IP route table. The distribution list does not prevent the routes from entering the OSPF database.

```
NetIron(config)# ip access-list standard no_ip
NetIron(config-std-nacl)# deny 78.0.0.0 0.255.255.255
NetIron(config-std-nacl)# permit any
NetIron(config)# router ospf
NetIron(config-ospf-router) # area 0
NetIron(config-ospf-router) # distribute-list no_ip in
```

In the following example, the first three commands configure an extended ACL that denies routes to any 172.31.39.x destination network and allows all other routes for eligibility to be installed in the IP route table. The last three commands change the CLI to the OSPF configuration level and configure an OSPF distribution list that uses the ACL as input. The distribution list prevents routes to any 172.31.39.x destination network from entering the IP route table. The distribution list does not prevent the routes from entering the OSPF database.

```
NetIron(config)# ip access-list extended DenyNet39
NetIron(config-ext-nacl)# deny ip 172.31.39.0 0.0.0.255 any
NetIron(config-ext-nacl)# permit ip any any
NetIron(config)# router ospf
NetIron(config-ospf-router) # area 0
NetIron(config-ospf-router) # distribute-list DenyNet39 in
```

In the following example, the first command configures a numbered ACL that denies routes to any 172.31.39.x destination network and allows all other routes for eligibility to be installed in the IP route table. The last three commands change the CLI to the OSPF configuration level and configure an OSPF distribution list that uses the ACL as input. The distribution list prevents routes to any 172.31.39.x destination network from entering the IP route table. The distribution list does not prevent the routes from entering the OSPF database.

```
NetIron(config)# ip access-list 100 deny ip 172.31.39.0 0.0.0.255 any
NetIron(config)# ip access-list 100 permit ip any any
NetIron(config)# router ospf
NetIron(config-ospf-router) # area 0
NetIron(config-ospf-router) # distribute-list 100 in
```

Syntax: [no] distribute-list <*acl-name*> **|** <*acl-number*> **in**

The **distribute-list** command is applied globally to all interfaces on the router where it is executed.

Configuring an OSPF distribution list using route maps

You can manage an OSPF Distribution List using route maps that apply match operations as defined by an ACL or an IP prefix list. Additionally, you can also use other options available within the route maps and ACLs to further control the contents of the routes that OSPF provides to the IP route table. This section describes an example where an OSPF distribute list uses a route map to specify an OSPF Admin Distance for routes identified by an IP Prefix list.

To configure an OSPF distribution list using route maps:

- Configure a route map that identifies the routes you want to manage.
- Optionally configure an OSPF Admin Distance to apply to the OSPF routes
- Configure an OSPF distribution list that uses the route map as input

Example

In the following example, the first two commands identify two routes using the **ip prefix-list test1** command. Next, a **route-map** is created that uses the **prefix-list test1** to identify the two routes and the **set distance** command to set the OSPF Admin Distance of those routes to 200. A **distribute-list** is then configured under the OSPF configuration that uses the **route map** titled "setdistance" as input.

```
NetIron(config)# ip prefix-list test1 seq 5 permit 100.100.1.0/24
NetIron(config)# ip prefix-list test1 seq 10 permit 100.100.2.0/24
NetIron(config)# route-map setdistance permit 1
NetIron(config-routemap setdistance)# match ip address prefix-list test1
NetIron(config-routemap setdistance)# set distance 200
NetIron(config-routemap setdistance)# exit
NetIron(config)# router ospf
NetIron(config-ospf-router)# area 0
NetIron(config-ospf-router)# area 1
NetIron(config-ospf-router)# distribute-list route-map setdistance in
NetIron(config-ospf-router)# exit
```

Once this configuration is implemented, the routes identified by the **ip prefix-list** command and matched in the Route Map will have their OSPF Admin Distance set to 200. This is displayed in the output from the **show ip route** command, as shown in the following.

```
NetIron# show ip route
Total number of IP routes: 4
Type Codes - B:BGP D:Connected I:ISIS S:Static R:RIP O:OSPF; Cost - Dist/Metric
        Destination        Gateway         Port         Cost           Type
1       11.1.1.0/24        DIRECT          eth 1/1      0/0             D
2       100.100.1.0/24     11.1.1.1        eth 1/1      200/2           O
3       100.100.2.0/24     11.1.1.1        eth 1/1      200/10          O2
4       100.100.6.0/24     11.1.1.1        eth 1/1      110/2           O
```

Routes 2 and 3 demonstrate the actions of the example configuration as both display an OSPF Admin Distance value of 200. Note that the value is applied to both OSPF learned routes that match the route-map configuration: internal (route 2) and external (route 3). The other OSPF internal route (route 4) that does not match the route-map continues to have the default OSPF admin distance of 110.

The following is an example of the **distribute-list** command applied with route-map **setdistance** set as the input.

```
NetIron(config-ospf-router)# distribute-list route-map setdistance in
```

Syntax: [no] distribute-list route-map <*routemap-name*> **in**

The <*routemap-name*> variable specifies the name of the route map being used to define the OSPF Distribute List.

The **distribute-list** command is applied to all OSPF LSAs on the router where it is executed.

NOTE
A Route Map used with the **distribute-list** command can use either the **ip prefix-list** command (as shown in the example) or an ACL to define the routes . For information about creating Route Maps, refer to 22, "Policy-Based Routing".

The **set distance** command that is used in association with a Route Map configuration.

