```

Syntax: show ip ospf routes [*<ip-addr>*]

The *<ip-addr>* parameter specifies a destination IP address. If you use this parameter, only the route entries for that destination are shown.

This display shows the following information.

TABLE 145 CLI display of OSPF route information

This field...	Displays...
Destination	The IP address of the route's destination.
Mask	The network mask for the route.
Path_Cost	The cost of this route path. (A route can have multiple paths. Each path represents a different exit port for the device.)
Type2_Cost	The type 2 cost of this path.
Path_Type	The type of path, which can be one of the following: • Inter – The path to the destination passes into another area. • Intra – The path to the destination is entirely within the local area. • External1 – The path to the destination is a type 1 external route. • External2 – The path to the destination is a type 2 external route.
Adv_Router	The OSPF router that advertised the route to this device.
Link-State	The link state from which the route was calculated.
Dest_Type	The destination type, which can be one of the following: • ABR – Area Border Router • ASBR – Autonomous System Boundary Router • Network – the network
State	The route state, which can be one of the following: • Changed • Invalid • Valid This information is used by Dell technical support.
Tag	The external route tag.
Flags	State information for the route entry. This information is used by Dell technical support.
Paths	The number of paths to the destination.
Out_Port	The router port through which the device reaches the next hop for this route path.
Next_Hop	The IP address of the next-hop router for this path.
Type	The route type, which can be one of the following: • OSPF • Static Replaced by OSPF
State	State information for the path. This information is used by Dell technical support.

Displaying the routes that have been redistributed into OSPF

You can display the routes that have been redistributed into OSPF. To display the redistributed routes, enter the following command at any level of the CLI.

```
NetIron# show ip ospf redistribute route
  4.3.0.0 255.255.0.0 static
  3.1.0.0 255.255.0.0 static
  10.11.61.0 255.255.255.0 connected
  4.1.0.0 255.255.0.0 static
```

In this example, four routes have been redistributed. Three of the routes were redistributed from static IP routes and one route was redistributed from a directly connected IP route.

Syntax: show ip ospf redistribute route [<*ip-addr*> <*ip-mask*>]

The <*ip-addr*> <*ip-mask*> parameter specifies a network prefix and network mask. Here is an example.

```
NetIron# show ip ospf redistribute route 3.1.0.0 255.255.0.0
  3.1.0.0 255.255.0.0 static
```

Displaying OSPF database information

The following command is used to display the OSPF database.

```
NetIron#show ip ospf database
Graceful Link States

```

Syntax: show ip ospf database

This display shows the information described in Table 146.

TABLE 146 CLI display of OSPF database information

This field...	Displays...
Area	The OSPF area that the interface configured for OSPF graceful restart is in.
Interface	The interface that is configured for OSPF graceful restart.

TABLE 146 CLI display of OSPF database information (Continued)

This field...	Displays...
Prd	Grace Period: The number of seconds that the router's neighbors should continue to advertise the router as fully adjacent, regardless of the state of database synchronization between the router and its neighbors. Since this time period began when grace-LSA's LS age was equal to 0, the grace period terminates when either: • the LS age of the grace-LSA exceeds the value of a Grace Period • the grace-LSA is flushed.
Rsn	Graceful restart reason: The reason for the router restart defined as one of the following: • UK – unknown • RS – software restart • UP – software upgrade or reload • SW – switch to redundant control processor
Nbr Intf IP	The IP address of the OSPF graceful restart neighbor .
Index	ID of the entry
Aging	The age of the LSA, in seconds.
Area ID	ID of the OSPF area
Type	Link state type of the route.
LS ID	The ID of the link-state advertisement from which the router learned this route.
Adv Rtr	ID of the advertised route.
Seq(Hex)	The sequence number of the LSA. The OSPF neighbor that sent the LSA stamps the LSA with a sequence number. This number enables the device and other OSPF routers to determine which LSA for a given route is the most recent.
Age	The age of the LSA in seconds.
Chksum	The checksum for the LSA packet. The checksum is based on all the fields in the packet except the age field. The device uses the checksum to verify that the packet is not corrupted.
Router	The router IP address.
Netmask	The subnet mask of the network.
Metric	The cost (value) of the route
Flag	State information for the route entry. This information is used by Dell technical support.

Displaying OSPF external link state information

To display external link state information, enter the following command at any CLI level.

```
NetIron#show ip ospf database external-link-state
Index Aging  LS ID           Router          Netmask  Metric    Flag
1     591    10.65.13.0      10.65.12.1      ffffff00 8000000a  0000
2     591    10.65.16.0      10.65.12.1      ffffff00 8000000a  0000
3     591    10.65.14.0      10.65.12.1      ffffff00 8000000a  0000
4     591    10.65.17.0      10.65.12.1      ffffff00 8000000a  0000
5     592    10.65.12.0      10.65.12.1      ffffff00 8000000a  0000
6     592    10.65.15.0      10.65.12.1      ffffff00 8000000a  0000
7     592    10.65.18.0      10.65.12.1      ffffff00 8000000a  0000
```

Syntax: **show ip ospf database external-link-state [advertise** <*num*> **| extensive | link-state-id** <*ip-addr*> **| router-id** <*ip-addr*> **| sequence-number** <*num(Hex)*> **]**

The **advertise** <*num*> parameter displays the hexadecimal data in the specified LSA packet. The <*num*> parameter identifies the LSA packet by its position in the router's External LSA table. To determine an LSA packet's position in the table, enter the **show ip ospf external-link-state** command to display the table.

The **extensive** option displays the LSAs in decrypted format.

NOTE
You cannot use the **extensive** option in combination with other display options. The entire database is displayed.

The **link-state-id** <*ip-addr*> parameter displays the External LSAs for the LSA source specified by <*IP-addr*>.

The **router-id** <*ip-addr*> parameter shows the External LSAs for the specified OSPF router.

The **sequence-number** <*num(Hex)*> parameter displays the External LSA entries for the specified hexadecimal LSA sequence number.

This display shows the following information.

TABLE 147 CLI display of OSPF external link state information

This field...	Displays...
Index	ID of the entry
Aging	The age of the LSA, in seconds.
LS ID	The ID of the link-state advertisement from which the device learned this route.
Router	The router IP address.
Netmask	The subnet mask of the network.
Metric	The cost (value) of the route
Flag	State information for the route entry. This information is used by Dell technical support.

Displaying OSPF database-summary information

To display database-summary information, enter the following command at any CLI level.

```
MLXe2#show ip ospf database database-summary
Area ID      Router  Network Sum-Net  Sum-ASBR  NSSA-Ext  Opq-Area  Subtotal
0.0.0.0      104      184     19       42        0         0         349
AS External                                                         308
Total       104     184     19      42       0         0        657
```

Syntax: show ip ospf database database-summary

TABLE 148 CLI display of OSPF database summary information

This field...	Displays...
Area ID	The area number.
Router	The number of router link state advertisements in that area.
Network	The number of network link state advertisements in that area.
Sum-Net	The number of summary link state advertisements in that area.
Sum-ASBR	The number of summary autonomous system boundary router (ASBR) link state advertisements in that area
NSSA-Ext	The number of not-so-stubby
Opq-area	the number of Type-10 (area-scope) Opaque LSA.s

Displaying OSPF database link state information

To display database link state information, enter the following command.

```
NetIron# show ip ospf database link-state
Index Area ID        Type   LS ID           Adv Rtr          Seq(Hex) Age  Cksum

```

Syntax: **show ip ospf database link-state** [**advertise** <*num*> | **asbr** [<*ip-addr*>] [**adv-router** <*ip-addr*>] | **extensive** | **link-state-id** <*ip-addr*> | **network** [<*ip-addr*>] [**adv-router** <*ip-addr*>] | **nssa** [<*ip-addr*>] [**adv-router** <*ip-addr*>] | **router** [<*ip-addr*>] [**adv-router** <*ip-addr*>] | **router-id** <*ip-addr*> | **self-originate l sequence-number** <*num(Hex)*> | **summary** [<*ip-addr*>] [**adv-router** <*ip-addr*>]

The **advertise** <*num*> parameter displays the hexadecimal data in the specified LSA packet. The <*num*> parameter identifies the LSA packet by its position in the router's LSA table. To determine an LSA packet's position in the table, enter the **show ip ospf link-state** command to display the table.

The **asbr** option shows ASBR LSAs.

The **extensive** option displays the LSAs in decrypted format.

NOTE
You cannot use the **extensive** option in combination with other display options. The entire database is displayed.

The **link-state-id** <*ip-addr*> parameter displays the LSAs for the LSA source specified by <*IP-addr*>.

The **network** option shows network LSAs.

The **nssa** option shows NSSA LSAs.

The **router-id** <*ip-addr*> parameter shows the LSAs for the specified OSPF router.

The **sequence-number** <*num(Hex)*> parameter displays the LSA entries for the specified hexadecimal LSA sequence number.

The **self-originate** option shows self-originated LSAs.

The **summary** option shows summary information.

TABLE 149 CLI display of OSPF database link state information

This field...	Displays...
Index	ID of the entry
Area ID	ID of the OSPF area
Type LS ID	Link state type of the route
Adv Rtr	ID of the advertised route
Seq(Hex)	The sequence number of the LSA. The OSPF neighbor that sent the LSA stamps the LSA with a sequence number. This number enables the device and other OSPF routers to determine which LSA for a given route is the most recent.
Age	The age of the LSA in seconds.
Cksum	The checksum for the LSA packet. The checksum is based on all the fields in the packet except the age field. The device uses the checksum to verify that the packet is not corrupted.

Displaying OSPF ABR and ASBR information

To display OSPF ABR and ASBR information, enter the following command at any CLI level.

```
NetIron# show ip ospf border-routers
```

Syntax: show ip ospf border-routers [<*ip-addr*>]

The <*ip-addr*> parameter displays the ABR and ASBR entries for the specified IP address.

```
NetIron# show ip ospf border-routers

      router ID       router type next hop router  outgoing interface  Area
1     10.65.12.1      ABR         10.1.49.2        v49                 0
1     10.65.12.1      ASBR        10.1.49.2        v49                 0
1     10.65.12.1      ABR         10.65.2.251      v201                65
1     10.65.12.1      ASBR        10.65.2.251      v201                65
```

Syntax: show ip ospf border-routers

TABLE 150 CLI display of OSPF border routers

This field...	Displays...
(Index)	Displayed index number of the border router.
Router ID	ID of the OSPF router
Router type	Type of OSPF router: ABR or ASBR
Next hop router	ID of the next hop router
Outgoing interface	ID of the interface on the router for the outgoing route.
Area	ID of the OSPF area to which the OSPF router belongs

Displaying OSPF trap status

All traps are enabled by default when you enable OSPF. To disable or re-enable an OSPF trap, refer to "Modify OSPF traps generated" on page 902.

To display the state of each OSPF trap, enter the following command at any CLI level.

```
NetIron# show ip ospf trap
Interface State Change Trap:                      Enabled
Virtual Interface State Change Trap:              Enabled
Neighbor State Change Trap:                       Enabled
Virtual Neighbor State Change Trap:               Enabled
Interface Configuration Error Trap:               Enabled
Virtual Interface Configuration Error Trap:       Enabled
Interface Authentication Failure Trap:            Enabled
Virtual Interface Authentication Failure Trap:    Enabled
Interface Receive Bad Packet Trap:                Enabled
Virtual Interface Receive Bad Packet Trap:        Enabled
Interface Retransmit Packet Trap:                 Disabled
Virtual Interface Retransmit Packet Trap:         Disabled
Originate LSA Trap:                               Disabled
Originate MaxAge LSA Trap:                        Disabled
Link State Database Overflow Trap:                Disabled
Link State Database Approaching Overflow Trap:    Disabled
```

Syntax: show ip ospf trap

Viewing Configured OSPF point-to-point links

You can use the show ip ospf interface command to display OSPF point-to-point information. Enter the following command at any CLI level.

```
NetIron# show ip ospf interface 192.168.1.1
```

```
Ethernet 2/1,OSPF enabled
IP Address 192.168.1.1, Area 0
OSPF state ptr2ptr, Pri 1, Cost 1, Options 2, Type pt-2-pt Events 1
Timers(sec): Transit 1, Retrans 5, Hello 10, Dead 40
DR: Router ID 0.0.0.0 Interface Address 0.0.0.0
BDR: Router ID 0.0.0.0 Interface Address 0.0.0.0
Neighbor Count = 0, Adjacent Neighbor Count= 1
Neighbor: 2.2.2.2
Authentication-Key:None
MD5 Authentication: Key None, Key-Id None, Auth-change-wait-time 300
```

Syntax: show ip ospf interface [<*ip-addr*>]

The <*ip-addr*> parameter displays the OSPF interface information for the specified IP address.

The following table defines the highlighted fields shown in the above example output of the show ip ospf interface command

TABLE 151 Output of the show ip ospf interface command

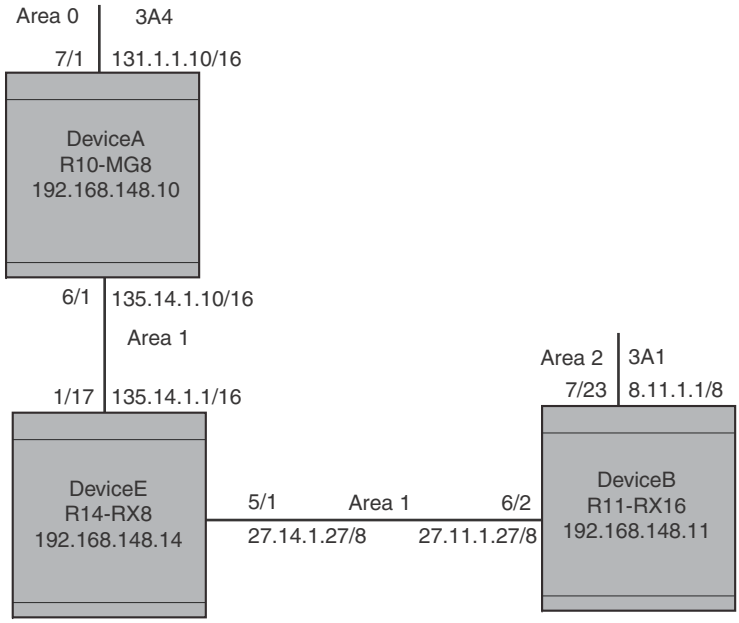
This field	Displays
IP Address	The IP address of the interface.
OSPF state	The OSPF state of the interface.
Pri	The router priority.
Cost	The configured output cost for the interface.
Options	OSPF Options (Bit7 - Bit0): • unused:1 • opaque:1 • summary:1 • dont_propagate:1 • nssa:1 • multicast:1 • externals:1 • tos:1
Type	The area type, which can be one of the following: • Broadcast = 0x01 • NBMA = 0x02 • Point to Point = 0x03 • Virtual Link = 0x04 • Point to Multipoint = 0x05
Events	OSPF Interface Event: • Interface_Up = 0x00 • Wait_Timer = 0x01 • Backup_Seen = 0x02 • Neighbor_Change = 0x03 • Loop_Indication = 0x04 • Unloop_Indication = 0x05 • Interface_Down = 0x06 • Interface_Passive = 0x07
Adjacent Neighbor Count	The number of adjacent neighbor routers.
Neighbor:	The IP address of the neighbor.

Displaying OSPF virtual neighbor and link information

You can display OSPF virtual neighbor and virtual link information. For example, the following show run display shows the configuration in Figure 140.

```
NetIron#show run
Current configuration:
!
ver V2.2.1T143
module 1 rx-bi-1g-24-port-fiber
module 2 rx-bi-10g-4-port
module 6 rx-bi-10g-4-port
module 7 rx-bi-1g-24-port-copper
!
!
no spanning-tree
!
vlan 1 name DEFAULT-VLAN
!
!
clock summer-time
clock timezone us Pacific
hostname R11-RX8
router ospf
 area 2
 area 1
 area 1 virtual-link 131.1.1.10
```

FIGURE 140 OSPF virtual neighor and virtual link example



Displaying OSPF virtual neighbor

Use the **show ip ospf virtual neighbor** command to display OSPF virtual neighbor information. The following example relates to the configuration in Figure 140.

```
NetIron# show ip ospf virtual neighbor
Indx Transit Area    Router ID       Neighbor address options
1    1               131.1.1.10      135.14.1.10      2
     Port   Address         state           events          count
     6/2    27.11.1.27      FULL            5               0
```

Syntax: show ip ospf virtual neighbor [<*num*>]

The <*num*> parameter displays the table beginning at the specified entry number.

Displaying OSPF virtual link information

Use the **show ip ospf virtual link** command to display OSPF virtual link information. The output below represents the virtual links configured in Figure 140.

```
NetIron# show ip ospf virtual link
Indx Transit Area     Router ID        Transit(sec) Retrans(sec) Hello(sec)
1    1                131.1.1.10       1            5            10
     Dead(sec)        events           state        Authentication-Key
     40               1                ptr2ptr      None
     MD5 Authentication-Key:       None
     MD5 Authentication-Key-Id:    None
     MD5 Authentication-Key-Activation-Wait-Time:      300
```

Syntax: show ip ospf virtual link [<*num*>]

The <*num*> parameter displays the table beginning at the specified entry number.

Clearing OSPF neighbors

You can clear all OSPF neighbors or a specified OSPF neighbor using the following command.

```
NetIron# clear ip ospf neighbor all
```

Syntax: clear ip ospf neighbor all | <*ip-address*>

Selecting the **all** option clears all of the OSPF neighbors on the router.

The <*ip-address*> variable allows you to clear a specific OSPF neighbor.

Displaying an OSPF Graceful Restart information

To display OSPF Graceful Restart information for OSPF neighbors use the **show ip ospf neighbors** command as shown in the following.

```
NetIron#show ip ospf neighbors
Port  Address        Pri State       Neigh Address   Neigh ID        Ev Opt Cnt
2/7   50.50.50.10    0   FULL/OTHER  50.50.50.1      10.10.10.30     21 66  0
  < in graceful restart state,  helping 1, timer 60 sec >
```

Use the following command to display Type 9 Graceful LSAs on a router.

```
NetIron#show ip ospf database grace-link-state
Graceful Link States
Area  Interface  Adv Rtr  Age Seq(Hex) Prd Rsn  Nbr Intf IP
0     eth 1/2    2.2.2.2  7   80000001 60  SW   6.1.1.2
```

This display shows the following information.

TABLE 152 CLI display of OSPF database grace link state information

This field...	Displays...
Area	The OSPF area that the interface configured for OSPF graceful restart is in.
Interface	The interface that is configured for OSPF graceful restart.
Adv Rtr	ID of the advertised route.
Age	The age of the LSA in seconds.
Seq(Hex)	The sequence number of the LSA. The OSPF neighbor that sent the LSA stamps the LSA with a sequence number. This number enables the device and other OSPF routers to determine which LSA for a given route is the most recent.
Prd	Grace Period: The number of seconds that the router's neighbors should continue to advertise the router as fully adjacent, regardless of the state of database synchronization between the router and its neighbors. Since this time period began when grace-LSA's LS age was equal to 0, the grace period terminates when either: • the LS age of the grace-LSA exceeds the value of a Grace Period • the grace-LSA is flushed.

TABLE 152 CLI display of OSPF database grace link state information (Continued)

This field...	Displays...
Rsn	Graceful restart reason: The reason for the router restart defined as one of the following: • UK – unknown • RS – software restart • UP – software upgrade or reload • SW – switch to redundant control processor
Nbr Intf IP	The IP address of the OSPF graceful restart neighbor .

Displaying OSPF Router Advertisement information

Using the **show ip ospf** command you can display the current OSPF Router Advertisement configuration. The text show below in bold is displayed for an OSPF Router Advertisement configuration.

```
NetIron# show ip ospf
OSPF Version                    Version 2
Router Id                       10.10.10.10
ASBR Status                     No
ABR Status                      No         (0)
Redistribute Ext Routes from
External LSA Counter            5
External LSA Checksum Sum       0002460e
Originate New LSA Counter       5
Rx New LSA Counter              8
External LSA Limit              14447047
Database Overflow Interval      0
Database Overflow State :       NOT OVERFLOWED
RFC 1583 Compatibility :        Enabled
Originating router-LSAs with maximum metric
   Condition: Always Current State: Active
   Link Type: PTP STUB TRANSIT
   Additional LSAs originated with maximum metric:
     LSA Type              Metric Value
     AS-External             16711680
     Type 3 Summary          16711680
     Type 4 Summary          16711680
     Opaque-TE               4294967295
```

The 03.5.00 release of the Multi-Service IronWare enhances the **show ip ospf** command to display LSAs that have been configured with a maximum metric as described in "Configuring OSPF router advertisement" on page 907 as shown above in bold.

Clearing OSPF information

You can use the **clear ip ospf** commands to clear OSPF data on an router as described in the following:

- neighbor information – refer to "Clearing OSPF neighbors" on page 932
- reset the OSPF process – "Disabling and re-enabling the OSPF process" on page 932
- clear and re-add OSPF routes – "Clearing OSPF routes" on page 932

Clearing OSPF neighbors

You can use the following command to delete and relearn all OSPF neighbors, all OSPF neighbors for a specified interface or a specified OSPF neighbor.

```
NetIron# clear ip ospf neighbor all
```

Syntax: clear ip ospf [vrf <*vrf-name*> **] neighbor all [** <*interface*> *]* | <*interface*> **|** <*ip-address*> **[** <*interface*> **]**

Selecting the **all** option without specifying an interface clears all of the OSPF neighbors on the router.

The <*interface*> variable specifies the interface that you want to clear all of the OSPF neighbors on. The following types of interfaces can be specified:

- ethernet <*slot/port*>
- tunnel <*tunnel-ID*>
- pos <*slot/port*>
- ve <*ve-ID*>

The <*ip-address*> variable allows you to clear a specific OSPF neighbor.

Disabling and re-enabling the OSPF process

You can use the following command to disable and re-enable the OSPF process on a router.

```
NetIron# clear ip ospf all
```

Syntax: clear ip ospf [vrf <*vrf-name*> **] all**

This command resets the OSPF process and brings it back up after releasing all memory used while retaining all configurations.

Clearing OSPF routes

You can use the following command to clear all OSPF routes or to clear a specific OSPF route.

```
NetIron# clear ip ospf routes all
```

Syntax: clear ip ospf [vrf <*vrf-name*> **] routes all |** <*ip-address/prefix-length*>

Selecting the **all** option resets the OSPF routes including external routes, and OSPF internal routes.

The <*ip-address/prefix-length*> variable specifies a particular route to delete and then reschedules the SPF calculation.

Configuring IS-IS (IPv4) 25

Overview

The following list displays the IPv4 IS-IS features supported by PowerConnect B-MLXe.

- IS-IS
- Level-1 Routing
- Level-2 Routing
- Restart helper-mode
- Broadcast Pseudonode
- Three-Way Handshake for Point-to-Point Adjacencies
- IS-IS PSPF Exponential back-off
- New encryption code for passwords, authentication keys, and community strings
- IS-IS Flooding
- IS-IS Point-to-Point over Ethernet
- IS-IS over a GRE IP Tunnel
- Formation of Adjacencies
- IS-IS Blackhole Avoidance (Setting the Overload Bit)
- Priority for Designated IS Election
- Limiting Access to Adjacencies With a Neighbor
- Changing the IS-IS Level on an Interface
- Disabling and Enabling Hello Padding on an Interface
- Displaying IPv4 IS-IS Information
- IS-IS SPF Scaling

The Intermediate System to Intermediate System (IS-IS) protocol is a link-state Interior Gateway Protocol (IGP) that is based on the International Standard for Organization/International Electrotechnical Commission (ISO/IEC) Open Systems Internet Networking model (OSI). In IS-IS, an intermediate system (router) is designated as either a Level 1 or Level 2 router. A Level 1 router routes traffic only within the area in which the router resides. A Level 2 router routes traffic between areas within a routing domain.

The implementation of IS-IS is based on the following specifications and draft specifications:

- ISO/IEC 10589 – “Information Technology – Telecommunication and information exchange between systems – Intermediate system to Intermediate system intra-domain routing information exchange protocol for use in conjunction with the protocol for providing the connection less-mode Network Service (ISO 8473)”, 1992
- ISO/IEC 8473 – “Information processing systems – Data Communications – Protocols for providing the connectionless-mode network service”, 1988

- ISO/IEC 9542 – "Information Technology – Telecommunication and information exchange between systems – End system to Intermediate system intra-domain routing information exchange protocol for use in conjunction with the protocol for providing the connection less-mode Network Service (ISO 8473)", 1988
- RFC 1195 – "Use of OSI IS-IS for Routing in TCP/IP and Dual Environments", 1990.
- RFC 2763 – "Dynamic Host Name Exchange Mechanism for IS-IS", 2000.
- RFC 2966 – "Domain-wide Prefix Distribution with Two-Level IS-IS", 2000
- RFC 3373 – "Three-Way Handshake for Intermediate System to Intermediate System (IS-IS) Point-to-Point Adjacencies", 2002
- Portions of the Internet Draft "IS-IS extensions for Traffic Engineering" draft-ieff-isis-traffic-02.txt (dated 2000). that describe the Extended IP reachability type-length-value (TLV type 135) and the extended Intermediate System (IS) reachability TLV (TLV type 22). These portions provide support for the wide metric version of IS-IS. No other portion is supported on Dell's implementation of IS-IS.

NOTE
The PowerConnect does not support routing of Connectionless-Mode Network Protocol (CLNP) packets. The PowerConnect uses IS-IS for TCP/IP only.

Relationship to IP route table

The IS-IS protocol has the same relationship to the PowerConnect's IP route table that OSPF has to the IP route table. The IS-IS routes are calculated and first placed in the IS-IS route table. The routes are then transferred to the IP route table.

The protocol sends the best IS-IS path for a given destination to the IP route table for comparison to the best paths from other protocols to the same destination. The CPU selects the path with the lowest administrative distance and places that path in the IP route table:

- If the path provided by IS-IS has the lowest administrative distance, then the CPU places that IS-IS path in the IP route table.
- If a path to the same destination supplied by another protocol has a lower administrative distance, the CPU installs the other protocol's path in the IP route table instead.

The ***administrative distance*** is a protocol-independent value from 1 – 255. Each path sent to the CPU, regardless of the source of the path (IS-IS, OSPF, static IP route, and so on) has an administrative distance.

Each route source has a default administrative distance. The default administrative distance for IS-IS is 115.

You can change the administrative distance for IS-IS and other routes sources.

Intermediate systems and end systems

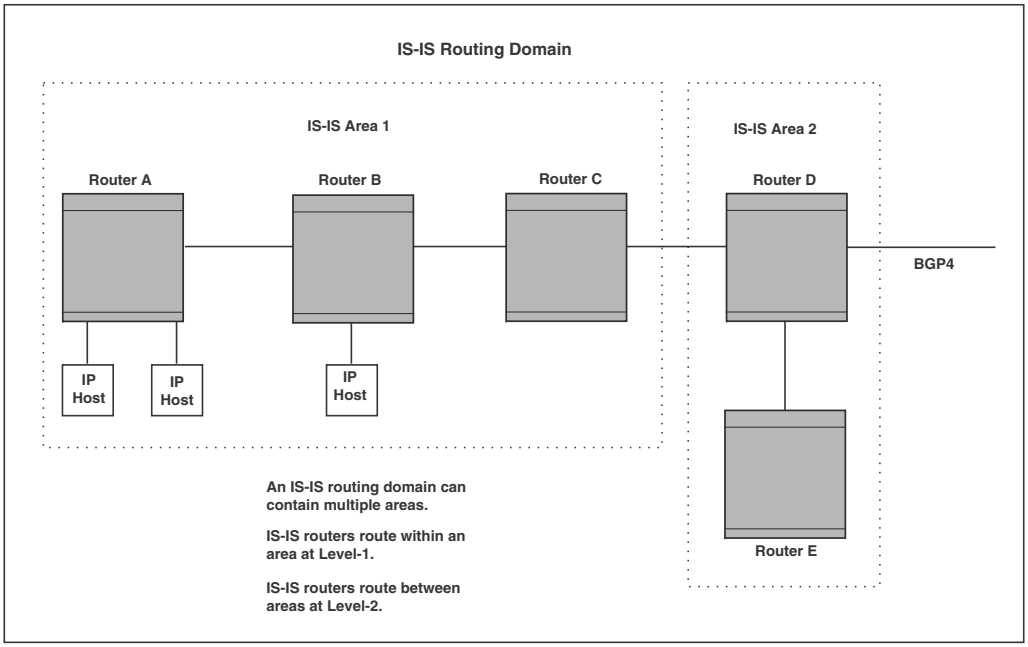
IS-IS uses the following categories to describe devices within an IS-IS routing domain (similar to an OSPF Autonomous System):

- ***Intermediate System (IS)*** – A device capable of forwarding packets from one device to another within the domain. In Internet Protocol (IP) terminology, an IS is a router.
- ***End System (ES)*** – A device capable of generating or receiving packets within the domain. In IP terminology, an ES is an end node or IP host.

When you configure IS-IS on a PowerConnect, the device is an IS.

Figure 141 shows an example of an IS-IS network.

FIGURE 141 An IS-IS network contains Intermediate Systems (ISs) and host systems



NOTE
Since the implementation of IS-IS does not route OSI traffic but instead routes IP traffic, IP hosts are shown instead of ESs.

The other basic IS-IS concepts illustrated in this figure are explained in the following sections.

Domain and areas

IS-IS is an IGP, and thus applies only to routes within a single routing domain. However, you can configure multiple areas within a domain. A PowerConnect can be a member of one area for each Network Entity Title (NET) you configure on the PowerConnect. The NET contains the area ID for the area the NET is in.

In Figure 141, Routers A, B, and C are in area 1. Routers D and E are in area 2. All the routers are in the same domain.

Level-1 routing and Level-2 routing

You can configure an IS-IS router such as a PowerConnect to perform one or both of the following levels of IS-IS routing[1]:

1. The ISO/IEC specifications use the spelling “routeing”, but this document uses the spelling “routing” to remain consistent with other Dell documentation.

- **Level-1** – A Level-1 router routes traffic only within the area the router is in. To forward traffic to another area, the Level-1 router sends the traffic to its nearest Level-2 router.
- **Level-2** – A Level-2 router routes traffic between areas within a domain.

In Figure 141 on page 935, Routers A and B are Level-1s only. Routers C and D are Level-1 and Level-2 ISs. Router E is a Level-1 IS only.

Neighbors and adjacencies

A PowerConnect configured for IS-IS forms an ***adjacency*** with each of the IS-IS devices to which it is directly connected. An adjacency is a two-way direct link (a link without router hops) over which the two devices can exchange IS-IS routes and other protocol-related information. The link is sometimes called a "circuit". The devices with which the PowerConnect forms adjacencies are its ***neighbors***, which are other ISs.

In Figure 141 on page 935, Router A has an IS-IS adjacency with Router B. Likewise, Router B has an IS-IS adjacency with Router A and Router C.

Designated IS

A ***Designated IS*** is an IS-IS router that is responsible for gathering and distributing link state information to other Level-1 or Level-2 ISs within the same broadcast network (LAN). The Level-1 and Level-2 Designated ISs within a broadcast network are independent, although the same PowerConnect can be a Level-1 Designated IS and a Level-2 Designated IS at the same time.

The Designated IS is elected based on the priority of each IS in the broadcast network. When an IS becomes operational, it sends a Level-1 or Level-2 Hello PDU to advertise itself to other ISs. If the IS is configured to be both a Level-1 and a Level-2 IS, the IS sends a separate advertisement for each level:

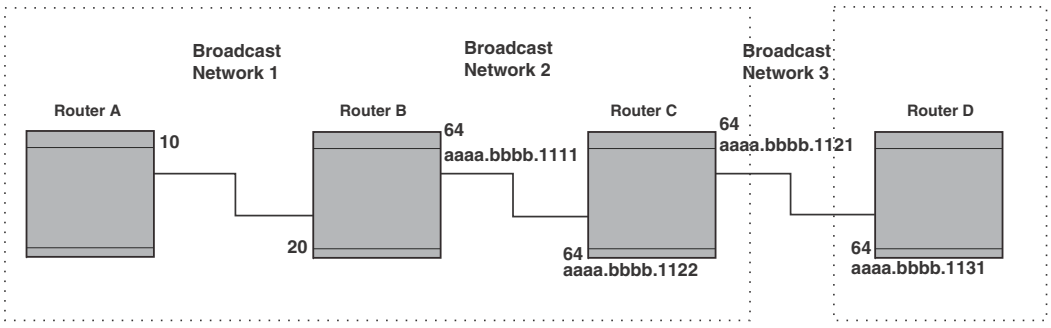
- The Level-1 IS that has the highest priority becomes the Level-1 Designated IS for the broadcast network.
- The Level-2 IS that has the highest priority becomes the Level-2 Designated IS for the broadcast network.

If the Designated IS becomes unavailable (for example, is rebooted), the IS with the next highest priority becomes the new IS. If two or more ISs have the highest priority, the IS with the highest MAC address becomes the Designated IS.

The priority is an interface parameter. Each interface that is enabled for IS-IS can have a different priority.

Figure 142 shows an example of the results of Designated IS elections. For simplicity, this example shows four of the five routers in Figure 141 on page 935, with the same domain and areas.

FIGURE 142 Each broadcast network has a Level-1 Designated IS and a Level-2 Designated IS



Designated IS election has the following results in this network topology:

- Router B is the Level-1 Designated IS for broadcast network 1
- Router C is the Level-1 Designated IS for broadcast network 2
- Router D is the Level-2 Designated IS for broadcast network 3

In this example, the IS-IS priorities for the IS-IS interfaces in broadcast network 1 have been changed by an administrator. The priorities for the interfaces in the other broadcast networks are still set to the default (64). When there is a tie, IS-IS selects the interface with the highest MAC address.

Broadcast pseudonode

In a broadcast network, the Designated IS maintains and distributes link state information to other ISs by maintaining a ***pseudonode***. A pseudonode is a logical host representing all the Level-1 or Level-2 links among the ISs in a broadcast network. Level-1 and Level-2 have separate pseudonodes, although the same device can be the pseudonode for Level-1 and Level-2.

Route calculation and selection

The Designated IS uses a ***Shortest Path First (SPF)*** algorithm to calculate paths to destination ISs and ESs. The SPF algorithm uses Link State PDUs (LSPDUs) received from other ISs as input, and creates the paths as output.

After calculating the paths, the Designated IS then selects the best paths and places them in the IS-IS route table. The Designated IS uses the following process to select the best paths.

1. Prefer the Level-1 path over the Level-2 path.
2. If there is no Level-1 path, prefer the internal Level-2 path over the external Level-2 path.
3. If there is still more than one path, prefer the path with the lowest metric.
4. If there is more than one path with the lowest metric, load share among the paths.

After selecting the best path to a destination, the software places the path in the IS-IS route table.

Three-way handshake for point-to-point adjacencies

Support was provided for Three-Way Handshake for Point-to-Point adjacencies as described in RFC 3373. This feature provides three-way handshake mechanisms on point-to-point interfaces for the following benefits:

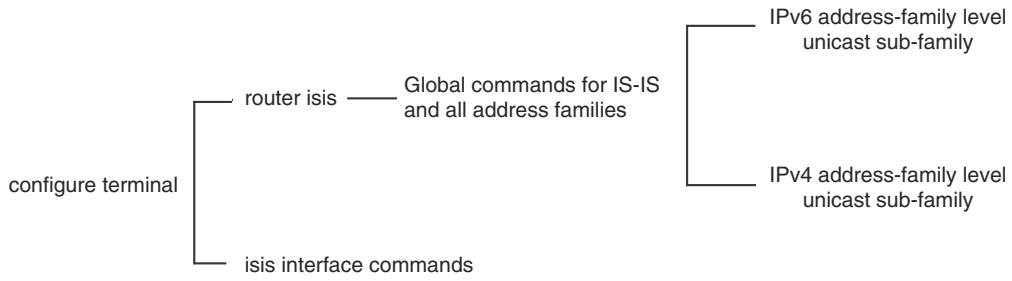
- Identifies neighbor restarts within the holding time period
- Identifies uni-directional link failures and stops forming of an adjacency with a peer where such link failures occur.

NOTE
This feature is the default operation and cannot be turned off. Routers with this feature are fully backward compatible with routers running an earlier release.

IS-IS CLI levels

The CLI includes various levels of commands for IS-IS. Figure 143 diagrams these levels.

FIGURE 143 IS-IS CLI levels



The IS-IS CLI levels are as follows:

- A global level for the configuration of the IS-IS protocol. At this level, all IS-IS configurations at this level apply to IPv4 and IPv6. You enter this layer using the **router isis** command.
  - Under the global level, you specify an address family. Address families to separate the IS-IS configurations for IPv4 and IPv6. You enter configurations that are for a specific You enter this level by entering the **address-family** command at the router isis level.
  - Under the address family level, you select a sub-address family, which is the type of routes for the configuration. For IS-IS, you specify **unicast**.
- An interface level.

Global configuration level

You enter the global configuration level of ISIS by entering the following command.

```
NetIron(config)#router isis
NetIron(config-isis-router)#
```

Syntax: [no] router isis

The (config-isis-router)# prompt indicates that you are at the global level for IS-IS. A configuration that you enter at this level applies to both IS-IS IPv4 and IS-IS IPv6.

Address family configuration level

The PowerConnect implementation of IS-IS includes the address family configuration level. Address families allow you to configure IPv4 IS-IS unicast settings that are separate and distinct from IPv6 IS-IS unicast settings (when IPv6 is supported).

Under the address family level, Dell currently supports the unicast address family configuration level only. The PowerConnect enters the IPv4 IS-IS unicast address family configuration level when you enter the following command while at the global IS-IS configuration level.

```
NetIron(config-isis-router)# address-family ipv4 unicast
NetIron(config-isis-router-ipv4u)#
```

Syntax: address-family ipv4 unicast

The (config-isis-router-ipv4u)# prompt indicates that you are at the IPv4 IS-IS unicast address family configuration level. While at this level, you can access several commands that allow you to configure IPv4 IS-IS unicast settings.

NOTE
Each address family configuration level allows you to access commands that apply to that particular address family only. To enable a feature in a particular address family, you must specify any associated commands for that feature in that particular address family. You cannot expect the feature, which you may have configured in the IPv4 IS-IS unicast address family, to work in the IPv6 IS-IS unicast address family unless it is explicitly configured in the IPv6 IS-IS unicast address family.

To exit from the ipv4 IS-IS unicast address family configuration level, enter the following command.

```
NetIron(config-isis-router-ipv4u)# exit-address-family
NetIron(config-isis-router)#
```

Entering this command returns you to the global IS-IS configuration level.

Interface level

Some IS-IS definitions are entered at the interface level. To enable IS-IS at the interface level, enter the following command.

```
NetIron(config)# interface ethernet 2/3
NetIron(config-if-e1000-2/3)#ip router isis
```

Syntax: [no] ip router isis

Enabling IS-IS globally

To configure IPv4 IS-IS, perform the tasks listed below.

1. Globally enable IS-IS by entering the following command.

   ```
   NetIron(config)# router isis
   ISIS: Please configure NET!
   ```

   Once you enter **router isis**, the device enters the IS-IS router configuration level.

Syntax: [no] router isis

To disable IS-IS, use the **no** form of this command.

2. If you have not already configured a NET for IS-IS, enter commands such as the following.

```
NetIron(config-isis-router)# net 49.2211.aaaa.bbbb.cccc.00
NetIron(config-isis-router)#
```

The commands in the example above configure a NET that has the area ID 49.2211, the system ID aaaa.bbbb.cccc (the device's base MAC address), and SEL value 00.

Syntax: [no] net <*area-id*>.<*system-id*>.<*sel*>

The <*area-id*> parameter specifies the area and has the format xx or xx.xxxx. For example, 49 and 49.2211 are valid area IDs.

The <*system-id*> parameter specifies the router's unique IS-IS router ID and has the format xxxx.xxxx.xxxx. You can specify any value for the system ID. A common practice is to use the device's base MAC address as the system ID. The base MAC address is also the MAC address of port 1. To determine the base MAC address, enter the following command at any level of the CLI: **show interfaces brief**. The base MAC address is listed in the first row of information, in the MAC column.

You must use the same system ID in all the NETs on the PowerConnect

NOTE
The parameter descriptions above are the recommended values for the NET. However, the CLI accepts any value that fits within the following lengths and formats:

xx.xxxx.xxxx.xxxx.00 – minimum length of NET

xx.xxxx.xxxx.xxxx.xxxx.xxxx.xxxx.xxxx.xxxx.xxxx.00 – maximum length of NET

The <*sel*> parameter specifies the NSAP Selector (SEL). This value must always be 00 (two zeros). The value 00 indicates that this address is an NET.

To delete a NET, use the **no** form of this command.

3. Configure ISIS parameters. Refer to the sections "Globally configuring IS-IS on a device" on page 940, "Configuring IPv4 address family route parameters" on page 951, and "Configuring ISIS properties on an interface" on page 968.

None of the IS-IS parameters require a software reload to places changes into effect and most parameter changes take effect immediately. However, changes for the following parameters take effect only after you disable and then re-enable redistribution:

- Change the default metric.
- Add, change, or negate route redistribution parameters.

Some IS-IS parameter changes take effect immediately while others do not take full effect until you disable, then re-enable route redistribution.

Globally configuring IS-IS on a device

This section describes how to change the global IS-IS parameters. These parameter settings apply to both IS-IS IPv4 and IS-IS IPv6.

Setting the overload bit

If an IS's resources are overloaded and are preventing the IS from properly performing IS-IS routing, the IS can inform other ISs of this condition by setting the overload bit in LSPDUs sent to other ISs from 0 (off) to 1 (on).

When an IS is overloaded, other ISs will not use the overloaded IS to forward traffic. An IS can be in the overload state for Level-1, Level-2, or both as described in the following section:

- If an IS is in the overload state for Level-1, other Level-1 ISs stop using the overloaded IS to forward Level-1 traffic. However, the IS can still forward Level-2 traffic, if applicable.
- If an IS is in the overload state for Level-2, other Level-2 ISs stop using the overloaded IS to forward Level-2 traffic. However, the IS can still forward Level-1 traffic, if applicable.
- If an IS is in the overload state for both levels, the IS cannot forward traffic at either level.

By default, the PowerConnect automatically sets the overload bit to 1 (on) in its LSPDUs to other ISs if an overload condition occurs.

You can set the overload bit on to administratively shut down IS-IS without disabling the protocol. Setting the overload bit on is useful when you want to make configuration changes without removing the PowerConnect from the network.

In addition, you can configure the PowerConnect to set the overload bit on for a specific number of seconds during startup, to allow IS-IS to become fully active before the device begins IS-IS routing. By default, there is no delay (0 seconds).

To immediately set the overload bit on, enter the following command.

```
NetIron(config-isis-router)# set-overload-bit
```

This command administratively shuts down IS-IS by configuring the PowerConnect to immediately set the overload bit to 1 (on) in all LSPs sent to other ISs.

To configure the PowerConnect to temporarily set the overload bit on after a software reload, enter a command such as the following.

```
NetIron(config-isis-router)# set-overload-bit on-startup 5
```

This command configures the PowerConnect to set the overload bit on in all its IS-IS LSPs sent to other ISs during the first five seconds following a successful software reload. After the five seconds expire, the PowerConnect resets the overload bit to off in all its IS-IS LSPs.

Syntax: [no] set-overload-bit [on-startup <*secs*>**]**

The **on-startup** <*secs*> parameter specifies the number of seconds following a reload to set the overload bit on. You can specify a number from 5 – 86400 (24 hours).

A new option has been added to the **set-overload-bit** command to prevent route black holing in support of RFC 3277. With this option set, the behavior of ISIS will be changed during a router reboot. During a router reboot, ISIS sets the overload bit in its LSPDUs until BGP has converged.

This feature is configured using the **set-overload-bit** command as shown in the following.

```
NetIron(config-isis-router)# set-overload-bit on-startup wait-for-bgp 1000
```

Syntax: [no] set-overload-bit on-startup wait-for-bgp <*max-bgp-wait-time*>

The <*max-bgp-wait-time*> variable is the maximum time IS-IS will wait for BGP convergence to complete. Once this time has been exceeded without BGP converging, IS-IS will exit the overload state. The default value is 600 seconds (10 minutes), possible values range: 5 to 86400 seconds.

Configuring authentication

By default, a PowerConnect router does not authenticate packets sent to or received from an end system (ES) or other intermediate system (IS). In previous releases, the Multi-Service IronWare software let you configure area, domain, and circuit passwords to direct the PowerConnect router to check for a password in packets sent from the device.

The new method of configuring an authentication password introduces the option of using the Hashed Message Authentication codes - Message Digest 5 (HMAC-MD5) algorithm.

This implementation is in conformance with RFC 3567 - Intermediate System to Intermediate System (IS-IS) Cryptographic Authentication.

NOTE
The commands for setting the password used in previous versions of the Multi-Service IronWare software are now hidden in the CLI, however they are backward compatible and will operate in this release.

Configuring ISIS authentication at the Router ISIS mode

To configure ISIS authentication at the Router ISIS mode on a PowerConnect router, you must perform the following tasks:

- Configure ISIS Authentication Mode
- Configure ISIS Authentication Key
- Disable ISIS Authentication Check (optional)

Configuring ISIS authentication mode

The following commands configure the ISIS for the authentication mode.

```
NetIron(config)# router isis
NetIron(config-isis-router)# auth-mode md5 level-1
```

Syntax: [no] auth-mode [cleartext | md5] [level-1 | level-2]

The **cleartext** parameter specifies that the ISIS PDUs will be authenticated using a cleartext password.

The **md5** parameter specifies that the ISIS PDUs will be authenticated using the Hashed Message Authentication codes - Message Digest 5 (HMAC-MD5) algorithm.

The **level-1** parameter specifies that the authentication type-length-value (TLV) tuple be added to the L1 LSP, L1 CSNP, and LI PSNP packets.

The **level-2** parameter specifies that the authentication TLV tuple be added to the L2 LSP, L2 CSNP, and L2 PSNP packets.

Configuring ISIS authentication key

The following commands configure an authentication key to be used with the mode specified in "Configuring ISIS authentication mode".

```
NetIron(config)# router isis
NetIron(config-isis-router)# auth-mode md5 level-1
NetIron(config-isis-router)# auth-key supervisor level-1
NetIron(config-isis-router)# auth-key supervisor level-2
```

Syntax: [no] auth-key <*string*> **[level-1 | level-2]**

The <*string*> variable specifies a text string that is used as an authentication password. The authentication mode must be configured before this value can be configured.

By default, the authentication key is encrypted. If you want the authentication key to be in clear text, insert a **0** between **auth-key** and <*string*>.

Example

```
NetIron(config-isis-router)# auth-key 0 supervisor level-1
```

The software adds a prefix to the authentication key string in the configuration. For example, the following portion of the code has the encrypted code "2".

```
auth-key 2 $on-n level-1
```

The prefix can be one of the following:

- 0 = the key string is not encrypted and is in clear text
- 1 = the key string uses proprietary simple crytographic 2-way algorithm
- 2 = the key string uses proprietary base64 crytographic 2-way algorithm

The **level-1** parameter specifies that the authentication key specified here is used to authenticate the L1 LSP, L1 CSNP and LI PSNP packets.

The **level-2** parameter specifies that the authentication key specified here is used to authenticate the L2 LSP, L2 CSNP and L2 PSNP packets.

You must enter a configuration for both level-1 and level-2 in order to enter the auth-key string.

NOTE
If the authentication mode is reset for the level specified, the authentication key must also be reset.

Disabling ISIS authentication checking

When transitioning from one authentication mode to another, changing the authentication mode can cause packets to drop because only some of the routers have been reconfigured. During such a transition, it can be useful to disable ISIS authentication checking temporarily until all routers are reconfigured and the network is stable.

You can use the following commands to disable ISIS authentication checking.

```
NetIron(config)# router isis
NetIron(config-isis-router)# no auth-check level-1
```

Syntax: [no] auth-check [level-1 | level-2]

This command enables and disables ISIS authentication checking. The default is enabled and the **[no]** parameter disables authentication checking.

The **level-1** parameter specifies that authentication checking is enabled/ disabled for L1 LSP, L1 CSNP and LI PSNP packets.

The **level-2** parameter specifies that authentication checking is enabled/disabled for L2 LSP, L2 CSNP and L2 PSNP packets.

Configuring ISIS MD5 authentication on a specified interface

To configure ISIS MD5 authentication on a specified interface on a PowerConnect router, you must perform the following tasks:

- Configure ISIS Interface Authentication Mode for a Specified Interface
- Configure ISIS Authentication Key on the Interface
- Disable ISIS Authentication Check on an Interface (optional)

Configuring ISIS authentication mode for a specified interface

The following commands configure the ISIS for the authentication mode on a specified interface.

```
NetIron(config)# interface ethernet 3/1
NetIron(config-if-e10000-3/1)# isis auth-mode md5 level-1
```

Syntax: [no] isis auth-mode [cleartext | md5] [level-1 | level-2]

The **cleartext** parameter specifies that the ISIS PDUs will be authenticated using a cleartext password.

The **md5** parameter specifies that the ISIS PDUs authenticated using the Hashed Message Authentication codes - Message Digest 5 (HMAC-MD5) algorithm.

The **level-1** parameter specifies that the authentication TLV tuple be added to the L1 Hello packets.

The **level-2** parameter specifies that the authentication TLV tuple be added to the L2 Hello packets.

NOTE
If either level-1 or level-2 are not specified, the configuration is applied to both level-1 and level-2.

Configuring an ISIS authentication key for a specified interface

The following commands configure an authentication key to be used with the mode specified in "Configuring ISIS authentication mode for a specified interface".

```
NetIron(config)# interface ethernet 3/1
NetIron(config-if-e10000-3/1)# isis auth-key supervisor level-1
```

Syntax: [no] isis auth-key <*key*> **[level-1 | level-2]**

The <*key*> value specifies a text string that is used as an authentication password. The authentication mode must be configured before this value can be configured.

The **level-1** parameter specifies that the authentication key specified here is used to authenticate the L1 Hello packets.

The **level-2** parameter specifies that the authentication key specified here is used to authenticate the L2 Hello packets.

NOTE
If either level-1 or level-2 are not specified, the configuration is applied to both level-1 and level-2.

NOTE
If the authentication mode is reset for the level specified, the authentication key must also be reset.

NOTE
The **isis auth-key** command allows the user to configure more 80 characters, but only the first 80 characters are used.

Disabling ISIS authentication checking on a specified interface

When transitioning from one authentication mode to another, changing the authentication mode can cause packets to drop because only some of the routers have been reconfigured. During such a transition, it can be useful to disable ISIS authentication checking temporarily until all routers are reconfigured and the network is stable.

You can use the following commands to disable ISIS authentication checking on a specified interface.

```
NetIron(config)# interface ethernet 3/1
NetIron(if-e10000-3/1)# no isis auth-check level-1
```

Syntax: [no] isis auth-check [level-1 | level-2]

This command enables and disables ISIS authentication checking. The default is enabled and the **[no]** parameter disables authentication checking.

The **level-1** parameter specifies that authentication checking is enabled/ disabled for L1 Hello packets.

The **level-2** parameter specifies that authentication checking is enabled/disabled for L2 Hello packets.

NOTE
If either level-1 or level-2 are not specified, the configuration is applied to both level-1 and level-2.

Changing the IS-IS level globally

By default, a PowerConnect can operate as both a Level-1 and IS-IS Level-2 router. To globally change the level supported from Level-1 and Level-2 to Level-1 only, enter the following command.

```
NetIron(config-isis-router)# is-type level-1
```

Syntax: [no] is-type level-1 | level-1-2 | level-2

The **level-1 | level-1-2 | level-2** parameter specifies the IS-IS type. If you want to re-enable support for both IS-IS types, re-enter the command you entered to change the IS-IS type, and use “no” in front of the command.

To change the IS-IS on an interface, refer to “Changing the IS-IS level on an interface” on page 970.

Disabling or re-enabling display of hostname

Dell’s implementation of IS-IS supports RFC 2763, which describes a mechanism for mapping IS-IS system IDs to the hostnames of the devices with those IDs. For example, if you set the hostname on the PowerConnect to “IS-IS Router 1”, the mapping feature uses this name instead of the PowerConnect’s IS-IS system ID in the output of the following commands:

- **show isis database**
- **show isis interface**
- **show isis neighbor**

The PowerConnect's hostname is displayed in each CLI command prompt, for example.

```
NetIron(config-isis-router)#
```

The name mapping feature is enabled by default. If you want to disable name mapping, enter the following command.

```
NetIron(config-isis-router)# no hostname
```

Syntax: [no] hostname

To display the name mappings, enter the **show isis hostname** command.

Changing the Sequence Numbers PDU interval

A ***Complete Sequence Numbers PDU (CSNP)*** is a complete list of the LSPs in the Designated IS' link state database. The CSNP contains a list of all the LSPs in the database, as well as other information that helps IS neighbors determine whether their LSP databases are in sync with one another. The Designated IS sends CSNPs to the broadcast interface. Level-1 and Level-2 each have their own Designated IS.

A ***Partial Sequence Numbers PDU (PSNP)*** is a partial list of LSPs. ISs other than the Designated IS (that is, the non-Designated ISs) send PSNPs to the broadcast interface.

The CSNP interval specifies how often the Designated IS sends a CSNP to the broadcast interface. Likewise, the PSNP interval specifies how often other ISs (non-Designated ISs) send a PSNP to the broadcast interface.

The interval you can configure on the PowerConnect applies to both Level-1 and Level-2 CSNPs and PSNPs. The default interval is 10 seconds. You can set the interval to a value from 0 – 65535 seconds.

To change the interval, enter a command such as the following.

```
NetIron(config-isis-router)# csnp-interval 15
```

Syntax: [no] csnp-interval <*secs*>

The <*secs*> parameter specifies the interval and can be from 0 – 65535 seconds. The default is 10 seconds.

NOTE
PSNP has a default interval of 2 seconds and is not configurable.

Changing the maximum LSP lifetime

The maximum LSP lifetime is the maximum number of seconds an unrefreshed LSP can remain in the PowerConnect's LSP database. The maximum LSP lifetime can be from 1 – 65535 seconds. The default is 1200 seconds (20 minutes).

To change the maximum LSP lifetime to 2400 seconds, enter a command such as the following.

```
NetIron(config-isis-router)# max-lsp-lifetime 2400
```

Syntax: [no] max-lsp-lifetime <*secs*>

The <*secs*> parameter specifies the maximum LSP lifetime and can be from 1 – 65535 seconds. The default is 1200 seconds (20 minutes).

NOTE
The **max-lsp-lifetime** and the **lsp-refresh-interval** must be set in such a way that the LSPs are refreshed before the **max-lsp-lifetime** expires; otherwise, the PowerConnect's originated LSPs may be timed out by it's neighbors. Refer to "Changing the LSP refresh interval" on page 947.

Changing the LSP refresh interval

The LSP refresh interval is the maximum number of seconds the PowerConnect waits between sending updated LSPs to its IS-IS neighbors. The interval can be from 1 – 65535 seconds. The default is 900 seconds.

To change the LSP refresh interval to 20000 seconds, enter a command such as the following.

```
NetIron(config-isis-router)# lsp-refresh-interval 20000
```

Syntax: [no] lsp-refresh-interval <*secs*>

The <*secs*> parameter specifies the maximum refresh interval and can be from 1 – 65535 seconds. The default is 900 seconds (15 minutes).

Changing the LSP generation interval

The LSP generation interval is the minimum number of seconds the PowerConnect waits between sending updated LSPs to its IS-IS neighbors. The interval can be from 1 – 120 seconds. The default is 10 seconds.

To change the LSP generation interval to 45 seconds, enter a command such as the following.

```
NetIron(config-isis-router)# lsp-gen-interval 45
```

Syntax: [no] lsp-gen-interval <*secs*>

The <*secs*> parameter specifies the minimum refresh interval and can be from 1 – 120 seconds. The default is 10 seconds.

Changing the LSP interval and retransmit interval

You LSP interval is the rate of transmission, in milliseconds of the LSPs. The retransmit interval is the time the device waits before it retransmits LSPs. To define an LSP interval, enter a command such as the following.

```
NetIron(config-isis-router)# lsp-interval 45
```

Syntax: [no] lsp-interval <*milliseconds*>

Enter 1 – 4294967295 milliseconds for the LSP interval. The default is 33 milliseconds.

To define an interval for retransmission of LSPs enter a command such as the following.

```
NetIron(config-isis-router)# retransmit-interval 3
```

Syntax: [no] retransmit-interval <*seconds*>

Enter 0 – 65535 seconds for the retransmission interval. The default is 5 seconds.

Changing the SPF timer

Every IS maintains a Shortest Path First (SPF) tree, which is a representation of the states of each of the IS's links to ESs and other ISs. If the IS is both a Level-1 and Level-2 IS, it maintains separate SPF trees for each level.

To ensure that the SPF tree remains current, the IS updates the tree at regular intervals following a change in network topology or the link state database. By default, the PowerConnect recalculates its IS-IS tree every five seconds following a change. You can change the SPF timer to a value from 1 – 120 seconds.

NOTE
This command has been superseded by the IS-IS PSPF Exponential back-off feature.

To change the SPF interval, enter a command such as the following.

```
NetIron(config-isis-router)# spf-interval 30
```

Syntax: [no] spf-interval <*secs*>

The <*secs*> parameter specifies the interval and can be from 1 – 120 seconds. The default is 5 seconds.

Configuring the IS-IS PSPF exponential back-off feature

The PowerConnect router uses the exponential back-off mechanism to provide a more responsive approach to running the PSPF calculations. With this new feature, there is a new configurable command called **partial-spf-interval** that allows you to schedule PSPF processing as described in the following.

An **initial-wait** interval can be configured as a wait time after an LSP change until the first PSPF calculation. Optionally, this value is followed by another configurable variable called the **second-wait** interval that is used as a wait time between the first and second PSPF calculations. The **second-wait** interval (if configured) is then increased in multiples of 2 until it reaches the maximum hold time as configured by the **max-wait** variable. Once reached, the maximum hold time remains the hold interval between PSPF calculations until there are no further changes in the network. When there are no network changes in a hold down period, the gap between PSPF calculations returns to the **initial-wait** interval and the process begins again. '

If an **initial-wait** interval is configured without a **second-wait** interval, the **max-wait** variable is used for the second and all subsequent intervals.

If the **initial-wait** and **second-wait** intervals are not configured, the **max-wait** variable is used for the first and all subsequent intervals.

The IS-IS PSPF exponential back-off mechanism is configured using the **partial-spf-interval** command , as shown in the following.

```
NetIron(config-isis-router)# partial-spf-interval 60 1000 5000
```

Syntax: [no] partial-spf-interval <*max-wait*> <*initial-wait*> <*second-wait*>

The <*max-wait*> variable specifies the maximum interval between PSPF recalculations. The range of acceptable values is 0 – 120000 milliseconds. The default is 5000 milliseconds (5 seconds).

The <*initial-wait*> variable is an optional value that specifies the wait time after an LSP change until the first PSPF calculation. The range of acceptable values is 0 – 120000 milliseconds. The default for this variable is value of the **max-wait** time.

The <*second-wait*> variable is an optional value that specifies the wait time between the first and second PSPF calculations. If this optional value is configured, it will be doubled with each PSPF recalculation until the value is equal to the <*spf-max-wait*> value. The range of acceptable values is 0 – 120000 milliseconds. The default for this variable is value of the **max-wait** time.

Configuring the IS-IS flooding mechanism

The IS-IS fast flooding feature allows you to configure IS-IS on the router to flood Link State PDUs to other routers in the network before running SPF. This improves database synchronization by allowing LSP changes to be propagated to neighbors before running SPF. The IS-IS fast-flood feature is implemented using the fast-flood command as shown in the following.

```
NetIron(config-isis-router)# fast-flood 10
```

Syntax: [no] fast-flood <*lsp-count*>

The <*lsp-count*> variable sets the number of LSPs that trigger SPF that must be flooded before running SPF. The SPF run will be delayed until the configured number of LSPs have been flooded. If the number of changed LSPs is less than the configured number, then only the changed LSPs are flooded. The variable can be set to the following values: 1 - 25. This variable is optional and will be set to a value of 4 if not specified.

Globally disabling or re-enabling hello padding

By default, the PowerConnect adds extra data to the end of a hello packet to make the packet the same size as the maximum length of PDU the PowerConnect supports.

The padding applies to the following types of hello packets:

- ES hello (ESH PDU)
- IS hello (ISH PDU)
- IS to IS hello (IIH PDU)

The padding consists of arbitrarily valued octets. A padded hello PDU indicates the largest PDU that the PowerConnect can receive. Other ISs that receive a padded hello PDU from the PowerConnect can therefore ensure that the IS-IS PDUs they send the PowerConnect. Similarly, if the PowerConnect receives a padded hello PDU from a neighbor IS, the PowerConnect knows the maximum size PDU that the PowerConnect can send to the neighbor.

When padding is enabled, the maximum length of a Hello PDU sent by the PowerConnect is 1514 bytes.

If you need to disable padding, you can do so globally or on individual interfaces. Generally, you do not need to disable padding unless a link is experiencing slow performance. If you enable or disable padding on an interface, the interface setting overrides the global setting.

To globally disable padding of IS-IS hello PDUs, enter the following command.

```
NetIron(config-isis-router)# no hello padding
```

This command disables all hello PDU padding on the PowerConnect. To re-enable padding, enter the following command.

```
NetIron(config-isis-router)# hello padding
```

Syntax: [no] hello padding [point-to-point]

By default, hello padding is enabled. Enter the **no** form of the command to disable hello padding.

The **point-to-point** option enables hello PDU padding on Point-to-Point interfaces.

To disable hello padding on an interface, refer to "Disabling and enabling hello padding on an interface" on page 970.

Logging adjacency changes

The PowerConnect can be configured to log changes in the status of an adjacency with another IS. Logging of the adjacency changes is disabled by default. To enable or disable them, use either of the following methods.

To enable logging of adjacency changes, enter the following command.

```
NetIron(config-isis-router)# log adjacency
```

Syntax: [no] log adjacency

To disable logging of adjacency changes, enter the following command.

```
NetIron(config-isis-router)# no log adjacency
```

Logging invalid LSP packets received

The PowerConnect can be configured to provide logging of invalid LSP packets. Logging of the invalid LSP packets is disabled by default. To enable or disable this function, use either of the following methods.

To enable logging of invalid LSP packets, enter the following command.

```
NetIron(config-isis-router)# log invalid-lsp-packets
```

Syntax: [no] log invalid-lsp-packets

To disable logging of invalid LSP packets, enter the following command.

```
NetIron(config-isis-router)# no log invalid-lsp-packets
```

Disabling partial SPF optimizations

IS-IS employs certain partial SPF optimizations to make partial changes to the routing table in network change situations where the topology of the network has not changed but where there may be changes in the IP networks advertised by routers. These optimizations are termed partial SPF optimizations.

You can optionally configure IS-IS to perform a full SPF calculation when any network (non-topology) change occurs by using the **disable-partial-spf-opt** command. When **disable-partial-spf-opt** is configured, IS-IS always runs full SPF for all such network changes.

To disable partial SPF calculations for IS-IS, enter the following command.

```
NetIron(config-isis-router)# disable-partial-spf-opt
```

Syntax: [no] disable-partial-spf-opt

To restore partial SPF optimizations, use the **no** form of this command.

Disabling incremental SPF optimizations

In the event of certain topology changes (for instance non-local adjacency flaps), IS-IS employs incremental SPF optimizations to efficiently update the routing table. An incremental SPF is faster and takes fewer CPU cycles than a full SPF.

You can optionally configure IS-IS to perform a full SPF calculation when any network topology change occurs by using the **disable-incremental-spf-opt** command. When **disable-incremental-spf-opt** is configured, IS-IS always runs full SPF for all such network topology changes.

To disable incremental SPF optimizations for IS-IS, enter the following command.

```
NetIron(config-isis-router)# disable-incremental-spf-opt
```

Syntax: [no] disable-incremental-spf-opt

To restore incremental SPF optimizations, use the **no** form of this command.

NOTE
If you disable the partial SPF optimizations (by using the **disable-partial-spf-opt** command), IS-IS automatically disables the incremental SPF optimizations and always runs full SPF, too. However, the reverse is not true: disabling incremental SPF optimizations does not disable partial optimizations.

Configuring IPv4 address family route parameters

This section describes how to modify the IS-IS parameters for the IS-IS IPv4 unicast address family. To enter the IPv4 unicast address family, refer to the "Address family configuration level" on page 939.

Changing the metric style

The metric style specifies the Types, Lengths, and Values (TLVs) an IS-IS LSP can have. The TLVs specify the types of data, the maximum length of the data, and the valid values for the data. One of the types of data the TLVs control is a route's default-metric. By default, the PowerConnect uses the standard IS-IS TLVs, which allows metric values from 1 – 63. The default metric style is called "narrow." You can increase the range of metric values supported by the PowerConnect by changing the metric style to wide. The wide metric style allows metric values in the range 1 – 16777215.

To change the metric style to wide, enter the following command.

```
NetIron(config-isis-router-ipv4)# metric-style wide
```

This command changes the metric style for both Level-1 and Level-2.

Syntax: [no] metric-style wide [level-1 | level-2]

The **level-1 | level-2** parameter specifies the levels to which the change applies. If not specified, the changes are applied to both levels.

Changing the maximum number of load sharing paths

By default, IPv4 IS-IS can calculate and install four equal-cost paths into the IPv4 forwarding table. You can change the number of paths IPv4 IS-IS can calculate and install in the IPv4 forwarding table to a value from
1 – 8. If you change the number of paths to one, the PowerConnect does not load share multiple route paths learned from IPv4 IS-IS.

For example, to change the number of paths IPv4 IS-IS can calculate and install in the IPv4 forwarding table to three, enter the following command at the IPv4 IS-IS unicast address family configuration level.

```
NetIron(config-isis-router-ipv4u)# maximum-paths 4
```

Syntax: [no] maximum-paths <*number*>

The <*number*> parameter specifies the number of paths IPv4 IS-IS can calculate and install in the IPv4 forwarding table. Enter a number from 1 to 4. The value specified in <*number*> is limited by the ip load-sharing value.

To return to the default number of maximum paths, enter the **no** form of this command.

Enabling advertisement of a default route

By default, the PowerConnect does not generate or advertise a default route to its neighboring ISs. A default route is not advertised even if the device's IPv4 route table contains a default route. You can enable the device to advertise a default route to all neighboring ISs using one of the following methods. By default, the feature originates the default route at Level 2 only. However, you can apply a route map to originate the default route to Level 1 only or at both Level 1 and Level 2.

NOTE
This feature requires the presence of a default route in the IPv4 route table.

To enable the PowerConnect to advertise a default route that is originated a Level 2, enter the following command at the IPv4 IS-IS unicast address family configuration level.

```
NetIron(config-isis-router-ipv4u)# default-information-originate
```

This command enables the device to advertise a default route into the IPv4 IS-IS area to which the device is attached.

Syntax: [no] default-information-originate [route-map <*name*>**]**

The **route-map** <*name*> parameter allows you to specify the level on which to advertise the default route. You can specify one of the following:

- Advertise to Level-1 ISs only.
- Advertise to Level-2 ISs only.
- Advertise to Level-1 and Level-2 ISs.

NOTE
The route map must be configured before you can use the route map as a parameter with the **default-information-originate** command.

To use a route map to specify the router to advertise a default route to Level 1, enter commands such as the following at the Global CONFIG level.

```
NetIron(config)# route-map default_level1 permit 1
NetIron(config-routemap default_level1)# set level level-1
NetIron(config-routemap default_level1)# exit
NetIron(config)# router isis
NetIron(config-isis-router)# address-family ipv4 unicast
NetIron(config-isis-router-ipv4u)# default-information-originate route-map
default_level1
```

These commands configure a route map to set the default advertisement level to Level 1 only.

Syntax: [no] route-map <*map-name*> **permit | deny** <*sequence-number*>

Syntax: [no] set level level-1 | level-1-2 | level-2

For this use of a route map, use the **permit** option and do not specify a **match** statement. Specify a **set** statement to set the level to one of the following:

- **level-1** – Level 1 only.
- **level-1-2** – Level 1 and Level 2.
- **level-2** – Level 2 only (default).

Matching based on ISIS protocol type

The **match** option has been added to the **route-map** command that allows IS-IS routes to be matched based on level-1 or level-2 or all IS-IS routes. .

```
NetIron(config-routemap test)# match protocol isis level-1
```

Syntax: [no] match protocol isis {level-1|level-2}

The **match protocol isis level-1** option can be used to match the IS-IS Level-1 routes.

The **match protocol isis level-2** option can be used to match the IS-IS Level-2 routes.

Changing the administrative distance for IPv4 IS-IS

When the PowerConnect has paths from multiple routing protocols to the same destination, it compares the administrative distances of the paths and selects the path with the lowest administrative distance to place in the IPv4 route table.

For example, if the router has a path from RIP, from OSPF, and IPv4 IS-IS to the same destination, and all the paths are using their protocols' default administrative distances, the router selects the OSPF path, because that path has a lower administrative distance than the RIP and IPv4 IS-IS paths.

Here are the default IPv4 administrative distances on the PowerConnect:

- Directly connected – 0 (this value is not configurable)
- Static – 1 (applies to all static routes, including default routes)
- EBGP – 20
- OSPF – 110
- IPv4 IS-IS – 115
- RIP – 120
- IBGP – 200
- Local BGP – 200

- Unknown – 255 (the device will not use this route)

Lower administrative distances are preferred over higher distances. For example, if the PowerConnect receives routes for the same network from IPv4 IS-IS and from RIP, it will prefer the IPv4 IS-IS route by default.

To change the administrative distance for IPv4 IS-IS routes, enter the following command at the IPv4 IS-IS unicast address family configuration level.

```
NetIron(config-isis-router-ipv4u)# distance 100
```

Syntax: [no] distance <*number*>

This command changes the administrative distance for all IPv4 IS-IS routes to 100.

The <*number*> parameter specifies the administrative distance. You can specify a value from 1 – 255. (Routes with a distance value of 255 are not installed in the routing table.) The default for IPv4 IS-IS is 115.

Configuring summary addresses

You can configure summary addresses to aggregate IS-IS route information. Summary addresses can enhance performance by reducing the size of the Link State database, reducing the amount of data the PowerConnect needs to send to its neighbors, and reducing the CPU cycles used for IS-IS.

When you configure a summary address, the address applies only to Level-2 routes by default. You can specify Level-1 only, Level-2 only, or Level-1 and Level-2 when you configure the address.

To configure a summary address, enter a command such as the following.

```
NetIron(config-isis-router-ipv4u)# summary-address 192.168.0.0 255.255.0.0
```

This command configures a summary address for all Level-2 IS-IS route destinations between 192.168.1.0 – 192.168.255.255.

Syntax: [no] summary-address <*ip-addr*> <*subnet-mask*> **[level-1 | level-1-2 | level-2]**

The <*ip-addr*> <*subnet-mask*> parameters specify the aggregate address. The mask indicates the significant bits in the address. Ones are significant, and zeros allow any value. In the command example above, the mask 255.255.0.0 matches on all addresses that begin with 192.168 and contain any values for the final two octets.

The **level-1 | level-1-2 | level-2** parameter specifies the route types to which the aggregate route applies. The default is **level-2**.

Redistributing routes into IPv4 IS-IS

To redistribute routes into IPv4 IS-IS, you can perform the following configuration tasks:

- Change the default redistribution metric (optional).
- Configure the redistribution of a particular route type into IPv4 IS-IS (mandatory).

The PowerConnect can redistribute routes from the following route sources into IPv4 IS-IS:

- BGP4+.
- RIP.
- OSPF.
- Static IPv4 routes.

- IPv4 routes learned from directly connected networks.

The PowerConnect can also can redistribute Level-1 IPv4 IS-IS routes into Level-2 IPv4 IS-IS routes, and Level-2 IPv4 IS-IS routes into Level-1 IPv4 IS-IS routes.

Route redistribution from other sources into IPv4 IS-IS is disabled by default. When you enable redistribution, the device redistributes routes only into Level 2 by default. You can specify Level 1 only, Level 2 only, or Level 1 and Level 2 when you enable redistribution.

The device automatically redistributes Level-1 routes into Level-2 routes. Thus, you do not need to enable this type of redistribution. You also can enable redistribution of Level-2 routes into Level-1 routes.

The device attempts to use the redistributed route's metric as the route's IPv4 IS-IS metric. For example, if an OSPF route has an OSPF cost of 20, the router uses 20 as the route's IPv4 IS-IS metric. The device uses the redistributed route's metric as the IPv4 IS-IS metric unless the route does not a have a valid metric. In this case, the device assigns the default metric value to the route. For information about the default metric, refer to the "Changing the default redistribution metric" section, which follows this section.

Changing the default redistribution metric

When IPv4 IS-IS redistributes a route from another route source (such as OSPF, BGP4+, or a static IPv4 route) into IPv4 IS-IS, it uses the route's metric value as its metric when the metric is not modified by a route map or metric parameter and the default redistribution metric is set to its default value of 0. You can change the default metric to a value from 0 – 65535.

NOTE
The implementation of IS-IS does not support the optional metric types Delay, Expense, or Error.

For example, to change the default metric to 20, enter the following command at the IPv4 IS-IS unicast address family configuration level.

```
NetIron(config-isis-router-ipv4u)# default-metric 20
```

Syntax: [no] default-metric <*value*>

The <*value*> parameter specifies the default metric. You can specify a value from 0 – 65535. The default is 0.

To restore the default value for the default metric, enter the **no** form of this command.

Redistributing static IPv4 routes into IPv4 IS-IS

To redistribute static IPv4 routes from the IPv4 static route table into IPv4 IS-IS routes, enter the following command at the IPv4 IS-IS unicast address family configuration level.

```
NetIron(config-isis-router-ipv4u)# redistribute static
```

This command configures the PowerConnect to redistribute all static IPv4 routes into Level-2 IS-IS routes.

Syntax: [no] redistribute static [level-1 | level-1-2 | level-2] |
metric <*num*> **| metric-type [external | internal] | route-map** <*name*>

The **level-1**, **level-1-2**, and **level-2** keywords restrict redistribution to the specified IPv4 IS-IS level.

The **metric** <*num*> parameter changes the metric. You can specify a value from 0 - 4294967295.

The **metric-type external** | **internal** parameter restricts redistribution to one of the following:

- **external** – The metric value is not comparable to an IPv4 IS-IS internal metric and is always higher than the IPv4 IS-IS internal metric.
- **internal** – The metric value is comparable to metric values used by IPv4 IS-IS. This is the default.

The **route-map** <*name*> parameter restricts redistribution to those routes that match the specified route map. The route map must already be configured before you use the route map name with the **redistribute** command. For example, to configure a route map that redistributes only the static IPv4 routes to the destination networks 192.168.0.0/24, enter commands such as the following:

```
NetIron(config)# access-list 10 permit 192.168.0.0 0.0.255.255
NetIron(config)# route-map static permit 1
NetIron(config-routemap static)# match ip address 10
NetIron(config-routemap static)# router isis
NetIron(config-isis-router)# address-family ipv4 unicast
NetIron(config-isis-router-ipv4u)# redistribute static route-map static
```

Redistributing directly connected routes into IPv4 IS-IS

To redistribute directly connected IPv4 routes into IPv4 IS-IS routes, enter the following command at the IPv4 IS-IS unicast address family configuration level.

```
NetIron(config-isis-router-ipv4u)# redistribute connected
```

This command configures the PowerConnect to redistribute all directly connected routes in the IPv4 route table into Level-2 IPv4 IS-IS.

Syntax: [no] **redistribute connected [level-1 | level-1-2 | level-2] | metric** <*number*> **| metric-type [external | internal] | route-map** <*name*>]

The parameters are the same as the parameters for the **redistribute static** command.

Redistributing RIP routes into IPv4 IS-IS

To redistribute RIP routes into IPv4 IS-IS, enter the following command at the IPv4 IS-IS unicast address family configuration level.

```
NetIron(config-isis-router-ipv4u)# redistribute rip
```

This command configures the PowerConnect to redistribute all RIP routes into Level-2 IS-IS.

Syntax: [no] **redistribute rip [level-1 | level-1-2 | level-2] | metric** <*number*> **| metric-type [external | internal] | route-map** <*name*>

The parameters are the same as the parameters for the **redistribute static** command.

Redistributing OSPF routes into IPv4 IS-IS

To redistribute OSPF routes into IPv4 IS-IS, enter the following command at the IPv4 IS-IS unicast address family configuration level.

```
NetIron(config-isis-router-ipv4u)# redistribute ospf
```

This command configures the PowerConnect to redistribute all OSPF routes into Level-2 IPv4 IS-IS.

Syntax: [no] redistribute ospf [level-1 | level-1-2 | level-2] |
match [external1 | external2 | internal] |
metric <*number*> |
metric-type [external | internal] |
route-map <*name*>

Most of the parameters are the same as the parameters for the **redistribute static** command. However, the **redistribute ospf** command also has the **match external1** | **external2** | **internal** parameter. This parameter specifies the OSPF route type you want to redistribute into IPv4 IS-IS. By default, the **redistribute ospf** command redistributes only internal routes.

- **external1** – An OSPF type 1 external route.
- **external2** – An OSPF type 2 external route.
- **internal** – An internal route calculated by OSPF.

Redistributing BGP4+ routes into IPv4 IS-IS

To redistribute BGP4+ routes into IPv4 IS-IS, enter the following command at the IPv4 IS-IS unicast address family configuration level.

```
NetIron(config-isis-router-ipv4u)# redistribute bgp
```

This command configures the router to redistribute all its BGP4 routes into Level-2 IPv4 IS-IS.

Syntax: [no] redistribute bgp [level-1 | level-1-2 | level-2] |
metric <*number*> | metric-type [external | internal] |
route-map <*name*>

The parameters are the same as the parameters for the **redistribute static** command.

Redistributing IPv4 IS-IS routes within IPv4 IS-IS

In addition to redistributing routes from other route sources into IPv4 IS-IS, the PowerConnect can redistribute Level 1 IPv4 IS-IS routes into Level 2 IPv4 IS-IS routes, and Level 2 IPv4 IS-IS routes into Level 1 IPv4 IS-IS routes. By default, the device redistributes routes from Level 1 into Level 2.

NOTE
The PowerConnect automatically redistributes Level 1 routes into Level 2 routes, even if you do not enable redistribution.

For example, to redistribute all IPv4 IS-IS routes from Level 2 into Level 1, enter the following command at the IPv4 IS-IS unicast address family configuration level.

```
NetIron(config-isis-router-ipv4u)# redistribute isis level-2 into level-1
```

The router automatically redistributes Level-1 routes into Level 2.

Syntax: [no] redistribute isis level-1 into level-2 | level-2 into level-1 [prefix-list <*name*>]

The **level-1 into level-2** | **level-2 into level-1** parameter specifies the direction of the redistribution:

- **level-1 into level-2** – Redistributes Level 1 routes into Level 2. This is the default.
- **level-2 into level-1** – Redistributes Level 2 routes into Level 1.

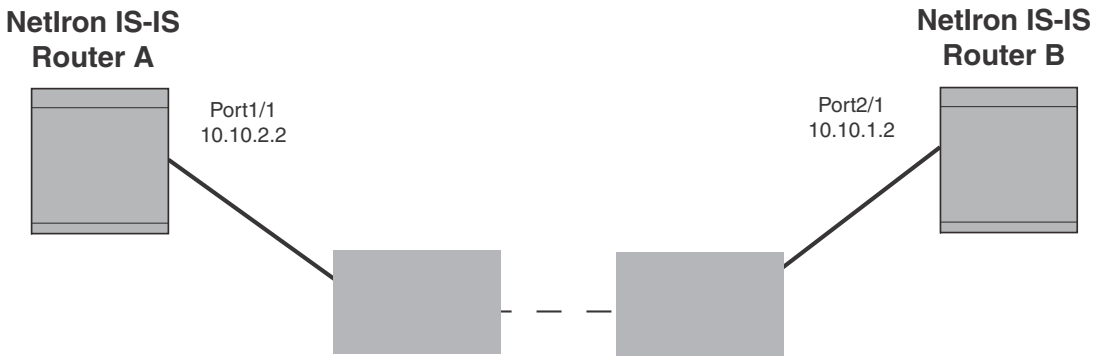
The **prefix-list** <*name*> specifies an IP prefix list.

Configuring IS-IS point-to-point over Ethernet

IS-IS uses its neighbor's MAC address to form an adjacency and stores the neighbors MAC address to recognize the adjacency in the future. This is no problem with directly adjacent routers but can become a problem when adjacency is required between routers that are more than one hop away. To accommodate an IS-IS network with this type of configuration, the IS-IS Point-to-Point over Ethernet feature has been developed.

Using the IS-IS Point-to-Point feature over ethernet, routers that are several hops away or available through an IP GRE tunnel (as described in "Configuring IS-IS over a GRE IP tunnel" on page 960) can form an IS-IS adjacency. It can be used when only two IS's are part of the broadcast network. This feature is configured at the interface level of the routers that are forming an adjacency. For example, Figure 144 shows two PowerConnect routers several hops away from each other that are configured for IS-IS adjacency.

FIGURE 144 IS-IS Point-to-Point configuration



You can use the commands in the following configurations to enable the IS-IS Point-to-Point feature:

PowerConnect IS-IS Router A configuration

To configure PowerConnect IS-IS Router A for the IS-IS Point-to-Point feature use the following commands.

```
NetIron(config)# interface ethernet 1/1
NetIron(config-if-e10000-1/1)# ip router isis
NetIron(config-if-e10000-1/1)# ip address 10.10.2.2
NetIron(config-if-e10000-1/1)# isis point-to-point
```

PowerConnect IS-IS Router B configuration

To configure PowerConnect IS-IS Router B for the IS-IS Point-to-Point feature use the following commands.

```
NetIron(config)# interface ethernet 2/1
NetIron(config-if-e10000-2/1)# ip router isis
NetIron(config-if-e10000-2/1)# ip address 10.10.1.2
NetIron(config-if-e10000-2/1)# isis point-to-point
```

Syntax: [no] isis point-to-point

NOTE
Point-to-Point is the default setting for POS interfaces and cannot be changed.

Displaying IS-IS point-to-point configuration

Use the **show isis interface** command to determine if IS-IS point-to-point is configured on an interface. In the example below, the lines in bold identify IS-IS point-to-point configuration.

```
NetIron# show isis interface
Total number of IS-IS Interfaces: 2
Interface : v128 Local Circuit Number: 0000000c
   Circuit Type : PTP Circuit Mode : LEVEL-1-2
   Circuit State: UP Passive State: FALSE
   MTU : 1497
   Level-1 Metric: 10, Level-1 Priority: 64
   Circuit State Changes: 1 Circuit Adjacencies State Changes: 1
   Rejected Adjacencies: 0
   Circuit Authentication Fails: 0 Bad LSP 0
   Control Messages Sent: 45600 Control Messages Received: 6778
   IP Enabled: TRUE
   IP Address and Subnet Mask:
    128.1.1.1 255.255.255.0
   IPv6 Enabled: FALSE
```

To determine if IS-IS point-to-point link is being used by ISs, use the **show isis neighbor** command.

```
NetIron# show isis neighbor
System Id   Interface  SNPA           State Holdtime Type Pri StateChgeTime
SFO-RX16    eth1/1     0004.badb.0eee UP    10       ISL2 64  0 :5 :5 :12
SFO-RX16    eth1/1     0004.badb.0eee UP    10       ISL1 64 0 :5 :5 :12
SFO-RX16    ve 128     0900.2b00.0005 UP    30       PTPT 127 0 :4 :46:59
```

Configuring IS-IS over a GRE IP tunnel

As described in "Configuring IS-IS point-to-point over Ethernet" on page 958, IS-IS adjacency can be established over ethernet between routers that are more than one hop away using the IS-IS Point-to-Point feature. IS-IS over a GRE IP tunnel extends this capability by allowing you to configure IS-IS adjacency between routers on either end of a GRE IP tunnel. To configure IS-IS over a GRE IP Tunnel you must configure the following:

- Configure the routers that you want to establish adjacency for IS-IS point-to-point as described in "Configuring IS-IS point-to-point over Ethernet" on page 958.
- Configure a GRE IP Tunnel.
- Configure the routers used for the GRE IP Tunnel for IS-IS using the **router isis** command.
- Configure the tunnel interfaces on the routers used for the GRE IP Tunnel for IS-IS point-to-point using the **isis point-to-point** command.

Configuration considerations

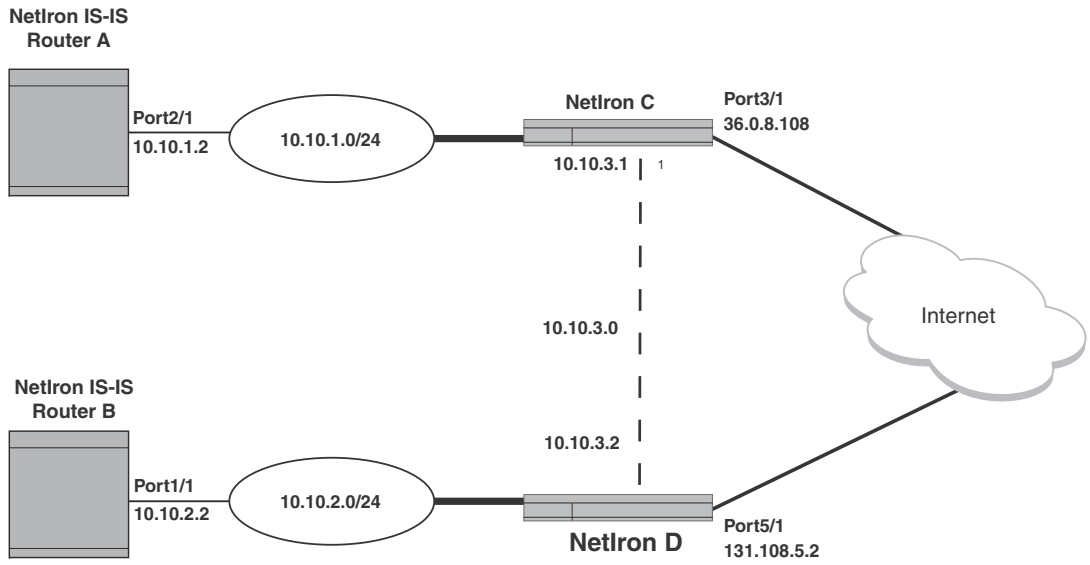
The configuration considerations are as follows:

- When a GRE tunnel is configured, you cannot configure the same routing protocol on the tunnel through which the router learns the route to the tunnel destination. For example, if a router learns the tunnel destination route through the OSPF protocol, you cannot configure the OSPF protocol on the same Tunnel and vice-versa. When a tunnel has OSPF configured, the router cannot learn the tunnel destination route through OSPF. This will cause the system to become unstable.
- When you have keepalive configured on both sides of a GRE tunnel, we recommend that you disable the tunnel before changing any tunnel configurations. You can then re-enable the tunnel to restore it to normal functionality.
- When configuring a GRE IP Tunnel, the router must be configured with one of the following CAM Profiles: ipv4, ipv6, mpls-l3vpn, ipv4-vpn, multi-service-2 or mpls-l3vpn-2

Configuring IS-IS over a GRE IP tunnel

Figure 145 displays a network configured for IS-IS over a GRE IP tunnel. In the example, PowerConnect IS-IS Router A and PowerConnect IS-IS Router B are configured for adjacency. Routers PowerConnect C and PowerConnect D are configured with a GRE IP tunnel. Following the illustration are examples of the configurations required for IS-IS over a GRE IP tunnel.

FIGURE 145 IS-IS over a GRE IP tunnel



The following examples describe the configurations that support IS-IS over a GRE IP tunnel for each of the routers in Figure 145.

PowerConnect IS-IS Router A configuration

To configure PowerConnect IS-IS Router A for the IS-IS Point-to-Point feature use the following commands.

```
NetIron(config)# interface ethernet 2/1
NetIron(config-if-e10000-2/1)# ip router isis
NetIron(config-if-e10000-2/1)# ip address 10.10.1.2
NetIron(config-if-e10000-2/1)# isis point-to-point
```

PowerConnect IS-IS Router B configuration

To configure PowerConnect IS-IS Router B for the IS-IS Point-to-Point feature use the following commands.

```
NetIron(config)# interface ethernet 1/1
NetIron(config-if-e10000-1/1)# ip router isis
NetIron(config-if-e10000-1/1)# ip address 10.10.2.2
NetIron(config-if-e10000-1/1)# isis point-to-point
```

PowerConnect C configuration

To configure the PowerConnect C router for the IS-IS over a GRE IP tunnel feature, use the following commands.

```
NetIron(config)# router isis
NetIron(config-isis-router)# exit
NetIron(config)# interface tunnel 1
NetIron(config-tnif-1)tunnel source 36.0.8.108
NetIron(config-tnif-1)tunnel destination 131.108.5.2
NetIron(config-tnif-1)tunnel mode gre ip
NetIron(config-tnif-1)isis point-to-point
NetIron(config-tnif-1)ip address 10.10.3.1/24
NetIron(config-tnif-1)exit
NetIron(config) ip route 10.10.2.0/24 10.10.3.1
```

PowerConnect D configuration

To configure the PowerConnect D router for the S-IS over a GRE IP tunnel feature, use the following commands.

```
NetIron(config)# router isis
NetIron(config-isis-router)# exit
NetIron(config)# interface tunnel 1
NetIron(config-tnif-1) tunnel source ethernet 5/1
NetIron(config-tnif-1) tunnel destination 36.0.8.108
NetIron(config-tnif-1) tunnel mode gre ip
NetIron(config-tnif-1) isis point-to-point
NetIron(config-tnif-1) ip address 10.10.3.2/24
NetIron(config-tnif-1) exit
NetIron(config) ip route 10.10.1.0/24 10.10.3.1
```

Displaying IS-IS over GRE IP tunnel

You can use the **show isis interface** command to determine if IS-IS point-to-point is configured on a tunnel interface. In the example below, the lines in bold identify IS-IS point-to-point configuration in the gre_tnl 1 interface.

```
NetIron# show isis interface
Total number of IS-IS Interfaces: 2
Interface : gre_tnl 1
   Circuit State: UP Circuit Mode: LEVEL-1-2
   Circuit Type : PTP Passive State: FALSE
   Circuit Number: 0x02, MTU: 1497
   Level-1 Metric: 10, Level-1 Priority: 64
   Level-1 Auth-mode: None
   Level-2 Auth-mode: None
   Level-1 Metric: 10, Level-1 Priority: 50
```

```
Level-1 Hello Interval: 10 Level-1 Hello Multiplier: 3
Level-1 Designated IS: MLXe1-02 Level-1 DIS Changes: 0
Level-2 Metric: 10, Level-2 Priority: 50
Level-2 Hello Interval: 10 Level-2 Hello Multiplier: 3
Level-2 Designated IS: MLX2-02 Level-2 DIS Changes: 0
Circuit State Changes: 1 Circuit Adjacencies State Changes: 1
Rejected Adjacencies: 0
Circuit Authentication L1 failures: 0
Circuit Authentication L2 failures: 0
Bad LSPs 0
Control Messages Sent: 318 Control Messages Received: 229
IP Enabled: TRUE
IP Address and Subnet Mask:
 50.50.50.20         255.255.255.0
IPv6 Enabled: FALSE
```

To determine if IS-IS point-to-point link is being used by ISs, use the **show isis neighbor** command. In the example below, the line in bold identifies a point-to-point configuration on the MLXe1 system for the gre_tnl 1 interface.