Modify SPF timers

The device uses the following timers when calculating the shortest path for OSPF routes:

- **SPF delay** – When the device receives a topology change, the software waits before it starts a Shortest Path First (SPF) calculation. By default, the software waits 0 (zero) seconds. You can configure the SPF delay to a value from 0 – 65535 seconds. If you set the SPF delay to 0 seconds, the software immediately begins the SPF calculation after receiving a topology change.
- **SPF hold time** – The device waits for a specific amount of time between consecutive SPF calculations. By default, the device waits zero seconds. You can configure the SPF hold time to a value from 0 – 65535 seconds. If you set the SPF hold time to 0 seconds, the software does not wait between consecutive SPF calculations.

You can set the delay and hold time to lower values to cause the device to change to alternate paths more quickly in the event of a route failure. Note that lower values require more CPU processing time.

You can change one or both of the timers.

To change the SPF delay and hold time, enter commands such as the following.

```
NetIron(config-ospf-router)# timers spf 10 20
```

The command in this example changes the SPF delay to 10 seconds and changes the SPF hold time to 20 seconds.

To set the timers back to their default values, enter a command such as the following.

```
NetIron(config-ospf-router)# no timers spf 10 20
```

Syntax: [no] timers spf <*delay*> <*hold-time*>

The <*delay*> parameter specifies the SPF delay.

The <*hold-time*> parameter specifies the SPF hold time.

NOTE
OSPF incrementally updates the OSPF routing table when new Type-3 or Type-4 Summary, Type-5 External, or Type-7 External NSSA LSAs are received.

Modify redistribution metric type

The redistribution metric type is used by default for all routes imported into OSPF unless you specify different metrics for individual routes using redistribution filters. Type 2 specifies a big metric (three bytes). Type 1 specifies a small metric (two bytes). The default value is type 2.

To modify the default value to type 1, enter the following command.

```
NetIron(config-ospf-router)# metric-type type1
```

Syntax: [no] metric-type type1 | type2

The default is **type2**.

Modify administrative distance

The device can learn about networks from various protocols, including Border Gateway Protocol version 4 (BGP4), RIP, ISIS, and OSPF. Consequently, the routes to a network may differ depending on the protocol from which the routes were learned. The default administrative distance for OSPF routes is 110.

The router selects one route over another based on the source of the route information. To do so, the router can use the administrative distances assigned to the sources. You can bias the decision the device makes by changing the default administrative distance for OSPF routes.

Configuring administrative distance based on route type

You can configure a unique administrative distance for each type of OSPF route. For example, you can use this feature to prefer a static route over an OSPF inter-area route but you also want to prefer OSPF intra-area routes to static routes.

The distance you specify influences the choice of routes when the device has multiple routes for the same network from different protocols. The device prefers the route with the lower administrative distance.

You can specify unique default administrative distances for the following route types:

- Intra-area routes
- Inter-area routes
- External routes

The default for all these OSPF route types is 110.

NOTE
This feature does not influence the choice of routes within OSPF. For example, an OSPF intra-area route is always preferred over an OSPF inter-area route, even if the intra-area route's distance is greater than the inter-area route's distance.

To change the default administrative distances for inter-area routes, intra-area routes, and external routes, enter the following command.

```
NetIron(config-ospf-router)# distance external 100
NetIron(config-ospf-router)# distance inter-area 90
NetIron(config-ospf-router)# distance intra-area 80
```

Syntax: [no] distance external | inter-area | intra-area <*distance*>

The **external | inter-area | intra-area** parameter specifies the route type for which you are changing the default administrative distance.

The <*distance*> parameter specifies the new distance for the specified route type. Unless you change the distance for one of the route types using commands such as those shown above, the default is 110.

To reset the administrative distance to its system default (110), enter a command such as the following.

```
NetIron(config-ospf-router)# no distance external 100
```

Configure OSPF group Link State Advertisement (LSA) pacing

The device paces LSA refreshes by delaying the refreshes for a specified time interval instead of performing a refresh each time an individual LSA refresh timer expires. The accumulated LSAs constitute a group, which the device refreshes and sends out together in one or more packets.

The pacing interval, which is the interval at which the device refreshes an accumulated group of LSAs, is configurable to a range from 10 – 1800 seconds (30 minutes). The default is 240 seconds (four minutes). Thus, every four minutes, the device refreshes the group of accumulated LSAs and sends the group together in the same packets.

Usage guidelines

The pacing interval is inversely proportional to the number of LSAs the device is refreshing and aging. For example, if you have approximately 10,000 LSAs, decreasing the pacing interval enhances performance. If you have a very small database (40 – 100 LSAs), increasing the pacing interval to 10 – 20 minutes might enhance performance slightly.

Changing the LSA pacing interval

To change the LSA pacing interval, use the following CLI method.

To change the LSA pacing interval to two minutes (120 seconds), enter the following command.

```
NetIron(config-ospf-router)# timers lsa-group-pacing 120
```

Syntax: [no] timers lsa-group-pacing <*secs*>

The <*secs*> parameter specifies the number of seconds and can be from 10 – 1800 (30 minutes). The default is 240 seconds (four minutes).

To restore the pacing interval to its default value, enter the following command.

```
NetIron(config-ospf-router)# no timers lsa-group-pacing
```

Modify OSPF traps generated

OSPF traps as defined by RFC 1850 are supported on device.

You can disable all or specific OSPF trap generation by entering the following CLI command.

```
NetIron(config)# no snmp-server trap ospf
```

To later re-enable the trap feature, enter **snmp-server trap ospf**.

To disable a specific OSPF trap, enter the command as **no snmp-server trap ospf** <*ospf-trap*>.

These commands are at the OSPF router Level of the CLI.