```
NetIron# show isis neighbor
Total number of IS-IS Neighbors: 3
System Id      Interface  SNPA           State Holdtime Type  Pri    StateChgeTime
0000.0000.0004 eth 6/2    0000.0576.4805  UP    30       ISL1  0   0  :0 :8 :42
0000.0000.0004 eth 6/2    0000.0576.4805  UP    30       ISL2  0   0  :0 :8 :42
MLXe1           gre_tnl 1  0900.2b00.0005  UP    30       PTPT  127 0  :0 :9 :16
```

You can use the **show ip route isis** command to determine if next hop is a tunnel. For example.

```
NetIron# show ip route isis
Type Codes - B:BGP D: Connected I: ISIS S: Static R: RIP O:O SPF; Cost - Dist/Metric
        Destination        Gateway         Port         Cost       Type
1       30.30.30.0/24      50.50.50.10     gre_tnl 1    115/20     IL1
2       100.100.100.0/24   50.50.50.10     gre_tnl 1    115/20     IL1
3       100.100.101.0/24   50.50.50.10     gre_tnl 1    115/20     IL1
4       100.100.102.0/24   50.50.50.10     gre_tnl 1    115/20     IL1
5       100.100.103.0/24   50.50.50.10     gre_tnl 1    115/20     IL1
6       100.100.104.0/24   50.50.50.10     gre_tnl 1    115/20     IL1
7       100.100.105.0/24   50.50.50.10     gre_tnl 1    115/20     IL1
8       100.100.106.0/24   50.50.50.10     gre_tnl 1    115/20     IL1
9       100.100.107.0/24   50.50.50.10     gre_tnl 1    115/20     IL1
```

IS-IS Non-Stop Routing

Overview

NOTE
IS-IS Non-Stop Routing (NSR) is applicable only to IPv4 routes computed by IS-IS and does not apply to IPv6 routes.

IS-IS Non-Stop Routing (NSR) enables the IS-IS router to maintain topology and data flow to avoid re-convergence in the network during a processor switchover or hitless-reload event. The IS-IS Bidirectional Forwarding Detection (BFD) sessions survive the switchover and hitless-reload conditions. In general, a router restart causes its peer to remove the routes originated from the router and reinstalls them. This IS-IS NSR feature enables the router to maintain neighborship and LSA database with its peer on the event of a router restart.

In IS-IS NSR, the processor switchovers and the hitless-reloads are treated the same as they are during startup and the overload bit is set in the same way as it is after a reboot. For more information on overload bit setup, refer to "Setting the overload-bit" in Chapter 31.

NOTE
IS-IS NSR is independent of Graceful Restart (GR) and GR help role mechanisms.

Limitations

- The IS-IS over GRE tunnel feature does not support IS-IS NSR. The GRE tunnel interface types are not supported.
- The IS-IS shortcuts are not supported because they depend on the MPLS tunnel.
- If the IS-IS hellos are forwarded at Layer 2 and the switch executes a hitless-reload, hellos will not be forwarded for a brief time. The IS-IS adjacencies are lost for 12 seconds and there will be data traffic loss.
- The configuration events that occur close to switchover or hitless-reload may get lost due to CLI synchronization issues.
- The neighbor or interface state changes close to switchover or hitless-reload cannot be handled.
- The IS-IS neighbor hold timer is restarted upon IS-IS NSR switchover or hitless-reload.
- The traffic counters are not synchronized because the neighbor and LSP database counters are recalculated on the standby module during synchronization.
- With IS-IS NSR enabled, after switchover or hitless-reload to standby MP, IS-IS routes, LSP database and neighbor adjacencies are maintained so that there will be no loss of existing traffic to the IS-IS destinations.
- The IS-IS NSR hitless failover event may not be completely invisible to the network because, after switchover, additional flooding of CSNP packets will occur in the directly connected neighbors.

Enabling and disabling IS-IS NSR

To globally enable IS-IS NSR, enter the following commands.

```
PowerConnect(config)# router isis
PowerConnect(config-isis-router)# nonstop-routing
```

To globally disable IS-IS NSR, enter the following commands.

```
PowerConnect(config)# router isis
PowerConnect(config-isis-router)# no nonstop-routing
```

Syntax: [no] nonstop-routing

Displaying the IS-IS NSR status

To display the IS-IS NSR status, enter the following command.

```
PowerConnect(config-isis-router)# show isis

```

The following table describes the output of the **show isis** command.

TABLE 153 Output from the **show isis** command

This field...	Displays...
IS-IS Routing Protocol Operation State	This field indicates the operating state of IS-IS and the possible states includes the following: • Enabled – IS-IS is enabled. • Disabled – IS-IS is disabled.
IS-Type	This field indicates the intermediate system type and the possible types includes the following: • Level 1 only – The PowerConnect routes traffic only within the area in which it resides. • Level 2 only – The PowerConnect routes traffic between areas of a routing domain. • Level 1-2 – The PowerConnect routes traffic within the area in which it resides and between areas of a routing domain.
System ID	This field indicates the unique IS-IS router ID. Typically, the router base MAC address is used as the system ID.
Manual area address(es)	This field indicates the Area address(es) of the PowerConnect router.
Level-1-2 Database State	This field indicates the state of the Level 1-2 Database: • On • Off
Administrative Distance	This field specifies the current setting of the IS-IS administrative distance.
Maximum Paths	This field specifies the number of paths IS-IS can calculate and install in the forwarding table.
Default redistribution metric	This field specifies the value of the default redistribution metric, which is the IS-IS cost of redistributing the route into IS-IS.
Number of Routes redistributed into IS-IS	This field specifies the number of routes distributed into IS-IS.
Level-1 Auth-mode	This field indicates one of the following authentication modes set for Level-1 on the router: • None • md5 • cleartext
Level-2 Auth-mode	This field indicates one of the following authentication modes set for Level-2 on the router: • None • md5 • cleartext
Metric Style Supported for Level-1	This field indicates the metric style supported for Level-1 and the following values are supported: • Wide – Wide Metric Style • Narrow – Narrow Metric Style

TABLE 153 Output from the **show isis** command (Continued)

This field...	Displays...
Metric Style Supported for Level-2	This field indicates the metric style supported for Level-2 and the following values are supported: • Wide – Wide Metric Style • Narrow – Narrow Metric Style
IS-IS Partial SPF Optimizations	This field indicates the IS-IS partial SPEF optiomization and the parameter can contain one of the following values: • Enabled • Disabled
Timers: L1 or L2 SPF:	The following values are displayed individually for IS-IS levels 1 and 2.
max-wait	This fields indicates the maximum time gap that will occur between running of SPF calculations. It is the value configured as the spf-max-wait variable in the **spf-interval** command as described in "Configuring the IS-IS PSPF exponential back-off feature" on page 948.
Init-wait	This fields indicates the initial time gap between an SPF event and the first running of SPF. This value reflects the spf-initial-time variable that is configured using the **spf-interval** command as described in "Configuring the IS-IS PSPF exponential back-off feature" on page 948.
Second-wait	This fields indicates the interval between the first running of SPF and the first recalculation of the SPF tree. If this optional value is configured, it will be doubled with each recalculation of the SPF tree until the value is equal to the max-wait value This value reflects the spf-second-wait variable that is configured using the **spf-interval** command as described in "Configuring the IS-IS PSPF exponential back-off feature" on page 948.
SPF run status.	This field is not specifically labeled but it is displayed directly under the SPF timers. It can be any of the three values shown below: • SPF is running • SPF will run in <*sec*> where the <*sec*> variable is a value in seconds until the next time that SPF will be run. • SPF is not scheduled
Timers: PSPF:	
max-wait	This fields indicates the maximum time gap that will occur between running of PSPF calculations. It is the value configured as the max-wait value in the **partial-spf-interval** command as described in "Configuring the IS-IS PSPF exponential back-off feature" on page 948.
Init-wait	This fields indicates the initial time gap between the wait time after an LSP change until the first PSPF calculation. This value reflects the initial-wait variable that is configured using the **partial-spf-interval** command as described in "Configuring the IS-IS PSPF exponential back-off feature" on page 948.
Second-wait	This fields indicates the wait time between the first and second PSPF calculations. If this optional value is configured, it will be doubled with each PSPF recalculation until the value is equal to the max-wait value This value reflects the second-wait variable that is configured using the **partial-spf-interval** command as described in "Configuring the IS-IS PSPF exponential back-off feature" on page 948.

TABLE 153 Output from the **show isis** command (Continued)

This field...	Displays...
PSPF run status.	This field is not specifically labeled but it is displayed directly under the PSPF timers. It can be any of the three values shown below: • PSPF is running • PSPF will run in <sec> where the <sec> variable is a value in seconds until the next time that PSPF will be run. • PSPF is not scheduled
Timers: LSP:	
max-lifetime	This fields indicates the maximum number of seconds an unrefreshed LSP can remain in the PowerConnect router's LSP database. The default value is 1000 sec.
refresh-interval	This fields indicates the maximum number of seconds that a PowerConnect router waits between sending updated LSPs to its IS-IS neighbors. The default value is 1 sec.
gen-interval	This fields indicates the minimum number of seconds that a PowerConnect router waits between sending updated LSPs to its IS-IS neighbors. The default value is 10 sec.
retransmit-interval	This fields indicates the amount of time the PowerConnect router waits before it retransmits LSPs. The default value is 5 sec.
lsp-interval	This fields indicates the rate of transmission (in milliseconds) of the LSPs. The default rate is 33 ms.
Timers: SNP:	
csnp-interval	This fields indicates how often the designated IS sends a CSNP to the broadcast interface. The default value is 10 sec.
psnp-interval	This fields indicates how often the IS sends a PSNP. The default value is 2 sec.
Global Hello Padding	The value can be: • Enabled • Disabled
Global Hello Padding For Point to Point Circuits	The value can be: • Enabled • Disabled
Ptpt Three Way HandShake Mechanism	The value can be: • Enabled • Disabled
IS-IS Traffic Engineering Support	The value can be: • Enabled • Disabled
BFD	The value can be: • Enabled • Disabled

TABLE 153 Output from the **show isis** command (Continued)

This field...	Displays...
Interfaces with IPv4 IS-IS configured	This field specifies the interfaces on which IPv4 IS-IS is configured.
NSR state	This field indicates the state of the IS-IS NSR and takes the following values: • Normal - This indicates that the switchover is either compete or the switchover event is not triggerd. • SwitchOver Detected - This indicates that the switchover event is recognized by the IS-IS. • All Card Done - This is an internal event after which the IS-IS starts sending hellos to its neighbors and schedules SPF. • SPF Run Complete - This indicates that the SPF run and updating of the IS-IS routes to RTM is complete. • Wait for BGP - This event indicates that the IS-IS is waiting for redistribution to complete. After redistribution to IS-IS is complete, the IS-IS NSR state will change to Normal.
Standby MP	This field indicates the standby MP is active, ready, or inactive: • Active - This indicates the standby MP is active. • Inactive - This indicates the standby MP is either down or not present. • Ready - This indicates the standby MP is ready to accept configuration updates or database updates.
Sync State	This field indicates whether the synchronization state is enabled or disabled. The state changes depending on whether or not the **Non Stop-Routing** command is configured under the router IS-IS.
Interfaces with IPv4 IS-IS configured	This field specifies the interfaces configured with IPv4 IS-IS.

Configuring ISIS properties on an interface

This section describe the IS-IS parameters for an interface.

Disabling and enabling IS-IS on an interface

In addition to enabling IS-IS globally, you also must enable the protocol on the individual interfaces connected to ISs or ESs. To enable IS-IS locally on specific interfaces, enter commands such as the following.

```
NetIron(config)# interface ethernet 1/1
NetIron(config-if-1/1)# ip router isis
NetIron(config-if-1/1)# exit
NetIron(config)# interface pos 2/3
NetIron(config-if-2/3)# ip router isis
```

These commands enable IS-IS on ports 1/1 and 2/3. The NET configured above (at the IS-IS configuration level) applies to both interfaces.

Syntax: [no] ip router isis

Disabling or re-enabling formation of adjacencies

When you enable IS-IS on any type of interface except a loopback interface, the interface also is enabled to send advertisements and form an adjacency with an IS at the other end of the link by default. Adjacency formation and advertisements are disabled by default on loopback interfaces.

You can enable or disable adjacency formation and advertisements on an interface.

NOTE
The PowerConnect advertises an IS-IS interface to its area regardless of whether adjacency formation is enabled.

To disable IS-IS adjacency formation on an interface, enter commands such as the following.

```
NetIron(config)# interface ethernet 2/8
NetIron(config-if-e1000-2/8)# isis passive
```

This command disables IS-IS adjacency formation on port 2/8. The device still advertises this IS-IS interface into the area, but does not allow the port to form an adjacency with the IS at the other end of the link.

Syntax: [no] isis passive

Setting the priority for designated IS election

The priority of an IS-IS interface determines the priority of the interface for being elected as a Designated IS. Level-1 has a Designated IS and Level-2 has a Designated IS. The Level-1 and Level-2 Designated ISs are independent, although the same device can become both the Level-1 Designated IS and the Level-2 Designated IS.

By default, the Level-1 and Level-2 priority is 64. You can configure an interface's priority to a value from 0 – 127. You can configure the same priority for both Level-1 and Level-2 or you can configure a different priority for each level. In case of a tie (if two or more devices have the highest priority within a given level), the device with the highest MAC address becomes the Designated IS for that level.

NOTE
You can set the IS-IS priority on an individual interface basis only. You cannot set the priority globally.

To set the IS-IS priority on an interface, enter commands such as the following.

```
NetIron(config)# interface ethernet 2/8
NetIron(config-if-e1000-2/8)# isis priority 127
```

This command sets the IS-IS priority on port 1/1 to 127. Since the command does not specify Level-1 or Level-2, the new priority setting applies to both IS-IS levels.

Syntax: [no] isis priority <*num*> **[level-1 | level-2]**

The <*num*> parameter specifies the priority and can be from 0 – 127. A higher numeric value means a higher priority. The default is 64.

The **level-1 | level-2** parameter applies the priority to Level-1 only or Level-2 only. By default, the priority is applied to both levels.

Limiting access to adjacencies with a neighbor

In addition to limiting access to an area (level-1) or domain (level-2), you can limit access to forming an IS-IS adjacency on a specific interface by entering a password at the interface configuration level. To enter this password, enter a command such as the following.

```
NetIron(config)# interface ethernet 2/8
NetIron(config-if-e1000-2/8)# isis password my-password
```

Syntax: [no] isis password <*string*>

The <*string*> parameter specifies the password. You can enter an alphanumeric string up to 80 characters long. The password can contain blank spaces. If you use a blank space in the password, you must use quotation marks (“ “) around the entire password; for example, **isis password “admin 2”.**

Changing the IS-IS level on an interface

The section “Changing the IS-IS level globally” on page 945 explains how to change the IS-IS level globally. By default, a PowerConnect can operate as both a Level-1 and IS-IS Level-2 router. You can change the IS-IS type on an individual interface to be Level-1 only or Level-2 only. You also can reset the type to both Level-1 and Level-2.

NOTE
If you change the IS-IS type on an individual interface, the type you specify must also be specified globally. For example, if you globally set the type to Level-2 only, you cannot set the type on an individual interface to Level-1. The software accepts the setting but the setting does not take effect.

To change the IS-IS type on a specific interface, enter commands such as the following.

```
NetIron(config)# interface ethernet 2/8
NetIron(config-if-e1000-2/8)# isis circuit-type level-1
```

Syntax: [no] isis circuit-type level-1 | level-1-2 | level-2

The **level-1 | level-1-2 | level-2** parameter specifies the IS-IS type. If you want to re-enable support for both IS-IS types, re-enter the command you entered to change the IS-IS type, and use “no” in front of the command.

Disabling and enabling hello padding on an interface

The section “Globally disabling or re-enabling hello padding” on page 949 explains what hello padding is, why it is important and how to globally disable or enable it on a device. You can also disable hello padding on a specific interface by entering commands such as the following.

```
NetIron(config)# interface ethernet 2/8
NetIron(config-if-e1000-2/8)# no isis hello padding
```

Syntax: [no] isis hello padding

By default, hello padding is enabled. Enter the **no** form of the command to disable hello padding.

Changing the hello interval

The hello interval controls how often an IS-IS interface sends hello messages to its IS-IS neighbors. The default interval is 10 seconds for Level-1 and Level-2. You can change the hello interval for one or both levels to a value from 1 – 65535 seconds.

To change the hello interval for Ethernet interface 2/8, enter commands such as the following.

```
NetIron(config)# interface ethernet 2/8
NetIron(config-if-e1000-2/8)# isis hello-interval 20
```

This command changes the hello interval to 20 seconds. By default, the change applies to Level-1 and Level-2.

Syntax: [no] isis hello-interval <*num*> **[level-1 | level-2]**

The <*num*> parameter specifies the interval, and can be from 1 – 65535 seconds. The default is 10 seconds.

The **level-1 | level-2** parameter applies the change to only the level you specify. If you do not use this parameter, the change applies to both levels.

Changing the hello multiplier

The hello multiplier is the number by which an IS-IS interface multiplies the hello interval to obtain the hold time for Level-1 and Level-2 IS-to-IS hello PDUs. The default multiplier is 3. You can set the multiplier to a value in the range 3 – 1000.

To change the hello multiplier for Ethernet interface 2/8, enter commands such as the following.

```
NetIron(config)# interface ethernet 2/8
NetIron(config-if-e1000-2/8)# isis hello-multiplier 50
```

This command changes the hello interval to 50. By default, the change applies to both Level-1 and Level-2.

Syntax: [no] isis hello-multiplier <*num*> **[level-1 | level-2]**

The <*num*> parameter specifies the multiplier, and can be from 3 – 1000. The default is 3.

The **level-1 | level-2** parameter applies the change to only the level you specify. If you do not use this parameter, the change applies to both levels.

Changing the metric added to advertised routes

When the PowerConnect originates an IS-IS route or calculates a route, the PowerConnect adds a metric (cost) to the route. Each IS-IS interface has a separate metric value. The default is 10.

The PowerConnect applies the interface-level metric to routes originated on the interface and also when calculating routes. The PowerConnect does not apply the metric to link-state information that the PowerConnect receives from one IS and floods to other ISs.

The default interface metric is 10. You can change the metric on an individual interface to a value in one of the following ranges:

- 1 – 63 for the narrow metric style (the default metric style for IPv4 ISIS)
- 1 – 16777215 for the wide metric style (the default metric style for IPv4 ISIS)

NOTE
If the metric value you want to use is higher than 63 but you have not changed the metric style to wide, change the metric style first, then set the metric. The IS-IS neighbors that will receive the advertisements also must be enabled to receive wide metrics.

To change the IS-IS metric on an interface, use the following CLI method.

```
NetIron(config)# interface ethernet 2/8
NetIron(config-if-e1000-2/8)# isis metric 15
```

Syntax: [no] isis metric <*num*> **[level-1 | level-2]**

The <*num*> parameter specifies the metric. The range of values you can specify depends on the metric style. You can specify 1 – 63 for the narrow metric style or 1 – 16777215 for the wide metric style. The default in either case is 10.

The **level-1 | level-2** parameter applies the change to only the level you specify. If you do not use this parameter, the change applies to both levels.

Displaying IPv4 IS-IS information

You can display the following information:

- General IS-IS Information – "Displaying ISIS general information" on page 972
- The active configuration (the IS-IS commands in the running-config) – refer to "Displaying the IS-IS configuration in the running-config" on page 976
- Name mappings – "Displaying the name mappings" on page 976
- Neighbor information – "Displaying neighbor information" on page 977
- Neighbor adjacency changes – "Displaying IS-IS Syslog messages" on page 979
- Interface information – "Displaying interface information" on page 979
- Route information – "Displaying route information" on page 983
- LSP database entries – "Displaying LSP database entries" on page 984
- Traffic statistics – "Displaying traffic statistics" on page 988
- Error statistics – "Displaying error statistics" on page 989
- IS-IS Log – "Displaying the IS-IS SPF Log" on page 992

Displaying ISIS general information

To display general IPv4 IS-IS information, enter the following command at any CLI level.

```
NetIron#show isis
 IS-IS Routing Protocol Operation State: Enabled
IS-Type: Level-1-2
System ID: 1111.1111.1111
Manual area address(es):
47
Level-1-2 Database State: On
Administrative Distance: 115
Maximum Paths: 4
Default redistribution metric: 0
Protocol Routes redistributed into IS-IS:
```

```
Static
Number of Routes redistributed into IS-IS: 11

Interfaces with IPv4 IS-IS configured:
eth 1/1
```

Syntax: show isis

This display shows the following information.

TABLE 154 IS-IS neighbor information

This field...	Displays...
IS-IS Routing Protocol Operation State	The operating state of IS-IS. Possible states include the following: • Enabled – IS-IS is enabled. • Disabled – IS-IS is disabled.
IS-Type	The intermediate system type. Possible types include the following: • Level 1 only – The PowerConnect routes traffic only within the area in which it resides. • Level 2 only – The PowerConnect routes traffic between areas of a routing domain. • Level 1-2 – The PowerConnect routes traffic within the area in which it resides and between areas of a routing domain.
System ID	The unique IS-IS router ID. Typically, the router's device's base MAC address is used as the system ID.
Manual area address(es)	Area address(es) of the PowerConnect router.
Level-1-2 Database State	The state of the Level 1-2 Database: • On • Off
Administrative Distance	The current setting of the IS-IS administrative distance.
Maximum Paths	The number of paths IS-IS can calculate and install in the forwarding table
Default redistribution metric	The value of the default redistribution metric, which is the IS-IS cost of redistributing the route into IS-IS.

TABLE 154 IS-IS neighbor information (Continued)

This field...	Displays...
Number of Routes redistributed into IS-IS	The number of routes distributed into IS-IS.
Level-1 Auth-mode	One of the following authentication modes set for Level-1 on the router: • None • md5 • cleartext
Level-2 Auth-mode	One of the following authentication modes set for Level-2 on the router: • None • md5 • cleartext
Metric Style Supported for Level-1	The following values are supported: • Wide – Wide Metric Style • Narrow – Narrow Metric Style
Metric Style Supported for Level-2	The following values are supported: • Wide – Wide Metric Style • Narrow – Narrow Metric Style
IS-IS Partial SPF Optimizations	This parameter can contain one of the following values: • Enabled • Disabled
Timers: L1 or L2 SPF:	These values are displayed individually for IS-IS levels 1 and 2.
max-wait	The maximum time gap that will occur between running of SPF calculations. It is the value configured as the spf-max-wait variable in the **spf-interval** command as described in "Configuring the IS-IS PSPF exponential back-off feature" on page 948.
Init-wait	The initial time gap between an SPF event and the first running of SPF. This value reflects the spf-initial-time variable that is configured using the **spf-interval** command as described in "Configuring the IS-IS PSPF exponential back-off feature" on page 948.
Second-wait	The interval between the first running of SPF and the first recalculation of the SPF tree. If this optional value is configured, it will be doubled with each recalculation of the SPF tree until the value is equal to the max-wait value This value reflects the spf-second-wait variable that is configured using the **spf-interval** command as described in "Configuring the IS-IS PSPF exponential back-off feature" on page 948.
SPF run status.	This field is not specifically labeled but is displayed directly under the SPF timers.) It can any of the three values shown below: • SPF is running • SPF will run in <*sec*> where the <*sec*> variable is a value in seconds until the next time that SPF will be run. • SPF is not scheduled
Timers: PSPF:	
max-wait	The maximum time gap that will occur between running of PSPF calculations. It is the value configured as the max-wait value in the **partial-spf-interval** command as described in "Configuring the IS-IS PSPF exponential back-off feature" on page 948.

TABLE 154 IS-IS neighbor information (Continued)

This field...	Displays...
Init-wait	The initial time gap between the wait time after an LSP change until the first PSPF calculation. This value reflects the initial-wait variable that is configured using the **partial-spf-interval** command as described in "Configuring the IS-IS PSPF exponential back-off feature" on page 948.
Second-wait	The wait time between the first and second PSPF calculations. If this optional value is configured, it will be doubled with each PSPF recalculation until the value is equal to the max-wait value This value reflects the second-wait variable that is configured using the **partial-spf-interval** command as described in "Configuring the IS-IS PSPF exponential back-off feature" on page 948.
PSPF run status.	This field is not specifically labeled but is displayed directly under the PSPF timers. It can any of the three values shown below: • PSPF is running • PSPF will run in <*sec*> where the <*sec*> variable is a value in seconds until the next time that PSPF will be run. • PSPF is not scheduled
Timers: LSP:	
max-lifetime	The maximum number of seconds an unrefreshed LSP can remain in the PowerConnect router's LSP database. The default value is 1000 sec.
refresh-interval	The maximum number of seconds that a PowerConnect router waits between sending updated LSPs to its IS-IS neighbors. The default value is 1 sec.
gen-interval	The minimum number of seconds that a PowerConnect router waits between sending updated LSPs to its IS-IS neighbors. The default value is 10 sec.
retransmit-interval	The amount of time the PowerConnect router waits before it retransmits LSPs. The default value is 5 sec.
lsp-interval	The rate of transmission (in milliseconds) of the LSPs. The default rate is 33 ms.
Timers: SNP:	
csnp-interval	How often the designated IS sends a CSNP to the broadcast interface. The default value is 10 sec.
psnp-interval	How often the IS sends a PSNP. The default value is 2 sec.
Global Hello Padding	This value can be: • Enabled • Disabled
Global Hello Padding For Point to Point Circuits	This value can be: • Enabled • Disabled
Ptpt Three Way HandShake Mechanism	This value can be: • Enabled • Disabled

TABLE 154 IS-IS neighbor information (Continued)

This field...	Displays...

BFD	This value can be: • Enabled • Disabled
Interfaces with IPv4 IS-IS configured	Interfaces on which IPv4 IS-IS is configured.

Displaying the IS-IS configuration in the running-config

You can display the global IS-IS configuration commands that are in effect on the PowerConnect using the following CLI method.

NOTE
The running-config does not list the default values. Only commands that change a setting or add configuration information are displayed.

To list the global IS-IS configuration commands in the PowerConnect's running-config, enter the following command at any level of the CLI.

```
NetIron# show isis config

router isis
 net  20.00e0.5200.0001.00
end
```

The running-config shown in this example contains the command that enables IS-IS and a command that configures a NET.

To display the interface configuration information in the running-config, enter one of the following commands at any level of the CLI:

- **show running-config**
- **write terminal**

Syntax: show isis config

Displaying the name mappings

To display the mappings, enter the following command at any level of the CLI.

```
NetIron# show isis hostname
Total number of entries in IS-IS Hostname Table: 1
   System ID        Hostname            * = local IS
 * bbbb.cccc.dddd   MLXe
```

Syntax: show isis hostname

The table in this example contains one mapping, for this PowerConnect. The PowerConnect's IS-IS system ID is "bbbb.cccc.dddd" and its hostname is "MLXe". The display contains one entry for each IS that supports name mapping.

NOTE
Name mapping is enabled by default. When name mapping is enabled, the output of the **show isis database**, **show isis interface**, and **show isis neighbor** commands uses the host name instead of the system ID. To disable mapping so that these displays use the system ID instead, refer to "Disabling or re-enabling display of hostname" on page 945.

Displaying neighbor information

To display IS-IS neighbor information, enter the following command at any level of the CLI.

```
NetIron# show isis neighbor
Total number of IS-IS Neighbors: 2
System ID      Interface   SNPA           State Holdtime Type Pri StateChgeTime
00e0.52b5.7800 Ether2/4    00e0.52b5.7843 UP    10       ISL2 64  0  :0 :16:8
00e0.52b5.7800 Ether2/4    00e0.52b5.7843 UP    10       ISL1 64  0  :0 :16:8
```

Syntax: show isis neighbor [detail]

The **detail** option displays more details for each neighbor.

This display shows the following information.

TABLE 155 IS-IS neighbor information

This field...	Displays...
Total number of IS-IS Neighbors	The number of ISs with which the PowerConnect has formed IS-IS adjacencies.
System ID	The System ID of the neighbor or the hostname of the neighbor.
Interface	The PowerConnect port or virtual interface attached to the neighbor.
SNPA	The Subnetwork Point of Attachment (SNPA), which is the MAC address of the PowerConnect port or virtual interface attached to the neighbor.
State	The state of the adjacency with the neighbor. The state can be one of the following: • DOWN – The adjacency is down. • INIT – The adjacency is being established and is not up yet. • UP – The adjacency is up.
Holdtime	The neighbor's advertised hold time.
Type	The IS-IS type of the adjacency. The type can be one of the following: • ISL1 – Level-1 IS • ISL2 – Level-2 IS • ES – ES **NOTE:** The PowerConnect forms a separate adjacency for each IS-IS type. Thus, if the PowerConnect has both types of IS-IS adjacencies with the neighbor, the display contains a separate row of information for each adjacency.
Pri	The priority of this IS to be elected as the Designated IS in this broadcast network.
StateChgeTime	The amount of time that has passed since the adjacency last changed state.
3-Way Handshake TLV received	
Area Address (es)	

TABLE 155 IS-IS neighbor information (Continued)

This field...	Displays...
Protocols Supported	
IP Address	
IPv6 Address	

To display IS-IS neighbor detail information, enter the following command at any level of the CLI.

```
NetIron(config-if-e10000-1/1)#show isis neighbor detail
Total number of IS-IS Neighbors: 1
System ID      Interface   SNPA           State Holdtime Type Pri StateChgeTime
NetIron            eth 1/1     0900.2b00.0005 UP    15       PTPT 127 0  :0 :0 :5
3-Way HandShake TLV received: circuit-id 1
Area Address(es): 47
 Protocols Supported: IP IPv6
 IP Address: 10.1.1.1, circuit-id 1
 IPv6 Address: fe80::200:ff:fe01:c000, circuit-id 1
```

The following table describes the contents of the example display.

TABLE 156 IS-IS neighbor information

This field...	Displays...
Total number of IS-IS Neighbors	The number of ISs with which the PowerConnect has formed IS-IS adjacencies.
System ID	The System ID of the neighbor or the hostname of the neighbor.
Interface	The PowerConnect port or virtual interface attached to the neighbor.
SNPA	The Subnetwork Point of Attachment (SNPA), which is the MAC address of the PowerConnect port or virtual interface attached to the neighbor.
State	The state of the adjacency with the neighbor. The state can be one of the following: • DOWN – The adjacency is down. • INIT – The adjacency is being established and is not up yet. • UP – The adjacency is up.
Holdtime	The neighbor's advertised hold time.
Type	The IS-IS type of the adjacency. The type can be one of the following: • ISL1 – Level-1 IS • ISL2 – Level-2 IS • ES – ES **NOTE:** The PowerConnect forms a separate adjacency for each IS-IS type. Thus, if the PowerConnect has both types of IS-IS adjacencies with the neighbor, the display contains a separate row of information for each adjacency.
Pri	The priority of this IS to be elected as the Designated IS in this broadcast network.
StateChgeTime	The amount of time that has passed since the adjacency last changed state.

Displaying IS-IS Syslog messages

When logging is enabled, the PowerConnect generates Syslog messages and SNMP traps for the following IS-IS events:

- Overload state (the PowerConnect entering or leaving the overload state)
- Memory overrun (IS-IS is demanding more memory than is available)

You also can enable the PowerConnect to generate Syslog messages and SNMP traps when an adjacency with a neighbor comes up or goes down. To enable logging of adjacency changes, refer to "Logging adjacency changes" on page 950.

To display Syslog entries, enter the following command at any level of the CLI.

```
NetIron# show logging

Syslog logging: enabled (0 messages dropped, 0 flushes, 0 overruns)
    Buffer logging: level ACDMEINW, 3 messages logged
    level code: A=alert C=critical D=debugging M=emergency E=error
                I=informational N=notification W=warning

Static Log Buffer:

Dynamic Log Buffer (50 lines):
00d00h00m42s:N:BGP Peer 192.147.202.10 UP (ESTABLISHED)
00d00h00m18s:N:ISIS L2 ADJACENCY UP 1234.1234.1234 on interface 2/8
00d00h00m08s:N:ISIS L1 ADJACENCY UP 1234.1234.1234 on interface 2/8
00d00h00m08s:N:ISIS L2 ADJACENCY UP 0000.86de.5520 on interface 5/1
00d00h00m00s:I:Warm start
```

The messages in this example indicate that the software has been reloaded (Warm start) and adjacencies between the PowerConnect and three ISs have come up.

Syntax: show logging

Displaying interface information

To display information about the PowerConnect's IS-IS interfaces, enter the **show isis** commands at any level of the CLI, as the examples in this section illustrate.

The following is an example of the **show isis interface** command for an Ethernet Interface module configured for a Circuit Type BCAST.

```
NetIron(config-if-e10000-1/1)#show isis interface
Total number of IS-IS Interfaces: 1
Interface: eth 1/1
Circuit State: UP Circuit Mode: LEVEL-1-2
Circuit Type: BCAST Passive State: FALSE
Circuit Number: 0x01, MTU: 1500
Level-1 Auth-mode: None
Level-2 Auth-mode: None
Level-1 Metric: 10, Level-1 Priority: 64
Level-1 Hello Interval: 5 Level-1 Hello Multiplier: 3
Level-1 Designated IS: mu2-01 Level-1 DIS Changes: 3
Level-2 Metric: 10, Level-2 Priority: 64
Level-2 Hello Interval: 5 Level-2 Hello Multiplier: 3
Level-2 Designated IS: mu2-01 Level-2 DIS Changes: 3
Next IS-IS LAN Level-1 Hello in 1 seconds
Next IS-IS LAN Level-2 Hello in 4 seconds
```

```
Number of active Level-1 adjacencies: 0
Number of active Level-2 adjacencies: 0
Circuit State Changes: 1 Circuit Adjacencies State Changes: 0
Rejected Adjacencies: 0
Circuit Authentication L1 failures: 0
Circuit Authentication L2 failures: 0
Bad LSPs: 0
Control Messages Sent: 63 Control Messages Received: 27
Hello Padding: Enabled
IP Enabled: TRUE
IP Addresses:
10.1.1.2/24
IPv6 Enabled: TRUE
IPv6 Addresses:
1000::1/32
IPv6 Link-Local Addresses:
fe80::200:ff:fe02:c000
MPLS TE Enabled: FALSE
```

The following is an example of the **show isis interface** command for a POS Interface module configured with a Circuit Type: PTP.

```
NetIron#show isis interface
Total number of IS-IS Interfaces: 1
Interface: eth 1/1
Circuit State: UP Circuit Mode: LEVEL-1-2
Circuit Type: PTP Passive State: FALSE
Circuit Number: 0x01, MTU: 1500
Level-1 Auth-mode: None
Level-1 Metric: 10
Level-1 Hello Interval: 5 Level-1 Hello Multiplier: 3
Level-2 Metric: 10
Circuit State Changes: 1 Circuit Adjacencies State Changes: 0
Rejected Adjacencies: 0
Circuit Authentication L1 failures: 0
Bad LSPs: 0
Control Messages Sent: 9 Control Messages Received: 1
Hello Padding: Enabled
IP Enabled: TRUE
IP Addresses:
10.1.1.2/24
IPv6 Enabled: TRUE
IPv6 Addresses:
1000::1/32
IPv6 Link-Local Addresses:
fe80::200:ff:fe02:c000
MPLS TE Enabled: FALSE
```

Syntax: show isis interface [brief | ethernet <*slot-number*>/<*port-number*> **| pos** <*slot-number*>/<*port-number*> **| loopback** <*number*> **| ve** <*number*>**]**

This display shows the following information.

TABLE 157 IS-IS interface information

This field...	Displays...
Total number of IS-IS interfaces	The number of interfaces on which IS-IS is enabled.
Interface	The port or virtual interface number to which the information listed below applies.

TABLE 157 IS-IS interface information (Continued)

This field...	Displays...
Circuit State	The state of the circuit, which can be one of the following: • DOWN • UP
Circuit Mode	The IS-IS type in use on the circuit. The mode can be one of the following: • LEVEL-1 • LEVEL-2 • LEVEL-1-2
Circuit Type	The type of IS-IS circuit running on the interface. The circuit type can be one of the following: • BCAST (broadcast). • PTP (Point-to-Point)
Passive State	The passive state determines whether the interface is allowed to form an IS-IS adjacency with the IS at the other end of the circuit. The state can be one of the following: • FALSE – The passive option is disabled. The interface can form an adjacency with the IS at the other end of the link. • TRUE – The passive option is enabled. The interface cannot form an adjacency, but can still advertise itself into the area.
Circuit Number	The ID that the instance of IS-IS running on the interface applied to the circuit between this interface and the interface at the other end of the link.
MTU	The maximum length supported for IS-IS PDUs sent on this interface.
Level-1 Auth-mode	One of the following authentication modes set for Level-1 on the router: • None • md5 • cleartext
Level-2 Auth-mode	One of the following authentication modes set for Level-2 on the router: • None • md5 • cleartext This parameter is not displayed for interfaces that are configured with a Point-to-Point circuit type. This is because separate Level-2 Hello messages are not sent on Point-to-Point interfaces. Consequently, "Hello Interval", "Hello Multiplier", and "Authentication" parameters should always be configured in the Level-1 mode for Point-to-Point interfaces.
Level-1 Metric	The default-metric value that the PowerConnect inserts in IS-IS Level-1 PDUs for this interface.
Level-1 Priority	The priority of this IS to be elected as the Designated IS for Level-1 in this broadcast network.
Level-1 Hello Interval	The number of seconds the software waits between sending Level-1 hello PDUs to the IS at the other end of the circuit.
Level-1 Hello Multiplier	The number by which the software multiplies the hello interval to calculate the hold time set in Level-1 Hello PDUs sent on the circuit.
Level-1 Designated IS	The NET of the Level-1 Designated IS.
Level-1 DIS Changes	The number of times the NET of the Level-1 Designated IS has changed.

TABLE 157 IS-IS interface information (Continued)

This field...	Displays...
Level-2 Metric	The default-metric value that the PowerConnect inserts in IS-IS Level-2 PDUs for this interface.
Level-2 Priority	The priority of this IS to be elected as the Designated IS for Level-2 in this broadcast network.
Level-2 Hello Interval	The number of seconds the software waits between sending Level-2 Hello messages to the IS at the other end of the circuit.
Level-2 Hello Multiplier	The number by which the software multiplies the hello interval to calculate the hold time set for Level-2 Hello PDUs sent on this circuit. This parameter is not displayed for interfaces that are configured with a Point-to-Point circuit type. This is because separate Level-2 Hello messages are not sent on Point-to-Point interfaces. Consequently, "Hello Interval", "Hello Multiplier", and "Authentication" parameters should always be configured in the Level-1 mode for Point-to-Point interfaces.
Level-2 Designated IS	The NET of the Level-2 Designated IS.
Level-2 DIS Changes	The number of times the NET of the Level-2 Designated IS has changed.
Next IS-IS LAN Level-1 Hello	Number of seconds before next Level-1 Hello PDU will be transmitted by the PowerConnect router.
Next IS-IS LAN Level-2 Hello	Number of seconds before next Level-2 Hello PDU will be transmitted by the PowerConnect router.
Number of active Level-1 adjacencies	The number of ISs with which this interface has an active Level-1 adjacency.
Number of active Level-2 adjacencies	The number of ISs with which this interface has an active Level-2 adjacency.
Circuit State Changes	The number of times the state of the circuit has changed.
Circuit State Adjacencies Changes	The number of times an adjacency has started or ended on this circuit.
Rejected Adjacencies	The number of adjacency attempts by other ISs rejected by the PowerConnect router.
Circuit Authentication L1 failures	The number of times the PowerConnect router rejected a circuit because the authentication did not match the authentication configured for Level-1on the PowerConnect router.
Circuit Authentication L2 failures	The number of times the PowerConnect router rejected a circuit because the authentication did not match the authentication configured for Level-2 on the PowerConnect router. This parameter is not displayed for interfaces that are configured with a Point-to-Point circuit type. This is because separate Level-2 Hello messages are not sent on Point-to-Point interfaces. Consequently, "Hello Interval", "Hello Multiplier", and "Authentication" parameters should always be configured in the Level-1 mode for Point-to-Point interfaces.
Bad LSP	The number of times the interface received a bad LSP from an IS at the other end of the circuit. The following conditions can cause an LSP to be bad: • Invalid checksum • Invalid length • Invalid lifetime value
Control Messages Sent	The number of IS-IS control PDUs sent on this interface.
Control Messages Received	The number of IS-IS control PDUs received on this interface.

TABLE 157 IS-IS interface information (Continued)

This field...	Displays...
Hello Padding:	The Hello Padding configuration, which can be: • Enabled • Disabled
IP Enabled	If set to TRUE, the IP protocol is enabled for this circuit.
IP Address and Subnet Mask	The IP address and subnet mask for this interface.
IPv6 Enabled	If set to TRUE, the IPv6 protocol is enabled for this circuit.
IPv6 Address and Subnet Mask	The IPv6 address and subnet mask for this interface.
Ipv6 Link-Local Addresses	The IPv6 link local address for this interface.
MPLS TE Enabled:	If set to TRUE, MPLS Traffic Engineering protocol is enabled for this circuit.
BFD Enabled:	If set to TRUE, BiDirectional Forwarding Detection is enabled for this circuit.

Displaying route information

To display the routes in the PowerConnect's IS-IS route table, use either of the following methods.

To display information about the routes in the PowerConnect's IS-IS route table, enter the following command at any level of the CLI.

```
NetIron# show isis routes
Total number of IS-IS routes: 173
Destination      Mask             Cost  Type Tag      Flags
1.0.0.0          255.255.255.0    21    L2   00000000 00000242
   Path: 1       Next Hop IP: 4.1.1.1          Interface: 7/1
1.0.0.0          255.255.255.255  30    L2   00000000 00000242
   Path: 1       Next Hop IP: 4.1.1.1          Interface: 7/1
1.0.0.1          255.255.255.255  30    L2   00000000 00000242
   Path: 1       Next Hop IP: 4.1.1.1          Interface: 7/1
1.0.10.0         255.255.255.0    30    L2   00000000 00000242
   Path: 1       Next Hop IP: 4.1.1.1          Interface: 7/1
```

Syntax: show isis routes [ip-address <*subnet-mask*> **| ip-address/prefix]**

You may enter **ip-address** <*subnet-mask*> or **ip-address/prefix** if you want information for a specific route.

Example

```
NetIron# show isis routes 1.0.111.0 255.255.255.0
1.0.111.0        255.255.255.0    21    L2   00000000 00000242
   Path: 1       Next Hop IP: 4.1.1.1          Interface: 7/1
```

This display shows the following information.

TABLE 158 IS-IS route information

This field...	Displays...
Total number of IS-IS routes	The total number of routes in the PowerConnect's IS-IS route table. The total includes Level-1 and Level-2 routes.
Destination	The IP destination of the route.
Mask	The subnet mask for the destination address.

TABLE 158 IS-IS route information (Continued)

This field...	Displays...
Cost	The IS-IS default metric for the route, which is the cost of using this route to reach the next-hop router to this destination.
Type	The route type, which can be one of the following: • L1 – Level-1 route • L2 – Level-2 route
Tag	The tag value associated with the route.
Path	The path number in the table. The IS-IS route table can contain multiple equal-cost paths to the same destination, in which case the paths are numbered consecutively. When IP load sharing is enabled, the PowerConnect can load balance traffic to the destination across the multiple paths.
Next Hop IP	The IP address of the next-hop interface to the destination.
Interface	The PowerConnect interface (port or virtual interface) attached to the next hop.
Flags	Values used by Dell technical support for troubleshooting.

Displaying LSP database entries

Use the following methods to display summary or detailed information about the entries in the LSP database.

NOTE
The PowerConnect maintains separate LSP databases for Level-1 LSPs and Level-2 LSPs.

Displaying summary information

To display summary information for all the LSPs in the PowerConnect's LSP databases, enter the following command at any level of the CLI.

```
NetIron)# show isis database
IS-IS Level-1 Link State Database
LSPID                 LSP Seq Num  LSP Checksum  LSP Holdtime      ATT/P/OL
MLXe-1.00-00           0x0000000c   0xd048        963               1/0/0
MLXe-1.01-00           0x00000004   0x09b0        957               0/0/0
MLXe-1.02-00           0x00000001   0xc57b        961               0/0/0
MLXe.00-00*            0x0000000b   0x23fb        1030              1/0/0

IS-IS Level-2 Link State Database
LSPID                 LSP Seq Num  LSP Checksum  LSP Holdtime      ATT/P/OL
MLXe-1.00-00           0x0000000d   0x7d97        964               1/0/0
MLXe-1.01-00           0x00000004   0x09b0        958               0/0/0
MLXe-1.02-00           0x00000001   0x200f        962               0/0/0
MLXe.00-00*            0x0000000b   0x5647        1030              1/0/0
0000.0100.0003.00-00  0x0000001f   0x761a        932               0/0/0
0000.0100.0003.00-01  0x0000001d   0x9c9d        606               0/0/0
```

The command in this example shows information for the LSPS in the PowerConnect's Level-1 and Level-2 LSP databases. Notice that the display groups the Level-1 and Level-2 LSPs separately.

Syntax: show isis database [<*lsp-id*> | **detail** | **l1** | **l2** | **level1** | **level2**]

The <*lsp-id*> parameter displays summary information about a particular LSP. Specify an LSPID for which you want to display information in HHHH.HHHH.HHHH.HH-HH format, for example, 3333.3333.3333.00-00. You can also enter name.HH-HH, for example, MLXe.00-00.

The **detail** parameter displays detailed information about the LSPs. Refer to "Displaying detailed information" on page 986.

The **l1** and **level1** parameters display the Level-1 LSPs only. You can use either parameter.

The **l2** and **level2** parameters display the Level-2 LSPs only. You can use either parameter.

The **show isis database** summary display shows the following information.

TABLE 159 IS-IS summary LSP database information

This field...	Displays...
LSPID	The LSP ID, which consists of the source ID (6 bytes), the pseudonode (1 byte), and LSPID (1 byte). **NOTE:** If the address has an asterisk (*) at the end, this indicates that the LSP is locally originated.
LSP Seq Num	The sequence number of the LSP.
LSP Checksum	The checksum calculated by the device that sent the LSP and used by the PowerConnect to verify that the LSP was not corrupted during transmission over the network.
LSP Holdtime	The maximum number of seconds during which the LSP will remain valid. **NOTE:** The IS that originates the LSP sets the timer for the LSP. As a result, LSPs do not all have the same amount of time remaining when they enter the PowerConnect's LSP database.
ATT	A 4-bit value extracted from bits 4 – 7 in the Attach field of the LSP.
P	The value in the Partition option field of the LSP. The field can have one of the following values: • 0 – The IS that sent the LSP does not support partition repair. • 1 – The IS that sent the LSP supports partition repair.
OL	The value in the LSP database overload field of the LSP. The field can have one of the following values: • 0 – The overload bit is off. • 1 – The overload bit is on, indicating that the IS that sent the LSP is overloaded and should not be used as a IS-IS transit router for that level.

Displaying detailed information

To display detailed information for all the LSPs in the PowerConnect's LSP databases, enter the following command at any level of the CLI.

```
NetIron# show isis database detail
IS-IS Level-1 Link State Database
LSPID  LSP Seq Num LSP Checksum      LSP Holdtime ATT/P/OL
MLX.00-00*    0x0000000b      0x23fb               971       1/0/0

```

TABLE 160 IS-IS detailed LSP database information

This field...	Displays...
LSPID	Refer to the description of the summary display.
LSP Seq Num	Refer to the description of the summary display.
LSP Checksum	Refer to the description of the summary display.
LSP Holdtime	Refer to the description of the summary display.
ATT or P or OL	Refer to the description of the summary display.
Area Address	The address of the area.
NLPID	The Network Layer Protocol Identifier (NLPID), which specifies the protocol the IS that sent the LSP is using. Usually, this value is "CC(IP)".
IP address	The IP address of the interface that sent the LSP. The PowerConnect can use this address as the next hop in routes to the addresses listed in the rows below.

TABLE 160 IS-IS detailed LSP database information (Continued)

This field...	Displays...

Destination addresses	The rows of information below the IP address row are the destinations advertised by the LSP. The PowerConnect can reach these destinations by using the IP address listed above as the next hop.
	Each destination entry contains the following information:
	• Metric – The value of the default metric, which is the IS-IS cost of using the IP address above as the next hop to reach this destination.
	• Device type – The device type at the destination. The type can be one of the following:
	  • End System – The device is an ES.
	  • IP-Internal – The device is an ES within the current area. The IP address and subnet mask are listed.
	  • IS – The device is another IS. The NET (NSAP address) is listed.
	  • IP-Extended – Same as IP-Internal, except the device uses the extended TLV fields described in draft-ietf-isis-traffic-02.txt to carry the information.
	  • IS-Extended – Same as IS, except the device uses the extended TLV fields described in draft-ietf-isis-traffic-02.txt to carry the information.

Flooding to <*num*> interface:	Identifies the number of interfaces on which the specific LSP entry will be flooded and identifies the interfaces.
Acking to <*num*> interface:	Identifies the number of interfaces on which the specific LSP entry will be acknowledged and identifies the interfaces.

Displaying database summary information

The following command is used to display the ISIS database.

```
NetIron# show isis database summary
IS-IS Level-1 Link State Database Summary
Number of LSPs :                    2
Number of LSPs loading :            0
Number of LSP fragments :           0
Number of Pseudo LSPs :             1
Number of Pseudo LSP fragments :    0
Number of My LSPs :                 1
Number of My LSP fragments :        0
Number of My Pseudo LSPs :          0
Number of My Pseudo LSP fragments : 0
Sum of LSPs Checksum :              0x00018004

IS-IS Level-2 Link State Database Summary

Number of LSPs :                    2
Number of LSPs loading :            0
Number of LSP fragments :           0
Number of Pseudo LSPs :             1
Number of Pseudo LSP fragments :    0
Number of My LSPs :                 1
Number of My LSP fragments :        0
```

```
Number of My Pseudo LSPs :          0
Number of My Pseudo LSP fragments : 0
Sum of LSPs Checksum :              0x00019775
```

Table 161 defines the fields shown in the above example output of the **show ip ospf interface brief** command.

TABLE 161 Output of the **show isis database summary** command

This field	Displays
Number of LSPs	Total number of LSPs in database (includes those in the loading state).
Number of LSPs loading	Number of LSPs pending a full LSP update. This value is generally non-zero during adjacency formation.
Number of LSP fragments	The number of LSPs with a non-zero LSP number (a fragment of an LSP)
Number of Pseudo LSPs	The number of pseudo LSPs.
Number of Pseudo LSP fragments	The number of pseudo LSPs with a non-zero LSP number (a fragment of an LSP).
Number of My LSPs	Total number of LSPs originated by this router.
Number of My LSP fragments	The number of LSPs originated by this router with a non-zero LSP number (a fragment of an LSP)
Number of My Pseudo LSPs	The number of pseudo LSPs originated by this router.
Number of My Pseudo LSP fragments	The number of pseudo LSPs originated by this router with a non-zero LSP number (a fragment of an LSP).
Sum of LSPs Checksum	Total checksum of all LSPs in database (including those in loading state). This number should be the same across ISIS routers during periods of network stability.

Displaying traffic statistics

The PowerConnect maintains statistics for common IS-IS PDU types. To display the statistics, use either of the following methods.

To display IS-IS PDU statistics, enter the following command at any level of the CLI.

```
NetIron# show isis traffic
                            Message Received     Message Sent
 Level-1 Hellos             1029                 115
 Level-2 Hellos             1027                 112
 Level-1 LSP                6                    3
 Level-2 LSP                6                    3
 Level-1 CSNP               0                    0
 Level-2 CSNP               0                    0
 Level-1 PSNP               107                  0
 Level-2 PSNP               107                  0
```

Syntax: show isis traffic

This display shows the following information.

TABLE 162 IS-IS traffic statistics

This field...	Displays...
Level-1 Hellos	The number of Level-1 hello PDUs sent and received by the PowerConnect.
Level-2 Hellos	The number of Level-2 hello PDUs sent and received by the PowerConnect.
Level-1 LSP	The number of Level-1 link-state PDUs sent and received by the PowerConnect.
Level-2 LSP	The number of Level-2 link-state PDUs sent and received by the PowerConnect.
Level-1 CSNP	The number of Level-1 Complete Sequence Number PDUs (CSNPs) sent and received by the PowerConnect.
Level-2 CSNP	The number of Level-2 CSNPs sent and received by the PowerConnect.
Level-1 PSNP	The number of Level-1 Partial Sequence Number PDUs (PSNPs) sent and received by the PowerConnect.
Level-2 PSNP	The number of Level-2 PSNPs sent and received by the PowerConnect.

Displaying error statistics

To display IS-IS error statistics, enter the following command at any level of the CLI.

```
NetIron# show isis counts
Area Mismatch: 0
Max Area Mismatch: 0
System ID Length Mismatch: 0
LSP Sequence Number Skipped: 0
LSP Max Sequence Number Exceeded: 0
Level-1 Database Overload: 0
Level-2 Database Overload: 0
Our LSP Purged: 0
PDU Drop Count
CSNP Auth Failures : [L1: 100] [L2: 0]
PSNP Auth Failures : [L1: 100] [L2: 0]
HELLO Auth Failures : [L1: 100] [L2: 0]
Adjacency not found : [L1: 100] [L2: 200]
Adjacency Level Mismatch : [L1: 100] [L2: 200]
IS Level Mismatch : [L1: 100] [L2: 200]
Length Too Short : [L1: 100] [L2: 200]
Length Too Large : [L1: 100] [L2: 200]
Max Area Check Failure : [L1: 100] [L2: 200]
Zero Checksum : [L1: 100] [L2: 200]
Checksum Mismatch : [L1: 100] [L2: 200]
Invalid Length : [L1: 100] [L2: 200]
```

Syntax: show isis counts

This display shows the following information.

TABLE 163 IS-IS error statistics

This field...	Displays...
Area Mismatch	The number of times the PowerConnect interface was unable to create a Level-1 adjacency with a neighbor because the PowerConnect interface and the neighbor did not have any areas in common.
Max Area Mismatch	The number of times the PowerConnect received a PDU whose value for maximum number of area addresses did not match the PowerConnect's value for maximum number of area addresses.
System ID Length Mismatch	The number of times the PowerConnect received a PDU whose ID field was a different length than the ID field length configured on the PowerConnect.
LSP Sequence Number Skipped	The number of times the PowerConnect received an LSP with a sequence number that was more than 1 higher than the sequence number of the previous LSP received from the same neighbor.
LSP Max Sequence Number Exceeded	The number of times the PowerConnect attempted to set an LSP sequence number to a value higher than the highest number in the CSNP sent by the Designated IS.
Level-1 Database Overload	The number of times the Level-1 state on the PowerConnect changed from Waiting to On or from On to Waiting. • Waiting to On – This change can occur when the PowerConnect recovers from a previous Level-1 LSP database overload and is again ready to receive new LSPs. • On to Waiting – This change can occur when the PowerConnect's Level-1 LSP database is full and the PowerConnect receives an additional LSP, for which there is no room.
Level-2 Database Overload	The number of times the Level-2 state on the PowerConnect changed from Waiting to On or from On to Waiting. • The change from Waiting to On can occur when the PowerConnect recovers from a previous Level-2 LSP database overload and is again ready to receive new LSPs. • The change from On to Waiting can occur when the PowerConnect's Level-2 LSP database is full and the PowerConnect receives an additional LSP, for which there is no room.
Our LSP Purged	The number of times the PowerConnect received an LSP that was originated by the PowerConnect itself and had age zero (aged out).
PDU Drop Count	
CSNP Auth Failures	The number of CSNP Authentication failures recorded for Level-1 and Level-2. This counter will only be displayed if it has a value greater than zero.
PSNP Auth Failures	The number of PSNP Authentication failures recorded for Level-1 and Level-2. This counter appears only if it has a value greater than 0.
HELLO Auth Failures	The number of HELLO Authentication failures recorded for Level-1 and Level-2. This counter will only be displayed if it has a value greater than zero.
Adjacency not found	The number of PDUs dropped at both Level-1 and Level-2 because there is no valid adjacency on the interface where they were received. This counter will only be displayed if it has a value greater than zero.

TABLE 163 IS-IS error statistics (Continued)

This field...	Displays...
Adjacency Level Mismatch	The number of PDUs dropped at both Level-1 and Level-2 because the adjacency from which the PDU is received has a different level than the PDU level. This counter will only be displayed if it has a value greater than zero.
IS Level Mismatch	The number of PDUs dropped at both Level-1 and Level-2 because the IS-IS router level mismatches with the PDU level received. This counter will only be displayed if it has a value greater than zero.
Length Too Short	The number of PDUs dropped at both Level-1 and Level-2 because the received PDU length is less than the standard PDU header length. This counter will only be displayed if it has a value greater than zero.
Length Too Long	The number of PDUs dropped at both Level-1 and Level-2 because the received PDU length is greater than the MTU of the link. This counter will only be displayed if it has a value greater than zero.
Max Area Check Failure	The number of PDUs dropped at both Level-1 and Level-2 because the received PDU has a maximum area count different than what is configured on this IS-IS router. This counter will only be displayed if it has a value greater than zero.
Zero Checksum	The number of PDUs dropped at both Level-1 and Level-2 because the received PDU has a zero checksum. This counter will only be displayed if it has a value greater than zero.
Checksum Mismatch	The number of PDUs dropped at both Level-1 and Level-2 because the received PDU has a checksum different than the computed checksum on the received PDU. This counter will only be displayed if it has a value greater than zero.
Invalid Length	The number of PDUs dropped at both Level-1 and Level-2 because the received PDU has a different length than what is advertised in the PDU header. This counter will only be displayed if it has a value greater than zero.

Displaying the IS-IS SPF Log

The **show isis spf-log** command displays the ISIS Log, as shown in the following.

```
NetIron#show isis spf-log detail
ISIS Level-1 SPF Log
When      Duration  Nodes  Count  Last-Trigger-LSP         Trigger
0h1m57s   0         3      2      mu1.00-00                Adjacency Change
 Ipv4 Route updates: 4000 Ipv6 Route updates: 0
     First Trigger: 0h1m45s       Adj TLV Changed in LSP mu2.00-00
     Last Trigger : 0h1m45s       Adj TLV Changed in LSP mu1.00-00

```

Syntax: show isis spf-log {detail | level-1 [detail] | level-2 [detail] }

This display shows the following information.

TABLE 164 IS-IS SPF log information

This field...	Displays...
When	When (in hours: minutes : seconds) a full SPF calculation occurred. The last 20 occurrences are logged.
Duration	The time required to complete this SPF run, Elapsed time is normal clock time (not CPU time). Other options for this field are: • Running – the SPF is still running and the duration will be updated after the SFP has run. • Pending – the event is pending and another SPF will be run once the currently executing SPF has completed.
Nodes	The number of routers and pseudonodes (LANs) that make up the topology calculated in this SPF run.
Count	The number of events that triggered this SPF run. When a topology change has occurred, multiple link-state packets (LSPs) are received in a short time. Since a router waits about 5 seconds before running a full SPF run, it can include all new information. This count includes the number of events (such as receiving new LSPs) that occurred while the router was waiting the 5 second interval before running full SPF.

TABLE 164 IS-IS SPF log information (Continued)

This field...	Displays...
Last Trigger LSP	When a full SPF calculation is triggered by the arrival of a new LSP, the router stores the LSP ID. The LSP ID can provide a clue about the source of routing instability in an area. If multiple LSPs in a single level are causing SPF runs, only the LSP ID of the last received LSP is recorded.
Triggers	The reason that a full SPF calculations was triggered. Table 165 describes each of the triggers that can be displayed in this field.

For a description of the trigger types, refer to the following table.

TABLE 165 Trigger types and description

Trigger	Description
Alternate Route Check	PSPF deleted an IPv4 or IPv6 route. Full SPF must run to find the alternate route.
Route Change in L1 SPF Run	The L1 SPF run added or deleted an IPv4 or IPv6 route. The L2 SPF must run to accommodate this change.
LSP Purged	An LSP was purged. A full SPF calculation must process this change.
LSP Added	A new LSP has appeared in the database. A full SPF calculation is needed to process this new LSP.
Summary Address Change	A summary address configuration change has occurred.
Adjacency State Change	An adjacency was added or deleted.
Admin Distance Change	The administrative distance configuration has changed.
LSP Header Change	The LSP header (attached or overload bits) is changed.
IS Neighbor TLV Change	An IS neighbor TLV was added or deleted in an LSP.
Area Address TLV Change	The area address TLV changed.
Interface IP Address Change	The IP address configuration changed.
IP Address TLV Change	An IP address TLV changed in the LSP.
IPv6 Address TLV Change	An IPv6 address TLV changed in the LSP.
IS-IS Level Change	The IS-IS level configuration changed.
Interface Metric Change	The IS-IS interface metric configuration changed.
LSP Changed - PSPF Disabled	The LSP changed and PSPF is disabled.
LSP Overload Bit Change	The overload bit in the LSP header changed.
Interface State Change	The interface state changed to up or down.
Redist Prefix-List Change	The redistribution list configuration changed.
Redist Policy Change	The redistribution policy configuration changed.
Maximum Path Change	The IS-IS maximum path configuration changed.
IP Load Sharing Change	The IP load sharing configuration changed.
User Cleared IS-IS Route	The user cleared a specific IS-IS route.
User Cleared IS-IS Routes	The user cleared all IS-IS routes.
Neighbor NLPID Change	NLPID set is changed in received hellos.
ISIS Enable	IS-IS was enabled.

TABLE 165 Trigger types and description (Continued)

Trigger	Description
User Cleared IS-IS All	The user issued the **clear isis all** command.
Interface Config Change	ISIS was enabled or disabled on a port.
User Trigger	The user issued the **clear isis spf-trigger** command.
Recompute InterLeve Routes	The neighbor IS-type is changed either from L1 to L12 or L12 to L1
Exited Overload State	IS-IS exited from an overload condition.

By using the **detail** option with the **show isis spf-log** command, you can display more detail about the total number of IPv4 and IPv6 route updates and the reason for the first and last SPF events. Like SPF events, the incremental SPF events are displayed. However, for incremental SPF, only the first trigger is displayed, as the example below illustrates. In addition, the logging changes include the number of RTM updates that were carried out in each SPF or incremental SPF run.

To show details about the RTM updates, use the **show isis spf-log detail** command, as follows.

```
NetIron#show isis spf-log detail
ISIS Level-2 SPF Log
 When     Duration Nodes Count Last-Trigger-LSP     Trigger

2h38m9s   0ms      3     2     MLXe14.00-00          Adjacency State Change
 Ipv4 Route updates: 4000 Ipv6 Route updates: 0
       First Trigger: 2h39m23s loopback 1 State Changed to Up
       Last Trigger : 2h38m14s Adjacency 0000.1100.0001 Added
2h41m17s 0ms       26    1     MLXe14.00-00          IS Neighbor TLV Change
 Ipv4 Route updates: 1 Ipv6 Route updates: 0
       First Trigger: 2h41m2s ISPF Run
```

Syntax: show isis spf-log detail

Clearing the IS-IS SPF Log

You can clear the IS-IS SPF Log accumulated since the last software reload or last clearing of the SPF Log through use of the following command.

```
NetIron# isis clear spf-log
```

Syntax: clear isis spf-log [level-1 | level-2]

When the **level-1** or **level-2** options are used, only the log for the specified level is cleared. If not specified, both will be cleared.

Triggering the router to run SPF

You can trigger the router to run the SPF calculations through use of the following command.

```
NetIron# clear isis spf-trigger
```

Syntax: clear isis spf-trigger [level-1 | level-2]

When the **level-1** or **level-2** options are used, the SPF calculation is only triggered for the specified level. If not specified, the SPF calculation will be triggered for both.

Clearing IS-IS information

To clear the IS-IS information that the PowerConnect has accumulated since the last time you cleared information or reloaded the software, use either of the following methods.

To clear IS-IS information, enter the **clear isis all** command at any level of the CLI except the User EXEC level.

```
NetIron# clear isis all
```

This command clears all the following:

- Neighbors (closes the PowerConnect's adjacencies with its IS-IS neighbors)
- Routes
- PDU statistics
- Error statistics

Syntax: **clear isis all | counts | neighbor | route** [<*ip-address*> <*subnet-mask*> **|** <*ip-address*>/<*prefix*>] **| traffic**

The **all** parameter clears all the IS-IS information. Using this option is equivalent to entering separate commands with each of the other options.

The **counts** parameter clears the error statistics.

The **neighbor** parameter closes the PowerConnect's adjacencies with its IS-IS neighbors and clears neighbor statistics.

The **route** [<*ip-address*> <*subnet-mask*> | <*ip-address*>/<*prefix*>] parameter clears the IS-IS route table or the specified matching route.

The **traffic** parameter clears the PDU statistics.

NOTE
The **traffic** option also clears the values displayed in the **show isis interface** command's Control Messages Sent and Control Messages Received fields.

The **neighbor** option of the **clear isis** command has been enhanced as described in the following:

Syntax: **clear isis neighbor all [ethernet** <*slot/port*> **| pos** <*slot/port*> **| tunnel** <*tunnel-id*> **| ve** <*port-number*>]

The **all** option directs the router to clear all neighbors on all IS-IS interfaces or clear all neighbors on an interface specified using one of the following options:

ethernet <*slot/port*> – clears all IS-IS neighbors on the specified Ethernet interface.

pos <*slot/port*> – clears all IS-IS neighbors on the specified POS interface.

ve <*port-no*> – clears all IS-IS neighbors on the specified virtual interface.

tunnel <*tunnel-port*> – clears all IS-IS neighbors on the specified tunnel interface.

Syntax: **clear isis neighbor** <*sys-id*> **[ethernet** <*slot/port*> **| pos** <*slot/port*> **| tunnel** <*tunnel-id*> **| ve** <*port-number*>]

This command directs the router to clear the IS-IS neighbor specified by the <*sys-id*> variable on all possible interfaces or to clear the IS-IS neighbor specified by the <*sys-id*> variable on an interface specified using one of the following options:

ethernet <*slot/port*> – clears the specified IS-IS neighbor on the specified Ethernet interface.

pos <*slot/port*> – clears the specified IS-IS neighbor on the specified POS interface.

ve <*port-no*> – clears the specified IS-IS neighbor on the specified virtual interface.

tunnel <*tunnel-port*> – clears the specified IS-IS neighbor on the specified tunnel interface.

Clearing a specified LSP from IS-IS database

A new command has been added that allows you to clear a specified LSP from the IS-IS database. Running this command causes the regeneration of the specified LSP where this LSP was originated by this router. For example, to clear the LSP named "MLXe-1.00-00" from the IS-IS database, enter the following command.

```
NetIron# clear isis database MLXe-1.00-00
```

Syntax: clear isis database <*lsp-id*> **[level-1 | level-2 | level-1-2]**

The <*lsp-id*> parameter displays summary information about a particular LSP. Specify an LSPID for which you want to display information in HHHH.HHHH.HHHH.HH-HH format, for example, 3333.3333.3333.00-00. You can also enter name.HH-HH, for example, MLXe.00-00.

The **level-1**parameter limits you to clear level-1 LSPs only.

The **level-2** parameter limits you to clear level-2 LSPs only.

The **level-1-2** parameter clears level-1 and level-2 LSPs. This is the default.

NOTE
The **clear isis all** command should be used to regenerate the complete database.

Configuring BGP4 (IPv4) 26

Overview

The following displays the BGP4 features supported by PowerConnect B-MLXe.

- BGP4
- BGP4 Restart
- BGP4 Restart Helper Mode
- Redistributing IBGP Routes
- Client-to-Client Routes
- Route Flap Dampening
- Originating the Default Route
- Multipath Load Sharing
- Using the IP Default Route as a Valid Next Hop for a BGP4 Route
- Next-Hop Recursion
- Next-Hop Update Timer
- Generalized TTL Security Mechanism Support
- Enhanced per-neighbor debug statements and new per-neighbor BGP4 debug filters
- BGP4 Peer Notification During a Management Module Switchover
- Auto Shutdown of BGP4 Neighbors on Initial Configuration
- New encryption code for passwords, authentication keys, and community strings
- BGP4 MD5 Authentication
- Route redistribution to other protocols
- BGP4 Peer Group
- BGP4 Route Reflectors
- BGP4 Neighbor Local-AS
- BGP4 Processing Optimization for Administratively Down Peers
- BGP4 Outbound Policy Processing Optimization
- Generalized TTL Security Mechanism Support
- Enhanced per-neighbor debug statements and new per-neighbor BGP4 debug filters
- Requiring the First AS to be the Neighbor's AS
- Four-byte AS Numbers (AS4)
- BGP4 AS4 Confederation Error Checking
- RTM Scalability Enhancement
- Route Map Continue Clause
- Static BGP4 Networks

- Limiting Advertisement of a Static BGP4 Network
- Use IGP cost instead of BGP MED value

This chapter provides details on how to configure Border Gateway Protocol version 4 (BGP4).

NOTE
BGP4 commands that are supported in IPv4 are listed in Table 166.

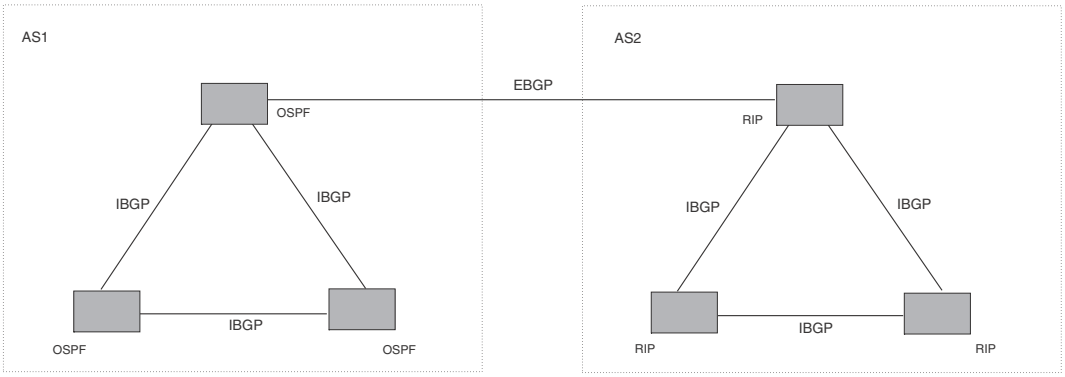
Overview of BGP4

BGP4 is the standard Exterior Gateway Protocol (EGP) used on the Internet to route traffic between Autonomous Systems (AS) and to maintain loop-free routing. An autonomous system is a collection of networks that share the same routing and administration characteristics. For example, a corporate Intranet consisting of several networks under common administrative control might be considered an AS. The networks in an AS can but do not need to run the same routing protocol to be in the same AS, nor do they need to be geographically close.

Devices within an AS can use different Interior Gateway Protocols (IGPs) such as RIP and OSPF to communicate with one another. However, for devices in different ASs to communicate, they need to use an EGP. BGP4 is the standard EGP used by Internet devices and therefore is the EGP implemented on the device.

Figure 146 shows a simple example of two BGP4 ASs. Each AS contains three BGP4 devices. All of the BGP4 devices within an AS communicate using IBGP. BGP4 devices communicate with other ASs using EBGP. Notice that each of the devices also is running an Interior Gateway Protocol (IGP). The devices in AS1 are running OSPF and the devices in AS2 are running RIP. The device can be configured to redistribute routes among BGP4, ISIS, RIP, and OSPF. They also can redistribute static routes.

FIGURE 146 Example BGP4 ASs



Relationship between the BGP4 route table and the IP route table

The device BGP4 route table can have multiple routes or paths to the same destination, which are learned from different BGP4 neighbors. A BGP4 neighbor is another device that also is running BGP4. BGP4 neighbors communicate using Transmission Control Protocol (TCP) port 179 for BGP4 communication. When you configure the device for BGP4, one of the configuration tasks you perform is to identify the device's BGP4 neighbors.

Although a device's BGP4 route table can have multiple routes to the same destination, the BGP4 protocol evaluates the routes and chooses only one of the routes to send to the IP route table. The route that BGP4 chooses and sends to the IP route table is the ***preferred route.*** This route is what the device advertises to other BGP4 neighbors. If the preferred route goes down, BGP4 updates the route information in the IP route table with a new BGP4 preferred route.

NOTE
If IP load sharing is enabled and you enable multiple equal-cost paths for BGP4, BGP4 can select more than one equal-cost path to a destination.

A BGP4 route consists of the following information:

- **Network number (prefix)** – A value comprised of the network mask bits and an IP address (*<IP address>/ <mask bits>*); for example, 192.215.129.0/18 indicates a network mask of 18 bits applied to the IP address 192.215.129.0. When a BGP4 device advertises a route to one of its neighbors, it uses this format.
- **AS-path** – A list of the other ASs through which a route passes. BGP4 devices can use the AS-path to detect and eliminate routing loops. For example, if a route received by a BGP4 device contains the AS that the device is in, the device does not add the route to its own BGP4 table. (The BGP4 RFCs refer to the AS-path as "AS_PATH", and RFC 4893 uses "AS4_PATH" in relation to AS4s.)
- **Additional path attributes** – A list of additional parameters that describe the route. The route MED and next hop are examples of these additional path attributes.

NOTE
The device re-advertises a learned best BGP4 route to the device's neighbors even when the route table manager does not select that route for installation in the IP route table. This can happen if a route from another protocol, for example, OSPF, is preferred. The best BGP4 route is the route that BGP4 selects based on comparison of the BGP4 route path's attributes.

After a device successfully negotiates a BGP4 session with a neighbor (a BGP4 peer), the device exchanges complete BGP4 route tables with the neighbor. After this initial exchange, the device and all other RFC 1771-compliant BGP4 devices send UPDATE messages to inform neighbors of new, changed, or no longer feasible routes. BGP4 devices do not send regular updates. However, if configured to do so, a BGP4 device does regularly send KEEPALIVE messages to its peers to maintain BGP4 sessions with them if the device does not have any route information to send in an UPDATE message. Refer to "BGP4 message types" on page 1001 for information about BGP4 messages.

How BGP4 selects a path for a route

When multiple paths for the same route prefix are known to a BGP4 device, the device uses the following algorithm to weigh the paths and determine the optimal path for the route. The optimal path depends on various parameters, which can be modified.

1. Is the next hop accessible though an Interior Gateway Protocol (IGP) route? If not, ignore the route.

NOTE
By default, the device does not use the default route to resolve BGP4 next hop. Refer to "Enabling next-hop recursion" on page 1051 and "Using the IP default route as a valid next-hop for a BGP4 route" on page 1051.

2. Use the path with the largest weight.
3. If the weights are the same, prefer the path with the largest local preference.
4. Prefer the route that was originated locally (by this device).
5. If the local preferences are the same, prefer the path with the shortest AS-path. An AS-SET counts as 1. A confederation path length, if present, is not counted as part of the path length.

NOTE
This step can be skipped if **BGP4-as-path-ignore** is configured.

6. If the AS-path lengths are the same, prefer the path with the lowest origin type. From low to high, route origin types are valued as follows:
   - IGP is lowest.
   - EGP is higher than IGP but lower than INCOMPLETE.
   - INCOMPLETE is highest.
7. If the paths have the same origin type, prefer the path with the lowest MED. For a definition of MED, refer to "Configuring the device to always compare Multi-Exit Discriminators" on page 1014".
   - device compares the MEDs of two otherwise equivalent paths ***if and only if*** the routes were learned from the same neighboring AS. This behavior is called ***deterministic MED***. Deterministic MED is always enabled and cannot be disabled.

     You can also enable the device to always compare the MEDs, regardless of the AS information in the paths. To enable this comparison, enter the **always-compare-med** command at the BGP4 configuration level of the CLI. This option is disabled by default.

NOTE
By default, value 0 (most favorable) is used in MED comparison when the MED attribute is not present. The default MED comparison results in the device favoring the route paths that are missing their MEDs. You can use the **med-missing-as-worst** command to make the device regard a BGP4 route with a missing MED attribute as the least favorable path, when comparing the MEDs of the route paths.

NOTE
MED comparison is not performed for internal routes originated within the local AS or confederation unless the **compare-med-empty-aspath** command is configured.

8. Prefer paths in the following order:
    - Routes received through EBGP from a BGP4 neighbor outside of the confederation
    - Routes received through EBGP from a BGP4 device within the confederation
    - Routes received through IBGP
9. If all the comparisons above are equal, prefer the route with the lowest IGP metric to the BGP4 next hop. This is the closest internal path inside the AS to reach the destination.
10. If the internal paths also are the same and BGP4 load sharing is enabled, load share among the paths. Otherwise go to step 11.

NOTE
The device supports BGP4 load sharing among multiple equal-cost paths. BGP4 load sharing enables the device to balance traffic across the multiple paths instead of choosing just one path based on device ID. For EBGP routes, load sharing applies only when the paths are from neighbors within the same remote AS. EBGP paths from neighbors in different ASs are not compared, unless multipath **multi-as** is enabled.

11. If **compare-router ID** is enabled, prefer the path that comes from the BGP4 device with the lowest device ID. If a path contains originator ID attributes, then originator ID is substituted for the ROUTER ID in the decision.
12. Prefer the path with the minimum cluster list length.
13. If the route is a BGP4 VRF instance, prefer the route with the smallest RD value.
14. Prefer the route that comes from the lowest BGP4 neighbor address.

BGP4 message types

BGP4 devices communicate with neighbors (other BGP4 devices) using the following types of messages:

- OPEN
- UPDATE
- KEEPALIVE
- NOTIFICATION
- ROUTE REFRESH

OPEN message

After a BGP4 device establishes a TCP connection with a neighboring BGP4 device, the devices exchange OPEN messages. An open message indicates the following:

- **BGP4 version** – Indicates the version of the protocol that is in use on the device. BGP4 version 4 supports Classless Interdomain Routing (CIDR) and is the version most widely used in the Internet. Version 4 also is the only version supported on the device.
- **AS number** – An autonomous system number (ASN) identifies the AS to which the BGP4 device belongs. The number can be up to four bytes.

Hold Time – The number of seconds a BGP4 device will wait for an UPDATE or KEEPALIVE message (described below) from a BGP4 neighbor before assuming that the neighbor is not operational. BGP4 devices exchange UPDATE and KEEPALIVE messages to update route information and maintain communication. If BGP4 neighbors are using different Hold Times, the lowest Hold Time is used by the neighbors. If the Hold Time expires, the BGP4 device closes the TCP connection to the neighbor and clears any information it has learned and cached from the neighbor.

You can configure the Hold Time to be 0, in which case a BGP4 device will consider neighbors to always be up. For directly-attached neighbors, you can configure the device to immediately close the TCP connection to the neighbor and clear entries learned from an EBGP neighbor if the interface to that neighbor goes down. This capability is provided by the fast external fail over feature, which is disabled by default.

- **BGP4 Identifier** – The device ID. The BGP4 Identifier (device ID) identifies the BGP4 device to other BGP4 devices. The device use the same device ID for OSPF and BGP4. If you do not set a device ID, the software uses the IP address on the lowest numbered loopback interface configured on the device. If the device does not have a loopback interface, the default device ID is the lowest numbered IP address configured on the device. For more information, or to change the device ID, refer to "Changing the router ID" on page 684.
- **Parameter list** – An optional list of additional parameters used in peer negotiation with BGP4 neighbors.

UPDATE message

After BGP4 neighbors establish a BGP4 connection over TCP and exchange their BGP4 routing tables, they do not send periodic routing updates. Instead, a BGP4 neighbor sends an update to a neighbor when it has a new route to advertise or routes have changed or become unfeasible. An UPDATE message can contain the following information:

- **Network Layer Reachability Information (NLRI)** – The mechanism by which BGP4 supports Classless Interdomain Routing (CIDR). An NLRI entry consists of an IP prefix that indicates a network being advertised by the UPDATE message. The prefix consists of an IP network number and the length of the network portion of the number. For example, an UPDATE message with the NLRI entry 192.215.129.0/18 indicates a route to IP network 192.215.129.0 with network mask 255.255.192.0. The binary equivalent of this mask is 18 consecutive one bits, thus "18" in the NLRI entry.
- **Path attributes** – Parameters that indicate route-specific information such as AS path information, route preference, next hop values, and aggregation information. BGP4 uses path attributes to make filtering and routing decisions.
- **Unreachable routes** – A list of routes that have been in the sending device BGP4 table but are no longer feasible. The UPDATE message lists unreachable routes in the same format as new routes: *<IP address>/<CIDR prefix>*.

KEEPALIVE message

BGP4 devices do not regularly exchange UPDATE messages to maintain BGP4 sessions. For example, if a device configured to perform BGP4 routing has already sent the latest route information to peers in UPDATE messages, the device does not send more UPDATE messages. Instead, BGP4 devices send KEEPALIVE messages to maintain BGP4 sessions. KEEPALIVE messages are 19 bytes long and consist only of a message header. They do not contain routing data.

BGP4 devices send KEEPALIVE messages at a regular interval, called the Keep Alive Time. The default Keep Alive Time is 60 seconds.

A parameter related to the Keep Alive Time is the Hold Time. The Hold Time for a BGP4 device determines how many seconds the device waits for a KEEPALIVE or UPDATE message from a BGP4 neighbor before deciding that the neighbor is not operational. The Hold Time is negotiated when BGP4 devices exchange OPEN messages, the lower Hold Time is then used by both neighbors. For example, if BGP4 device A sends a Hold Time of 5 seconds and BGP4 device B sends a Hold Time of 4 seconds, both devices use 4 seconds as the Hold Time for their BGP4 session. The default Hold Time is 180 seconds. Generally, the Hold Time is configured to three times the value of the Keep Alive Time.

If the Hold Time is 0, a BGP4 device assumes that a neighbor is alive regardless of how many seconds pass between receipt of UPDATE or KEEPALIVE messages.

NOTIFICATION message

When you close the BGP4 session with a neighbor, the device detects an error in a message received from the neighbor, or an error occurs on the device, the device sends a NOTIFICATION message to the neighbor. No further communication takes place between the BGP4 device that sent the NOTIFICATION and the neighbors that received the NOTIFICATION.

REFRESH message

BGP4 sends a REFRESH message to a neighbor to request that the neighbor resend route updates. This type of message can be useful if an inbound route filtering policy has been changed.

Implementation of BGP4

BGP4 is described in RFC 1771 and the latest BGP4 drafts. The implementation fully complies with RFC 1771 and supports the following:

- RFC 1745 (OSPF Interactions)
- RFC 1997 (BGP4 Communities Attributes)
- RFC 2385 (TCP MD5 Signature Option)
- RFC 2439 (Route Flap Dampening)
- RFC 4456 (Route Reflection)
- RFC 2842 and 3392 (Capability Advertisement)
- RFC 3065 (BGP4 Confederations)
- RFC 2858 (Multiprotocol Extensions)
- RFC 2918 (Route Refresh Capability)
- RFC 3392 (BGP4 Capability Advertisement)
- Draft-ietf-idr-restart-10.txt (restart mechanism for BGP4)

Memory considerations

BGP4 can handle a very large number of routes and therefore requires a lot of memory. For example, in a typical configuration with a single BGP4 neighbor, a BGP4 device may need to hold up to 150,000 routes. Many configurations, especially those involving more than one neighbor, can require the device to hold even more routes. The device provides dynamic memory allocation for BGP4 data. BGP4 devices automatically allocate memory when needed to support BGP4 neighbors, routes, and route attribute entries. Dynamic memory allocation is performed automatically by the software and does not require a reload.

As a guideline, a device with a 2 GB Management 4 module can accommodate 150 – 200 neighbors, with the assumption that the device receives about one million routes total from all neighbors, and sends about eight million routes total to neighbors. For each additional one million incoming routes, the capacity for outgoing routes decreases by about two million.

Grouping of RIB-out peers

To improve efficiency in the calculation of outbound route filters, the device groups BGP4 peers together based on their outbound policies. To reduce RIB-out memory usage, the device then groups the peers within an outbound policy group according to their RIB-out routes. All peers sharing a single RIB-out route (up to 32 peers per group) also share a single physical RIB-out entry, resulting in as much as a 30-fold memory usage reduction.

NOTE
RIB-out peer grouping is not shared between different VRFs or address families, and is not supported for VPNV4 or L2VPN peers.

BGP4 Restart

The Restart feature supports high-availability routing. With this feature enabled, disruptions in forwarding are minimized and route flapping is diminished to provide continuous service during the time that a device is performing a restart.

Under normal operation, restarting a BGP4 device causes the network to be reconfigured. In this situation, routes available through the restarting device are first deleted when the device goes down, and are then rediscovered and added back to the routing tables when the device is back up and running. In a network with devices that regularly restart, performance can degrade significantly and limit availability of network resources. BGP4 restart dampens the network response and limits route flapping by allowing routes to remain available between devices during a restart. BGP4 Restart operates between a device and peers, and must be configured on each participating device.

A BGP4 device with Restart enabled advertises this capability to establish peering relationships with other devices. After a restart begins, all of the routes from the restarting device are marked as stale by neighbor devices, but continue to be used for the length of time configured for the restart timer. After the device is restarted, it begins to receive routing updates from the peers. When the restarting device receives the end-of-RIB marker that indicates it has received all of the BGP4 route updates, all of the routes are recomputed and newly computed routes replace the routes labeled as stale in the route map. If the device does not come back up within the time configured for the purge timer, the routes marked stale are removed.

NOTE
A second management module must be installed for the device to function as a restart device. If the device functions as a restart helper device only, there is no requirement for a secondary management module.

The implementation of BGP4 Restart supports the following Internet Draft:

- Draft-ietf-idr-restart-10.txt: restart mechanism for BGP4

For details concerning configuration of the BGP4 Restart feature, refer to "Configuring BGP4 Restart" on page 1098.

BGP4 Peer notification during a management module switchover

The BGP4 Peer notification process restores BGP4 adjacency quickly and allows packet forwarding between the newly active management module and the BGP4 peers. The handling of TCP packets with an MD5 digest prevents the silent dropping of TCP packets without triggering a RESET packet.

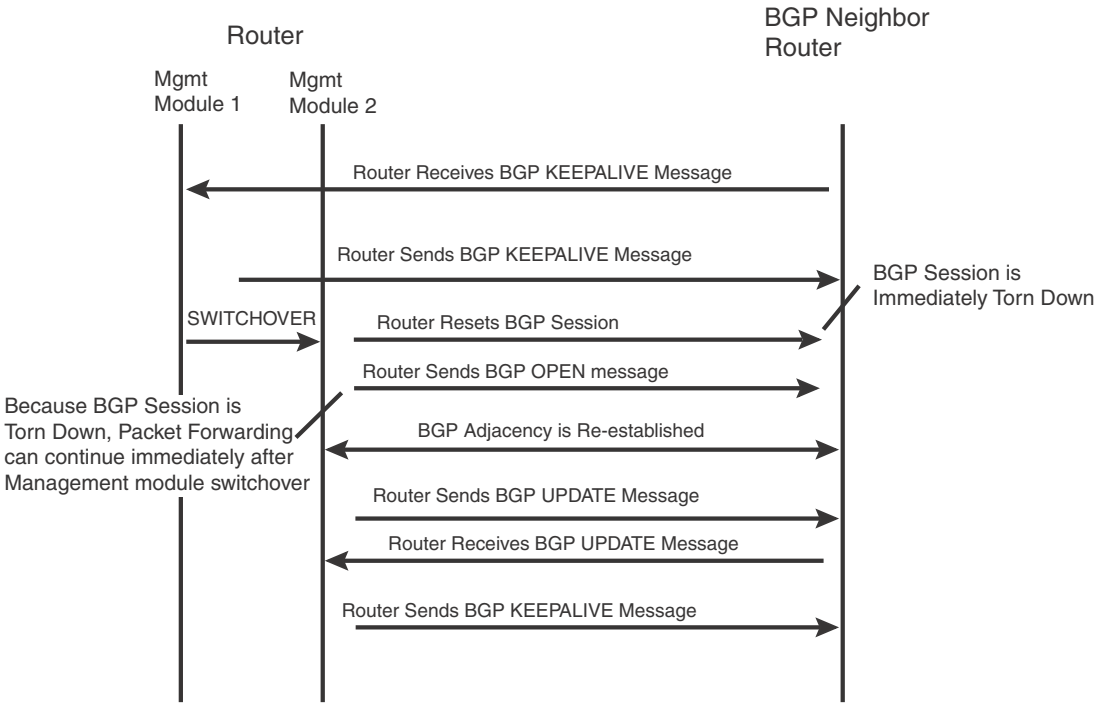
The BGP4 peer notification process operates effectively when implemented for the following processes that involve the intentional switching of the active status from one management module to another:

- **System Reload** – When a device undergoes the reload process, both management modules and all interface modules are rebooted. All BGP4 sessions are terminated BEFORE the system triggers the hardware reset.
- **Switchover Requested by User** – Switching over to a standby management module can be triggered by the **switchover**, **reset**, **reload**, and **hitless-reload** commands. When these commands are executed, the active management module resets the BGP4/TCP sessions with BGP4 neighbors before transferring control to the standby management module.

NOTE
Graceful-restart-enabled BGP4 sessions are not reset. The BGP4 graceful-restart protocol allows a BGP4 session to reconnect gracefully without going through the normal process.

Figure 147 describes the procedure used between the management modules in a device and a BGP4 neighbor device.

FIGURE 147 Management module switchover behavior for BGP4 peer notification



If the active management module fails due to a fault, the management module does not have the opportunity to reset BGP4 sessions with neighbors as described for intentional failovers, and illustrated in Figure 147. In this situation the management module will reboot, or the standby management module becomes the new active management module. Since the new active management module does not have the TCP/BGP4 information needed to reset the previous sessions, a remote BGP4 peer session is only reset when it sends a BGP4/TCP keep-alive packet to this device, or when the BGP4 hold-time expires.

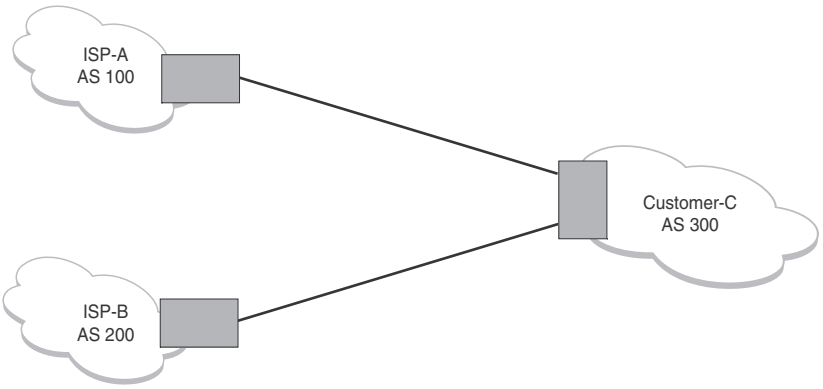
To help reduce the reconnection time after a management module failover or system reload, if an incoming TCP packet contains an MD5 digest, and no matching TCP session is found, the device attempts to find a matching BGP4 peer based on the IP address. If a BGP4 peer configuration can be found, the device looks up the MD5 password configured for the peer, and uses it to send a RESET packet.

BGP4 neighbor local AS

This feature allows you to configure a device so that it adds a peer to an AS that is different from the AS to which it actually belongs. This feature is useful when an ISP is acquired by another ISP. In this situation, customers of the acquired ISP might not want to (or might not be able to) adjust their configuration to connect to the AS of the acquiring provider.

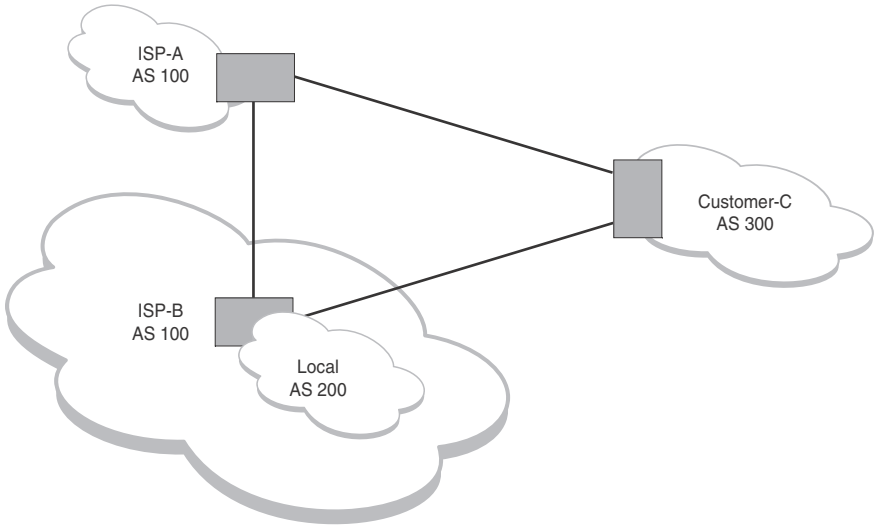
For example in Figure 168, Customer C is connected to ISP-A which is in AS 100 and ISP-B which is in AS 200.

FIGURE 148 Example of customer connected to two ISPs



In the example shown in Figure 149, ISP-A has purchased ISP-B. The AS associated with ISP-B changes to AS 100. If Customer C cannot or does not want to change their configuration or peering relationship with ISP-B, a peer with Local-AS configured with the value 200 can be established on ISP-B.

FIGURE 149 Example of Local AS configured on ISP-B



A Local AS is configured using the BGP4 **neighbor** command, as described in "Configuring BGP4 neighbors" on page 1037. To confirm that a Local AS has been configured use the **show ip BGP4 neighbor** command, as described in "Displaying BGP4 neighbor information" on page 1109.

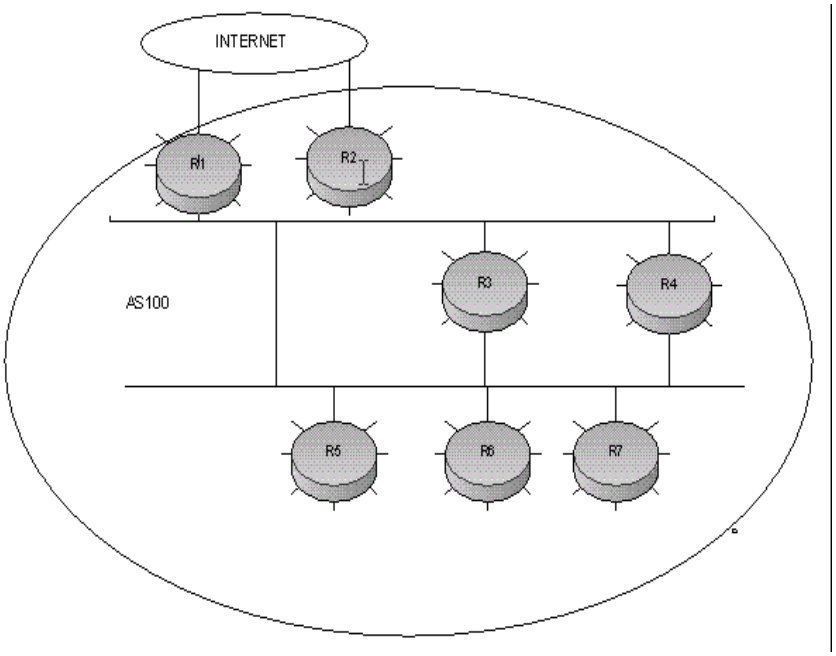
BGP4 null0 routing

BGP4 considers the null0 route in the routing table (for example, static route) as a valid route, and can use the null0 route to resolve the next hop. If the next hop for BGP4 resolves into a null0 route, the BGP4 route is also installed as a null0 route in the routing table.

The null0 routing feature allows network administrators to block certain network prefixes using null0 routes and route-maps, directing a remote device to drop all traffic for a network prefix by redistributing a null0 route into BGP4.

Figure 150 shows a topology for a null0 routing application example.

FIGURE 150 SAMPLE null0 routing application



Refer to "Configuring BGP4 null0 routing" on page 1099 for an example of how to configure a null0 routing application to stop denial of service attacks from remote hosts on the Internet

Configuring BGP4

Once you activate BGP4, you can configure the BGP4 options. There are two configuration levels: global and address family.

At the *global level*, all BGP4 configurations apply to IPv4 and IPv6. Enter this layer using the **device BGP4** command

Under the global level, you specify an ***address family***. Address families separate IPv4 and IPv6 BGP4 configurations. Go to this level by entering the **address-family** command at the device BGP4 level. The command requires you to specify the IPv4 or IPv6 network protocol.

The **address family** command also requires you to select a sub-address family, which is the type of routes for the configuration. Specify multicast or unicast routes.

FIGURE 151 BGP4 configuration levels

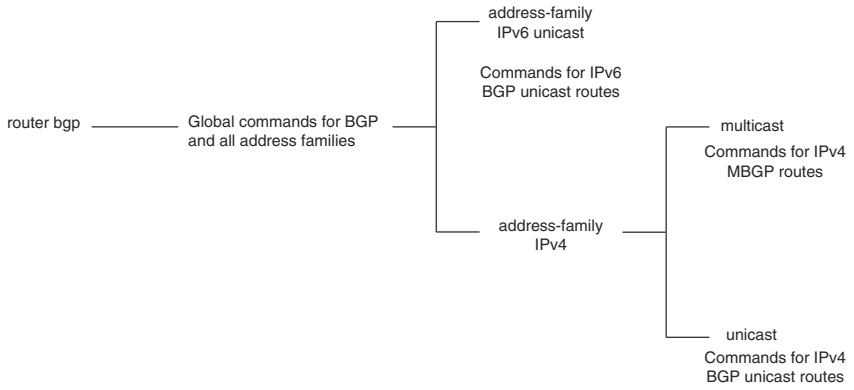


Table • shows the commands that are available at the various BGP4 configuration levels.

TABLE 166 IPv4 BGP4 commands for different configuration levels

Command	Global (IPv4 and IPv6)	IPv4 address family unicast	IPv4 address family multicast	See
address-family	x	x	x	"Entering and exiting the address family configuration level" on page 1013
aggregate-address		x	x	"Aggregating routes advertised to BGP4 neighbors" on page 1013
always-compare-med	x			"Configuring the device to always compare Multi-Exit Discriminators" on page 1014
as-path-ignore	x			"Disabling or re-enabling comparison of the AS-Path length" on page 1015
bgp-redistribute-internal		x		"Redistributing IBGP routes" on page 1015
client-to-client-reflection				"Disabling or re-enabling client-to-client route reflection" on page 1016
cluster-id	x			"Configuring a route reflector" on page 1016
compare-med-empty-as path	x			"Configuring the device to always compare Multi-Exit Discriminators" on page 1014
compare-routerid	x			"Enabling or disabling comparison of device IDs" on page 1016
confederation	x			"Configuring confederations" on page 1017
dampening		x	x	"Configuring route flap dampening" on page 1028
default-information-originate		x	x	"Originating the default route" on page 1029
default-local-preference	x			"Changing the default local preference" on page 1029
default-metric		x	x	"Changing the default metric used for redistribution" on page 1030

TABLE 166 IPv4 BGP4 commands for different configuration levels (Continued)

Command	Global (IPv4 and IPv6)	IPv4 address family unicast	IPv4 address family multicast	See
distance	x			"Changing administrative distances" on page 1030
enforce-first-as	x			"Requiring the first AS to be the neighbor AS" on page 1032
exit-address-family	x	x	x	"Entering and exiting the address family configuration level" on page 1013
fast-external-fallover	x			"Enabling fast external fallover" on page 1033
local-as	x			"Setting the local AS number" on page 1033
maximum-paths		x		"Configuring BGP4 multipath load sharing" on page 1034
med-missing-as-worst	x			"Configuring paths without MEDs as the least favorable" on page 1037
multipath		x		"Configuring paths without MEDs as the least favorable" on page 1037
neighbor	x	x	x	"Configuring BGP4 neighbors" on page 1037 "Configuring a BGP4 peer group" on page 1046
network		x	x	"Specifying a list of networks to advertise" on page 1049
next-hop-enable-default		x		"Using the IP default route as a valid next-hop for a BGP4 route" on page 1051
next-hop-recursion		x		"Enabling next-hop recursion" on page 1051
redistribute		x	x	"Modifying redistribution parameters" on page 1054
show	x	x	x	"Displaying BGP4 information" on page 1104
table-map		x	x	"Using a table map to set the tag value" on page 1057
timers	x			"Changing the Keep Alive Time and Hold Time" on page 1057
update-time		x	x	"Changing the BGP4 next-hop update timer" on page 1058

Parameter changes that take effect immediately

The following parameter changes take effect immediately:

- Enable or disable BGP4.
- Set or change the local AS.
- Add neighbors.
- Change the update timer for route changes.
- Disable or enable fast external fallover.

- Specify individual networks that can be advertised.
- Change the default local preference, default information originate setting, or administrative distance.
- Enable or disable use of a default route to resolve a BGP4 next-hop route.
- Enable or disable MED (metric) comparison.
- Require the first AS in an update from an EBGP neighbor to be the neighbor AS.
- Change MED comparison parameters.
- Disable comparison of the AS-Path length.
- Enable comparison of the device ID.
- Enable next-hop recursion.
- Change the default metric.
- Disable or re-enable route reflection.
- Configure confederation parameters.
- Disable or re-enable load sharing.
- Change the maximum number of load sharing paths.
- Change other load-sharing parameters.
- Define route flap dampening parameters.
- Add, change, or negate redistribution parameters (except changing the default MED; see below).
- Add, change, or negate route maps (when used by the **network** command or a redistribution command).
- Aggregate routes.
- Apply maximum AS path limit settings for UPDATE messages.

Parameter changes that take effect after resetting neighbor sessions

The following parameter changes take effect only after the BGP4 sessions on the device are cleared, or reset using the "soft" clear option. (Refer to "Closing or resetting a neighbor session" on page 1095.)

- Change the Hold Time or Keep Alive Time.
- Add, change, or negate filter tables that affect inbound and outbound route policies.
- Apply maximum AS path limit settings to the RIB.

Parameter changes that take effect after disabling and re-enabling redistribution

Changing the default MED (metric) change takes effect only after you disable and then re-enable redistribution:

Enabling and disabling BGP4

BGP4 is disabled by default. To enable BGP4, you must perform the following steps.

1. Enable the BGP4 protocol.
2. Set the local AS number.

NOTE
BGP4 is not functional until you specify the local AS number.

3. Add each BGP4 neighbor (peer BGP4 device) and identify the AS the neighbor is in.
4. Save the BGP4 configuration information to the system configuration file.

For example, enter commands such as the following.