Here is a summary of OSPF traps supported on device, their corresponding CLI commands, and their associated MIB objects from RFC 1850. The first list are traps enabled by default:

- **interface-state-change-trap** – [MIB object: OspfIfstateChange]
- **virtual-interface-state-change-trap** – [MIB object: OspfVirtIfStateChange
- **neighbor-state-change-trap** – [MIB object:ospfNbrStateChange]

- **virtual-neighbor-state-change-trap** – [MIB object: ospfVirtNbrStateChange]
- **interface-config-error-trap** – [MIB object: ospfIfConfigError]
- **virtual-interface-config-error-trap** – [MIB object: ospfVirtIfConfigError]
- **interface-authentication-failure-trap** – [MIB object: ospfIfAuthFailure]
- **virtual-interface-authentication-failure-trap** – [MIB object: ospfVirtIfAuthFailure]
- **interface-receive-bad-packet-trap** – [MIB object: ospfIfrxBadPacket]
- **virtual-interface-receive-bad-packet-trap** – [MIB object: ospfVirtIfRxBadPacket]

The following traps are disabled by default.

- **interface-retransmit-packet-trap** – [MIB object: ospfTxRetransmit]
- **virtual-interface-retransmit-packet-trap** – [MIB object: ospfVirtIfTxRetransmit]
- **originate-lsa-trap** – [MIB object: ospfOriginateLsa]
- **originate-maxage-lsa-trap** – [MIB object: ospfMaxAgeLsa]
- **link-state-database-overflow-trap** – [MIB object: ospfLsdbOverflow]
- **link-state-database-approaching-overflow-trap** – [MIB object: ospfLsdbApproachingOverflow

Example

To stop an OSPF trap from being collected, use the CLI command: **no trap** <*ospf-trap*>, at the Router OSPF level of the CLI. To disable reporting of the neighbor-state-change-trap, enter the following command.

```
NetIron(config-ospf-router)# no trap neighbor-state-change-trap
```

Example

To reinstate the trap, enter the following command.

```
NetIron(config-ospf-router)# trap neighbor-state-change-trap
```

Syntax: [no] trap <*ospf-trap*>

Modify OSPF standard compliance setting

The device is configured, by default, to be compliant with the RFC 1583 OSPF V2 specification.

To configure a router to operate with the latest OSPF standard, RFC 2328, enter the following commands.

```
NetIron(config)# router ospf
NetIron(config-ospf-router)# no rfc1583-compatibility
```

Syntax: [no] rfc1583-compatibility

Modify exit overflow interval

If a database overflow condition occurs on a router, the router eliminates the condition by removing entries that originated on the router. The exit overflow interval allows you to set how often a device checks to see if the overflow condition has been eliminated. The default value is 0. The range is 0 – 86400 seconds (24 hours). If the configured value of the database overflow interval is zero, then the router never leaves the database overflow condition.

To modify the exit overflow interval to 60 seconds, enter the following command.

```
NetIron(config-ospf-router)# database-overflow-interval 60
```

Syntax: [no] database-overflow-interval <*value*>

The <*value*> can be from 0 – 86400 seconds. The default is 0 seconds.

Specify types of OSPF Syslog messages to log

You can specify which kinds of OSPF-related Syslog messages are logged. By default, the only OSPF messages that are logged are those indicating possible system errors. If you want other kinds of OSPF messages to be logged, you can configure the device to log them.

For example, to specify that all OSPF-related Syslog messages be logged, enter the following commands.

```
NetIron(config)# router ospf
NetIron(config-ospf-router)# log all
```

Syntax: [no] log all | adjacency [dr-only] | bad_packet [checksum] | database | memory | retransmit

The **log** command has the following options:

The **all** option causes all OSPF-related Syslog messages to be logged. If you later disable this option with the **no log all** command, the OSPF logging options return to their default settings.

The **adjacency** option logs essential OSPF neighbor state changes, especially on error cases. This option is disabled by default. The **dr-only** sub-option only logs essential OSPF neighbor state changes where the interface state is designated router (DR).

NOTE
For interfaces where the designated router state is not applicable, such as point-to-point and virtual links, OSPF neighbor state changes will always be logged irrespective of the setting of the **dr-only** sub-option.

NOTE
A limitation with the **dr-only** sub-option is that when a DR/BDR election is underway, OSPF neighbor state changes pertaining to non-DR/BDR routers are not logged. Logging resumes once a DR is elected on that network.

The **bad_packet checksum** option logs all OSPF packets that have checksum errors. This option is enabled by default.

The **bad_packet** option logs all other bad OSPF packets. This option is disabled by default.

The **database** option logs OSPF LSA-related information. This option is disabled by default.

The **memory** option logs abnormal OSPF memory usage. This option is enabled by default.

The **retransmit** option logs OSPF retransmission activities. This option is disabled by default.

Configuring an OSPF network type

To configure an OSPF network, enter commands such as the following.

```
NetIron(config)# interface eth 1/5
NetIron(config-if-1/5)# ip ospf network point-to-point
```

This command configures an OSPF point-to-point link on Interface 5 in slot 1.

Syntax: [no] ip ospf network point-to-point | broadcast | non-broadcast

The **point-to-point** option configures the network type as a point to point connection. This is the default option for POS interfaces.

NOTE
Dell supports numbered point-to-point networks, meaning the OSPF router must have an IP interface address which uniquely identifies the router over the network. Dell does not support unnumbered point-to-point networks.

The **broadcast** option configures the network type as a broadcast connection. This is the default option for Ethernet, VE and Loopback interfaces.

The **non-broadcast** option configures the network type as a non-broadcast connection. This allows you to configure the interface to send OSPF traffic to its neighbor as unicast packets rather than multicast packets. This can be useful in situations where multicast traffic is not feasible (for example when a firewall does not allow multicast packets).

On a non-broadcast interface, the routers at either end of this interface must configure non-broadcast interface type and the neighbor IP address. There is no restriction on the number of routers sharing a non-broadcast interface (for example, through a hub/switch).

To configure an OSPF interface as a non-broadcast interface, you enable the feature on a physical interface or a VE, following the **ip ospf area** statement, and then specify the IP address of the neighbor in the OSPF configuration. The non-broadcast interface configuration must be done on the OSPF routers at either end of the link.

For example, the following commands configure VE 20 as a non-broadcast interface.

```
NetIron(config)# int ve 20
NetIron(config-vif-20)# ip address 1.1.20.4/24
NetIron(config-vif-20)# ip ospf area 0
NetIron(config-vif-20)# ip ospf network non-broadcast
```

The following commands specify 1.1.20.1 as an OSPF neighbor address. The address specified must be in the same sub-net as the non-broadcast interface.

```
NetIron(config)# router ospf
NetIron(config-ospf-router)# neighbor 1.1.20.1
```

For example, to configure the feature in a network with three routers connected by a hub or switch, each router must have the linking interface configured as a non-broadcast interface, and the two other routers must be specified as neighbors.

Configuring OSPF Graceful Restart

OSPF Graceful Restart can be enabled in the following configurations:

- **Configuring OSPF Graceful Restart for the Global Instance** – In this configuration all OSPF neighbors other than those used by VRFs are made subject to the Graceful Restart capability. The restart timer set globally does not apply to Graceful Restart on a configured VRF.
- **Configuring OSPF Graceful Restart per VRF** – In this configuration all OSPF neighbors for the specified VRF are made subject to the Graceful Restart capability. The restart timer set for a specific VRF only applies to that VRF.

Configuring OSPF Graceful Restart for the global instance

OSPF Graceful restart can be configured for the global instance or for a specified Virtual Routing and Forwarding (VRF) instance. Configuring OSPF Graceful restart for the global instance does not configure it for any VRFs. The following sections describe how to enable the OSPF graceful restart feature for the global instance on a device.

Use the following command to enable the graceful restart feature for the global instance on a device.

```
NetIron(config)# router ospf
NetIron(config-ospf-router)# graceful-restart
```

Syntax: [no] **graceful-restart**

Configuring OSPF Graceful Restart time for the global instance

Use the following command to specify the maximum amount of time advertised to a neighbor router to maintain routes from and forward traffic to a restarting router.

```
NetIron(config) router ospf
NetIron(config-ospf-router)# graceful-restart restart-time 120
```

Syntax: [no] **graceful-restart restart-time** <*seconds*>

The <*seconds*> variable sets the maximum restart wait time advertised to neighbors.

Possible values are 10 - 1800 seconds.

The default value is 120 seconds.

Disabling OSPF Graceful Restart helper mode for the global instance

By default, a router supports other restarting routers as a helper. You can prevent your router from participating in OSPF Graceful Restart by using the following command.

```
NetIron(config) router ospf
NetIron(config-ospf-router)# graceful-restart helper-disable
```

Syntax: [no] **graceful-restart helper-disable**

This command disables OSPF Graceful Restart helper mode.

The default behavior is to help the restarting neighbors.

Configuring OSPF Graceful Restart per VRF

The following sections describe how to enable the OSPF Graceful Restart feature on a specified VRF.

Use the following command to enable the graceful restart feature on a specified VRF.

```
NetIron(config)# router ospf vrf blue
NetIron(config-ospf-router)# graceful-restart
```

Syntax: [no] **graceful-restart**

Configuring OSPF Graceful Restart time per VRF

Use the following command to specify the maximum amount of time advertised to an OSPF neighbor router to maintain routes from and forward traffic to a restarting router.

```
NetIron(config) router ospf vrf blue
NetIron(config-ospf-router)# graceful-restart restart-time 120
```

Syntax: [no] **graceful-restart restart-time** <*seconds*>

The <*seconds*> variable sets the maximum restart wait time advertised to OSPF neighbors of the VRF.

Possible values are 10 - 1200 seconds.

The default value is 60 seconds.

Disabling OSPF Graceful Restart helper mode per VRF

You can prevent your router from participating in OSPF Graceful Restart with VRF neighbors by using the following command.

```
NetIron(config) router ospf vrf blue
NetIron(config-ospf-router)# graceful-restart helper-disable
```

Syntax: [no] **graceful-restart helper-disable**

This command disables OSPF Graceful Restart helper mode.

The default behavior is to help the restarting neighbors.

For information about how to display OSPF Graceful Restart Information, refer to "Displaying an OSPF Graceful Restart information" on page 930.

Configuring OSPF router advertisement

You can configure OSPF router advertisement in the **router ospf** mode or **router ospf vrf** mode as shown in the following examples.

```
NetIron(config)# router ospf
NetIron(config-ospf-router)# max-metric router-lsa all-vrfs on-startup 30 link
all
NetIron(config)# router ospf vrf blue
NetIron(config-ospf-router)# max-metric router-lsa on-startup 30 link all
```

Syntax: [no] **max-metric router-lsa** [**all-vrfs**] [**on-startup** { <*time*> | **wait-for-bgp**}] [**summary-lsa** <*metric-value*>] [**external-lsa** <*metric-value*>] [**te-lsa** <*metric-value*>] [**all-lsas**] [**link** {**ptp** | **stub** | **transit** | **all** }]

The **all-vrfs** parameter specifies that the command will be applied to all VRF instances of OSPFv2. Note: this command is supported only for VRFs that are already configured when the **max-metric router-lsa all-vrfs** command is issued. Any new OSPF instance configured after the **max-metric** configuration is completed requires that the **max-metric** command be configured again to take in the new OSPF instance.