```
NetIron> enable
NetIron# configure terminal
NetIron(config)# router bgp
BGP4: Please configure 'local-as' parameter in order to enable BGP4.
NetIron(config-bgp)# local-as 10
NetIron(config-bgp)# write memory
```

Syntax: router bgp

The **router bgp** command enables the BGP4 protocol.

For information on the local AS number, refer to "Setting the local AS number" on page 1033.

NOTE
By default, the Dell device ID is the IP address configured on the lowest numbered loopback interface. If the device does not have a loopback interface, the default device ID is the lowest numbered IP interface address configured on the device. For more information, refer to "Changing the device ID" on page 1058. If you change the device ID, all current BGP4 sessions, OSPF adjacencies, and OSPFv3 adjacencies are cleared.

NOTE
When BGP4 is enabled on a device, resetting the system is unnecessary. The protocol is activated when you enable it. The device begins a BGP4 session with a BGP4 neighbor when you add the neighbor.

Disabling BGP4

If you disable BGP4, the device removes all the running configuration information for the disabled protocol from the running configuration. To restore the BGP4 configuration, you must reload the software to load the BGP4 configuration from the startup configuration. When you save the startup configuration file after disabling the protocol, all of the BGP4 configuration information for the disabled protocol is removed from the startup configuration file.

The CLI displays a warning message such as the following.

```
NetIron(config)# no router bgp
router bgp mode now disabled. All bgp config data will be lost when writing to
flash!
```

The Web Management Interface does not display a warning message.

If you are testing a BGP4 configuration and may need to disable and re-enable the protocol, you should make a backup copy of the startup configuration file containing the BGP4 configuration information. If you remove the configuration information by saving the configuration after disabling the protocol, you can restore the BGP4 configuration by copying the backup copy of the startup configuration file onto the flash memory.

To disable BGP4 without losing the BGP4 configuration information, remove the local AS (for example, by entering the **no local-as** <*num*> command). When you remove the local AS, BGP4 retains the other configuration information but will not become operational until you reset the local AS.

Entering and exiting the address family configuration level

The BGP4 address family contains a unicast or multicast sub-level.

To go to the IPv4 BGP4 unicast address family configuration level, enter the following command.

```
NetIron(config-bgp)# address-family ipv4 unicast
NetIron(config-bgp)#
```

NOTE
The CLI prompt for the global BGP4 level and the BGP4 address-family IPv4 unicast level is the same.

To go to the IPv4 BGP4 multicast address family configuration level, enter the following command.

```
NetIron(config-bgp)# address-family ipv4 multicast
NetIron(config-bgp-ipv4m)#
```

Syntax: [**no**] **address-family ipv4 unicast** [**vrf** <*vrf-name*>] | **ipv4 multicast**

The default is the ipv4 unicast address family level.

The **vrf** option allows you to configure a unicast instance for the VRF specified by the <*vrf-name*> variable.

To exit an address family configuration level, enter the following command.

```
NetIron(config-bgp-ipv6u)# exit-address-family
NetIron(config-bgp)#
```

Syntax: [**no**] **exit-address-family**

Aggregating routes advertised to BGP4 neighbors

By default, the device advertises individual routes for all networks. The aggregation feature allows you to configure the device to aggregate routes from a range of networks into a single network prefix. For example, without aggregation, the device will individually advertise routes for networks 207.95.1.0/24, 207.95.2.0/24, and 207.95.3.0/24. You can configure the device to end a single, aggregate route for the networks instead. The aggregate route can be advertised as 207.95.0.0/16.

To aggregate routes for 209.157.22.0/24, 209.157.23.0/24, and 209.157.24.0/24, enter the following command.

```
NetIron(config-bgp)# aggregate-address 209.157.0.0 255.255.0.0
```

Syntax: [**no**] **aggregate-address** <*ip-addr*> <*ip-mask*> [**as-set**] [**summary-only**] [**suppress-map** <*map-name*>] [**advertise-map** <*map-name*>] [**attribute-map** <*map-name*>]

The <*ip-addr*> and <*ip-mask*> parameters specify the aggregate value for the networks. Specify 0 for the host portion and for the network portion that differs among the networks in the aggregate. For example, to aggregate 10.0.1.0/24, 10.0.2.0/24, and 10.0.3.0/24, enter the IP address 10.0.0.0 and the network mask 255.255.0.0.

The **as-set** parameter causes the device to aggregate AS-path information for all the routes in the aggregate address into a single AS-path.

The **summary-only** parameter prevents the device from advertising more specific routes contained within the aggregate route.

The **suppress-map** <*map-name*> parameter prevents the more specific routes contained in the specified route map from being advertised.

The **advertise-map** <*map-name*> parameter configures the device to advertise the more specific routes in the specified route map.

The **attribute-map** <*map-name*> parameter configures the device to set attributes for the aggregate routes based on the specified route map.

NOTE
For the **suppress-map**, **advertise-map**, and **attribute-map** parameters, the route map must already be defined. Refer to "“Defining route maps” on page 1068 for information on defining a route map.

Configuring the device to always compare Multi-Exit Discriminators

A Multi-Exit Discriminator (MED) is a value that the BGP4 algorithm uses when it compares multiple paths received from different BGP4 neighbors in the same AS for the same route. In BGP4, a MED for a route is equivalent to its metric.

BGP4 compares the MEDs of two otherwise equivalent paths ***if and only if*** the routes were learned from the same neighboring AS. This behavior is called ***deterministic MED***. Deterministic MED is always enabled and cannot be disabled.

You can enable the device to always compare the MEDs, regardless of the AS information in the paths. For example, if the device receives UPDATES for the same route from neighbors in three ASs, the device can compare the MEDs of all the paths together instead of comparing the MEDs for the paths in each AS individually.

To enable this comparison, enter the **always-compare-med** command at the BGP4 configuration level of the CLI. This option is disabled by default.

By default, value 0 (most favorable) is used in MED comparison when the MED attribute is not present. The default MED comparison results in the device favoring route paths that do not have their MEDs. Use the **med-missing-as-worst** command to force the device to regard a BGP4 route with a missing MED attribute as the least favorable route.

NOTE
MED comparison is not performed for internal routes originated within the local AS or confederation unless the **compare-med-empty-aspath** command is configured.

To configure the device to always compare MEDs, enter the following command.

```
NetIron(config-bgp)# always-compare-med
```

Syntax: [no] **always-compare-med**

The following BGP4 command directs BGP4 to take the MED value into consideration even if the route has an empty as-path path attribute.

```
NetIron(config) router bgp
NetIron(config-bgp-router)# compare-med-empty-aspath
```

Syntax: [no] **compare-med-empty-aspath**

Disabling or re-enabling comparison of the AS-Path length

AS-Path comparison is Step 5 in the algorithm that BGP4 uses to select the next path for a route. Comparison of the AS-Path length is enabled by default. To disable it, enter the following command at the BGP4 configuration level of the CLI.

```
NetIron(config-bgp)# as-path-ignore
```

Syntax: [no] **as-path-ignore**

This command disables comparison of the AS-Path lengths of otherwise equal paths. When you disable AS-Path length comparison, the BGP4 algorithm shown in "How BGP4 selects a path for a route" on page 1000 skips from Step 4 to Step 6.

Redistributing IBGP routes

By default, the device does not redistribute IBGP routes from BGP4 into RIP, OSPF, or ISIS. This behavior helps eliminate routing loops. However, if your network can benefit from redistributing IBGP routes from BGP4 into OSPF, ISIS or RIP, you can enable the device to redistribute the routes.

To enable the device to redistribute BGP4 routes into OSPF, RIP, or ISIS, enter the following command.

```
NetIron(config-bgp)# bgp-redistribute-internal
```

Syntax: [no] **bgp-redistribute-internal**

To disable redistribution of IBGP routes into RIP, ISIS, and OSPF, enter the following command.

```
NetIron(config-bgp)# no bgp-redistribute-internal
```

Disabling or re-enabling client-to-client route reflection

By default, the clients of a route reflector are not required to be fully meshed. Routes from a client are reflected to other clients. However, if the clients are fully meshed, route reflection is not required between clients.

If you need to disable route reflection between clients, enter the **no client-to-client-reflection** command. When this feature is disabled, route reflection does not occur between clients does still occur between clients and non-clients.

```
NetIron(config-bgp)# no client-to-client-reflection
```

Enter the following command to re-enable the feature.

```
NetIron(config-bgp)# client-to-client-reflection
```

Syntax: [**no**] **client-to-client-reflection**

Configuring a route reflector

You can configure one cluster ID on the device so that all route-reflector clients for the device become members of the cluster.

To configure a device with cluster id 1, enter the following command.

```
NetIron(config-bgp)# cluster-id 1
```

Syntax: [**no**] **cluster-id** <*num*> | <*ip-addr*>

The <*num*> | <*ip-addr*> parameters specify the cluster ID (1 – 4294967295) or an IP address. The default is the device ID.

NOTE
If the cluster contains more than one route reflector, you need to configure the same cluster ID on all the route reflectors in the cluster. The cluster ID helps route reflectors avoid loops within the cluster.

Enabling or disabling comparison of device IDs

Device ID comparison is Step 11 in the algorithm BGP4 uses to select the next path for a route.

NOTE
Comparison of device IDs is applicable only when BGP4 load sharing is disabled.

When device ID comparison is enabled, the path comparison algorithm compares the device IDs of the neighbors that sent the otherwise equal paths:

- If BGP4 load sharing is disabled (maximum-paths 1), the device selects the path that came from the neighbor with the lower device ID.

- If BGP4 load sharing is enabled, the device load shares among the remaining paths. In this case, the device ID is not used to select a path.

NOTE
Device ID comparison is disabled by default.

To enable device ID comparison, enter the **compare-routerid** command at the BGP4 configuration level of the CLI.

```
NetIron(config-bgp)# compare-routerid
```

Syntax: [**no**] **compare-routerid**

For more information, refer to "How BGP4 selects a path for a route" on page 1000.

Configuring confederations

A **confederation** is a BGP4 Autonomous System (AS) that has been subdivided into multiple, smaller ASs. Subdividing an AS into smaller ASs simplifies administration and reduces BGP4-related traffic, which in turn reduces the complexity of the Interior Border Gateway Protocol (IBGP) mesh among the BGP4 devices in the AS.

The implementation of this feature is based on RFC 3065.

Normally, all BGP4 devices within an AS must be fully meshed, so that each BGP4 device has BGP4 sessions to all the other BGP4 devices within the AS. This is feasible in smaller ASs, but becomes unmanageable in ASs containing many BGP4 devices.

When you configure BGP4 devices into a confederation, all the devices within a sub-AS (a subdivision of the AS) use IBGP and must be fully meshed. However, devices use EBGP to communicate between different sub-ASs.

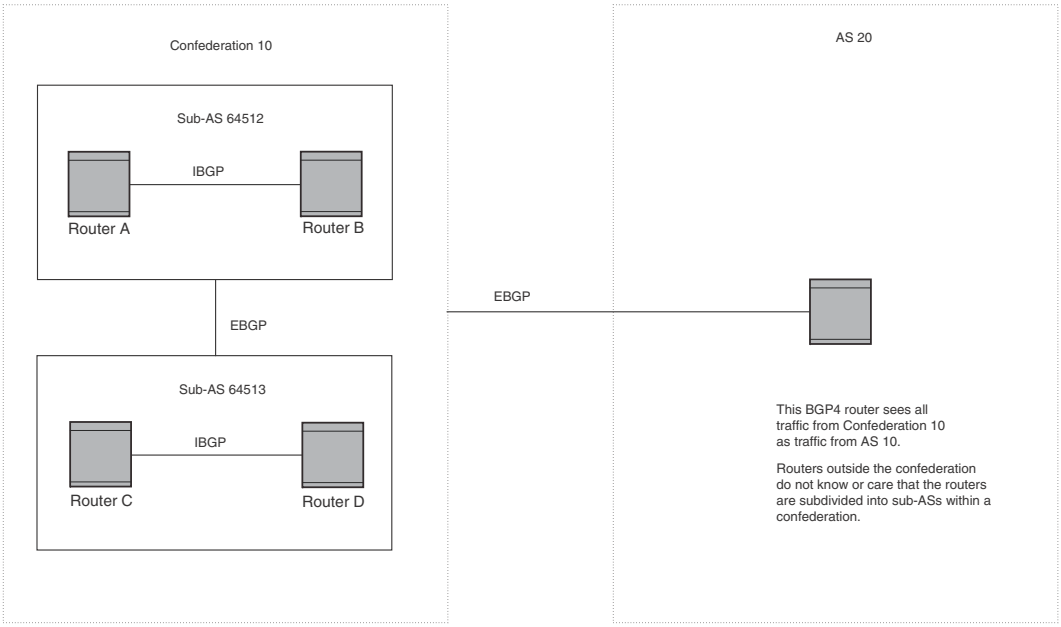
Another way to reduce the complexity of an IBGP mesh is to use route reflection. However, if you want to run different Interior Gateway Protocols (IGPs) within an AS, you must configure a confederation. You can run a separate IGP within each sub-AS.

To configure a confederation, configure groups of BGP4 devices into sub-ASs. A sub-AS is simply an AS. The term "sub-AS" distinguishes ASs within a confederation from ASs that are not in a confederation. For the viewpoint of remote ASs, the confederation ID is the AS ID. Remote ASs do not know that the AS represents multiple sub-ASs with unique AS IDs.

NOTE
You can use any valid AS numbers for the sub-ASs. If your AS is connected to the Internet, it is recommended that you use numbers from within the private AS range (64512 – 65535). These are private ASs numbers and BGP4 devices do not propagate these AS numbers to the Internet.

Figure 152 shows an example of a BGP4 confederation.

FIGURE 152 Example BGP4 confederation



In this example, four devices are configured into two sub-ASs, each containing two of the devices. The sub-ASs are members of confederation 10. Devices within a sub-AS must be fully meshed and communicate using IBGP. In this example, devices A and B use IBGP to communicate. Devices C and D also use IBGP. However, the sub-ASs communicate with one another using EBGP. For example, device A communicates with device C using EBGP. The devices in the confederation communicate with other ASs using EBGP.

Devices in other ASs are unaware that devices A – D are configured in a confederation. In fact, when devices in confederation 10 send traffic to devices in other ASs, the confederation ID is the same as the AS number for the devices in the confederation. Thus, devices in other ASs see traffic as coming from AS 10 and are unaware that the devices in AS 10 are subdivided into sub-ASs within a confederation.

Configuring a BGP4 confederation

To configure a BGP4 configuration, perform these configuration tasks on each BGP4 device within the confederation:

- Configure the local AS number. The local AS number indicates membership in a sub-AS. All BGP4 devices with the same local AS number are members of the same sub-AS. BGP4 devices use the local AS number when communicating with other BGP4 devices in the confederation.
- Configure the confederation ID. The confederation ID is the AS number by which BGP4 devices outside the confederation recognize the confederation. A BGP4 device outside the confederation is not aware of, and does not care that BGP4 devices are in multiple sub-ASs. A BGP4 device uses the confederation ID to communicate with devices outside the confederation. The confederation ID must differ from the sub-AS numbers.
- Configure the list of the sub-AS numbers that are members of the confederation. All devices within the same sub-AS use IBGP to exchange device information. Devices in different sub-ASs within the confederation use EBGP to exchange device information.

The following command examples show how to implement the confederation shown in Figure 152.

To configure four device devices to be members of confederation 10 (consisting of sub-ASs 64512 and 64513), enter commands such as the following.

Commands for Device A

```
NetIronA(config)# router bgp
NetIronA(config-bgp)# local-as 64512
NetIronA(config-bgp)# confederation identifier 10
NetIronA(config-bgp)# confederation peers 64512 64513
NetIronA(config-bgp)# write memory
```

Syntax: [**no**] **local-as** <*num*>

The <*num*> parameter with the **local-as** command indicates the AS number for the BGP4 devices within the sub-AS. You can specify a number in the range 1 – 4294967295. It is recommended that you use a number within the range of well-known private ASs, 64512 – 65535.

Syntax: [**no**] **confederation identifier** <*num*>

The <num> parameter with the **confederation identifier** command indicates the confederation number. The confederation ID is the AS number by which BGP4 devices outside the confederation recognize the confederation. A BGP4 device outside the confederation is not aware of, and does not care that your BGP4 devices are in multiple sub-ASs. BGP4 devices use the confederation ID when communicating with devices outside the confederation. The confederation ID must be different from the sub-AS numbers. For the <*num*> parameter, you can specify a number in the range 1 – 4294967295.

Syntax: [**no**] **confederation peers** <*num*> [<*num*> ...]

The <*num*> parameter with the **confederation peers** command indicates the sub-AS numbers for the sub-ASs in the confederation. You can list all sub-ASs in the confederation. You must specify all the sub-ASs with which this device has peer sessions in the confederation. All the devices within the same sub-AS use IBGP to exchange device information. Devices in different sub-ASs within the confederation use EBGP to exchange device information. The <*num*> is a number in the range 1 – 4294967295.

Commands for Device B

```
NetIronB(config)# router bgp
NetIronB(config-bgp)# local-as 64512
NetIronB(config-bgp)# confederation identifier 10
NetIronB(config-bgp)# confederation peers 64512 64513
NetIronB(config-bgp)# write memory
```

Commands for Device C

```
NetIronC(config)# router bgp
NetIronC(config-bgp)# local-as 64513
NetIronC(config-bgp)# confederation identifier 10
NetIronC(config-bgp)# confederation peers 64512 64513
NetIronC(config-bgp)# write memory
```

Commands for Device D

```
NetIronD(config)# router bgp
NetIronD(config-bgp)# local-as 64513
NetIronD(config-bgp)# confederation identifier 10
NetIronD(config-bgp)# confederation peers 64512 64513
NetIronD(config-bgp)# write memory
```

Four-byte Autonomous System Numbers (AS4)

This section describes the reasons for enabling four-byte autonomous system numbers (AS4s). AS4s are supported by default. You can specify and view AS4s by default and using the enable facility described in this section. However, because not all devices in a network are always capable of utilizing AS4s, the act of enabling them on the local device initiates a facility for announcing the capability and negotiating its use with neighbors. If you do not enable AS4s on a device, other devices do not know that this device is sending them.

The system uses a hierarchy to prioritize the utilization of the AS4 capability. The prioritization depends on the CLI configuration commands. AS4s can be enabled and configured at the level of a neighbor, a peer group, or globally for the entire device, according to the following bottom-up hierarchy:

- If a neighbor has no configuration for AS4s but it belongs to a peer group, the neighbor uses the configuration from the peer group. For example, if you configure a neighbor but do not include a specification for AS4s, one of the following applies:
  - The neighbor uses the AS4 configuration for a peer group if it belongs to a peer group.
  - The neighbor uses the device configuration if it does not belong to a peer group or the peer group has no AS4 configuration.
- If a peer group has no configuration for AS4s, it can use the global configuration of the device. If the device has no configuration for AS4s, then a neighbor or peer group without a configuration for AS4s use the device default—no announcement or negotiation of AS4s.
- If a neighbor belongs to peer group with an AS4 configuration but you want that neighbor to be disabled or have a different AS4 configuration, the neighbor AS4 configuration overrides the peer group configuration. For example, you can ensure that neighbor has no AS4 announcement and negotiation activity even though the peer group is enabled for AS4 capability.

NOTE
The configuration for AS4 can be enabled, disabled, or can have no explicit configuration.

CLI commands allow you to disable AS4s on an entity whose larger context has AS4s enabled. For example, you can use a CLI command to disable AS4s on a neighbor that is a member of a peer group that is enabled for AS4s. Refer to "Enabling AS4 numbers" on page 1021.

Normally, AS4s are sent only to a device, peer group, or neighbor that is similarly configured for AS4s. If a AS4 is configured for a local-AS, the system signals this configuration by sending AS_TRANS in the My Autonomous System field of the OPEN message. However, if the AS4 capability for a neighbor is disabled, the local device does not send the four-octet Autonomous System number capability to the neighbor.

Enabling AS4 numbers

This section describes how to enable the announcement and negotiation of AS4s and describes the different types of notation that you can use to represent a AS4.

You can enable AS4s on a device, a peer group, and a neighbor. For global configuration, the **capability** command in the BGP4 configuration context enables or disables AS4 support. For a peer group or a neighbor, **capability** is a keyword for the **neighbor** command. In addition to enabling AS4s for a neighbor or a peer group, you can also use the combination of the **capability** keyword and the optional **enable** or **disable** keyword to disable this feature in a specific case where the AS4s are enabled for a larger context. The "Neighbor configuration of AS4s"section illustrates this capability.

Global AS4 configuration

To enable AS4s globally, use the **capability** command in the BGP4 configuration context, as shown.

```
NetIron(config-bgp)# capability as4 enable
```

Syntax: [**no**] **capability as4 enable** | **disable**

The no form of the **capability** command deletes the announcement and negotiation configuration of AS4s (if it has been enabled) at the global level. Using the regular form of the command with the **disable** keyword has the same effect on the global configuration. Disabling or using the no form of the command does not affect the configuration at the level of a peer or neighbor.

The consequences of choosing between the **enable** or **disable** keyword are reflected in the output of the **show running configuration** command.

Peer group configuration of AS4s

To enable AS4s for a peer group, use the **capability** keyword with the **neighbor** command in the BGP4 configuration context, as the following example for the Peergroup_1 peer group illustrates.

```
NetIron(config-bgp)# neighbor Peergroup_1 capability as4 enable
```

Syntax: [**no**] **neighbor** <*peer-group-name*> **capability as4 enable** | **disable**

The **no** form of the **neighbor** command along with the **capability as4** keywords disables the announcement and negotiation of AS4s in the named peer group. Using the regular form of the command with the **disable** keyword has the same effect on the neighbor configuration.

The consequences using the **enable** or **disable** keywords are reflected in the output of the **show running configuration** command. However, if the peer group configuration omits an explicit AS4 argument, the **show running configuration** output will not contain AS4 information.

Neighbor configuration of AS4s

To enable AS4s for a neighbor, use the **capability** and **as4** keywords with the **neighbor** command in the BGP4 configuration context, as the following example for IP address 1.1.1.1 illustrates.

```
NetIron(config-bgp)# neighbor 1.1.1.1 capability as4 enable
```

Syntax: [**no**] **neighbor** <*IP address*> **capability as4 enable** | **disable**

The **no** form of the **neighbor** command with the **capability as4** keywords deletes the neighbor-enable for AS4s.

The consequences of using the **enable** or **disable** keywords are reflected in the output of the **show running configuration** command. However, if the neighbor configuration omits an explicit AS4 argument, the **show running configuration** output will not contain AS4 information.

To disable AS4s on a particular neighbor within a peer group that is enabled for AS4s, enter a command similar to the following.

```
NetIron(config-bgp)# neighbor 1.1.1.1 capability as4 disable
```

Specifying the local AS number

The local autonomous system number (ASN) identifies the AS where the BGP4 device resides.

Normally, AS4s are sent only to a device, peer group, or neighbor that is similarly configured for AS4s. Typically, if you try to set up a connection from an AS4-enabled device to a device that processes only two-byte ASNs, the connection fails to come up unless you specify the reserved ASN 23456 as the local ASN to send to the far-end device.

To set the local AS number, enter commands such as the following.

```
NetIron(config)# router bgp
BGP4: Please configure 'local-as' parameter in order to enable BGP4.
NetIron(config-bgp)# local-as 100000
NetIron(config-bgp)# write memory
```

Syntax: [**no**] **local-as** <*num*>

The <*num*> parameter specifies a local ASN in the range 1 – 4294967295. No default exists for <*num*>. ASNs 64512 – 65535 are the well-known private BGP4 AS numbers and are not advertised to the Internet community.

Route-map set commands and AS4s

You can prepend a AS4 number to an AS path or make the AS number a tag attribute for a route map, as shown here.

```
NetIron(config-routemap test)# set as-path prepend 7701000
```

Syntax: [**no**] **set as-path prepend** <*num, num*, ...> | **tag**

Use the **no** form of this command to remove the configuration.

NOTE
If the AS path for a route map has prepended ASNs and you want to use the **no** form of the command to delete the configuration, you must include the prepended ASNs in the **no set as-path** entry. For example, if 70000 and 70001 have been prepended to a route map, enter **no set as-path prepend 70000 70001**. As a shortcut, in the configuration context of a particular route map, you can also copy and paste ASNs from the output of **show** commands, such as show **route-map** or **show ip bgp route**.

Use the **prepend** keyword to prepend one or more ASNs. The maximum number of ASNs that you can prepend is 16. The range for each ASN is 1 – 4294967295.

Entering the **tag** keyword sets the tag as an AS-path attribute.

You can specify a route target (art) or a site of origin (soo) for an extended community, as shown in the following example.

```
NetIron(config-routemap test)# set extcommunity rt 7701000:10
```

Syntax: [**no**] **set extcommunity rt** <*asn:nn* | *ip-address:nn*> | **soo** <*asn:nn* | *ip-address:nn*>

The **rt** keyword specifies a route target in the form of a route ID. The route ID can be an ASN or IP address. The second part of the route ID is a user-specific numeric variable *nn*. The ASN can be a maximum of 4 bytes (in the range 1 – 4294967295). If you specify an AS4 or IP address, the *nn* variable is limited to a maximum length of 2 bytes. If the feature for announcing and negotiating AS4 is disabled, *nn* can be 4 bytes.

The **soo** keyword specifies a site or origin in the form of a route ID. The route ID can be an ASN4 or IP address. The second part of the route ID is a user-specific numeric variable *nn*. The AS4 can be a maximum of 4 bytes (in the range 1 – 4294967295). If you specify an AS4 or IP address, the *nn* variable is limited to a maximum length of 2 bytes. If the feature for announcing and negotiating AS4 is disabled, *nn* can be 4 bytes.

Clearing BGP4 routes to neighbors

You can clear BGP4 connections using the AS4 as an argument with the **clear ip bgp neighbor** command in the configuration context level of the CLI. as shown.

```
NetIron(config)# clear ip bgp neighbor 80000
```

Syntax: **clear ip bgp neighbor** < **all** | <*ip-addr*> | <*peer-group-name*> | <*as-num*> >
[**last-packet-with-error** | **notification-errors** | [**soft** [**in** | **out**] | **soft-outbound**]

The neighbor specification is either **all,** <*ip-addr*>, <*peer-group-name*>, or <*as-num*>. The **all** parameter specifies all neighbors. The <*ip-addr*> parameter specifies a neighbor by its IP interface with the device. The <*peer-group-name*> specifies all neighbors in a specific peer group. The <*as-num*> parameter specifies all neighbors within the specified AS. After choosing one mandatory parameter, you can choose an optional parameter.

The **soft** [**in** | **out**] parameter determines whether to refresh the routes received from the neighbor or the routes sent to the neighbor. If you do not specify **in** or **out**, the device performs a soft refresh in both options:

- **soft in** performs one of the following actions on inbound routes, according to other configuration settings:
  - If you enabled soft reconfiguration for the neighbor or peer group, **soft in** updates the routes by comparing the route policies against the route updates that the device has stored. Soft reconfiguration does not request additional updates from the neighbor or otherwise affect the session with the neighbor.
  - If you did not enable soft reconfiguration, **soft in** requests the entire BGP4 route table on the neighbor (Adj-RIB-Out), then applies the filters to add, change, or exclude routes.
  - If a neighbor does not support dynamic refresh, **soft in** resets the neighbor session.
- **soft out** updates all outbound routes and then sends the entire BGP4 route table for the device (Adj-RIB-Out) to the neighbor after the device changes or excludes the routes affected by the filters.
- The **soft-outbound** parameter updates all outbound routes by applying the new or changed filters, but sends only the existing routes affected by the new or changed filters to the neighbor.

NOTE
Use **soft-outbound** only if the outbound policy is changed. The **soft-outbound** parameter updates all outbound routes by applying the new or changed filters. However, the device sends to the neighbor only the existing routes that are affected by the new or changed filters.The **soft out** parameter updates all outbound routes and then sends the entire BGP4 route table on the device to the neighbor after the device changes or excludes the routes affected by the filters.

AS4 notation

A AS4 can appear in either a plain or a dot notation format in the output of **show** commands. To select one of these formats, specify the format before entering the **show** command. This section defines these formats and describes how to select a format. The section "Formats of AS4s in show command output" on page 1134 contains examples of output in the various formats. The following notations are currently supported:

- With the default **asplain**, the ASN is a decimal integer in the range 1 – 4294967295.
- With **asdot+**, all ASNs are two integer values joined by a period character in the following format:

  <high order 16-bit value in decimal>.<low order 16-bit value in decimal>

  Using asdot+ notation, an AS number of value 65526 is represented as the string "0.65526," and an AS number of value 65546 is represented as the string "1.10."
- With **asdot,** an ASN less than 65536 uses asplain notation (and represents AS number values equal to or greater than 65536 using asdot+ notation). Using asdot notation, ASN 65526 is represented as the string "65526," and ASN 65546 is represented as the string "1.10".

NOTE
You can enter AS numbers in any format. However, if you want the asdot or asdot+ format to appear in the output of a **show** command, you must specify these in the CLI.

NOTE
Remember that AS path matching that uses regular expression is based on the configured AS format.

The following command sequences show how to enable the different notations for AS4s and how these notations appear in the output display.

To see ASNs in asplain, use the **show ip bgp** command.

```
NetIron(config)# show ip bgp
Total number of BGP Routes: 1
Status codes: s suppressed, d damped, h history, * valid, > best, i internal, S
stale
Origin codes: i - IGP, e - EGP,? - incomplete
Network            Next Hop        Metric LocPrf Weight Path
*>  47.1.1.0/24        192.168.1.5     1      100    0      90000 100 200 65535
65536 65537 65538 65539 75000 ?
```

To specify **asdot** notation before displaying IP BGP4 information, use the **as-format** command.

```
NetIron(config)# as-format asdot
NetIron(config)# show ip bgp
Total number of BGP Routes: 1
Status codes: s suppressed, d damped, h history, * valid, > best, i internal, S
stale
Origin codes: i - IGP, e - EGP, ? - incomplete
Network            Next Hop        Metric LocPrf Weight Path
*>  47.1.1.0/24        192.168.1.5     1      100    0      1.24464 100 200 65535
1.0 1.1 1.2 1.3 1.9464 ?
```

Syntax: [no] **as-format asplain** | **asdot** | **asdot+**

The default is **asplain** and can be restored using the **no** version of the command, if the CLI is currently using **asdot** or **asdot+**.

To activate **asdot+** notation, enter **as-format asdot+** in the CLI.

```
NetIron(config)# as-format asdot+
NetIron(config)# show ip bgp
Total number of BGP Routes: 1
Status codes: s suppressed, d damped, h history, * valid, > best, i internal, S
stale
Origin codes: i - IGP, e - EGP,? - incomplete
    Network            Next Hop        Metric LocPrf Weight Path
*>  47.1.1.0/24        192.168.1.5     1      100    0      1.24464 0.100 0.200
0.65535 1.0 1.1 1.2 1.3 1.9464 ?
```

BGP4 AS4 attribute errors

This section describes the handling of the confederation path segments in the AS4_PATH attribute, and also specifies the error handling for the new attributes.

To support AS4, the following attributes: AS4_PATH and AS4_Aggregator were specified in RFC 4893. Confederation path segments in an AS4_PATH are discarded and if there are any other errors such as: *attribute length, flag, confederation segments after AS_SEQ/AS_SET, Invalid segment types* and *More than one AS4_PATH* in these new attributes, the attribute is discarded and the error is logged.

Error logs

The device generates a log when it encounters attribute errors in AS4_PATH and AS4_AGGREGATOR.

NOTE
Logging of errors is rate-limited to not more than one message for every two minutes. Some errors may be lost due to this rate-limiting.

Sample log messages for various attribute errors are shown here.

Attribute length error (ignore the AS4_PATH)

```
SYSLOG: Sep  9 19:02:03:<11>mu2, BGP: From Peer 192.168.1.1 received invalid
AS4_PATH attribute length (3) - entire AS4_PATH ignored
```

Attribute flag error (ignore the AS4_PATH)

```
SYSLOG: Sep  9 19:02:03:<11>mu2, BGP: From Peer 192.168.1.1 received invalid
AS4_PATH attribute flag (0x40) - entire AS4_PATH ignored
```

Confederation segments after AS_SEQ/AS_SET (ignore the AS4_PATH)

```
SYSLOG: Sep  9 19:02:03:<11>mu2, BGP: From Peer 192.168.1.1 received invalid
Confed info in AS4_PATH (@byte 43) - entire AS4_PATH ignored
```

Invalid segment types (ignore the AS4_ PATH)

```
SYSLOG: Sep  9 19:02:03:<11>mu2, BGP: From Peer 192.168.1.1 received incorrect Seq
type/len in AS4_PATH (@byte 41) - entire AS4_PATH ignored
```

More than one AS4_PATH (Use the first one and ignore the others)

```
SYSLOG: Sep  9 19:02:03:<11>mu2, BGP: From Peer 192.168.1.1 received multiple
AS4_PATH attributes - used first AS4_PATH attribute only
```

Specifying a maximum AS path length

You can use the **maxas-limit in** command to configure a router running BGP4 to discard routes that exceed a specified AS path limit. This limit can be configured globally, for peer groups, and for BGP neighbors.

When you configure the **maxas-limit in** setting, the behavior of the router changes to first check the length of the AS paths in the UPDATE messages and then to apply the inbound policy. If the AS path exceeds the configured length, then the router performs the following actions:

- Does not store the route in the RIB and does not forward the NLRIs and attributes contained in the UPDATE message for that route
- Logs an error
- Processes the withdrawn NLRIs in the same update message

If a route from a peer exceeds the configured Maximum AS path limit, the router also removes the same route from that peer, if it exists, from its own RIB.

After a maximum AS path length is configured, the maximum AS path limit applies to all new inbound routes. To update previously stored routes, you must perform an inbound soft reset for all of the address families activated for that particular BGP neighbor session.

NOTE
If the neighbor soft-reconfiguration feature is enabled, you must perform a hard reset on the router to impose the maximum length limit.

NOTE
Maxas-limit is checked against the received AS_PATH and AS4_PATH attributes.

BGP routers check for and, if configured, apply the **maxas-limit in** setting in the following order:

1. Neighbor value
2. Peer group value
3. Global value

In a case where a neighbor has no maximum AS limit, a peer group has a value of 3 configured, and the system has a value of 9 configured, all of the routers in the peer group will only use the peer group value; the global value will never be used.

Setting a global maximum AS path limit

The syntax for the global maximum AS path limit command is:

[no] maxas-limit in *<num>*

The **maxas-limit** keyword specifies the limit on the AS numbers in the as-path attribute. The **in** keyword allows the as-path attribute from any neighbor imposing a limit on AS numbers received. The default maximum length for the global system is 300. The range is 0 – 300. The **no** keyword removes the configuration at the global level.

NOTE
The router applies the BGP4 maximum AS path limit on a per virtual router basis.

To configure the global Maximum AS path limit to 15, enter the following command:

```
NetIron(config-bgp)# maxas-limit in 15
```

Setting a maximum AS path limit for a peer group or neighbor

To set maximum AS path limit for a peer group or a neighbor, the syntax is:

neighbor {*<ip-addr>* | *<peer-group-name>*} **maxas-limit in** *[<num> | disable]*

By default, neighbors or peer groups have no configured maximum values. The range is 0 – 300. The **disable** keyword is used to stop a neighbor from inheriting the configuration from the peer-group or global and to the use system default value.

To configure a peer group named “PeerGroup1” and set a maximum AS path value of 7, enter the following commands:

```
NetIron(config-bgp)# neighbor PeerGroup1 peer-group
NetIron(config-bgp)# neighbor PeerGroup1 maxas-limit in 7
```

BGP4 max-as error messages

This section lists error log messages that you might see when the router receives routes that exceed the configured AS segment limit or the internal memory limit. The log messages can contain a maximum of 30 ASNs. If a message contains more than 30 ASNs, the message is truncated and an ellipsis appears.

Maximum AS path limit error

```
SYSLOG: <11>Jan  1 00:00:00 mu1, BGP: From Peer 192.168.1.2 received Long AS_PAT
H= AS_CONFED_SET(4) 1 2 3 AS_CONFED_SEQUENCE(3) 4 AS_SET(1) 5 6 7 AS_SEQ(2) 8 9
attribute length (9) More than configured MAXAS-LIMIT 7
```

Memory limit error

```
SYSLOG: <11>Jan  1 00:00:00 mu1, BGP: From Peer 192.168.1.2 received Long AS_PAT
```

```
H= AS_CONFED_SET(4) 1 2 3 AS_CONFED_SEQUENCE(3) 4 AS_SET(1) 5 6 7 AS_SEQ(2) 8 9
attribute length (9) Exceeded internal memory limit
```

NOTE
The router generates a log message one time every two minutes. Because of this rate limit, it is possible that some errors might not appear in the log. In this case, you can use the **debug ip bgp events** command to view errors pertaining to the **maxas-limit** value and the actual AS path attributes received.

Configuring route flap dampening

Route flap dampening reduces the amount of route state changes propagated by BGP4 due to unstable routes. This in turn reduces processing requirements.

To enable route flap dampening using the default values, enter the following command.