The **on-startup** parameter specifies that the OSPF router advertisement be performed at the next system startup. This is an optional parameter.

When using the **on-startup** option you can set a <*time*> in seconds for which the specified links in Router LSA will be advertised with the metric set to a maximum value of 0xFFFF. Optional values for <*time*> are 5 to 86400 seconds. There is no default value for <*time*> .

The **wait-for-bgp** option for the **on-startup** parameter directs OSPF to wait for either 600 seconds or until BGP has finished route table convergence (whichever event happens first), before advertising the links with the normal metric.

Using the **link** parameter you can specify the type of links for which the maximum metric is to be advertised. The default value is for maximum metric to be advertised for transit links only. This is an optional parameter.

With release 03.5.00 of the Multi-Service IronWare, additional options are supported that allow you to select the following LSA types and set the required metric:

The **summary-lsa** option specifies that the metric for all summary type 3 and type 4 LSAs will be modified to the specified <*metric-value*> or the default value. The range of possible values for the <*metric-value*> variable are 1 to 16777214 (Hex: 0x00001 to 0x00FFFFFE). The default value is 16711680 (Hex: 0x00FF0000).

The **external-lsa** option specifies that the metric for all external type 5 and type 7 LSAs will be modified to the specified <*metric-value*> or a default value. The range of possible values for the <*metric-value*> variable are 1 to 16777214 (Hex: 0x00001 to 0x00FFFFFE). The default value is 16711680 (Hex: 0x00FF0000).

The **te-lsa** option specifies that the TE metric field in the TE metric sub tlv for all type 10 Opaque LSAs LINK TLV originated by the router will be modified to the specified <*metric-value*> or a default value. The range of possible values for the <*metric-value*> variable are 1 to 4294967295 (Hex: 0x00001 to 0xFFFFFFFF). The default value is 4294967295 (Hex: 0xFFFFFFFF). This parameter only applies to the default instance of OSPF.

Examples

The following examples of the command max-metric router-lsa command demonstrate how it can be used:

The following command indicates that OSPF is being shutdown and that all links in the router LSA should be advertised with the value 0xFFFF and the metric value for all external and summary LSAs is set to 0xFF0000 until OSPF is restarted. This configuration will not be saved.

```
NetIron(config)# router ospf
NetIron(config-ospf-router)# max-metric router-lsa external-lsa summary-lsa
link all
```

The following command indicates that OSPF is being shutdown and that all links in the router LSA should be advertised with the value 0xFFFF and the metric value for all external and summary LSAs should be set to 0xFF0000 until OSPF is restarted. Also, if OSPF TE is enabled then all LINK TLVs advertised by the router in Opaque LSAs should be updated with the TE Metric set to 0xFFFFFFFF and the available bandwidth set to 0. This configuration will not be saved.

```
NetIron(config)# router ospf
NetIron(config-ospf-router)# max-metric router-lsa all-lsas link all
```

The following command indicates that OSPF is being shutdown and that all links in the router LSA should be advertised with the value 0xFFFF and the metric value for all summary LSAs should be set to 0xFFFFFE until OSPF is restarted. This configuration will not be saved.

```
NetIron(config)# router ospf
NetIron(config-ospf-router)# max-metric router-lsa summary-lsa 16777214 link
all
```

The following command turns off the advertisement of special metric values in all Router, Summary, and External LSAs.

```
NetIron(config)# router ospf
NetIron(config-ospf-router)# no max-metric router-lsa
```

Configuring OSPF shortest path first throttling

To set OSPF shortest path first throttling to the values in the previous example, use the following command.

```
NetIron(configure)# timer throttle spf 200 300 2000
```

Syntax: [no] timer throttle spf <*initial-delay*> <*hold-time*> <*max-hold-time*>

The <*initial-delay*> variable sets the initial value for the SPF delay in milliseconds. Possible values are between 0 and 65535 milliseconds.

The <*hold-time*> variable sets the minimum hold time between SPF calculations after the initial delay. This value will be doubled after hold-time expires until the max-hold-time is reached. Possible values are between 0 and 65535 milliseconds.

The <*max-hold-time*> variable sets the maximum hold time between SPF calculations Possible values are between 0 and 65535 milliseconds.

NOTE
The hold time values that you specify are rounded up to the next highest 100 ms value. For example, any value between 0 and 99 will be configured as 100 ms.

Command replacement

This command overlaps in functionality with the timer throttle spf command which will be phased out from the Multi-Service IronWare software. To use this command to replicate the exact functionality of the timer throttle spf command configure it as shown in the following.

```
NetIron(configure)# timer throttle spf 1000 5000 5000
```

Displaying OSPF Router Advertisement

Using the **show ip ospf** command you can display the current OSPF Router Advertisement configuration. The text show below in bold is displayed for an OSPF Router Advertisement configuration.

```
NetIron#show ip ospf
OSPF Version                  Version 2
Router Id                     10.10.10.10
ASBR Status                   No
ABR Status                    No         (0)
Redistribute Ext Routes from
External LSA Counter          5
External LSA Checksum Sum     0002460e
Originate New LSA Counter     5
Rx New LSA Counter            8

```

Displaying OSPF information

You can display the following OSPF information:

- Trap, area, and interface information – refer to "Displaying general OSPF configuration information" on page 911.
- CPU utilization statistics – refer to "Displaying CPU utilization and other OSPF tasks" on page 912.
- Area information – refer to "Displaying OSPF area information" on page 913.
- Neighbor information – refer to "Displaying OSPF neighbor information" on page 914.
- Interface information – refer to "Displaying OSPF interface information" on page 916.
- Route information – refer to "Displaying OSPF route information" on page 919.
- External link state information – refer to "Displaying OSPF external link state information" on page 923.
- Database Information – refer to "Displaying OSPF database information" on page 921
- Link state information – refer to "Displaying OSPF database link state information" on page 924.
- Virtual Neighbor information – refer to "Displaying OSPF virtual neighbor and link information" on page 928.
- Virtual Link information – refer to "Displaying OSPF virtual link information" on page 929.
- ABR and ASBR information – refer to "Displaying OSPF ABR and ASBR information" on page 925.
- Trap state information – refer to "Displaying OSPF trap status" on page 926.
- OSPF Point-to-Point Links – refer to "Viewing Configured OSPF point-to-point links" on page 926.
- OSPF Graceful Restart information refer to "Displaying an OSPF Graceful Restart information" on page 930
- OSPF Router Advertisement information refer to "Displaying OSPF Router Advertisement information" on page 931

Displaying general OSPF configuration information

To display general OSPF configuration information, enter the following command at any CLI level.

```
NetIron# show ip ospf config
Router OSPF: Enabled
Redistribution: Disabled
Default OSPF Metric: 10
OSPF Redistribution Metric: Type2

OSPF External LSA Limit: 1447047

OSPF Database Overflow Interval: 0

RFC 1583 Compatibility: Enabled

Router id: 207.95.11.128

Interface State Change Trap:                      Enabled
Virtual Interface State Change Trap:              Enabled
Neighbor State Change Trap:                       Enabled
Virtual Neighbor State Change Trap:               Enabled
Interface Configuration Error Trap:               Enabled
Virtual Interface Configuration Error Trap:       Enabled
Interface Authentication Failure Trap:            Enabled
Virtual Interface Authentication Failure Trap:    Enabled
Interface Receive Bad Packet Trap:                Enabled
Virtual Interface Receive Bad Packet Trap:        Enabled
Interface Retransmit Packet Trap:                 Disabled
Virtual Interface Retransmit Packet Trap:         Disabled
Originate LSA Trap:                               Disabled
Originate MaxAge LSA Trap:                        Disabled
Link State Database Overflow Trap:                Disabled
Link State Database Approaching Overflow Trap:    Disabled

OSPF Area currently defined:
Area-ID          Area-Type Cost
0                normal    0

Ethernet Interface: v1
ip ospf md5-authentication-key-activation-wait-time 300
ip ospf cost 0
ip ospf area 0
```

Syntax: show ip ospf config

Displaying CPU utilization and other OSPF tasks

You can display CPU utilization statistics for OSPF and other tasks.

To display CPU utilization statistics, enter the following command.

```
NetIron#show tasks
Task Name   Pri   State     PC     Stack  Size  CPU Usage(%) task id  task vid
----------  ---  -----  ---------  --------  -----  ---------  ------ -------
       idle 0    ready  00001904  04058fa0  4096    99          0        0
    monitor 20    wait  0000d89c  0404bd80  8192    0           0        0
        int 16    wait  0000d89c  04053f90  16384   0           0        0
      timer 15    wait  0000d89c  04057f90  16384   0           0        0
        dbg 30    wait  0000d89c  0404ff08  8192    0           0        0
      flash 17    wait  0000d89c  0409ff90  8192    0           0        0
         wd 31    wait  0000d89c  0409df80  8192    0           0        0
       boot 17    wait  0000d89c  04203e28  65536   0           0        0
       main 3     wait  0000d89c  2060cf38  65536   0           0        1
        itc 6     wait  0000d89c  20612ae8  16384   0           0        1
        tmr 5     wait  0000d89c  20627628  16384   0           0        1
      ip_rx 5     wait  0000d89c  2062ff48  16384   0           0        1
        scp 5     wait  0000d89c  20635628  16384   0           0        1
    console 5     wait  0000d89c  2063e618  32768   0           0        1

```

Syntax: show tasks

The displayed information shows the following:

TABLE 140 CLI display of show tasks

This field...	Displays...
Task Name	Name of task running on the device.
Pri	Priority of the task in comparison to other tasks
State	Current state of the task
PC	current instruction for the task
Stack	Stack location for the task
Size	Stack size of the task
CPU Usage(%)	Percentage of the CPU being used by the task
task id	Task's ID number assigned by the operating system.
task vid	A memory domain ID.

Displaying OSPF area information

To display OSPF area information, enter the following command at any CLI level.

```
NetIron# show ip ospf area
Indx  Area        Type    Cost  SPFR  ABR  ASBR  LSA  Chksum(Hex)
1    0.0.0.0      normal  0     1      0     0    1    0000781f
2   192.147.60.0  normal  0     1      0     0    1    0000fee6
3   192.147.80.0  stub    1     1      0     0    2    000181cd
```

Syntax: show ip ospf area [<*area-id*>] | [<*num*>]

The <*area-id*> parameter shows information for the specified area.

The <*num*> parameter displays the entry that corresponds to the entry number you enter. The entry number identifies the entry's position in the area table.

This display shows the following information.

TABLE 141 CLI display of OSPF area information

This field...	Displays...
Indx	The row number of the entry in the router's OSPF area table.
Area	The area number.
Type	The area type, which can be one of the following: • nssa • normal • stub
Cost	The area's cost.
SPFR	The SPFR value.
ABR	The ABR number.
ASBR	The ABSR number.

TABLE 141 CLI display of OSPF area information (Continued)

This field...	Displays...
LSA	The LSA number.
Chksum(Hex)	The checksum for the LSA packet. The checksum is based on all the fields in the packet except the age field. The device uses the checksum to verify that the packet is not corrupted.