```
NetIron(config-bgp)# dampening
```

Syntax: [**no**] **dampening** [<*half-life*> <*reuse*> <*suppress*> <*max-suppress-time*>]

The <*half-life*> parameter specifies the number of minutes after which the penalty for a route becomes half its value. The route penalty allows routes that have remained stable for a period despite earlier instability to eventually become eligible for use again. The decay rate of the penalty is proportional to the value of the penalty. After the half-life expires, the penalty decays to half its value. A dampened route that is no longer unstable can eventually again become eligible for use. You can configure the half-life to be from 1 - 45 minutes. The default is 15 minutes.

The <*reuse*> parameter specifies how low a penalty for a route must be before the route becomes eligible for use again, after being suppressed. You can set the reuse threshold to a value from 1 – 20000. The default is 750 (0.75, or three-fourths, of the penalty assessed for a one flap).

The <*suppress*> parameter specifies how high the penalty for a route can be before the device suppresses the route. You can set the suppression threshold to a value from 1 – 20000. The default is 2000 (more than two flaps).

The <*max-suppress-time*> parameter specifies the maximum number of minutes that a route can be suppressed regardless of how unstable it is. You can set the maximum suppression time to a value from 1 – 255 minutes. The default is 40 minutes.

This example shows how to change the dampening parameters.

```
NetIron(config-bgp)# dampening 20 200 2500 40
```

This command changes the half-life to 20 minutes, the reuse threshold to 200, the suppression threshold to 2500, and the maximum number of minutes a route can be dampened to 40.

NOTE
To change any of the parameters, you must specify all the parameters with the command. To want to leave any parameters unchanged, enter their default values.

Originating the default route

By default, the device does not originate and advertise a default route using BGP4. A BGP4 default route is the IP address 0.0.0.0 and the route prefix 0 or network mask 0.0.0.0. For example, 0.0.0.0/0 is a default route.

NOTE
The device checks for the existence of an IGP route for 0.0.0.0/0 in the IP route table before creating a local BGP4 route for 0.0.0.0/0.

To configure the device to originate and advertise a default BGP4 route, enter this command.

```
NetIron(config-bgp)# default-information-originate
```

Syntax: [no] **default-information-originate**

Changing the default local preference

When the device uses the BGP4 algorithm to select a route to send to the IP route table, one of the parameters the algorithm uses is the local preference. Local preference indicates a degree of preference for a route relative to other routes. BGP4 neighbors can send the local preference value as an attribute of a route in an UPDATE message.

Local preference applies only to routes within the local AS. BGP4 devices can exchange local preference information with neighbors who also are in the local AS, but BGP4 devices do not exchange local preference information with neighbors in remote ASs.

The default local preference is 100. For routes learned from EBGP neighbors, the default local preference is assigned to learned routes. For routes learned from IBGP neighbors, the local preference value is not changed for the route.

When the BGP4 algorithm compares routes on the basis of local preferences, the route with the higher local preference is chosen.

NOTE
To set the local preference for individual routes, use route maps. Refer to "Defining route maps" on page 1068. Refer to "How BGP4 selects a path for a route" on page 1000 for information about the BGP4 algorithm.

To change the default local preference to 200, enter the following command.

```
NetIron(config-bgp)# default-local-preference 200
```

Syntax: [no] **default-local-preference** <*num*>

The <*num*> parameter indicates the preference and can be a value from 0 – 4294967295.

Changing the default metric used for redistribution

The device can redistribute directly connected routes, static IP routes, RIP routes, ISIS routes, and OSPF routes into BGP4. By default, BGP4 uses zero (0) for direct connected routes and the metric (MED) value of IGP routes in the IP route table. The MED is a global parameter that specifies the cost that will be applied to all routes, if assigned, when they are redistributed into BGP4. When routes are selected, lower metric values are preferred over higher metric values. The default, the BGP4 MED value is not assigned.

NOTE
RIP, ISIS, and OSPF also have default metric parameters. The parameters are set independently for each protocol and have different ranges.

To change the default metric to 40, enter the following command.

```
NetIron(config-bgp)# default-metric 40
```

Syntax: [**no**] **default-metric** <*value*>

The <*value*> indicates the metric and can be a value from 0 – 4294967295.

Changing the default metric used for route cost

By default, BGP4 uses the BGP MED value as the route cost when adding the route to the RTM. However, you can configure BGP4 to use the IGP cost instead.

NOTE
It is recommended that you change the default to IGP cost only in mixed-vendor environments, and that you change it on all PowerConnect and Dell devices in the environment.

To change the route cost default from BGP MED to IGP cost, enter a command such as the following:

```
NetIron(config-router-bgp)# install-igp-cost
```

Syntax: [**no**] **install-igp-cost**

Use the **no** form of the command to revert to the default of BGP MED.

Changing administrative distances

Because the device can learn about networks from various protocols, including the EBGP portion of BGP4, and IGPs such as OSPF, ISIS, and RIP, the routes to a network may differ depending on the protocol from which the routes were learned.

To select one route over another based on the source of the route information, the device can use the administrative distances assigned to the sources. The administrative distance is a protocol-independent metric that IP devices use to compare routes from different sources.

The device re-advertises a learned best BGP4 route to neighbors even when the route table manager does not also select that route for installation in the IP route table. The best BGP4 route is the BGP4 path that BGP4 selects based on comparison of the paths' BGP4 route parameters. Refer to "How BGP4 selects a path for a route" on page 1000.

When selecting a route from among different sources (BGP4, OSPF, RIP, ISIS, static routes, and so on), the software compares the routes on the basis of the administrative distance for each route. If the administrative distance of the paths is lower than the administrative distance of paths from other sources (such as static IP routes, RIP, or OSPF), the BGP4 paths are installed in the IP route table.

The default administrative distances on the device are:

- Directly connected – 0 (this value is not configurable)
- Static – 1 is the default and applies to all static routes, including default routes. This can be assigned a different value.
- EBGP – 20
- OSPF – 110
- ISIS – 115
- RIP – 120
- IBGP – 200
- Local BGP4 – 200
- Unknown – 255 (the device will not use this route)

Lower administrative distances are preferred over higher distances. For example, if the device receives routes for the same network from OSPF and from RIP, the device will prefer the OSPF route by default. The administrative distances are configured in different places in the software. The device re-advertises a learned best BGP4 route to neighbors by default, regardless of whether the administrative distance for the route is lower than the administrative distances of other routes from different route sources to the same destination:

- To change the EBGP, IBGP, and Local BGP4 default administrative distances, refer to the instructions in this section.
- To change the default administrative distance for OSPF, RIP, ISIS, refer to "Changing administrative distances" on page 1030.
- To change the administrative distance for static routes, refer to "Configuring static routes" on page 714.

To change the default administrative distances for EBGP, IBGP, and Local BGP4, enter a command such as the following.

```
NetIron(config-bgp)# distance 200 200 200
```

Syntax: [**no**] **distance** <*external-distance*> <*internal-distance*> <*local-distance*>

The <*external-distance*> sets the EBGP distance and can be a value from 1 – 255.

The <*internal-distance*> sets the IBGP distance and can be a value from 1 – 255.

The <*local-distance*> sets the Local BGP4 distance and can be a value from 1 – 255.

Requiring the first AS to be the neighbor AS

By default, a device does not require the first AS listed in the AS_SEQUENCE field of an AS path update message from EBGP neighbors to be the AS of the neighbor that sent the update. However, you can enable the device to have this requirement. You can enable this requirement globally for the device, or for a specific neighbor or peer group. This section describes how to enable this requirement.

When you configure the device to require that the AS an EBGP neighbor is in be the same as the first AS in the AS_SEQUENCE field of an update from the neighbor, the device accepts the update only if the AS numbers match. If the AS numbers do not match, the device sends a notification message to the neighbor and closes the session. The requirement applies to all updates received from EBGP neighbors.

The hierarchy for enforcement of this feature is: a neighbor will try to use the enforce-first-as value if one is configured; if none is configured, the neighbor will try to use the configured value for a peer group. If neither configuration exists, enforcement is simply that of the global configuration (which is disabled by default).

To enable this feature globally, enter the **enforce-first-as** command at the BGP4 configuration level of the CLI.

```
NetIron(config-bgp)# enforce-first-as
```

Syntax: [**no**] **enforce-first-as**

To enable this feature for a specific neighbor, enter the following command at the BGP4 configuration level.

```
NetIron(config-bgp)# neighbor 1.1.1.1 enforce-first-as enable
```

Syntax: [**no**] **neighbor** <*ip-address*> **enforce-first-as** [**enable** | **disable**]

The <*ip-address*> value is the IP address of the neighbor.

When the first-as requirement is enabled, its status appears in the output of the **show running configuration** command. The optional last keyword choice of **enable** or **disable** lets you specify whether the output of the **show running configuration** command includes the configuration of the first-as requirement. This option allows the **show running configuration** command output to show what is actually configured.

To enable this feature for a peer group, enter the following command at the BGP4 configuration level.

```
NetIron(config-bgp)# neighbor Peergroup1 enforce-first-as enable
```

Syntax: [**no**] **neighbor** <*peer-group-name*> **enforce-first-as** [**enable** | **disable**]

The <*peer-group-name*> value is the name of the peer group.

When the first-as requirement is enabled, its status appears in the output of the show running configuration command. The optional last keyword choice, that of **enable** or **disable**, lets you specify whether the output of the show running configuration command includes the configuration of the first-as requirement: this option helps the show running command output to show what you have actually configured.

The following example shows a running configuration with the first-as enforcement items (for global, peer group, and neighbor) in bold.

```
NetIron(config)# router bgp
BGP4: Please configure 'local-as' parameter in order to enable BGP4.
NetIron(config-bgp)# local-as 1
```

```
NetIron(config-bgp)# enforce-first-as
NetIron(config-bgp)# neighbor abc peer-group
NetIron(config-bgp)# neighbor abc remote-as 2
NetIron(config-bgp)# neighbor abc enforce-first-as disable
NetIron(config-bgp)# neighbor 192.168.1.2 peer-group abc
NetIron(config-bgp)# neighbor 192.168.1.2 enforce-first-as enable
```

Enabling fast external fallover

BGP4 devices rely on KEEPALIVE and UPDATE messages from neighbors to signify that the neighbors are alive. For BGP4 neighbors that are two or more hops away, such messages are the only indication that the BGP4 protocol has concerning the alive state of the neighbors. As a result, if a neighbor becomes non-operational, the device waits until the Hold Time expires or the TCP connection fails before concluding that the neighbor is not operational and closing its BGP4 session and TCP connection with the neighbor.

The device waits for the Hold Time to expire before ending the connection to a directly-attached BGP4 neighbor that becomes non-operational.

For directly-attached neighbors, the device immediately senses loss of a connection to the neighbor from a change of state of the port or interface that connects the device to the neighbor. For directly-attached EBGP neighbors, the device uses this information to immediately close the BGP4 session and TCP connection to locally attached neighbors that become non-operational.

NOTE
The fast external fallover feature applies only to directly attached EBGP neighbors. The feature does not apply to IBGP neighbors.

To enable fast external fallover, enter the following command.

```
NetIron(config-bgp)# fast-external-fallover
```

To disable fast external fallover again, enter the following command.

```
NetIron(config-bgp)# no fast-external-fallover
```

Syntax: [no] fast-external-fallover

Setting the local AS number

The local autonomous system number (ASN) identifies the AS in which the BGP4 device resides.

To set the local AS number, enter commands such as the following.

```
NetIron(config)# router bgp
BGP4: Please configure 'local-as' parameter in order to enable BGP4.
NetIron(config-bgp)# local-as 10
NetIron(config-bgp)# write memory
```

Syntax: [no] local-as <*num*>

The <*num*> parameter specifies a local AS number in the range 1 – 4294967295. It has no default. AS numbers 64512 – 65535 are the well-known private BGP4 AS numbers and are not advertised to the Internet community.

Configuring BGP4 multipath load sharing

To change the maximum number of BGP4 shared paths, enter commands such as the following.

```
NetIron(config)# router bgp
NetIron(config-bgp)# maximum-paths 4
NetIron(config-bgp)# write memory
```

Syntax: [**no**] **maximum-paths** <*number*> | **use-load-sharing**

The <*number*> parameter specifies the maximum number of paths across which the device can balance traffic to a given BGP4 destination. You can change the maximum number of paths to a value from 2 – 8. The default is 1.

When the **use-load-sharing** option is used in place of the <*number*> variable, the maximum IP ECMP path value is determined solely by the value configured using the **ip load-sharing** command.

Customizing BGP4 multipath load sharing

By default, when BGP4 Multipath load sharing is enabled, both IBGP and EBGP paths are eligible for load sharing, while paths from different neighboring ASs are not eligible. You can change load sharing to apply only to IBGP or EBGP paths, or to support load sharing among paths from different neighboring ASs.

To enable load sharing of IBGP paths only, enter the following command at the BGP4 configuration level of the CLI.

```
NetIron(config-bgp)# multipath ibgp
```

To enable load sharing of EBGP paths only, enter the following command at the BGP4 configuration level of the CLI.

```
NetIron(config-bgp)# multipath ebgp
```

To enable load sharing of paths from different neighboring ASs, enter the following command at the BGP4 configuration level of the CLI.

```
NetIron(config-bgp)# multipath multi-as
```

Syntax: [**no**] **multipath ebgp** | **ibgp** | **multi-as**

The **ebgp | ibgp | multi-as** parameter specifies the change you are making to load sharing:

- **ebgp** – Load sharing applies only to EBGP paths. Load sharing is disabled for IBGP paths.
- **ibgp** – Load sharing applies only to IBGP paths. Load sharing is disabled for EBGP paths.
- **multi-as** – Load sharing is enabled for paths from different ASs.

By default, load sharing applies to EBGP and IBGP paths, and does not apply to paths from different neighboring ASs.

Enhancements to BGP4 load sharing

Enhancements to BGP4 Load Sharing allows support for load sharing of BGP4 routes in IP ECMP even if the BGP4 multipath load sharing feature is not enabled through the **use-load-sharing** option to the **maximum-paths** command. Using the following commands, you can also set separate values for IGMP and EGMP multipath load sharing.

To set the number of equal-cost multipath IBGP routes or paths that will be selected, enter commands such as the following.

```
NetIron(config)# router bgp
NetIron(config-bgp)# maximum-paths ibgp
```

Syntax: [**no**] **maximum-paths ibgp** <*num*>

The <*num*> variable specifies the number of equal-cost multipath IBGP routes that will be selected. Possible values are 1 - 8. If the value is set to 1, BGP4 level equal-cost multipath is disabled for IBGP routes.

To set the number of equal-cost multipath EBGP routes or paths that will be selected, enter commands such as the following.

```
NetIron(config)# router bgp
NetIron(config-bgp)# maximum-paths ebgp
```

Syntax: [**no**] **maximum-paths ebgp** <*num*>

The <*num*> variable specifies the number of equal-cost multipath EBGP routes that will be selected. Possible values are 1 - 8. If the value is set to 1, BGP4 level equal-cost multipath is disabled for EBGP routes.

Configuring a static BGP4 network

This feature allows you to configure a static network in BGP4, creating a stable BGP4 network in the core. While a route configured with this feature will never flap unless it is manually deleted, a "static" BGP4 network will not interrupt the normal BGP4 decision process on other learned routes being installed into the RTM (Routing Table Manager). Consequently, when there is a route that can be resolved, it will be installed into the RTM.

To configure a static BGP4 network, enter commands such as the following.

```
NetIron(config)# router bgp
NetIron(config-bgp)# static-network 209.157.22.26/16
```

Syntax: [**no**] **static-network** <*ipAddressPrefix/mask*>

The <*ipAddress/mask*> variable is the IPv4 address prefix and mask of the static BGP4 network you are creating.

Using the **no** option uninstalls a route (that was previously installed) from BGP4 RIB-IN and removes the corresponding drop route from the RTM. If there is a new best route, it is advertised to peers if necessary. Otherwise, a withdraw message is sent.

NOTE
The BGP4 network route and the BGP4 static network route are mutually exclusive. They cannot be configured with the same prefix and mask.

When you configure a route using the **static-network** command, BGP4 automatically generates a local route in BGP4 RIB-IN, and installs a NULL0 route in the RTM if there is no other valid route with the same prefix/mask learned from any peer. Otherwise, the learned BGP4 route will be installed in the RTM. In either situation, the new locally generated route will be the best route in RIB-IN and will be advertised to peers if it passes the per-peer outbound policies.

Setting an administrative distance for a static BGP4 network

When a static BGP4 network route is configured, its type is *local BGP4 route* and has a default administrative distance value of 200. To change the administrative distance value, change the value of all local BGP4 routes using the **distance** command at the router bgp level of the CLI, and set a new value for local routes as described in "Changing administrative distances" on page 1030. You can also assign a specific administrative distance value for each static network using the **distance** option as shown.

```
NetIron(config)# router bgp
NetIron(config-bgp)# static-network 209.157.22.26/16 distance 100
```

Syntax: [**no**] **static-network** <*ipAddressPrefix/mask*> **distance** <*distance-value*>

The <*ipAddress/mask*> variable is the IPv4 address prefix and mask of the static BGP4 network for which you are setting an administrative distance.

The <*distance-value*> sets the administrative distance of the static BGP4 network route. The range for this value is 1 – 255.

Limiting advertisement of a static BGP4 network to selected neighbors

You can control the advertisement of a static BGP4 network to BGP4 neighbors that are configured as Service Edge Devices. When this feature is configured for a BGP4 neighbor, static BGP4 network routes that are installed in the routing table as DROP routes are not advertised to that neighbor. When this feature is configured, the route is only advertised to identified Service Edge devices if it is installed as a forward route, such as the routes described in these steps.

1. There is a learned route from a customer BGP4 peering.
2. There is a valid learned route from another Services Edge device as a result of a customer route present on that device.

To configure a BGP4 neighbor to limit the advertisement of Static BGP4 Network routes, enter the **static-network-edge** command as shown.

```
NetIron(config)# router bgp
NetIron(config-bgp)# neighbor 1.2.3.4 static-network-edge
```

Syntax: [**no**] **neighbor** <*ip-address*> | <*peer-group-name*> **static-network-edge**

The <*ip-addr*> | <*peer-group-name*> variable indicates whether you are configuring an individual neighbor or a peer group. If you specify a neighbor IP address, you are configuring that individual neighbor. If you specify a peer group name, you are configuring a peer group. Refer to "Configuring a BGP4 peer group" on page 1046.

Configuring paths without MEDs as the least favorable

During MED comparison, by default, the device favors a lower MED over a higher MED. Since the device assigns the value 0 to a route path MED if the MED value is missing, the default MED comparison results in the device favoring the route paths that do not have MEDs.

To configure the device to favor a route with a MED over a route that does not have a MED, enter the following command at the BGP4 configuration level of the CLI.

```
NetIron(config-bgp)# med-missing-as-worst
```

Syntax: [no] **med-missing-as-worst**

NOTE
This command affects route selection only when route paths are selected based on MED comparison. It is still possible for a route path without a MED to be selected based on other criteria. For example, a route path with no MED can be selected if its weight is larger than the weights of the other route paths.

Configuring BGP4 neighbors

Because BGP4 does not contain a peer discovery process, for each BGP4 neighbor (peer), you must indicate the IP address and the AS number of each neighbor. Neighbors that are in different ASs communicate using EBGP. Neighbors within the same AS communicate using IBGP.

NOTE
If the device has multiple neighbors with similar attributes, you can simplify configuration by configuring a peer group, then adding individual neighbors to it. The configuration steps are similar, except you specify a peer group name instead of a neighbor IP address when configuring the neighbor parameters, then add individual neighbors to the peer group. Refer to "Configuring a BGP4 peer group" on page 1046.

NOTE
The device attempts to establish a BGP4 session with a neighbor as soon as you enter a command specifying the IP address of the neighbor. If you want to completely configure the neighbor parameters before the device establishes a session with the neighbor, you can administratively shut down the neighbor. Refer to "Administratively shutting down a session with a BGP4 neighbor" on page 1049.

To add a BGP4 neighbor with an IP address 209.157.22.26 remote-as 100, enter the following command.

```
NetIron(config-bgp)# neighbor 209.157.22.26 remote-as 100
```

The neighbor's <*ip-addr*> must be a valid IP address.

The **neighbor** command has additional parameters, as shown in the following syntax:

Syntax: [**no**] **neighbor** {<*ip-addr*> | <*peer-group-name*>}
{
[**activate**]
[**advertisement-interval** <*seconds*>

[**allowas-in** <*num*>]
[**bfd holdover-interval** <*num*>]
[**bfd min-tx** <*num*> **min-rx** <*num*> **multiplier** <*num*>]
[**capability as4** [**enable** | **disable**]]
[**capability orf prefixlist** [**send** | **receive**]]
[**default-originate** [**route-map** <*map-name*>]]
[**description** <*string*>]
[**distribute-list in** | **out** <*num,num,...*> | <*acl-num*> **localin** | **out**]
[**ebgp-btsh**]
[**ebgp-multihop** <*num*>]
[**enforce-first-as**]
[**filter-list** <*access-list-name*> [**in** | **out**]]
[**local-as** <*as-num*> [**no-prepend**]]
[**maxas-limit in** [<*num*> |**disable**]
[**maximum-prefix** <*num*> [<*threshold*>] [**teardown**]
[**next-hop-self**]
[**password** <*string*>]
[**peer-group** <*group-name*>]
[**prefix-list** <*string*> **in** | **out**]
[**remote-as** <*as-number*>]
[**remove-private-as**]
[**route-map in** | **out** <*map-name*>]
[**route-reflector-client**]
[**send-community**]
[**shutdown** [**generate-rib-out**]]
[**soft-reconfiguration inbound**]
[**static-network-edge**]
[**timers keep-alive** <*num*> **hold-time** <*num*>]
[**unsuppress-map** <*map-name*>]
[**update-source** <*ip-addr*> | **ethernet** <*slot*>/<*portnum*> | **pos** <*slot*>/<*portnum*> | **loopback** <*num*> | **ve** <*num*>]
[**weight** <*num*>]
}

The <*ip-addr*> | <*peer-group-name*> parameter indicates whether you are configuring an individual neighbor or a peer group. If you specify a neighbor IP address, you are configuring that individual neighbor. If you specify a peer group name, you are configuring a peer group. Refer to "Configuring a BGP4 peer group" on page 1046.

activate allows exchange of routes in the current family mode.

advertisement-interval <*seconds*> configures an interval in seconds over which the specified neighbor or peer group will hold all route updates before sending them. At the expiration of the timer, the routes are sent as a batch. The default value for this parameter is zero. Acceptable values are 0 to 600 seconds.

allowas-in <*num*> disables the AS_PATH check function for routes learned from a specified location. BGP4 usually rejects routes that contain an AS number within an AS_PATH attribute to prevent routing loops. In an MPLS or VPN hub and spoke topology this can prevent legitimate routes from being accepted. The **allowas-in** option stops this blockage. <*num*> specifies the number of occurrences of the AS number.

bfd holdover-interval and **bfd min-tx** options are described in "Configuring BFD for BGP4" on page 2156.

capability as4 [**enable** | **disable**] enables the capability of processing AS4s. The optional keywords **enable** | **disable** specify whether the feature should be changed from its current state. For example, if this neighbor belongs to a peer group that is enabled for AS4s but you want disable it on the current interface, use the command and include the **disable** keyword.

capability orf prefixlist [**send** | **receive**] configures cooperative device filtering. The **send** | **receive** parameter specifies the support you are enabling:

- **send** – The device sends the IP prefix lists as Outbound Route Filters (ORFs) to the neighbor.
- **receive** – The device accepts filters as Outbound Route Filters (ORFs) from the neighbor.

If you do not specify either **send** or **receive**, both capabilities are enabled. The **prefixlist** parameter specifies the type of filter you want to send to the neighbor.

For more information, refer to "Configuring cooperative BGP4 route filtering" on page 1083.

NOTE
The current release supports cooperative filtering only for filters configured using IP prefix lists.

default-originate [**route-map** <*map-name*>] configures the device to send the default route 0.0.0.0 to the neighbor. If you use the route-map <*map-name*> parameter, the route map injects the default route conditionally, based on the match conditions in the route map.

description <*string*> specifies a name for the neighbor. You can enter an alphanumeric text string up to 80 characters long.

distribute-list in | out <*num,num,...*> specifies a distribute list to be applied to updates to or from the specified neighbor. The **in** | **out** keywords specify whether the list is applied on updates received from the neighbor, or sent to the neighbor. The <*num,num,...*> parameter specifies the list of address-list filters. The device applies the filters in the order in which you list them and stops applying the filters in the distribute list when a match is found.

To use an IP ACL instead of a distribute list, you can specify **distribute-list** <*acl-num*> **in** | **out** . In this case, <*acl-num*> is an IP ACL.

NOTE
By default, if a route does not match any of the filters, the device denies the route. To change the default behavior, configure the last filter as **permit any any**.

NOTE
The address filter must already be configured. Refer to "Defining and applying IP prefix lists" on page 1067.

ebgp-btsh enables GTSM protection for the specified neighbor. For details, see "Generalized TTL Security Mechanism support" on page 1103.

ebgp-multihop [<*num*>] specifies that the neighbor is more than one hop away and that the session type with the neighbor is EBGP-multihop. This option is disabled by default. The <*num*> parameter specifies the TTL you are adding for the neighbor. You can specify a number from 0 – 255. The default is 0. If you leave the EBGP TTL value set to 0, the software uses the IP TTL value.

enforce-first-as ensures, for this neighbor, that the first AS listed in the AS_SEQUENCE field of an AS path update message from EBGP neighbors is the AS of the neighbor that sent the update. For details, refer to "Requiring the first AS to be the neighbor AS" on page 1032.

filter-list in | out <*num,num,...*> specifies an AS-path filter list or a list of AS-path ACLs. The **in | out** keywords specify whether the list is applied on updates received from the neighbor or sent to the neighbor. If you specify **in** or **out**, The <*num,num,...*> parameter specifies the list of AS-path filters. The device applies the filters in the order in which you list them and stops applying the filters in the AS-path filter list when a match is found. The **weight** <*num*> parameter specifies a weight that the device applies to routes received from the neighbor that match the AS-path filter or ACL. You can specify a number from 0 – 65535.

Alternatively, you can specify **filter-list** <*acl-num*> **in | out | weight** to use an AS-path ACL instead of an AS-path filter list. In this case, <*acl-num*> is an AS-path ACL.

NOTE
By default, if an AS-path does not match any of the filters or ACLs, the device denies the route. To change the default behavior, configure the last filter or ACL as **permit any any**.

NOTE
The AS-path filter or ACL must already be configured. Refer to "Filtering AS-paths" on page 1063.

local-as <*as-num*> assigns a local AS number with the value specified by the <*as-num*> variable to the neighbor being configured. The <*as-number*> has no default value. Its range is 1 – 4294967295.

NOTE
When the **local-as** option is used, the device automatically prepends the local AS number to the routes that are received from the EBGP peer; to disable this behavior, include the **no-prepend** keyword.

maxas-limit in <*num*> |**disable** specifies that the router discard routes that exceed a maximum AS path length received in UPDATE messages. You can specify a value from 0 – 300. The default value is 300. The **disable** keyword is used to stop a neighbor from inheriting the configuration from the peer-group or global and to the use system default value.

maximum-prefix <*num*> specifies the maximum number of IP network prefixes (routes) that can be learned from the specified neighbor or peer group. You can specify a value from 0 – 4294967295. The default is 0 (unlimited).

- The <*num*> value is the maximum number. The range is 0 – 4294967295. The default is 0 (unlimited).
- The <*threshold*> parameter specifies the percentage of the value you specified for the **maximum-prefix** <*num*>, at which you want the software to generate a Syslog message. You can specify a value from 1 (one percent) to 100 (100 percent). The default is 100.
- The **teardown** parameter tears down the neighbor session if the maximum-prefix limit is exceeded. The session remains shutdown until you clear the prefixes using the **clear ip bgp neighbor all** or **clear ip bgp neighbor** <*ip-addr*> command, or change the maximum-prefix configuration for the neighbor. The software also generates a Syslog message.

next-hop-self specifies that the device should list itself as the next hop in updates sent to the specified neighbor. This option is disabled by default.

password <*string*> specifies an MD5 password for securing sessions between the device and its neighbor. You can enter a string up to 80 characters long. The string can contain any alphanumeric characters and spaces if the words in the password are placed inside quotes.

The system creates an MD5 hash of the password and use it for securing sessions between the device and its neighbors. To display the configuration, the system uses a 2-way encoding scheme to be able to retrieve the original password that was entered.

By default, password is encrypted. If you want password to be in clear text, insert a **0** between **password** and <*string*>.

```
NetIron(config-bgp)# neighbor 209.157.22.26 remote-as password 0 marmalade
```

The system adds an encryption code followed by the encrypted text of the original password. For example, the following portion of the code has the encrypted code "2".

```
password 2 $IUA2PWc9LW9VIW9zVQ=="
```

One of the following may be displayed:

- 0 = the password is not encrypted and is in clear text
- 1 = the password uses proprietary simple crytographic 2-way algorithm
- 2 = the password uses proprietary base64 crytographic 2-way algorithm

peer-group <*group-name*> assigns the neighbor to the specified peer group.

prefix-list <*string*> **in** | **out** specifies an IP prefix list. You can use IP prefix lists to control routes to and from the neighbor. IP prefix lists are an alternative method to AS-path filters. The **in** | **out** keywords specify whether the list is applied on updates received from the neighbor or sent to the neighbor. The filters can use the same prefix list or different prefix lists. To configure an IP prefix list, refer to "Defining and applying IP prefix lists" on page 1067.

remote-as <*as-number*> specifies the AS in which the remote neighbor resides. The <*as-number*> has no default value. The range is 1 – 4294967295.

remove-private-as configures the device to remove private AS numbers from update messages the device sends to this neighbor. The device will remove AS numbers 64512 – 65535 (the well-known BGP4 private AS numbers) from the AS-path attribute in update messages the device sends to the neighbor. This option is disabled by default.

route-map in | **out** <*map-name*> specifies a route map the device will apply to updates sent to or received from the specified neighbor. The **in** | **out** keywords specify whether the list is applied on updates received from the neighbor or sent to the neighbor.

NOTE
The route map must already be configured. Refer to """Defining route maps" on page 1068.

route-reflector-client specifies that this neighbor is a route-reflector client of the device. Use the parameter only if this device is going to be a route reflector. For information, refer to "Configuring a route reflector" on page 1016. This option is disabled by default.

send-community enables sending the community attribute in updates to the specified neighbor. By default, the device does not send the community attribute.

shutdown administratively shuts down the session with this neighbor. Shutting down the session lets you configure the neighbor and save the configuration without actually establishing a session with the neighbor.

When a peer is put into the shutdown state, ribout routes are not produced for that peer. You can elect to produce ribout routes using the **generate-rib-out** option. This option is disabled by default.

soft-reconfiguration inbound enables the soft reconfiguration feature, which stores all the route updates received from the neighbor. If you request a soft reset of inbound routes, the software performs the reset by comparing the policies against the stored route updates, instead of requesting the neighbor BGP4 route table or resetting the session with the neighbor. Refer to "Using soft reconfiguration" on page 1090.

static-network-edge controls the advertisement of a static BGP4 network to BGP4 neighbors that are configured as Service Edge Devices. For more information, refer to "Limiting advertisement of a static BGP4 network to selected neighbors" on page 1036.

timers keep-alive <*num*> **hold-time** <*num*> overrides the global settings for the Keep Alive Time and Hold Time. For the Keep Alive Time, you can specify 0 – 65535 seconds. For the Hold Time, you can specify 0 or a number in the range 3 – 65535 (1 and 2 are not allowed). If you set the Hold Time to 0, the device waits indefinitely for messages from a neighbor without concluding that the neighbor is non-operational. The defaults for these parameters are the currently configured global Keep Alive Time and Hold Time. For more information about these parameters, refer to "Changing the Keep Alive Time and Hold Time" on page 1057.

unsuppress-map <*map-name*> removes route suppression from neighbor routes when those routes have been suppressed due to aggregation. Refer to "Removing route dampening from suppressed routes" on page 1043.

update-source <*ip-addr*> | **ethernet** <*slot*>/<*portnum*> | **pos** <*slot*>/<*portnum*> | **loopback** <*num*> | **ve** <*num*> configures the device to communicate with the neighbor through the specified interface. There is no default.

weight <*num*> specifies a weight the device will add to routes received from the specified neighbor. BGP4 prefers larger weights over smaller weights. The default weight is 0.

Auto shutdown of BGP4 neighbors on initial configuration

You can use the global **auto-shutdown-new-neighbors** command within the **router bgp** configuration to disable establishment of the BGP4 connection with a remote peer when the peer is first configured, as follows.

```
NetIron(config)# router bgp
NetIron(config-bgp)# auto-shutdown-new-neighbors
```

Once all of the configuration parameters for the peer are complete, you can start the BGP4 session establishment process using the **no** option with the existing peer shutdown option command to disable the peer shutdown state.

```
NetIron(config)# router bgp
NetIron(config-bgp)# no neighbor 1.1.1.1 shutdown
```

Syntax: [**no**] **neighbor** <*ip-address*> **shutdown**

If auto shutdown of BGP4 neighbors is enabled and you want to disable it to allow a new BGP4 peer configured to establish a connection with remote peers, use the **no** option with the command.

```
NetIron(config)# router bgp
NetIron(config-bgp)# no auto-shutdown-new-neighbors
```

Syntax: [**no**] **auto-shutdown-new-neighbors**

The default state for auto shutdown of BGP4 neighbors is disabled.

NOTE
When the **auto-shutdown-new-neighbors** value is changed, the value of the shutdown parameter for any of the existing configured neighbors is not changed. Any new BGP4 neighbor configured after the setting of the **auto-shutdown-new-neighbors** command will have the shutdown state set to the current value of the **auto-shutdown-new-neighbors** command. Previously configured peer group parameters are not affected by the **auto-shutdown-new-neighbors** command.

When a new peer group is created and new neighbors belonging to this peer group are being configured, you can use the **peer group shutdown** parameter to prevent the establishment of connections with remote peers.

Using the auto shutdown of BGP4 neighbors during a configuration

To control when a newly-configured BGP4 neighbor establishes a BGP4 session, use the **auto-shutdown-new-neighbors** command.

```
NetIron(config)# router bgp
NetIron(config-bgp)# auto-shutdown-new-neighbors
NetIron(config-bgp)# neighbor 1.1.1.1 remote-as 200
```

Once all of the BGP4 neighbor configuration parameters are configured, use the following commands to establish the BGP4 session.

```
NetIron(config)# router bgp
NetIron(config-bgp)# no neighbor 1.1.1.1 shutdown
```

Removing route dampening from suppressed routes

You can selectively unsuppress specific routes that have been suppressed due to aggregation, and allow these routes to be advertised to a specific neighbor or peer group.

```
NetIron(config-bgp)# aggregate-address 209.1.0.0 255.255.0.0 summary-only
NetIron(config-bgp)# show ip bgp route 209.1.0.0/16 longer
Number of BGP Routes matching display condition : 2
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED F:FILTERED
Prefix             Next Hop        Metric     LocPrf     Weight Status
1      209.1.0.0/16       0.0.0.0                   101        32768  BAL
AS_PATH:
2      209.1.44.0/24      10.2.0.1        1         101        32768  BLS
AS_PATH:
```

In this example, the **aggregate-address** command configures an aggregate address of 209.1.0.0 255.255.0.0. and the **summary-only** parameter prevents the device from advertising more specific routes contained within the aggregate route.

Entering a **show ip bgp route** command for the aggregate address 209.1.0.0/16 shows that the more specific routes aggregated into 209.1.0.0/16 have been suppressed. In this case, the route to 209.1.44.0/24 has been suppressed. If you enter this command, the display shows that the route is not being advertised to the BGP4 neighbors.

```
NetIron(config-bgp)# show ip bgp route 209.1.44.0/24
Number of BGP Routes matching display condition : 1
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED F:FILTERED
Prefix             Next Hop        Metric     LocPrf     Weight Status
1      209.1.44.0/24      10.2.0.1        1          101        32768  BLS
AS_PATH:
Route is not advertised to any peers
```

To override the **summary-only** parameter and allow a specific route to be advertised to a neighbor, enter commands such as the following

```
NetIron(config)# ip prefix-list Unsuppress1 permit 209.1.44.0/24
NetIron(config)# route-map RouteMap1 permit 1
NetIron(config-routemap RouteMap1)# match prefix-list Unsuppress1
NetIron(config-routemap RouteMap1)# exit
NetIron(config)# router bgp
NetIron(config-bgp)# neighbor 10.1.0.2 unsuppress-map RouteMap1
NetIron(config-bgp)# clear ip bgp neighbor 10.1.0.2 soft-out
```

The **ip prefix-list** command configures an IP prefix list for network 209.1.44.0/24, which is the route you want to unsuppress. The next two commands configure a route map that uses the prefix list as input. The **neighbor** command enables the device to advertise the routes specified in the route map to neighbor 10.1.0.2. The **clear** command performs a soft reset of the session with the neighbor so that the device can advertise the unsuppressed route.

Syntax: [**no**] **neighbor** <*ip-addr*> | <*peer-group-name*> **unsuppress-map** <*map-name*>

The **show ip bgp route** command verifies that the route has been unsuppressed.

```
NetIron(config-bgp)# show ip bgp route 209.1.44.0/24
Number of BGP Routes matching display condition : 1
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED F:FILTERED
Prefix             Next Hop        Metric     LocPrf     Weight Status
1      209.1.44.0/24      10.2.0.1        1          101        32768  BLS
AS_PATH:
Route is advertised to 1 peers:
10.1.0.2(4)
```

Encrypting BGP4 MD5 authentication keys

When you configure a BGP4 neighbor or neighbor peer group, you can specify an MD5 authentication string to authenticate packets exchanged with the neighbor or peer group of neighbors.

For added security, by default, the software encrypts the display of the authentication string. The software also provides an optional parameter to disable encryption of the authentication string, on an individual neighbor or peer group basis. By default, MD5 authentication strings are displayed in encrypted format in the output of the following commands:

- **show running-config** (or **write terminal**)
- **show configuration**
- **show ip bgp config**

When encryption of the authentication string is enabled, the string is encrypted in the CLI regardless of the access level you are using.

When you save the configuration to the startup configuration file, the file contains the new BGP4 command syntax and encrypted passwords or strings.

NOTE
It is recommended that you save a copy of the startup configuration file for each device you plan to upgrade.

Encryption example

The following commands configure a BGP4 neighbor and a peer group, and specify MD5 authentication strings (passwords) to authenticate packets exchanged with the neighbor or peer group.

```
NetIron(config-bgp)# local-as 2
NetIron(config-bgp)# neighbor xyz peer-group
NetIron(config-bgp)# neighbor xyz password abc
NetIron(config-bgp)# neighbor 10.10.200.102 peer-group xyz
NetIron(config-bgp)# neighbor 10.10.200.102 password test
```

The BGP4 configuration commands appear in the following format as a result of the **show ip bgp configuration** command.

```
NetIron(config-bgp)# show ip bgp configuration
Current BGP configuration:
router bgp
 local-as 2
 neighbor xyz peer-group
 neighbor xyz password 2 $b24tbw==
 neighbor 10.10.200.102 peer-group xyz
 neighbor 10.10.200.102 remote-as 1
 neighbor 10.10.200.102 password 2 $on-o
```

In this output, the software has converted the commands that specify an authentication string into the new syntax (described below), and has encrypted display of the authentication strings.

Syntax: [**no**] **neighbor** <*ip-addr*> |<*peer-group-name*> **password** <*string*>

The <*ip-addr*> | <*peer-group-name*> parameters indicate whether you are configuring an individual neighbor or a peer group. If you specify the IP address of a neighbor, you are configuring that individual neighbor. If you specify a peer group name, you are configuring a peer group.

The password <*string*> parameter specifies an MD5 authentication string to secure sessions between the device and the neighbor. You can enter a string of up to 80 characters. The string can contain any alphanumeric characters, but must be placed inside quotes if it contains a space.

The system creates an MD5 hash of the password and uses it to secure sessions between the device and the neighbors. To display the configuration, the system uses a 2-way encoding scheme to retrieve the original password.

By default, password is encrypted. If you want the password to be in clear text, insert a **0** between **password** and <*string*>.

```
NetIron(config-bgp)# neighbor 209.157.22.26 remote-as password 0 admin
```

The system adds an encryption code followed by the encrypted text of the original password. For example, the following portion of the code has the encrypted code “2”.

```
password 2 $IUA2PWc9LW9VIW9zVQ=="

NetIron(config-bgp)# neighbor 209.157.22.26 remote-as password 0 marmalade
```

One of the following may be displayed:

- 0 - the password is not encrypted and is in clear text
- 1 - the password uses proprietary simple crytographic 2-way algorithm
- 2 - the password uses proprietary base64 crytographic 2-way algorithm

Displaying the authentication string

To display the authentication string, enter the following commands.

```
NetIron(config)# enable password-display
NetIron(config)# show ip bgp neighbors
```

The **enable password-display** command enables display of the authentication string, but only in the output of the **show ip bgp neighbors** command. String display is still encrypted in the startup configuration file and running configuration.

Configuring a BGP4 peer group

A ***peer group*** is a set of BGP4 neighbors that share common parameters. The benefits of peer groups are:

- **Simplified neighbor configuration** – You can configure a set of neighbor parameters and then apply them to multiple neighbors. You do not need to configure the common parameters individually on each neighbor.
- **Flash memory conservation** – Using peer groups instead of individually configuring all the parameters for each neighbor requires fewer configuration commands in the startup configuration file.

You can perform the following tasks on a peer-group basis:

- Reset neighbor sessions
- Perform soft-outbound resets (the device updates outgoing route information to neighbors but does not entirely reset the sessions with those neighbors)
- Clear BGP4 message statistics
- Clear error buffers

Peer group parameters

You can set all neighbor parameters in a peer group. When you add a neighbor to the peer group, the neighbor receives all the parameter settings you set in the group, except parameter values you have explicitly configured for the neighbor. If you do not set a neighbor parameter in the peer group and the parameter also is not set for the individual neighbor, the neighbor uses the default value.

Configuration rules

The following rules apply to peer group configuration.

- You must configure a peer group before you can add neighbors to the peer group.
- If you remove a parameter from a peer group, the value for that parameter is reset to the default for all the neighbors within the peer group, unless you have explicitly set that parameter on individual neighbors. In this case, the value you set on the individual neighbors applies to those neighbors, while the default value applies to neighbors for which you have not explicitly set the value.

NOTE
If you enter a command to remove the remote AS parameter from a peer group, the software makes sure that the peer group does not contain any neighbors. If the peer group contains neighbors, the software does not allow you to remove the remote AS so that the neighbors in the peer group that are using the remote AS do not lose connectivity to the device.

You can override neighbor parameters on an individual neighbor basis:

- If you do not specify a parameter for an individual neighbor, the neighbor uses the value in the peer group.
- If you set the parameter for the individual neighbor, that value overrides the value you set in the peer group.
- If you add a parameter to a peer group that already contains neighbors, the parameter value is applied to neighbors that do not already have the parameter explicitly set. If a neighbor has the parameter explicitly set, the explicitly set value overrides the value you set for the peer group.
- If you remove the setting for a parameter from a peer group, the value for that parameter changes to the default value for all the neighbors in the peer group that do not have that parameter individually set.

Configuring a peer group

To configure a peer group, enter commands such as the following at the BGP4 configuration level.