Displaying OSPF neighbor information

To display OSPF neighbor information, enter the following command at any CLI level.

```
NetIron# show ip ospf neighbor

Port  Address         Pri  State      Neigh Address   Neigh ID     Ev Op Cnt
v10   10.1.10.1       1    FULL/DR    10.1.10.2       10.65.12.1    5  2   0
v11   10.1.11.1       1    FULL/DR    10.1.11.2       10.65.12.1    5  2   0
v12   10.1.12.1       1    FULL/DR    10.1.12.2       10.65.12.1    5  2   0
v13   10.1.13.1       1    FULL/DR    10.1.13.2       10.65.12.1    5  2   0
v14   10.1.14.1       1    FULL/DR    10.1.14.2       10.65.12.1    5  2   0
```

Syntax: show ip ospf neighbor [router-id <*ip-addr*> **|** <*num*> **| extensive]**

The **router-id** <*ip-addr*> parameter displays only the neighbor entries for the specified router.

The <*num*> parameter displays only the entry in the specified index position in the neighbor table. For example, if you enter "1", only the first entry in the table is displayed.

The **extensive** option displays detailed information about the neighbor.

These displays show the following information.

TABLE 142 CLI display of OSPF neighbor information

Field	Description
Port	The port through which the device is connected to the neighbor.
Address	The IP address of the port on which this device is connected to the neighbor.
Pri	The OSPF priority of the neighbor. • For multi-access networks, the priority is used during election of the Designated Router (DR) and Backup designated Router (BDR). • For point-to-point links, this field shows one of the following values: • 1 = point-to-point link • 3 = point-to-point link with assigned subnet

TABLE 142 CLI display of OSPF neighbor information (Continued)

Field	Description
State	The state of the conversation between the device and the neighbor. This field can have one of the following values: • Down – The initial state of a neighbor conversation. This value indicates that there has been no recent information received from the neighbor. • Attempt – This state is only valid for neighbors attached to non-broadcast networks. It indicates that no recent information has been received from the neighbor. • Init – A Hello packet has recently been seen from the neighbor. However, bidirectional communication has not yet been established with the neighbor. (The router itself did not appear in the neighbor's Hello packet.) All neighbors in this state (or higher) are listed in the Hello packets sent from the associated interface. • 2-Way – Communication between the two routers is bidirectional. This is the most advanced state before beginning adjacency establishment. The Designated Router and Backup Designated Router are selected from the set of neighbors in the 2-Way state or greater. • ExStart – The first step in creating an adjacency between the two neighboring routers. The goal of this step is to decide which router is the master, and to decide upon the initial Database Description (DD) sequence number. Neighbor conversations in this state or greater are called adjacencies. • Exchange – The router is describing its entire link state database by sending Database Description packets to the neighbor. Each Database Description packet has a DD sequence number, and is explicitly acknowledged. Only one Database Description packet can be outstanding at any time. In this state, Link State Request packets can also be sent asking for the neighbor's more recent advertisements. All adjacencies in Exchange state or greater are used by the flooding procedure. In fact, these adjacencies are fully capable of transmitting and receiving all types of OSPF routing protocol packets. • Loading – Link State Request packets are sent to the neighbor asking for the more recent advertisements that have been discovered (but not yet received) in the Exchange state. • Full – The neighboring routers are fully adjacent. These adjacencies will now appear in router links and network link advertisements.
Neigh Address	The IP address of the neighbor. For point-to-point links, the value is as follows: • If the **Pri** field is "1", this value is the IP address of the neighbor router's interface. • If the **Pri** field is "3", this is the subnet IP address of the neighbor router's interface.
Neigh ID	The neighbor router's ID.
Ev	The number of times the neighbor's state changed.
Opt	The sum of the option bits in the Options field of the Hello packet. This information is used by Dell technical support. Refer to Section A.2 in RFC 2178 for information about the Options field in Hello packets.
Cnt	The number of LSAs that were retransmitted.

Displaying OSPF interface information

To display OSPF interface information, enter the following command at any CLI level.

```
NetIron# show ip ospf interface ethernet 1/11

Ethernet 1/11 admin up, oper up
     IP Address 15.1.1.15, Area 0
     Database Filter: Not Configured
     State BDR, Pri 1, Cost 1, Options 2, Type broadcast Events 2
    Timers(sec): Transmit 1, Retrans 5, Hello 10, Dead 40
     DR:  Router ID 192.168.254.1     Interface Address 15.1.1.1
     BDR: Router ID 10.0.0.15         Interface Address 15.1.1.15
     Neighbor Count = 1, Adjacent Neighbor Count= 1
     Neighbor:         15.1.1.1 (DR)
     Authentication-Key: None
     MD5 Authentication: Key None, Key-Id None, Auth-change-wait-time 300
```

If you specify an interface that is not configured within a specified VRF, then the following error message will display as shown in the example below:

```
NetIron# show ip ospf vrf one interface ethernet 1/1
Error: Interface(eth 1/1) not part of VRF(one)
```

NOTE
You cannot display multiple ports for any interfaces. For example, when displaying OSPF interface information on ethernet 1/1 only one port can displayed at a given time.

Syntax: **show ip ospf [vrf** <*vrf-name*>**] interface [**<*ip-addr*>**] [brief] [ethernet** <*port*> **| pos** <*port*> **| loopback** <*number*> **| tunnel** <*number*> **| ve** <*number*> **]**

The [**vrf** <*vrf-name*>] parameter displays information for VRF, or a specific vrf-name.

The [<*ip-addr*>] parameter displays the OSPF interface information for the specified IP address.