```
NetIron(config-bgp)# neighbor PeerGroup1 peer-group
NetIron(config-bgp)# neighbor PeerGroup1 description “EastCoast Neighbors”
NetIron(config-bgp)# neighbor PeerGroup1 remote-as 100
NetIron(config-bgp)# neighbor PeerGroup1 distribute-list out 1
NetIron(config-bgp)# neighbor PeerGroup1 capability as4
```

The commands in this example configure a peer group called “PeerGroup1” and set the following parameters for the peer group:

- A description, “EastCoast Neighbors”
- A remote AS number, 100
- A distribute list for outbound traffic
- The capability of Peergroup1 to utilize four-byte AS number

The software applies these parameters to each neighbor you add to the peer group. You can override the description parameter for individual neighbors. If you set the description parameter for an individual neighbor, the description overrides the description configured for the peer group.

Syntax: **neighbor** <*peer-group-name*> **peer-group**

The <*peer-group-name*> parameter specifies the name of the group and can be up to 80 characters long. The name can contain special characters and internal blanks. If you use internal blanks, you must use quotation marks around the name. For example, the command **neighbor "My Three Peers"** peer-group is valid, but the command **neighbor My Three Peers** peer-group is not valid.

Syntax: [**no**] **neighbor** <*ip-addr*> |<*peer-group-name*>
[**default-originate** [**route-map** <*map-name*>]]
[**description** <*string*>]
[**distribute-list in** | **out** <*num,num,...*> | <*acl-num*> **in** | **out**]
[**ebgp-multihop** [<*num*>]]
[**filter-list in** | **out** <*num,num,...*> | <*acl-num*> **in** | **out** | **weight**]
[**maxas-limit in** [<*num*> |**disable**]
[**maximum-prefix** <*num*> [<*threshold*>] [**teardown**]]
[**next-hop-self**]
[**password** <*string*>]
[**prefix-list** <*string*> **in** | **out**]
[**remote-as** <*as-number*>]
[**remove-private-as**]
[**route-map in** | **out** <*map-name*>]
[**route-reflector-client**]
[**send-community**]
[**soft-reconfiguration inbound**]
[**shutdown**]
[**timers keep-alive** <*num*> **hold-time** <*num*>]
[**update-source loopback** <*num*> **ethernet** <*slot*>/<*portnum*> | **pos** <*slot*>/<*portnum*> | **loopback** <*num*> | **ve** <*num*>]
[**weight** <*num*>]
[**local-as** <*as-num*>]

The <*ip-addr*> |<*peer-group-name*> parameters indicate whether you are configuring a peer group or an individual neighbor. You can specify a peer group name or IP address with the **neighbor** command. If you specify a peer group name, you are configuring a peer group. If you specify a neighbor IP address, you are configuring that individual neighbor. Use the <*ip-addr*> parameter if you are configuring an individual neighbor instead of a peer group. Refer to "Configuring BGP4 neighbors" on page 1037 and "Configuring a BGP4 peer group" on page 1046.

The remaining parameters are the same ones supported for individual neighbors. Refer to "Configuring BGP4 neighbors" on page 1037 and "Configuring a BGP4 peer group" on page 1046.

Applying a peer group to a neighbor

After you configure a peer group, you can add neighbors to the group. When you add a neighbor to a peer group, you are applying all the neighbor attributes specified in the peer group to the neighbor.

To add neighbors to a peer group, enter commands such as the following.

```
NetIron(config-bgp)# neighbor 192.168.1.12 peer-group PeerGroup1
NetIron(config-bgp)# neighbor 192.168.2.45 peer-group PeerGroup1
NetIron(config-bgp)# neighbor 192.168.3.69 peer-group PeerGroup1
```

The commands in this example add three neighbors to the peer group “PeerGroup1”. As members of the peer group, the neighbors automatically receive the neighbor parameter values configured for the peer group. You also can override the parameters on an individual neighbor basis. For neighbor parameters not specified for the peer group, the neighbors use the default values.

Syntax: [**no**] **neighbor** <*ip-addr*> **peer-group** <*peer-group-name*>

The <*ip-addr*> parameter specifies the IP address of the neighbor.

The <*peer-group-name*> parameter specifies the peer group name.

NOTE
You must add the peer group before you can add neighbors to it.

Administratively shutting down a session with a BGP4 neighbor

You can prevent the device from starting a BGP4 session with a neighbor by administratively shutting down the neighbor. This option is very useful for situations in which you want to configure parameters for a neighbor, but are not ready to use the neighbor. You can shut the neighbor down as soon as you have added it the device, configure the neighbor parameters, then allow the device to reestablish a session with the neighbor by removing the shutdown option from the neighbor.

When you apply the option to shut down a neighbor, the option takes place immediately and remains in effect until you remove it. If you save the configuration to the startup configuration file, the shutdown option remains in effect even after a software reload.

The software also contains an option to end the session with a BGP4 neighbor and clear the routes learned from the neighbor. Unlike this clear option, the option for shutting down the neighbor can be saved in the startup configuration file and can prevent the device from establishing a BGP4 session with the neighbor even after reloading the software.

NOTE
If you notice that a particular BGP4 neighbor never establishes a session with the device, check the running configuration and startup configuration files for that device to see whether the configuration contains a command that is shutting down the neighbor. The neighbor may have been shut down previously by an administrator.

To shut down a BGP4 neighbor, enter commands such as the following.

```
NetIron(config)# router bgp
NetIron(config-bgp)# neighbor 209.157.22.26 shutdown
NetIron(config-bgp)# write memory
```

Syntax: [**no**] **neighbor** <*ip-addr*> **shutdown**

The <*ip-addr*> parameter specifies the IP address of the neighbor.

Specifying a list of networks to advertise

By default, the device sends BGP4 routes only for the networks you either identify with the **network** command or are redistributed into BGP4 from OSPF, ISIS, RIP, or connected routes.

NOTE
The exact route must exist in the IP route table before the device can create a local BGP4 route.

To configure the device to advertise network 209.157.22.0/24, enter the following command.

```
NetIron(config-bgp)# network 209.157.22.0 255.255.255.0
```

Syntax: [**no**] **network** <*ip-addr*> <*ip-mask*> [**route-map** <*map-name*>] | [**weight** <*num*>] | [**backdoor**]

The <*ip-addr*> is the network number and the <*ip-mask*> specifies the network mask.

The **route-map** <*map-name*> parameter specifies the name of the route map you want to use to set or change BGP4 attributes for the network you are advertising. The route map must already be configured. If it is not, the default action is to deny redistribution.

The **weight** <*num*> parameter specifies a weight to be added to routes to this network.

The **backdoor** parameter changes the administrative distance of the route to this network from the EBGP administrative distance (20 by default) to the Local BGP4 weight (200 by default), tagging the route as a backdoor route. Use this parameter when you want the device to prefer IGP routes such as RIP or OSPF routes over the EBGP route for the network.

Specifying a route map when configuring BGP4 network advertising

You can specify a route map when you configure a BGP4 network to be advertised. The device uses the route map to set or change BGP4 attributes when creating a local BGP4 route.

NOTE
You must configure the route map *before* you can specify the route map name in a BGP4 network configuration; otherwise, the route is not imported into BGP4.

To configure a route map, and use it to set or change route attributes for a network you define for BGP4 to advertise, enter commands such as the following.

```
NetIron(config)# route-map set_net permit 1
NetIron(config-routemap set_net)# set community no-export
NetIron(config-routemap set_net)# exit
NetIron(config)# router bgp
NetIron(config-bgp)# network 100.100.1.0/24 route-map set_net
```

The first two commands in this example create a route map named “set_net” that sets the community attribute for routes that use the route map to “NO_EXPORT”. The next two commands change the CLI to the BGP4 configuration level. The last command configures a network for advertising from BGP4, and associates the “set_net” route map with the network. When BGP4 originates the 100.100.1.0/24 network, BGP4 also sets the community attribute for the network to “NO_EXPORT”.

Syntax: [**no**] **network** <*ip-addr*> <*ip-mask*> [**route-map** <*map-name*>] | [**weight** <*num*>] | [**backdoor**]

The **route-map** <*map-name*> parameter specifies the name of the route map you want to use to set or change BGP4 attributes for the network you are advertising. The route map must already be configured.

For information about the other parameters, refer to “Defining route maps” on page 1068.

Using the IP default route as a valid next-hop for a BGP4 route

By default, the device does not use a default route to resolve a BGP4 next-hop route. If the IP route lookup for the BGP4 next-hop does not result in a valid IGP route (including static or direct routes), the BGP4 next-hop is considered to be unreachable and the BGP4 route is not used.

In some cases, such as when the device is acting as an edge device, you can allow the device to use the default route as a valid next-hop. To do so, enter the following command at the BGP4 configuration level of the CLI.

```
NetIron(config-bgp)# next-hop-enable-default
```

Syntax: [no] next-hop-enable-default

Enabling next-hop recursion

For each BGP4 route learned, the device performs a route lookup to obtain the IP address of the next-hop for the route. A BGP4 route is eligible for addition in the IP route table only if the following conditions are true:

- The lookup succeeds in obtaining a valid next-hop IP address for the route.
- The path to the next-hop IP address is an IGP path or a static route path.

By default, the software performs only one lookup for the next-hop IP address for the BGP4 route. If the next-hop lookup does not result in a valid next-hop IP address, or the path to the next-hop IP address is a BGP4 path, the software considers the BGP4 route destination to be unreachable. The route is not eligible to be added to the IP route table.

The BGP4 route table can contain a route with a next-hop IP address that is not reachable through an IGP route, even though the device can reach a hop farther away through an IGP route. This can occur when the IGPs do not learn a complete set of IGP routes, so the device learns about an internal route through IBGP instead of through an IGP. In this case, the IP route table will not contain a route that can be used to reach the BGP4 route destination.

To enable the device to find the IGP route to the next-hop gateway for a BGP4 route, enable recursive next-hop lookups. With this feature enabled, if the first lookup for a BGP4 route results in an IBGP path that originated within the same AS, rather than an IGP path or static route path, the device performs a lookup on the next-hop IP address for the next-hop gateway. If this second lookup results in an IGP path, the software considers the BGP4 route to be valid and adds it to the IP route table. Otherwise, the device performs another lookup on the next-hop IP address of the next-hop for the next-hop gateway, and so on, until one of the lookups results in an IGP route.

NOTE
You must configure a static route or use an IGP to learn the route to the EBGP multihop peer.

Example when recursive route lookups are disabled

The output here shows the results of an unsuccessful next-hop lookup for a BGP4 route. In this case, next-hop recursive lookups are disabled. This example is for the BGP4 route to network 240.0.0.0/24.

```
NetIron# show ip bgp route
Total number of BGP Routes: 5
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED
       Prefix             Next Hop        Metric     LocPrf      Weight Status
1      0.0.0.0/0           10.1.0.2       0          100         0      BI
         AS_PATH: 65001 4355 701 80
2      102.0.0.0/24        10.0.0.1       1          100         0      BI
         AS_PATH: 65001 4355 1
3      104.0.0.0/24        10.1.0.2       0          100         0      BI
         AS_PATH: 65001 4355 701 1 189
4      240.0.0.0/24        102.0.0.1      1          100         0      I
         AS_PATH: 65001 4355 3356 7170 1455
5      250.0.0.0/24        209.157.24.1   1          100         0      I
         AS_PATH: 65001 4355 701
```

In this example, the device cannot reach 240.0.0.0/24, because the next-hop IP address for the route is an IBGP route instead of an IGP route, and is considered unreachable by the device. The IP route table entry for the next-hop gateway for the BGP4 route's next-hop gateway (102.0.0.1/24) is shown here.

```
NetIron# show ip route 102.0.0.1
Total number of IP routes: 37
      Network Address   Gateway          Port    Cost   Type
      102.0.0.0         10.0.0.1         1/1     1      B
```

Since the route to the next-hop gateway is a BGP4 route, and not an IGP route, it cannot be used to reach 240.0.0.0/24. In this case, the device tries to use the default route, if present, to reach the subnet that contains the BGP4 route next-hop gateway.

```
NetIron# show ip route 240.0.0.0/24
Total number of IP routes: 37
      Network Address   Gateway          Port    Cost   Type
      0.0.0.0           10.0.0.202       1/1     1      S
```

Example when recursive route lookups are enabled

When recursive next-hop lookups are enabled, the device continues to look up the next-hop gateways along the route until the device finds an IGP route to the BGP4 route destination.

```
NetIron# show ip bgp route
Total number of BGP Routes: 5
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED
       Prefix         Next Hop        Metric     LocPrf      Weight Status
1      0.0.0.0/0       10.1.0.2       0          100         0      BI
         AS_PATH: 65001 4355 701 80
2      102.0.0.0/24    10.0.0.1       1          100         0      BI
         AS_PATH: 65001 4355 1
3      104.0.0.0/24    10.1.0.2       0          100         0      BI
         AS_PATH: 65001 4355 701 1 189
4      240.0.0.0/24   102.0.0.1       1          100         0      BI
         AS_PATH: 65001 4355 3356 7170 1455
5      250.0.0.0/24   209.157.24.1    1          100         0       I
         AS_PATH: 65001 4355 701
```

The first lookup results in an IBGP route, to network 102.0.0.0/24.

```
NetIron# show ip route 102.0.0.1
Total number of IP routes: 38
      Network Address   Gateway           Port    Cost   Type
      102.0.0.0         10.0.0.1          1/1     1      B
         AS_PATH: 65001 4355 1
```

Since the route to 102.0.0.1/24 is not an IGP route, the device cannot reach the next hop through IP, and so cannot use the BGP4 route. In this case, since recursive next-hop lookups are enabled, the device next performs a lookup for the next-hop gateway to 102.0.0.1's next-hop gateway, 10.0.0.1.

```
NetIron# show ip bgp route 102.0.0.0
Number of BGP Routes matching display condition : 1
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED
       Prefix         Next Hop        Metric     LocPrf      Weight Status
1      102.0.0.0/24   10.0.0.1        1          100        0      BI
         AS_PATH: 65001 4355 1
```

The next-hop IP address for 102.0.0.1 is not an IGP route, which means the BGP4 route destination still cannot be reached through IP. The recursive next-hop lookup feature performs a lookup on the next-hop gateway for 10.0.0.1

```
NetIron# show ip route 10.0.0.1
Total number of IP routes: 38
      Network Address   Gateway           Port    Cost   Type
      10.0.0.0          0.0.0.0           1/1     1      D
        AS_PATH: 65001 4355 1
```

This lookup results in an IGP route that is a directly-connected route. As a result, the BGP4 route destination is now reachable through IGP, which means the BGP4 route can be added to the IP route table. The IP route table with the BGP4 route is shown here.

```
NetIron# show ip route 240.0.0.0/24
Total number of IP routes: 38
      Network Address    Gateway           Port    Cost   Type
      240.0.0.0          10.0.0.1          1/1     1      B
         AS_PATH: 65001 4355 1
```

The device can use this route because it has an IP route to the next-hop gateway. Without recursive next-hop lookups, this route would not be in the IP route table.

Enabling recursive next-hop lookups

The recursive next-hop lookups feature is disabled by default.

To enable recursive next-hop lookups, enter the following command at the BGP4 configuration level of the CLI.

```
NetIron(config-bgp)# next-hop-recursion
```

Syntax: [no] **next-hop-recursion**

Modifying redistribution parameters

By default, the device does not redistribute route information between BGP4 and the IP IGPs (RIP, ISIS, and OSPF). You can configure the device to redistribute OSPF, ISIS, or RIP routes, directly connected routes, or static routes into BGP4.

To enable redistribution of all OSPF routes and directly attached routes into BGP4, enter the following commands.

```
NetIron(config)# router bgp
NetIron(config-bgp)# redistribute ospf
NetIron(config-bgp)# redistribute connected
NetIron(config-bgp)# write memory
```

Syntax: [no] **redistribute connected** | **ospf** | **rip** | **isis** | **static**

The **connected** parameter indicates that you are redistributing routes to directly attached devices into BGP4.

The **ospf** parameter indicates that you are redistributing OSPF routes into BGP4.

NOTE
Entering **redistribute ospf** simply redistributes internal OSPF routes. To redistribute external OSPF routes also, use the **redistribute ospf match external...** command. Refer to "Redistributing OSPF external routes" on page 1055.

The **rip** parameter indicates that you are redistributing RIP routes into BGP4.

The **isis** parameter indicates that you are redistributing ISIS routes into BGP4.

The **static** parameter indicates that you are redistributing static routes into BGP4.

Redistributing connected routes

To configure BGP4 to redistribute directly connected routes, enter the following command.

```
NetIron(config-bgp)# redistribute connected
```

Syntax: [**no**] **redistribute connected** [**metric** <*num*>] [**route-map** <*map-name*>]

The **connected** parameter indicates that you are redistributing routes to directly attached devices into BGP4.

The **metric** <*num*> parameter changes the metric. You can specify a value from 0 – 4294967295. The default is not assigned.

The **route-map** <*map-name*> parameter specifies a route map to be consulted before adding the RIP route to the BGP4 route table.

NOTE
The route map you specify must already be configured on the device. Refer to "Defining route maps" on page 1068 for information about defining route maps.

Redistributing RIP routes

To configure BGP4 to redistribute RIP routes and add a metric of 10 to the redistributed routes, enter the following command.

```
NetIron(config-bgp)# redistribute rip metric 10
```

Syntax: [**no**] **redistribute rip** [**metric** <*num*>] [**route-map** <*map-name*>]

The **rip** parameter indicates that you are redistributing RIP routes into BGP4.

The **metric** <*num*> parameter changes the metric. You can specify a value from 0 – 4294967295. The default is not assigned.

The **route-map** <*map-name*> parameter specifies a route map to be consulted before adding the RIP route to the BGP4 route table.

NOTE
The route map you specify must already be configured on the device. Refer to "Defining route maps" on page 1068 for information about defining route maps.

Redistributing OSPF external routes

To configure the device to redistribute OSPF external type 1 routes, enter the following command.

```
NetIron(config-bgp)# redistribute ospf match external1
```

Syntax: [**no**] **redistribute ospf** [**match internal** | **external1** | **external2**] [**metric** <*num*>] [**route-map** <*map-name*>]

The **ospf** parameter indicates that you are redistributing OSPF routes into BGP4.

The match **internal | external1 | external2** parameters apply only to OSPF. These parameters specify the types of OSPF routes to be redistributed into BGP4. The default is internal.

NOTE
If you do not enter a value for the **match** parameter, (for example, you enter r**edistribute ospf** only) then only internal OSPF routes will be redistributed.

The **metric** <*num*> parameter changes the metric. You can specify a value from 0 – 4294967295. The default is not assigned.

The **route-map** <*map-name*> parameter specifies a route map to be consulted before adding the OSPF route to the BGP4 route table.

NOTE
The route map you specify must already be configured on the device. Refer to "Defining route maps" on page 1068 for information about defining route maps.

NOTE
If you use both the **redistribute ospf route-map** <*map-name*> command and the **redistribute ospf match internal** | **external1** | **external2** command, the software uses only the route map for filtering.

Redistributing IS-IS

To configure the device to redistribute IS-IS routes, enter the following command.

```
NetIron(config-bgp)# redistribute isis level-1
```

Syntax: [**no**] **redistribute isis level-1** | **level-1-2** | **level-2** [**metric** <*num*>] [**route-map** <*map-name*>]

The **isis** parameter indicates that you are redistributing IS-IS routes into BGP4.

The **level-1** parameter redistributes IS-IS routes only within the area the routes.

The **level-2** parameter redistributes IS-IS routes between areas within a domain.

The **level-1-2** parameter redistributes IS-IS routes within the area of the routes and between areas within a domain.

The **metric** <*num*> parameter changes the metric. You can specify a value from 0 – 4294967295. The default is not assigned.

The **route-map** <*map-name*> parameter specifies a route map to be consulted before adding the OSPF route to the BGP4 route table.

Redistributing static routes

To configure the device to redistribute static routes, enter the following command.

```
NetIron(config-bgp)# redistribute static
```

Syntax: [**no**] **redistribute static** [**metric** <*num*>] [**route-map** <*map-name*>]

The **static** parameter indicates that you are redistributing static routes into BGP4.

The **metric** <*num*> parameter changes the metric. You can specify a value from 0 – 4294967295. The default is 0.

The **route-map***p-name*> parameter specifies a route map to be consulted before adding the static route to the BGP4 route table.

NOTE
The route map you specify must already be configured on the device. Refer to "Defining route maps" on page 1068 for information about defining route maps.

Using a table map to set the tag value

Route maps that contain set statements change values in routes when the routes are accepted by the route map. For inbound route maps (route maps that filter routes received from neighbors), the routes are changed before they enter the BGP4 route table.

For tag values, if you do not want the value to change until a route enters the IP route table, you can use a table map to change the value. A table map is a route map that you have associated with the IP routing table. The device applies the set statements for tag values in the table map to routes before adding them to the route table.

To configure a table map, you first configure the route map, then identify it as a table map. The table map does not require separate configuration. You can have one table map.

NOTE
Use table maps only for setting the tag value. Do not use table maps to set other attributes. To set other route attributes, use route maps or filters.

To create a route map and identify it as a table map, enter commands such as following. These commands create a route map that uses an address filter. For routes that match the IP prefix list filter, the route map changes the tag value to 100 and is then considered as a table map. This route map is applied only to routes the device places in the IP route table. The route map is not applied to all routes. This example assumes that IP prefix list p11 has already been configured.

```
NetIron(config)# route-map TAG_IP permit 1
NetIron(config-routemap TAG_IP)# match ip address prefix-list p11
NetIron(config-routemap TAG_IP)# set tag 100
NetIron(config-routemap TAG_IP)# router bgp
NetIron(config-bgp)# table-map TAG_IP
```

Changing the Keep Alive Time and Hold Time

The Keep Alive Time specifies how frequently the device will send KEEPALIVE messages to its BGP4 neighbors. The Hold Time specifies how long the device will wait for a KEEPALIVE or UPDATE message from a neighbor before concluding that the neighbor is dead. When the device concludes that a BGP4 neighbor is dead, the device ends the BGP4 session and closes the TCP connection to the neighbor.

The default Keep Alive time is 60 seconds. The default Hold Time is 180 seconds.

NOTE
Generally, you should set the Hold Time to three times the value of the Keep Alive Time.

NOTE
You can override the global Keep Alive Time and Hold Time on individual neighbors. Refer to "Configuring BGP4 neighbors" on page 1037 and "Configuring a BGP4 peer group" on page 1046.

To change the Keep Alive Time to 30 and Hold Time to 90, enter the following command.

```
NetIron(config-bgp)# timers keep-alive 30 hold-time 90
```

Syntax: [no] timers keep-alive <*num*> **hold-time** <*num*>

For each keyword, <*num*> indicates the number of seconds. The Keep Alive Time can be 0 – 65535. The Hold Time can be 0 or 3 – 65535 (1 and 2 are not allowed). If you set the Hold Time to 0, the device waits indefinitely for messages from a neighbor without concluding that the neighbor is dead.

Changing the BGP4 next-hop update timer

By default, the device updates the BGP4 next-hop tables and affected BGP4 routes five seconds after IGP route changes. You can change the update timer to a value from 1 – 30 seconds.

To change the BGP4 update timer value to 15 seconds, for example, enter a command such as the following at the BGP4 configuration level of the CLI.

```
NetIron(config-bgp)# update-time 15
```

Syntax: [**no**] **update-time** <*secs*>

The <*secs*> parameter specifies the number of seconds and can be from 0 – 30. The default is 5. The value of 0 permits fast BGP4 convergence for situations such as link-failure or IGP route changes. Setting the value to 0 starts the BGP4 route calculation in sub-second time. All other values from 1 to 30 are still calculated in seconds

Changing the device ID

The OSPF and BGP4 protocols use device IDs to identify devices that are running the protocols. A device ID is a valid, unique IP address and sometimes is an IP address configured on the device. The device ID cannot be an IP address in use by another device.

By default, the device ID on a device is one of the following:

- If the device has loopback interfaces, the default device ID is the IP address on the lowest numbered loopback interface configured on the device. For example, if you configure loopback interfaces 1, 2, and 3 as follows, the default device ID is 9.9.9.9/24:
  - Loopback interface 1, 9.9.9.9/24
  - Loopback interface 2, 4.4.4.4/24
  - Loopback interface 3, 1.1.1.1/24
- If the device does not have any loopback interfaces, the default device ID is the lowest numbered IP interface address configured on the device.

NOTE
A device uses the same device ID for both OSPF and BGP4. If the device is already configured for OSPF, you may want to use the device ID that already assigned to the device rather than set a new one. To display the current device ID, enter the **show ip** CLI command at any CLI level.

To change the device ID, enter a command such as the following.

```
NetIron(config)# ip router-id 209.157.22.26
```

Syntax: [**no**] **ip router-id** <*ip-addr*>

The <*ip-addr*> can be any valid, unique IP address.

NOTE
You can specify an IP address used for an interface on the device, but do not specify an IP address that is being used by another device.

Adding a loopback interface

You can configure the device to use a loopback interface instead of a specific port or virtual routing interface to communicate with a BGP4 neighbor. A loopback interface adds stability to the network by working around route flap problems that can occur due to unstable links between the device and neighbors.

Loopback interfaces are always up, regardless of the states of physical interfaces. Loopback interfaces are especially useful for IBGP neighbors (neighbors in the same AS) that are multiple hops away from the device. When you configure a BGP4 neighbor on the device, you can specify whether the device uses the loopback interface to communicate with the neighbor. As long as a path exists between the device and the neighbor, BGP4 information can be exchanged. The BGP4 session is not associated with a specific link, but is instead associated with the virtual interfaces.

NOTE
If you configure the device to use a loopback interface to communicate with a BGP4 neighbor, the peer IP address on the remote device pointing to your loopback address must be configured.

To add a loopback interface, enter commands such as the following.

```
NetIron(config-bgp)# exit
NetIron(config)# int loopback 1
NetIron(config-lbif-1)# ip address 10.0.0.1/24
```

Syntax: [**no**] **interface loopback** <*num*>

The <*num*> value can be from 1 – 64.

Changing the maximum number of paths for BGP4 load sharing

Load sharing enables the device to balance traffic to a route across multiple equal-cost paths of the same route type (EBGP or IBGP).

To configure the device to perform BGP4 load sharing:

- Enable IP load sharing if it is disabled.
- Set the maximum number of BGP4 load sharing paths. The default maximum number is 1, which means no BGP4 load sharing takes place by default. Refer to "Configuring BGP4 multipath load sharing" on page 1034.

NOTE
The maximum number of BGP4 load sharing paths cannot be greater than the maximum number of IP load sharing paths.

How load sharing affects route selection

During evaluation of multiple paths to select the best path to a given destination (for installment in the IP route table), the device performs a final comparison of the internal paths. The following events occur when load sharing is enabled or disabled:

- When load sharing is disabled, the device prefers the path with the lower device ID if the **compare-routerid** command is enabled.
- When load sharing and BGP4 load sharing are enabled, the device balances the traffic across multiple paths instead of choosing just one path based on device ID.

Refer to "How BGP4 selects a path for a route" on page 1000 for a description of the BGP4 algorithm.

When you enable IP load sharing, the device can load-balance BGP4 or OSPF routes across up to four equal paths by default. You can change the number load sharing paths to a value from 2 – 8.

Configuring route reflection parameters

Normally, all the BGP4 devices within an AS are fully meshed. Since each device has an IBGP session with each of the other BGP4 devices in the AS, each device has a route for each IBGP neighbor. For large ASs containing many IBGP devices, the IBGP route information in each fully-meshed IBGP device may introduce too much administrative overhead.

To avoid this overhead, you can organize your IGP devices into clusters:

- A ***cluster*** is a group of IGP devices organized into route reflectors and route reflector clients. You configure the cluster by assigning a cluster ID on the route reflector and identifying the IGP neighbors that are members of that cluster. All configuration for route reflection takes place on the route reflectors. Clients are unaware that they are members of a route reflection cluster. All members of the cluster must be in the same AS. The cluster ID can be any number from 1 – 4294967295, or an IP address. The default is the device ID.

  NOTE
  If the cluster contains more than one route reflector, you need to configure the same cluster ID on all the route reflectors in the cluster. The cluster ID helps route reflectors avoid loops within the cluster.

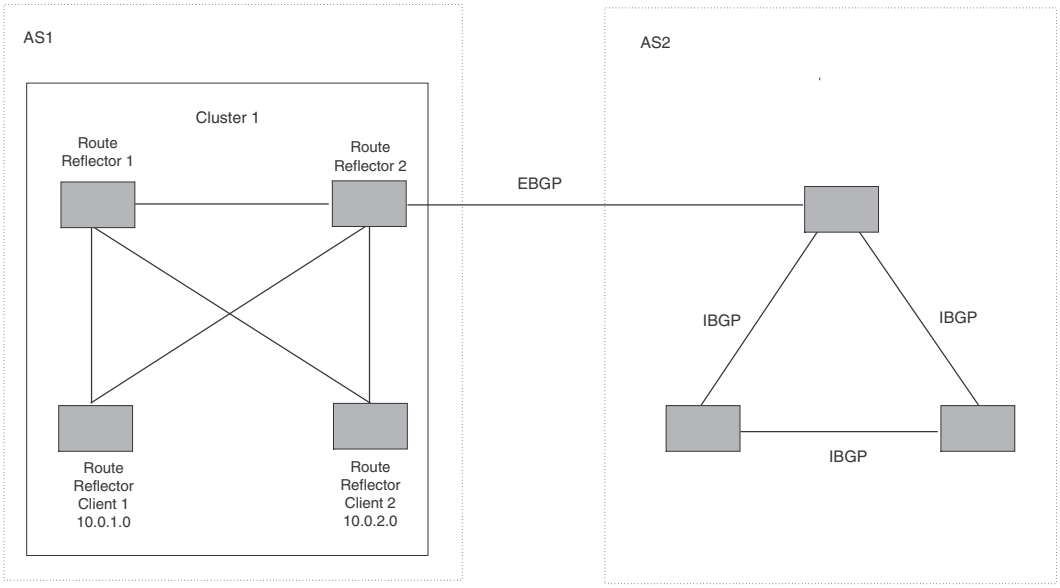
- A ***route reflector*** is an IGP device configured to send BGP4 route information to all the clients (other BGP4 devices) within the cluster. Route reflection is enabled on all BGP4 devices by default but does not take effect unless you add route reflector clients to the device.
- A ***route reflector client*** is an IGP device identified as a member of a cluster. You identify a device as a route reflector client on the device that is the route reflector, not on the client. The client itself requires no additional configuration. In fact, the client does not know that it is a route reflector client. The client just knows that it receives updates from its neighbors and does not know whether one or more of those neighbors are route reflectors.

NOTE
Route reflection applies only among IBGP devices within the same AS. You cannot configure a cluster that spans multiple ASs.

Figure 26.4 shows an example of a route reflector configuration. In this example, two devices are configured as route reflectors for the same cluster, which provides redundancy in case one of the reflectors becomes unavailable. Without redundancy, if a route reflector becomes unavailable, the clients for that router are cut off from BGP4 updates.

AS1 contains a cluster with two route reflectors and two clients. The route reflectors are fully meshed with other BGP4 devices, but the clients are not fully meshed and rely on the route reflectors to propagate BGP4 route updates.

FIGURE 153 A route reflector configuration



Support for RFC 4456

Route reflection is based on RFC 4456. This updated RFC helps eliminate routing loops that are possible in some implementations of the older specification, RFC 1966. These instances include:

- The device adds the route reflection attributes only if it is a route reflector, and only when advertising IBGP route information to other IBGP neighbors. The attributes are not used when communicating with EBGP neighbors.
- A device configured as a route reflector sets the ORIGINATOR_ID attribute to the device ID of the device that originated the route. The route reflector sets this attribute only if this is the first time the route is being reflected (sent by a route reflector).
- If a device receives a route with an ORIGINATOR_ID attribute value that is the same as the ID of the device, the device discards the route and does not advertise it. By discarding the route, the device prevents a routing loop.
- The first time a route is reflected by a device configured as a route reflector, the route reflector adds the CLUSTER_LIST attribute to the route. Other route reflectors that receive the route from an IBGP neighbor add their cluster IDs to the front of the routes CLUSTER_LIST. If the route reflector does not have a cluster ID configured, the device adds its device ID to the front of the CLUSTER_LIST.
- If a device configured as a route reflector receives a route with a CLUSTER_LIST that contains the cluster ID of the route reflector, the route reflector discards the route.

Configuration procedures

NOTE
All configuration for route reflection takes place on the route reflectors, not on the clients.

Enter the following commands to configure a device as route reflector 1 in "Route filters used by each protocol" on page 1080. To configure route reflector 2, enter the same commands on the device that will be route reflector 2. The clients require no configuration for route reflection.

```
NetIron(config-bgp)# cluster-id 1
```

Syntax: [**no**] **cluster-id** <*num*> | <*ip-addr*>

The <*num*> | <*ip-addr*> parameters specify the cluster ID and can be a number from 1 – 4294967295, or an IP address. The default is the device ID. You can configure one cluster ID on the device. All route-reflector clients for the device are members of the cluster.

NOTE
If the cluster contains more than one route reflector, you need to configure the same cluster ID on all the route reflectors in the cluster. The cluster ID helps route reflectors avoid loops in the cluster.

To add an IBGP neighbor to the cluster, enter the following command:

```
NetIron(config-bgp)# neighbor 10.0.1.0 route-reflector-client
```

Syntax: [**no**] **neighbor** <*ip-addr*> **route-reflector-client**

For more information about the **neighbor** command, refer to "Configuring BGP4 neighbors" on page 1037 and "Configuring a BGP4 peer group" on page 1046.

Filtering

This section describes how to configure filters for AS-paths, communities, and other BGP4 attributes.

Filtering AS-paths

You can filter updates received from BGP4 neighbors based on the contents of the AS-path list accompanying the updates. For example, to deny routes that have the AS 4.3.2.1 in the AS-path from entering the BGP4 route table, you can define a filter.

The device provides the following methods for filtering on AS-path information:

- AS-path filters - refer to "Setting the local AS number" on page 1033.
- AS-path ACLs

NOTE
The device cannot support AS-path filters and AS-path ACLs at the same time. Use one method or the other, but do not mix methods.

NOTE
Once you define a filter or ACL, the default action for updates that do not match a filter is **deny**. To change the default action to **permit**, configure the last filter or ACL as **permit any any**.

AS-path filters or AS-path ACLs can be referred to by the filter list number of a BGP4 neighbor as well as by match clauses in a route map.

Defining an AS-path ACL

To configure an AS-path list that uses ACL 1, enter a command such as the following.

```
NetIron(config)# ip as-path access-list acl1 permit 100
NetIron(config)# router bgp
NetIron(config-bgp)# neighbor 10.10.10.1 filter-list 1 in
```

Syntax: [**no**] **ip as-path access-list** <*string*> [**seq** <*seq-value*>] **deny** | **permit** <*regular-expression*>

The **ip as-path** command configures an AS-path ACL that permits routes containing AS number 100 in their AS paths. The **neighbor** command then applies the AS-path ACL to advertisements and updates received from neighbor 10.10.10.1. In this example, the only routes the device permits from neighbor 10.10.10.1 are those whose AS-paths contain AS-path number 100.

The <*string*> parameter specifies the ACL name. (If you enter a number, the CLI interprets the number as a text string.)

The **seq** <*seq-value*> parameter is optional and specifies the sequence number for the AS-path list. If you do not specify a sequence number, the software numbers in increments of 5, beginning with number 5. The software interprets the entries in an AS-path list in numerical order, beginning with the lowest sequence number.

The **deny** | **permit** parameter specifies the action the software takes if the AS-path list for a route matches a match clause in this ACL. To configure the AS-path match clauses in a route map, use the match as-path command. Refer to "Matching based on AS-path ACL" on page 1071.

The <*regular-expression*> parameter specifies the AS path information you want to permit or deny to routes that match any of the match clauses within the ACL. You can enter a specific AS number or use a regular expression.

The **neighbor** command uses the **filter-list** parameter to apply the AS-path ACL to the neighbor. Refer to "Configuring BGP4 neighbors" on page 1037 and "Configuring a BGP4 peer group" on page 1046.

Using regular expressions

Use a regular expression for the <*as-path*> parameter to specify a single character or multiple characters as a filter pattern. If the AS-path matches the pattern specified in the regular expression, the filter evaluation is true; otherwise, the evaluation is false.

You can also include special characters that influence the way the software matches the AS-path against the filter value.

To filter on a specific single-character value, enter the character for the <*as-path*> parameter. For example, to filter on AS-paths that contain the letter "z", enter the following command:

```
NetIron(config-bgp)# ip as-path access-list acl1 permit z
```

To filter on a string of multiple characters, enter the characters in brackets. For example, to filter on AS-paths that contain "x", "y", or "z", enter the following command.

```
NetIron(config-bgp)# ip as-path access-list acl1 permit [xyz]
```

Special characters

When you enter a single-character expression or a list of characters, you also can use the special characters listed in Table 167. The description for each character includes an example. Some special characters must be placed in front of the characters they control and others must be placed after the characters they control. The examples show where to place the special character.

TABLE 167 BGP4 special characters for regular expressions

Character	Operation
.	The period matches on any single character, including a blank space. For example, the following regular expression matches for "aa", "ab", "ac", and so on, but not just "a". a.
*	The asterisk matches on zero or more sequences of a pattern. For example, the following regular expression matches on an AS-path that contains the string "1111" followed by any value: 1111*
+	The plus sign matches on one or more sequences of a pattern. For example, the following regular expression matches on an AS-path that contains a sequence of "g"s, such as "deg", "degg", "deggg", and so on: deg+
?	The question mark matches on zero occurrences or one occurrence of a pattern. For example, the following regular expression matches on an AS-path that contains "dg" or "deg": de?g
^	A caret (when not used within brackets) matches on the beginning of an input string. For example, the following regular expression matches on an AS-path that begins with "3": ^3

TABLE 167 BGP4 special characters for regular expressions (Continued)

Character	Operation
$	A dollar sign matches on the end of an input string. For example, the following regular expression matches on an AS-path that ends with “deg”: deg$
_	An underscore matches on one or more of the following: • , (comma) • { (left curly brace) • } (right curly brace) • ((left parenthesis) •) (right parenthesis) • The beginning of the input string • The end of the input string • A blank space For example, the following regular expression matches on “100” but not on “1002”, “2100”, and so on. _100_
[ ]	Square brackets enclose a range of single-character patterns. For example, the following regular expression matches on an AS-path that contains “1”, “2”, “3”, “4”, or “5”: [1-5] You can use the following expression symbols within the brackets. These symbols are allowed only inside the brackets: • ^ – The caret matches on any characters except the ones in the brackets. For example, the following regular expression matches on an AS-path that does not contain “1”, “2”, “3”, “4”, or “5”: [^1-5] • - The hyphen separates the beginning and ending of a range of characters. A match occurs if any of the characters within the range is present. Refer to the example above.
|	A vertical bar (sometimes called a pipe or a “logical or”) separates two alternative values or sets of values. The AS-path can match one or the other value. For example, the following regular expression matches on an AS-path that contains either “abc” or “defg”: (abc)|(defg) **NOTE:** The parentheses group multiple characters to be treated as one value. Refer to the following row for more information about parentheses.
( )	Parentheses allow you to create complex expressions. For example, the following complex expression matches on “abc”, “abcabc”, or “abcabcabcdefg”, but not on “abcdefgdefg”: ((abc)+)|((defg)?)

To filter for a special character instead of using the special character as described in Table 167, enter “\” (backslash) in front of the character. For example, to filter on AS-path strings containing an asterisk, enter the asterisk portion of the regular expression as “*”.

```
NetIron(config-bgp)# ip as-path access-list acl2 deny \*
```

To use the backslash as a string character, enter two slashes. For example, to filter on AS-path strings containing a backslash, enter the backslash portion of the regular expression as “\\”.

```
NetIron(config-bgp)# ip as-path access-list acl2 deny \\
```

Filtering communities

You can filter routes received from BGP4 neighbors based on community names.

A community is an optional attribute that identifies the route as a member of a user-defined class of routes. Community names are arbitrary values made of two five-digit integers joined by a colon. You determine what the name means when you create the community name as a route attribute. Each string in the community name can be a number from 0 – 65535.

This format allows you to easily classify community names. For example, a common convention used in community naming is to configure the first string as the local AS and the second string as the unique community within that AS. Using this convention, communities 1:10, 1:20, and 1:30 can be easily identified as member communities of AS 1.

The device provides the following methods for filtering on community information.

- Community filters - refer to "Filtering communities" on page 1065.
- Community list ACLs

NOTE
The device cannot actively support community filters and community list ACLs at the same time. Use one method or the other but do not mix methods.

NOTE
Once you define a filter or ACL, the default action for communities that do not match a filter or ACL is **deny**. To change the default action to **permit**, configure the last filter or ACL entry as **permit any any**.

Community filters or ACLs can be referred to by match clauses in a route map.

Defining a community ACL

To configure community ACL 1, enter a command such as the following. This command configures a community ACL that permits routes that contain community 123:2.

NOTE
Refer to "Matching based on community ACL" on page 1072 for information about how to use a community list as a match condition in a route map.

```
NetIron(config)# ip community-list 1 permit 123:2
```

Syntax: [**no**] **ip community-list standard** <*string*> [**seq** <seq-value>] **deny** | **permit** <*community-num*>

Syntax: [**no**] **ip community-list extended** <*string*> [**seq** <*seq-value*>] **deny** | **permit** <*community-num*> | <*regular-expression*>

The <*string*> parameter specifies the ACL name. (If you enter a number, the CLI interprets the number as a text string.)

The **standard** or **extended** parameter specifies whether you are configuring a standard or extended community ACL. The difference between standard and extended communities is that a standard community ACL does not support regular expressions and an extended one does.

The **seq** <*seq-value*> parameter is optional and specifies the sequence number for the community list. You can configure up to 199 entries in a community list. If you do not specify a sequence number, the software numbers the entries in increments of 5, beginning with number 5. The software interprets the entries in a community list in numerical order, beginning with the lowest sequence number.

The **deny** | **permit** parameters specify the action the software takes if a route community list matches a match clause in this ACL. To configure the community-list match clauses in a route map, use the **match community** command. Refer to "Matching based on community ACL" on page 1072.

The <*community-num*> parameter specifies the community type or community number. This parameter can have the following values:

- <*num*>:<*num*> – A specific community number
- **internet** – The Internet community
- **no-export** – The community of sub-ASs within a confederation. Routes with this community can be exported to other sub-ASs within the same confederation but cannot be exported outside the confederation to other ASs or otherwise sent to EBGP neighbors.
- **local-as** – The local sub-AS within the confederation. Routes with this community can be advertised only within the local subAS.
- **no-advertise** – Routes with this community cannot be advertised to any other BGP4 devices at all.

The <*regular-expression*> parameter specifies a regular expression for matching on community names. For information about regular expression syntax, refer to "Using regular expressions" on page 1064. You can specify a regular expression only in an extended community ACL.

To use a community-list filter, use route maps with the **match community** parameter.

Defining and applying IP prefix lists

An IP prefix list specifies a list of networks. When you apply an IP prefix list to a neighbor, the device sends or receives only a route whose destination is in the IP prefix list. The software interprets the prefix lists in order, beginning with the lowest sequence number.

To configure an IP prefix list and apply it to a neighbor, enter commands such as the following.

```
NetIron(config)# ip prefix-list Routesfor20 permit 20.20.0.0/24
NetIron(config)# router bgp
NetIron(config-bgp)# neighbor 10.10.10.1 prefix-list Routesfor20 out
```

These commands configure an IP prefix list named Routesfor20, which permits routes to network 20.20.0.0/24. The **neighbor** command configures the device to use IP prefix list Routesfor20 to determine which routes to send to neighbor 10.10.10.1. The device sends routes that go to 20.20.x.x to neighbor 10.10.10.1 because the IP prefix list explicitly permits these routes to be sent to the neighbor.

Syntax: [**no**] **ip prefix-list** <*name*> [**seq** <*seq-value*>] [**description** <*string*>] **deny** | **permit** <*network-addr*>/<*mask-bits*> [**ge** <*ge-value*>] [**le** <*le-value*>]

The <*name*> parameter specifies the prefix list name. Use this name when applying the prefix list to a neighbor.

The **description** <*string*> parameter is a text string describing the prefix list.

The **seq** <*seq-value*> parameter is optional and specifies the sequence number of the IP prefix list. If you do not specify a sequence number, the software numbers the entries in increments of 5, beginning with prefix list entry 5. The software interprets the prefix list entries in numerical order, beginning with the lowest sequence number.

The **deny | permit** parameter specifies the action the software takes if a neighbor route is in this prefix list.

The <*network-addr*>/<*mask-bits*> parameters specify the network number and the number of bits in the network mask.

You can specify a range of prefix length for prefixes that are more specific than <*network-addr*>/<*mask-bits*>.

The prefix-list matches only on this network unless you use the **ge** <*ge-value*> or **le** <*le-value*> parameters.

- If you specify only **ge** <*ge-value*>, the mask-length range is from <*ge-value*> to 32.
- If you specify only **le** <*le-value*>, the mask-length range is from length to <*le-value*>.

The <*ge-value*> or <*le-value*> you specify must meet the following condition:

length < ge-value <= le-value <= 32

If you do not specify **ge** <*ge-value*> or **le** <*le-value*>, the prefix list matches only on the exact network prefix you specified with the <*network-addr*>/<*mask-bits*> parameter.

For the syntax of the **neighbor** command shown in this example, refer to "Configuring BGP4 neighbors" on page 1037 and "Configuring a BGP4 peer group" on page 1046.

Defining neighbor distribute lists

A neighbor distribute list is a list of BGP4 address filters or ACLs that filter the traffic to or from a neighbor.

To configure a distribute list that uses ACL 1, enter a command such as the following.