The [**brief**] parmeter displays interface information in the brief mode. Refer to "Displaying OSPF interface brief information" on page 918.

The **ethernet | pos | loopback | tunnel | ve** parameter specifies the interface for which to display information. If you specify an Ethernet interface or a POS interface, you can also specify the port number associated with the interface. If you specify a loopback, tunnel, or VE interface, you can also specify the number associated with the interface.

The following table defines the highlighted fields shown in the above example output of the **show ip ospf interface ethernet** command.

TABLE 143 Output of the **show ip ospf interface** command

This field	Displays
Interface	The type of interface type and the port number or number of the interface.
IP Address	The IP address of the interface.
Area	The OSPF area configured on the interface
Database Filter	The router's configuration for blocking outbound LSAs on an OSPF interface as described in "Block flooding of outbound LSAs on specific OSPF interfaces" on page 878. If Not Configured is displayed, there is no outbound LSA filter configured. This is the default condition.

TABLE 143 Output of the **show ip ospf interface** command (Continued)

This field	Displays
State	The state of the interface. Possible states include the following: • DR – The interface is functioning as the Designated Router for OSPFv2. • BDR – The interface is functioning as the Backup Designated Router for OSPFv2. • Loopback – The interface is functioning as a loopback interface. • P2P – The interface is functioning as a point-to-point interface. • Passive – The interface is up but it does not take part in forming an adjacency. • Waiting – The interface is trying to determine the identity of the BDR for the network. • None – The interface does not take part in the OSPF interface state machine. • Down – The interface is unusable. No protocol traffic can be sent or received on such a interface. • DR other – The interface is a broadcast or NBMA network on which another router is selected to be the DR.
Pri	The link ID as defined in the router-LSA. This value can be one of the following: 1 = point-to-point link 3 = point-to-point link with an assigned subnet
Cost	The configured output cost for the interface.
Options	OSPF Options (Bit7 - Bit0): • unused:1 • opaque:1 • summary:1 • dont_propagate:1 • nssa:1 • multicast:1 • externals:1 • tos:1
Type	The area type, which can be one of the following: • Broadcast • Point to Point • non-broadcast • Virtual Link
Events	OSPF Interface Event: • Interface_Up = 0x00 • Wait_Timer = 0x01 • Backup_Seen = 0x02 • Neighbor_Change = 0x03 • Loop_Indication = 0x04 • Unloop_Indication = 0x05 • Interface_Down = 0x06 • Interface_Passive = 0x07
Timer intervals	The interval, in seconds, of the transmit-interval, retransmit-interval, hello-interval, and dead-interval timers.
DR	The router ID (IPv4 address) of the DR.
BDR	The router ID (IPv4 address) of the BDR.
Neighbor Count	The number of neighbors to which the interface is connected.
Adjacent Neighbor Count	The number of adjacent neighbor routers.
Neighbor:	The IP address of the neighbor.

Displaying OSPF interface brief information

The following command is used to display the OSPF database brief information.

```
NetIron# show ip ospf interface brief
Number of Interfaces is 1
Interface Area IP Addr/Mask Cost State Nbrs(F/C)
eth 1/2    0    16.1.1.2/24   1     down  0/0
```

Table 144 defines the fields shown in the above example output of the **show ip ospf interface brief** command.

TABLE 144 Output of the **show ip ospf interface brief** command

This field	Displays
Interface	The interface through which the router is connected to the neighbor.
Area	The OSPF Area that the interface is configured in.
IP Addr/Mask	The IP address and mask of the interface.
Cost	The configured output cost for the interface.
State	The state of the conversation between the router and the neighbor. This field can have one of the following values: • Down – The initial state of a neighbor conversation. This value indicates that there has been no recent information received from the neighbor. • Attempt – This state is only valid for neighbors attached to non-broadcast networks. It indicates that no recent information has been received from the neighbor. • Init – A Hello packet has recently been seen from the neighbor. However, bidirectional communication has not yet been established with the neighbor. (The router itself did not appear in the neighbor's Hello packet.) All neighbors in this state (or higher) are listed in the Hello packets sent from the associated interface. • 2-Way – Communication between the two routers is bidirectional. This is the most advanced state before beginning adjacency establishment. The Designated Router and Backup Designated Router are selected from the set of neighbors in the 2-Way state or greater. • ExStart – The first step in creating an adjacency between the two neighboring routers. The goal of this step is to decide which router is the master, and to decide upon the initial Database Description (DD) sequence number. Neighbor conversations in this state or greater are called adjacencies. • Exchange – The router is describing its entire link state database by sending Database Description packets to the neighbor. Each Database Description packet has a DD sequence number, and is explicitly acknowledged. Only one Database Description packet can be outstanding at any time. In this state, Link State Request packets can also be sent asking for the neighbor's more recent advertisements. All adjacencies in Exchange state or greater are used by the flooding procedure. In fact, these adjacencies are fully capable of transmitting and receiving all types of OSPF routing protocol packets. • Loading – Link State Request packets are sent to the neighbor asking for the more recent advertisements that have been discovered (but not yet received) in the Exchange state. • Full – The neighboring routers are fully adjacent. These adjacencies will now appear in router links and network link advertisements.
Nbrs(F/C)	The number of adjacent neighbor routers. The number to the left of the "/" are the neighbor routers that are fully adjacent and the number to the right represents all adjacent neighbor routers.

Displaying OSPF route information

To display OSPF route information, enter the following command at any CLI level.

```
NetIron#show ip ospf route
OSPF Area 0x00000000 ASBR Routes 1:

      Destination     Mask            Path_Cost Type2_Cost Path_Type