```
NetIron(config-bgp)# neighbor 10.10.10.1 distribute-list 1 in
```

This command configures the device to use ACL 1 to select the routes that the device will accept from neighbor 10.10.10.1.

Syntax: [**no**] **neighbor** <*ip-addr*> **distribute-list** <*name-or-num*> **in** | **out**

The <*ip-addr*> parameter specifies the neighbor.

The <*name-or-num*> parameter specifies the name or number of a standard, extended, or named ACL.

The **in** | **out** parameters specify whether the distribute list applies to inbound or outbound routes:

- **in** – controls the routes the device will accept from the neighbor.
- **out** – controls the routes sent to the neighbor.

Defining route maps

A ***route map*** is a named set of match conditions and parameter settings that the device can use to modify route attributes and to control redistribution of the routes into other protocols. A route map consists of a sequence of ***instances***. If you think of a route map as a table, an instance is a row in that table. The device evaluates a route according to route map instances in ascending numerical order. The route is first compared against instance 1, then against instance 2, and so on. When a match is found, the device stops evaluating the route.

Route maps can contain ***match clauses*** and ***set*** statements. Each route map contains a **permit** or **deny** action for routes that match the match clauses:

- If the route map contains a **permit** action, a route that matches a match statement is permitted; otherwise, the route is denied.
- If the route map contains a **deny** action, a route that matches a match statement is denied.
- If a route does not match any match statements in the route map, the route is denied. This is the default action. To change the default action, configure the last match statement in the last instance of the route map to **permit any any**.
- If there is no match statement, the software considers the route to be a match.
- For route maps that contain address filters, AS-path filters, or community filters, if the action specified by a filter conflicts with the action specified by the route map, the route map action takes precedence over the filter action.

If the route map contains set clauses, routes that are permitted by the route map match statements are modified according to the set clauses.

Match statements compare the route against one or more of the following:

- The route BGP4 MED (metric)
- A sequence of AS-path filters
- A sequence of community filters
- A sequence of address filters
- The IP address of the next hop device
- The route tag
- For OSPF routes only, the route type (internal, external type-1, or external type-2)
- An AS-path ACL
- A community ACL
- An IP prefix list
- An IP ACL

For routes that match all of the match statements, the route map set clauses can perform one or more of the following modifications to the route attributes:

- Prepend AS numbers to the front of the route AS-path. By adding AS numbers to the AS-path, you can cause the route to be less preferred when compared to other routes based on the length of the AS-path.
- Add a user-defined tag an automatically calculated tag to the route.
- Set the community value.
- Set the local preference.
- Set the MED (metric).
- Set the IP address of the next-hop device.
- Set the origin to IGP or INCOMPLETE.
- Set the weight.
- Set a BGP4 static network route.

When you configure parameters for redistributing routes into BGP4, one of the optional parameters is a route map. If you specify a route map as one of the redistribution parameters, the device matches the route against the match statements in the route map. If a match is found and if the route map contains set clauses, the device sets the attributes in the route according to the set clauses.

To create a route map, you define instances of the map by a sequence number.

To define a route map, use the procedures in the following sections.

Entering the route map into the software

To add instance 1 of a route map named "GET_ONE" with a permit action, enter the following command.

```
NetIron(config)# route-map GET_ONE permit 1
NetIron(config-routemap GET_ONE)#
```

Syntax: [**no**] **route-map** <*map-name*> **permit** | **deny** <*num*>

As shown in this example, the command prompt changes to the route map level. You can enter the match and set clauses at this level. Refer to "Specifying the match conditions" on page 1070 and "Setting parameters in the routes" on page 1075.

The <*map-name*> is a string of characters that names the map. Map names can be up to 32 characters in length.

The **permit** | **deny** parameter specifies the action the device will take if a route matches a match statement:

- If you specify **deny**, the device does not advertise or learn the route.
- If you specify **permit**, the device applies the match and set clauses associated with this route map instance.

The <*num*> parameter specifies the instance of the route map you are defining.

To delete a route map, enter a command such as the following. When you delete a route map, all the permit and deny entries in the route map are deleted.

```
NetIron(config)# no route-map Map1
```

This command deletes a route map named Map1. All entries in the route map are deleted.

To delete a specific instance of a route map without deleting the rest of the route map, enter a command such as the following.

```
NetIron(config)# no route-map Map1 permit 10
```

This command deletes the specified instance from the route map but leaves the other instances of the route map intact.

Specifying the match conditions

Use the following command to define the match conditions for instance 1 of the route map GET_ONE. This instance compares the route updates against BGP4 address filter 11.

```
NetIron(config-routemap GET_ONE)# match address-filters 11
```

Syntax: [**no**] **match**
[**as-path** <*name*>]
[**community** <*acl*> **exact-match**] |
[**ip address** <*acl*> | **prefix-list** <*string*>] |
[**ip route-source** <*acl*> | **prefix** <*name*>]
[**metric** <*num*>] |
[**next-hop** <*address-filter-list*>] |

[**route-type internal** | **external-type1** | **external-type2**] | [**level-1** | **level-2** | **level-1-2**]
[**tag** <tag-value>] |
interface <*interface*> <*interface*> <*interface*> ..
protocol bgp static-network
protocol bgp external
protocol bgp internal

The **as-path** <*num*> parameter specifies an AS-path ACL. You can specify up to five AS-path ACLs. To configure an AS-path ACL, use the **ip as-path access-list** command. Refer to "Defining an AS-path ACL" on page 1063.

The **community** <*num*> parameter specifies a community ACL.

NOTE
The ACL must already be configured.

The **community** <*acl*> **exact-match** parameter matches a route if (and only if) the route community attributes field contains the same community numbers specified in the match statement.

The **ip address** | **next-hop** <*acl-num*> | **prefix-list** <*string*> parameters specify an ACL or IP prefix list. Use this parameter to match based on the destination network or next-hop gateway. To configure an IP ACL for use with this command, use the **ip access-list** command. Refer to the Access Control List chapter. To configure an IP prefix list, use the **ip prefix-list** command.

The **ip route-source** <*acl*> | **prefix** <*name*> parameters match based on the source of a route (the IP address of the neighbor from which the device learned the route).

The **metric** <*num*> parameter compares the route MED (metric) to the specified value.

The **next-hop** <*address-filter-list*> parameter compares the IP address of the route next-hop to the specified IP address filters. The filters must already be configured.

The **route-type internal** | **external-type1 | external-type2** parameters apply only to OSPF routes. These parameters compare the route type to the specified value. The **level-1** parameter compares IS-IS routes only with routes within the same area. The **level-2** parameter compares IS-IS routes only with routes in different areas, but within a domain. The **level-1-2** parameter compares IS-IS routes with routes in the same area and in different areas, but within a domain.

The **tag** <*tag-value*> parameter compares the route tag to the specified tag value.

The **protocol bgp static-network** parameter matches on BGP4 static network routes.

The **protocol bgp external** parameter matches on eBGP (external) routes.

The **protocol bgp internal** parameter matches on iBGP (internal) routes.

The following sections contain examples of how to configure route maps that include match statements that match on ACLs.

Matching based on AS-path ACL

To construct a route map that matches based on AS-path ACL 1, enter the following commands.

```
NetIron(config)# route-map PathMap permit 1
NetIron(config-routemap PathMap)# match as-path 1
```

Syntax: [**no**] **match as-path** <*num*>

The <*num*> parameter specifies an AS-path ACL and can be a number from 1 – 199. You can specify up to five AS-path ACLs. To configure an AS-path ACL, use the **ip as-path access-list** command. Refer to "Defining an AS-path ACL" on page 1063.

Matching based on community ACL

To construct a route map that matches based on community ACL 1, enter the following commands.

```
NetIron(config)# ip community-list 1 permit 123:2
NetIron(config)# route-map CommMap permit 1
NetIron(config-routemap CommMap)# match community 1
```

Syntax: [**no**] **match community** <*string*>

The <*string*> parameter specifies a community list ACL. To configure a community list ACL, use the **ip community-list** command. Refer to "Defining a community ACL" on page 1066.

Matching based on destination network

You can use the results of an IP ACL or an IP prefix list as the match condition.

To construct a route map that matches based on destination network, enter commands such as the following.

```
NetIron(config)# route-map NetMap permit 1
NetIron(config-routemap NetMap)# match ip address 1
```

Syntax: [**no**] **match ip address** <*ACL-name-or-num*>

Syntax: [**no**] **match ip address prefix-list** <*name*>

The <*name-or-num*> parameter with the first command specifies an IP ACL and can be a number from 1 – 199 or the ACL name if it is a named ACL. To configure an IP ACL, use the **ip access-list** or **access-list** command. Refer to the Access Control List chapter.

The <*name*> parameter with the second command specifies an IP prefix list name. To configure an IP prefix list, refer to "Defining and applying IP prefix lists" on page 1067.

Matching based on next-hop device

You can use the results of an IP ACL or an IP prefix list as the match condition.

To construct a route map that matches based on the next-hop device, enter commands such as the following.

```
NetIron(config)# route-map HopMap permit 1
NetIron(config-routemap HopMap)# match ip next-hop 2
```

Syntax: [**no**] **match ip next-hop** <*num*>

Syntax: [**no**] **match ip next-hop prefix-list** <*name*>

The <*num*> parameter with the first command specifies an IP ACL and can be a number from 1 – 199 or the ACL name if it is a named ACL. To configure an IP ACL, use the **ip access-list** or **access-list** command. Refer to the Access Control List chapter.

The <*name*> parameter with the second command specifies an IP prefix list name. To configure an IP prefix list, refer to "Defining and applying IP prefix lists" on page 1067.

Matching based on the route source

To match a BGP4 route based on its source, use the **match ip route-source** command.

```
NetIron(config)# access-list 10 permit 192.168.6.0 0.0.0.255
NetIron(config)# route-map bgp1 permit 1
NetIron(config-routemap bgp1)# match ip route-source 10
```

The first command configures an IP ACL that matches on routes received from 192.168.6.0/24. The remaining commands configure a route map that matches on all BGP4 routes advertised by the BGP4 neighbors whose addresses match addresses in the IP prefix list. You can add a set clause to change a route attribute in the routes that match. You also can use the route map as input for other commands, such as the **neighbor** and **network** commands and some show commands.

Syntax: [**no**] **match ip route-source** <*acl*> | **prefix** <*name*>

The <*acl*> | prefix <*name*> parameters specify the name or ID of an IP ACL, or an IP prefix list.

Matching on routes containing a specific set of communities

The device can match routes based on the presence of a community name or number in a route. To match based on a set of communities, configure a community ACL that lists the communities, then compare routes against the ACL.

```
NetIron(config)# ip community-list standard std_1 permit 12:34 no-export
NetIron(config)# route-map bgp2 permit 1
NetIron(config-routemap bgp2)# match community std_1 exact-match
```

The first command configures a community ACL that contains community number 12:34 and community name no-export. The remaining commands configure a route map that matches the community attributes field in BGP4 routes against the set of communities in the ACL. A route matches the route map only if the route contains all the communities in the ACL and no other communities.

Syntax: [**no**] **match community** <*acl*> **exact-match**

The <*acl*> parameter specifies the name of a community list ACL. You can specify up to five ACLs. Separate the ACL names or IDs with spaces.

```
NetIron(config)# ip community-list standard std_2 permit 23:45 56:78
NetIron(config)# route-map bgp3 permit 1
NetIron(config-routemap bgp3)# match community std_1 std_2 exact-match
```

These commands configure an additional community ACL, std_2, that contains community numbers 23:45 and 57:68. Route map bgp3 compares each BGP4 route against the sets of communities in ACLs std_1 and std_2. A BGP4 route that contains ***either but not both*** sets of communities matches the route map. For example, a route containing communities 23:45 and 57:68 matches. However, a route containing communities 23:45, 57:68 and 12:34, or communities 23:45, 57:68, 12:34, and no-export does not match. To match, the route communities must be the same as those in exactly one of the community ACLs used by the match community statement.

Matching based on BGP4 static network

The **match** option has been added to the **route-map** command that allows you to match on a BGP4 static network. In the following example, the route-map is configured to match on the BGP4 static network. The device is then configured to advertise to the core BGP4 peer (IP address 192.168.6.0) only the BGP4 static routes and nothing else.

```
NetIron(config)# route-map policygroup3 permit 10
NetIron(config-routemap policygroup3)# match protocol bgp static-network
NetIron(config-routemap policygroup3)# set localpref 150
NetIron(config-routemap policygroup3)# community no-export
NetIron(config-routemap policygroup3)# exit
NetIron(config)# router bgp
NetIron(config-bgp)# neighbor 192.168.6.0 route-map out policymap3
```

Syntax: [**no**] **match protocol bgp** [**external**|**internal**|**static-network**]

The **match protocol bgp external** option will match the eBGP routes.

The **match protocol bgp internal** option will match the iBGP routes.

The **match protocol bgp static-network** option will match the static-network BGP4 route, applicable at BGP4 outbound policy only.

Matching based on interface

The *match* option has been added to the **route-map** command that distributes any routes that have their next hop out one of the interfaces specified. This feature operates with the following conditions:

- The **match interface** option can only use the interface name (for example ethernet 1/2) and not the IP address as an argument.
- The **match interface** option is only effective during redistribution and does not apply for other route map usage such as: bgp outbound route update policy.
- The **match interface** option can be applied to other types of redistribution such as redistributing OSPF routes to BGP4, or filtering out all OSPF routes that point to a specific interface.

To configure the match-interface option, use the following command.

```
NetIron(config)# route-map test-route permit 99
NetIron(config-routemap test-route)# match interface ethernet 1/1 pos 3/2
NetIron(config-routemap test-route)# exit
```

Syntax: [**no**] **match interface** <*interface*> <*interface*>...

The <*interface*> variable specifies the interface that you want to use with the **match interface** command. Up to 5 interfaces of the following types can be specified:

- **ethernet** <*slot/port*>
- **loopback** <*loopback-number*>
- **null0**
- **pos** <*slot/port*>
- **tunnel** <*tunnel-ID*>
- **ve** <*ve-ID*>

Setting parameters in the routes

Use the following command to define a set clause that prepends an AS number to the AS path on each route that matches the corresponding match statement.

```
NetIron(config-routemap GET_ONE)# set as-path prepend 65535
```

Syntax: [**no**] **set**
[**as-path** [**prepend** <*as-num,as-num,...*>]] |
[**automatic-tag**] |
[**comm-list** <*acl*> **delete**] |
[**community** <*num*>:<*num*> | <*num*> | **internet** | **local-as** | **no-advertise** | **no-export**] |
[**dampening** [<*half-life*> <*reuse*> <*suppress*> <*max-suppress-time*>]]
[**ip next hop** <*ip-addr*>]
[**ip next-hop peer-address**] |
[**local-preference** <*num*>] |
[**metric** [**+** | **-**]<*num*> | **none**] |
[**metric-type type-1** | **type-2**] | **external**
[**metric-type internal**] |
[**next-hop** <*ip-addr*>] |
[origin igp | **incomplete**] |
[**tag**] |
[**weight** <*num*>]

The **as-path prepend** <*num,num,...*> parameter adds the specified AS numbers to the front of the AS-path list for the route. The range of <num> values is 1 – 65535 for two-byte ASNs and 1 – 4294967295 if AS4s have been enabled.

The **automatic-tag** parameter calculates and sets an automatic tag value for the route.

NOTE
This parameter applies only to routes redistributed into OSPF.

The **comm-list** parameter deletes a community from the community attributes field for a BGP4 route.

The **community** parameter sets the community attribute for the route to the number or well-known type you specify.

The **dampening** [<*half-life*> <*reuse*> <*suppress*> <*max-suppress-time*>] parameter sets route dampening parameters for the route. The <*half-life*> parameter specifies the number of minutes after which the route penalty becomes half its value. The <*reuse*> parameter specifies how low a route penalty must become before the route becomes eligible for use again after being suppressed. The <*suppress*> parameter specifies how high a route penalty can become before the device suppresses the route. The <*max-suppress-time*> parameter specifies the maximum number of minutes that a route can be suppressed regardless of how unstable it is. For information and examples, refer to "Configuring route flap dampening" on page 1028.

The **ip next hop** <*ip-addr*> parameter sets the next-hop IP address for route that matches a match statement in the route map.

The **ip next-hop peer-address** parameter sets the BGP4 next hop for a route to the neighbor address.

The **local-preference** <*num*> parameter sets the local preference for the route. You can set the preference to a value from 0 – 4294967295.

The **metric** [**+** | **-**] <*num*> | **none** parameter sets the MED (metric) value for the route. The default MED value is 0. You can set the preference to a value from 0 – 4294967295.

- **set metric** <*num*> – Sets the metric for the route to the number you specify.
- **set metric +** <*num*> – Increases route metric by the number you specify.
- **set metric -** <*num*> – Decreases route metric by the number you specify.
- **set metric none** – Removes the metric from the route (removes the MED attribute from the BGP4 route).

The **metric-type type-1** | **type-2** parameter changes the metric type of a route redistributed into OSPF.

The **metric-type internal** parameter sets the route MED to the same value as the IGP metric of the BGP4 next-hop route. The parameter does this when advertising a BGP4 route to an EBGP neighbor.

The **next-hop** <*ip-addr*> parameter sets the IP address of the route next-hop device.

The **origin igp incomplete** parameter sets the route's origin to IGP or INCOMPLETE.

The **tag** parameter is a keyword that sets the tag to be an AS-path attribute.

NOTE
This parameter applies only to routes redistributed into OSPF.

NOTE
You also can set the tag value using a table map. The table map changes the value only when the device places the route in the IP route table instead of changing the value in the BGP4 route table. Refer to "Using a table map to set the tag value" on page 1057.

The **weight** <*num*> parameter sets the weight for the route. The range for the weight value is 0 – 4294967295.

Setting a BGP4 route MED to equal the next-hop route IGP metric

To set a route's MED to the same value as the IGP metric of the BGP4 next-hop route, when advertising the route to a neighbor, enter commands such as the following.

```
NetIron(config)# access-list 1 permit 192.168.9.0 0.0.0.255
NetIron(config)# route-map bgp4 permit 1
NetIron(config-routemap bgp4)# match ip address 1
NetIron(config-routemap bgp4)# set metric-type internal
```

The first command configures an ACL that matches on routes with destination network 192.168.9.0. The remaining commands configure a route map that matches on the destination network in ACL 1, then sets the metric type for those routes to the same value as the IGP metric of the BGP4 next-hop route.

Syntax: [**no**] **set metric-type internal**

Setting the next-hop of a BGP4 route

To set the next-hop address of a BGP4 route to a neighbor address, enter commands such as the following.

```
NetIron(config)# route-map bgp5 permit 1
NetIron(config-routemap bgp5)# match ip address 1
NetIron(config-routemap bgp5)# set ip next-hop peer-address
```

These commands configure a route map that matches on routes whose destination network is specified in ACL 1, and sets the next hop in the routes to the neighbor address (inbound filtering) or the local IP address of the BGP4 session (outbound filtering).

Syntax: [no] **set ip next-hop peer-address**

The value that the software substitutes for **peer-address** depends on whether the route map is used for inbound filtering or outbound filtering:

- When you use the **set ip next-hop peer-address** command in an inbound route map filter, **peer-address** substitutes for the neighbor IP address.
- When you use the **set ip next-hop peer-address** command in an outbound route map filter, **peer-address** substitutes for the local IP address of the BGP4 session.

NOTE
You can use this command for a peer group configuration.

Deleting a community from a BGP4 route

To delete a community from a BGP4 route's community attributes field, enter commands such as the following.

```
NetIron(config)# ip community-list standard std_3 permit 12:99 12:86
NetIron(config)# route-map bgp6 permit 1
NetIron(config-routemap bgp6)# match ip address 1
NetIron(config-routemap bgp6)# set comm-list std_3 delete
```

The first command configures a community ACL containing community numbers 12:99 and 12:86. The remaining commands configure a route map that matches on routes whose destination network is specified in ACL 1, and deletes communities 12:99 and 12:86 from those routes. The route does not need to contain all the specified communities in order for them to be deleted. For example, if a route contains communities 12:86, 33:44, and 66:77, community 12:86 is deleted.

Syntax: [no] **set comm-list** <*acl*> **delete**

The <*acl*> parameter specifies the name of a community list ACL.

Route-map continue clauses for BGP4 routes

A continuation clause in a route-map directs program flow to skip over route-map instances to another, user-specified instance. If a matched instance contains a continue clause, the system looks for the instance that is identified in the continue clause.

The continue clause in a matching instance initiates another traversal at the instance that you specify in the continue clause. The system records all of the matched instances and, if no deny statements are encountered, proceeds to execute the set clauses of the matched instances.

If the system scans all route map instances but finds no matches, or if a deny condition is encountered, then it does not update the routes. Whenever a matched instance contains a deny parameter, the current traversal terminates, and none of the updates specified in the set clauses of the matched instances in both current and previous traversals are applied to the routes.

This feature supports a more programmable route map configuration and route filtering scheme for BGP4 peering. It can also execute additional instances in a route map after an instance is executed with successful match clauses. You can configure and organize more modular policy definitions to reduce the number of instances that are repeated within the same route map.

This feature currently applies to BGP4 routes only. For protocols other than BGP4, continue statements are ignored.

Specifying route-map continuation clauses

This section describes the configuration of route-map continuation clauses. The following sequence of steps (with referenced items in the screen output in bold) is described:

- The configuration context for a route-map named *test* is entered.
- Two route-map **continue** statements are added to route-map *test*.
- The **show route-map** output displays the modified route-map *test*.
- Subsequent **neighbor** commands identify the route map *test* in the inbound and outbound directions for the neighbor at 8.8.8.3.
- The **show ip bgp config** output shows inbound and outbound route-map *test* for the neighbor at 8.8.8.3.

```
NetIron(config-bgp)# route-map test permit 1
NetIron(config-routemap test)# match metric 10
NetIron(config-routemap test)# set weight 10
NetIron(config-routemap test)# continue 2
NetIron(config-routemap test)# route-map test permit 2
NetIron(config-routemap test)# match tag 10
NetIron(config-routemap test)# set weight 20
NetIron(config-routemap test)# continue 3
NetIron(config-routemap test)# router bgp
NetIron(config-bgp)# exit
NetIron(config-bgp)# show route-map test
route-map test permit 1
 match metric 10
 set weight 10
 continue 2
route-map test permit 2
 match tag 10
 set weight 20
 continue 3
NetIron(config-bgp)# neighbor 8.8.8.3 route-map in test
NetIron(config-bgp)# neighbor 8.8.8.3 route-map out test
NetIron(config-bgp)# show ip bgp config
Current BGP configuration:
router bgp
 local-as 100
 neighbor 8.8.8.3 remote-as 200
 address-family ipv4 unicast
 neighbor 8.8.8.3 route-map in test
 neighbor 8.8.8.3 route-map out test
 exit-address-family
 address-family ipv4 multicast
 exit-address-family
 address-family ipv6 unicast
 exit-address-family
 address-family ipv6 multicast
 exit-address-family
 address-family vpnv4 unicast
 exit-address-family
end of BGP configuration
```

Syntax: [no] **route-map** <*map-name*> **permit** | **deny** <*num*>

The **no** form of the command deletes the route map. The <*map-name*> is a string of up to 32 characters that specifies the map.

The **permit** option means the device applies match and set clauses associated with this route map instance.

The **deny** option means that any match causes the device to ignore the route map.

The <*num*> parameter specifies the instance of the route map defined in the route-map context that the CLI enters. Routes are compared to the instances in ascending numerical order. For example, a route is compared to instance 1, then instance 2, and so on.

Syntax: [no] **continue** [<*instance-number*>]

The **continue** command is entered in the context of a route-map instance. The [**no**] form of the command deletes the continue clause specified by <*instance-number*>. The instance number range is 0 – 4294967295, and the occurrences of <*instance-number*> must be in ascending numeric order. If you specify a continue clause without an instance number, it means "continue to the next route-map instance."

Syntax: [**no**] **neighbor** <*ip-addr*> | <*peer-group-name*> [**route-map in** | **out** <*map-name*>]

This syntax shows only the **neighbor** parameters that apply to this example. The <*ip-addr*> or <*peer-group-name*> identifies the neighbor, and the [**route-map in** | **out** <*map-name*>] option lets you specify a route map and direction to apply to the neighbor.

Dynamic route filter update

Routing protocols use various route filters to control the distribution of routes. Route filters are used to filter routes received from and advertised to other devices. Protocols also use route-map policies to control route redistribution from other routing protocols. In addition, route filter policies are used to select routes to be installed in the routing tables, and used by forwarding engine to forward traffic.

There are currently 6 different types of route filters defined for use in a device:

- Access List (ACL)
- Prefix-List
- BGP4 as-path Access-list
- BGP4 community-list
- BGP4 extended community-list
- Route-map

Not every protocol uses all of these route filters. A protocol will usually use two or three filter types. The filters used by BGP4, OSPF, RIP, IS-IS, RIPng, OSPFv3, MSDP, and MCast protocols are described in Table 168.

TABLE 168 Route filters used by each protocol

Protocol	Route map	Prefix list	Community- list	Extended community- list	As-path access- list	ACL
BGP4	X	X	BGP4 does not use Community- List filters directly. It does use them indirectly through route-map filters that contain Community-List filters.	BGP4 does not directly use Extended Community-List filters, but indirectly uses them through route-map filters that contain Extended Community-List filters.	X	X
OSPF	X	X				X
RIP	X	X				
IS-IS	X	X				
RIPng		X				
OSPFv3	X	X				
MSDP	X					
MCast						X

When a route filter is changed (created, modified or deleted) by a user, the filter change notification will be sent to all relevant protocols, so that protocols can take appropriate actions. For example if BGP4 is using a route-map (say MapX) to control the routes advertised to a particular peer, the change of route-map (MapX) will cause BGP4 to re-evaluate the advertised routes, and make the appropriate advertisements or withdrawals according to the new route-map policy.

A route filter change action can happen in three ways.

1. A new filter is defined (created).

   This filter name may be already referenced by an application. The application needs to be notified of the addition of the new filter, and will bind to and use the new filter. In general, if a filter name is referenced by an application, but is not actually defined, the application assumes the default **deny** action for the filter.

2. An existing filter is undefined (removed).

   If the deleted filter is already used and referenced by an application, the application will unbind itself from the deleted filter.

3. An existing filter is modified (updated).

   If the filter is already used and referenced by an application, the application will be notified.

Protocols are automatically notified when a route filter is created, deleted or modified. In addition, when a protocol is notified of a filter change, appropriate steps are taken to apply the new or updated filter to existing routes.

Commands for dynamic route filter updating

In order to allow multiple filter updates to be processed together by applications, the device waits 10 seconds by default before notifying applications of the filter change. You can force an immediate update notification or modify the time delay from when a change is made to a route filter to when the protocols are notified.

Route filter update delay settings can be configured using the commands shown here.

Setting a time delay for route filter update notification

Set the amount of time that the device waits before sending filter additions and modification notification to protocols using the following command.

```
NetIron# filter-change-update-delay 100
```

Syntax: [**no**] **filter-change-update-delay** <*delay-time*>

The <*delay-time*> variable specifies the amount of time in seconds that the device waits before sending filter addition and modification notification to protocols. The valid range is 0 to 600 seconds. If you set the value to 0, filter change notifications will not be automatically sent to protocols. The default value is 10 seconds.

NOTE
The **filter-change-update-delay** command also affects a route map that is being used in a PBR policy.

NOTE
Filter deletion notifications are sent to protocols without a delay.

Performing an immediate route filter update

To force an immediate filter update to the relevant protocols, use the following command.

```
NetIron# clear filter-change-update
```

Syntax: clear filter-change-update

This command forces an immediate filter update regardless of the filter-change-update-delay setting. It can also be used to simultaneously submit multiple change notifcations when the filter-change-update-delay is set to 0. When changes are complete, run the **clear filter-change-update** command to update protocols.

NOTE
There may be delays in sending route filter change notifications to applications, and delays in applying the new or updated filter to all existing routes retroactively. However any *new* routes or changes to existing routes will be subject to the new filters.

Filter update delay and BGP

The filter-changes-update-delay command applies *only* to *changes* of filters that are already used or referenced by applications. If the content of a filter is changed, the new filter action takes effect after **filter-changes-update-delay** for *existing* routes. The notification delay does *not* apply to situations where the usage or reference of a filter is changed in a protocol.

For example, the following BGP neighbor command sets or changes the route-map filter on a neighbor:

```
NetIron(config-bgp)# neighbor x.x.x.x route-map <map_abc> out
```

In this case, the router applies the route-map “map_abc” to the peer immediately, and automatically applies the new route-map filter retroactively to existing routes.

NOTE
The auto-update action for a BGP peer filter is newly introduced in release 3.5. In previous releases, a user needs to manually issue the **clear ip bgp neighbor x.x.x.x soft out** command to cause the router to apply the new route-map retroactively to existing routes.

The general guideline is to define a policy *first*, then apply it to a BGP peer.

BGP4 policy processing order

The order of application of policies when processing inbound and outbound route advertisements on the device is:

1. Ip prefix-list
2. Outbound Ip prefix-list ORF, if negotiated
3. Outbound extended-community ORF, if negotiated
4. Filter-list (using As-path access-list)
5. Distribute list (using IP ACL - ipv4 unicast only)
6. Route-map

Configuring cooperative BGP4 route filtering

By default, the device performs all filtering of incoming routes locally, on the device itself. You can use cooperative BGP4 route filtering to cause the filtering to be performed by a neighbor before it sends the routes to the device. Cooperative filtering conserves resources by eliminating unnecessary route updates and filter processing. For example, the device can send a deny filter to a neighbor, which the neighbor uses to filter out updates before sending them to the device. The neighbor saves the resources it would otherwise use to generate the route updates, and the device saves the resources it would use to filter out the routes.

When you enable cooperative filtering, the device advertises this capability in its Open message to the neighbor when initiating the neighbor session. The Open message also indicates whether the device is configured to send filters, receive filters, or both, and the types of filters it can send or receive. The device sends the filters as Outbound Route Filters (ORFs) in route refresh messages.

To configure cooperative filtering, perform the following tasks on the device and on the BGP4 neighbor:

- Configure the filter.

  NOTE
  Cooperative filtering is currently supported only for filters configured using IP prefix lists.

- Apply the filter as an ***inbound*** filter to the neighbor.
- Enable the cooperative route filtering feature on the device. You can enable the device to send ORFs to the neighbor, to receive ORFs from the neighbor, or both. The neighbor uses the ORFs you send as outbound filters when it sends routes to the device. Likewise, the device uses the ORFs it receives from the neighbor as outbound filters when sending routes to the neighbor.
- Reset the BGP4 neighbor session to send and receive ORFs.
- Perform these steps on the other device.

NOTE
If the device has inbound filters, the filters are still processed even if equivalent filters have been sent as ORFs to the neighbor.

Enabling cooperative filtering

To configure cooperative filtering, enter commands such as the following.

```
NetIron(config)# ip prefix-list Routesfrom1234 deny 20.20.0.0/24
NetIron(config)# ip prefix-list Routesfrom1234 permit 0.0.0.0/0 le 32
NetIron(config)# router bgp
NetIron(config-bgp)# neighbor 1.2.3.4 prefix-list Routesfrom1234 in
NetIron(config-bgp)# neighbor 1.2.3.4 capability orf prefixlist send
```

The first two commands configure statements for the IP prefix list Routesfrom1234. The first command configures a statement that denies routes to 20.20.20./24. The second command configures a statement that permits all other routes. Once you configure an IP prefix list statement, all routes not explicitly permitted by statements in the prefix list are denied.

The next two commands change the CLI to the BGP4 configuration level, then apply the IP prefix list to neighbor 1.2.3.4. The last command enables the device to send the IP prefix list as an ORF to neighbor 1.2.3.4. When the device sends the IP prefix list to the neighbor, the neighbor filters out the 20.20.0.x routes from its updates to the device. This assumes that the neighbor is also configured for cooperative filtering.

Syntax: [**no**] **neighbor** <*ip-addr*> | <*peer-group-name*> **capability orf prefixlist** [**send** | **receive**]

The <*ip-addr*> | <*peer-group-name*> parameters specify the IP address of a neighbor or the name of a peer group of neighbors.

The **send** | **receive** parameters specify the support you are enabling:

- **send** – The device sends the IP prefix lists to the neighbor.
- **receive** – The device accepts filters from the neighbor.

If you do not specify the capability, both capabilities are enabled.

The **prefixlist** parameter specifies the type of filter you want to send to the neighbor.

NOTE
The current release supports cooperative filtering only for filters configured using IP prefix lists.

Sending and receiving ORFs

Cooperative filtering affects neighbor sessions that start after the filtering is enabled, but do not affect sessions that are already established.

To activate cooperative filtering, reset the session with the neighbor. This is required because the cooperative filtering information is exchanged in Open messages during the start of a session.

To place a prefix-list change into effect after activating cooperative filtering, perform a soft reset of the neighbor session. A soft reset does not end the current session, but sends the prefix list to the neighbor in the next route refresh message.

NOTE
Make sure cooperative filtering is enabled on the device and on the neighbor before you send the filters.

To reset a neighbor session and send ORFs to the neighbor, enter a command such as the following.

```
NetIron# clear ip bgp neighbor 1.2.3.4
```

This command resets the BGP4 session with neighbor 1.2.3.4 and sends the ORFs to the neighbor. If the neighbor sends ORFs to the device, the device accepts them if the send capability is enabled.

To perform a soft reset of a neighbor session and send ORFs to the neighbor, enter a command such as the following.

```
NetIron# clear ip bgp neighbor 1.2.3.4 soft in prefix-list
```

Syntax: **clear ip bgp neighbor** <*ip-addr*> [**soft in prefix-filter**]

If you use the **soft in prefix-filter** parameter, the device sends the updated IP prefix list to the neighbor as part of its route refresh message to the neighbor.

NOTE
If the device or the neighbor is not configured for cooperative filtering, the command sends a normal route refresh message.

Displaying cooperative filtering information

You can display the following cooperative filtering information:

- The cooperative filtering configuration on the device.
- The ORFs received from neighbors.

To display the cooperative filtering configuration on the device, enter a command such as the following. The line shown in bold type shows the cooperative filtering status.

```
NetIron# show ip bgp neighbor 10.10.10.1
1   IP Address: 10.10.10.1, AS: 65200 (IBGP), RouterID: 10.10.10.1
    State: ESTABLISHED, Time: 0h0m7s, KeepAliveTime: 60, HoldTime: 180
       RefreshCapability: Received
       CooperativeFilteringCapability: Received
    Messages:    Open    Update  KeepAlive Notification Refresh-Req
       Sent    : 1       0       1         0            1
       Received: 1       0       1         0            1
    Last Update Time: NLRI       Withdraw          NLRI       Withdraw

```

Syntax: show ip bgp neighbor <*ip-addr*>

To display the ORFs received from a neighbor, enter a command such as the following:

```
NetIron# show ip bgp neighbor 10.10.10.1 received prefix-filter
ip prefix-list 10.10.10.1: 4 entries
     seq 5 permit 10.10.0.0/16 ge 18 le 28
     seq 10 permit 20.20.10.0/24
     seq 15 permit 30.0.0.0/8 le 32
     seq 20 permit 40.10.0.0/16 ge 18
```

Syntax: show ip bgp neighbor <*ip-addr*> **received prefix-filter**

Configuring route flap dampening

A route flap is a change in the state of a route, from up to down or down to up. A route state change causes changes in the route tables of the devices that support the route. Frequent route state changes can cause Internet instability and add processing overhead to the devices that support the route.

Route flap dampening helps reduce the impact of route flap by changing the way a BGP4 device responds to route state changes. When route flap dampening is configured, the device suppresses unstable routes until the number of route state changes drops enough to meet an acceptable degree of stability. The Dell implementation of route flap dampening is based on RFC 2439.

Route flap dampening is disabled by default. You can enable the feature globally or on an individual route basis using route maps.

NOTE
The device applies route flap dampening only to routes learned from EBGP neighbors.

The route flap dampening mechanism is based on penalties. When a route exceeds a configured penalty value, the device stops using that route and stops advertising it to other devices. The mechanism also allows route penalties to reduce over time if route stability improves.

The route flap dampening mechanism uses the following parameters:

- **Suppression threshold** – Specifies the penalty value at which the device stops using the route. Each time a route becomes unreachable or is withdrawn by a BGP4 UPDATE from a neighbor, the route receives a penalty of 1000. By default, when a route penalty is greater than 2000, the device stops using the route. By default, if a route goes down more than twice, the device stops using the route. You can set the suppression threshold to a value from 1 – 20000. The default is 2000.
- **Half-life** – Once a route has been assigned a penalty, the penalty decreases exponentially and decreases by half after the half-life period. The default half-life period is 15 minutes. The software reduces route penalties every five seconds. For example, if a route has a penalty of 2000 and does not receive any more penalties during the half-life, the penalty is reduced to 1000 after the half-life expires. You can configure the half-life to be from 1 – 45 minutes. The default is 15 minutes.
- **Reuse threshold** – Specifies the minimum penalty a route can have and still be suppressed by the device. If the route penalty falls below this value, the device un-suppresses the route and can use it again. The software evaluates the dampened routes every ten seconds and un-suppresses the routes that have penalties below the reuse threshold. You can set the reuse threshold to a value from 1 – 20000. The default is 750.
- **Maximum suppression time** – Specifies the maximum number of minutes a route can be suppressed regardless of how unstable the route has been before this time. You can set the parameter to a value from 1 – 20000 minutes. The default is four times the half-life. When the half-life value is set to its default (15 minutes), the maximum suppression time defaults to 60 minutes.

You can configure route flap dampening globally or for individual routes using route maps. If you configure route flap dampening parameters globally and also use route maps, the settings in the route maps override the global values.

Using a route map to configure route flap dampening for specific routes

Route maps enable you to fine tune route flap dampening parameters for individual routes. To configure route flap dampening parameters using route maps, configure BGP4 address filters for each route you want to set the dampening parameters for, then configure route map entries that set the dampening parameters for those routes. The following sections show examples.

Using a route map to configure route flap dampening for a specific neighbor

You can use a route map to configure route flap dampening for a specific neighbor by performing the following tasks:

- Configure an empty route map with no match or set clauses. This route map does not specify particular routes for dampening but does allow you to enable dampening globally when you refer to this route map from within the BGP4 configuration level.
- Configure another route map that explicitly enables dampening. Use a set clause within the route map to enable dampening. When you associate this route map with a specific neighbor, the route map enables dampening for all routes associated with the neighbor. You also can use match clauses within the route map to selectively perform dampening on some routes from the neighbor.

NOTE
You still need to configure the first route map to enable dampening globally. The second route map does not enable dampening by itself; it just applies dampening to a neighbor.

- Apply the route map to the neighbor.

To enable route flap dampening for a specific BGP4 neighbor, enter commands such as the following.

```
NetIron(config)# route-map DAMPENING_MAP_ENABLE permit 1
NetIron(config-routemap DAMPENING_MAP_ENABLE)# exit
NetIron(config)# route-map DAMPENING_MAP_NEIGHBOR_A permit 1
NetIron(config-routemap DAMPENING_MAP_NEIGHBOR_A)# set dampening
NetIron(config-routemap DAMPENING_MAP_NEIGHBOR_A)# exit
NetIron(config)# router bgp
NetIron(config-bgp)# dampening route-map DAMPENING_MAP_ENABLE
NetIron(config-bgp)# neighbor 10.10.10.1 route-map in DAMPENING_MAP_NEIGHBOR_A
```

In this example, the first command globally enables route flap dampening. This route map does not contain any match or set clauses. At the BGP4 configuration level, the **dampening route-map** command refers to the DAMPENING_MAP_ENABLE route map created by the first command, thus enabling dampening globally.

The third and fourth commands configure a second route map that explicitly enables dampening. Notice that the route map does not contain a match clause. The route map implicitly applies to all routes. Since the route map will be applied to a neighbor at the BGP4 configuration level, the route map will apply to all routes associated with the neighbor.

Although the second route map enables dampening, the first route map is still required. The second route map enables dampening for the neighbors to which the route map is applied. However, unless dampening is already enabled globally by the first route map, the second route map has no effect.

The last two commands apply the route maps. The **dampening route-map** command applies the first route map, which enables dampening globally. The **neighbor** command applies the second route map to neighbor 10.10.10.1. Since the second route map does not contain match clauses for specific routes, the route map enables dampening for all routes received from the neighbor.

Removing route damping from a route

You can un-suppress routes by removing route flap damping from the routes. The device allows you to un-suppress all routes at once or un-suppress individual routes.

To un-suppress all the suppressed routes, enter the following command at the Privileged EXEC level of the CLI.

```
NetIron# clear ip bgp damping
```

Syntax: clear ip bgp damping [<*ip-addr*> <*ip-mask*>]

The <*ip-addr*> parameter specifies a particular network.

The <*ip-mask*> parameter specifies the network's mask.

To un-suppress a specific route, enter a command such as the following.

```
NetIron# clear ip bgp damping 209.157.22.0 255.255.255.0
```

This command un-suppresses only the routes for network 209.157.22.0/24.

Displaying and clearing route flap dampening statistics

The software provides many options for displaying and clearing route flap statistics.

Displaying route flap dampening statistics

To display route dampening statistics or all the dampened routes, enter the following command at any CLI level.

```
NetIron# show ip bgp flap-statistics
Total number of flapping routes: 414
    Status Code  >:best d:damped h:history *:valid
    Network            From            Flaps Since    Reuse    Path
h>  192.50.206.0/23    166.90.213.77   1     0 :0 :13 0 :0 :0  65001 4355 1 701
h>  203.255.192.0/20   166.90.213.77   1     0 :0 :13 0 :0 :0  65001 4355 1 7018
h>  203.252.165.0/24   166.90.213.77   1     0 :0 :13 0 :0 :0  65001 4355 1 7018
h>  192.50.208.0/23    166.90.213.77   1     0 :0 :13 0 :0 :0  65001 4355 1 701
h>  133.33.0.0/16      166.90.213.77   1     0 :0 :13 0 :0 :0  65001 4355 1 701
*>  204.17.220.0/24    166.90.213.77   1     0 :1 :4  0 :0 :0  65001 4355 701 62
```

Syntax: show ip bgp flap-statistics [**regular-expression** <*regular-expression*> | <*address*> <*mask*> [**longer-prefixes**] | **neighbor** <*ip-addr*>]

The **regular-expression** <*regular-expression*> parameter is a regular expression. Regular expressions are the same ones supported for BGP4 AS-path filters. Refer to "Using regular expressions" on page 1064.

The <*address*> <*mask*> parameters specify a particular route. If you also use the optional **longer-prefixes** parameter, all statistics for routes that match the specified route or have a longer prefix than the specified route are displayed. For example, if you specify **209.157.0.0 longer**, all routes with the prefix 209.157. or longer (such as 209.157.22.) are displayed.

The **neighbor** <*ip-addr*> parameter displays route flap dampening statistics only for routes learned from the specified neighbor. You also can display route flap statistics for routes learned from a neighbor by entering the following command: **show ip bgp neighbor** <*ip-addr*> **flap-statistics**.

This display shows the following information.

TABLE 169 Route flap dampening statistics

This field...	Displays...
Total number of flapping routes	The total number of routes in the BGP4 route table that have changed state and have been marked as flapping routes.
Status code	Indicates the dampening status of the route, which can be one of the following: • > – This is the best route among those in the BGP4 route table to the route destination. • d – This route is currently dampened, and unusable. • h – The route has a history of flapping and is unreachable now. • * – The route has a history of flapping but is currently usable.
Network	The destination network of the route.
From	The neighbor that sent the route to the device.
Flaps	The number of flaps the route has experienced.
Since	The amount of time since the first flap of this route.
Reuse	The amount of time remaining until this route will be un-suppressed and can be used again.
Path	Shows the AS-path information for the route.

You also can display all dampened routes by entering the **show ip bgp dampened-paths** command.

Clearing route flap dampening statistics

Clearing the dampening statistics for a route does not change the dampening status of the route. To clear all the route dampening statistics, enter the following command at any level of the CLI.

```
NetIron# clear ip bgp flap-statistics
```

Syntax: **clear ip bgp flap-statistics** [**regular-expression** <*regular-expression*> | <*address*> <*mask*> | **neighbor** <*ip-addr*>]

The parameters are the same as those for the **show ip bgp flap-statistics** command (except the **longer-prefixes** option is not supported). Refer to "Configuring route flap dampening" on page 1028.

NOTE
The **clear ip bgp damping** command not only clears statistics but also un-suppresses the routes. Refer to "Configuring route flap dampening" on page 1028.

Generating traps for BGP4

You can enable and disable SNMP traps for BGP4. BGP4 traps are enabled by default.

To enable BGP4 traps after they have been disabled, enter the following command.

```
NetIron(config)# snmp-server enable traps bgp
```

Syntax: [**no**] **snmp-server enable traps bgp**

Use the **no** form of the command to disable BGP4 traps.

Updating route information and resetting a neighbor session

The following sections describe how to update route information with a neighbor, reset a session with a neighbor, and close a session with a neighbor.

Any change to a policy (ACL, route map, and so on) is automatically applied to outbound routes that are learned from a BGP4 neighbor or peer group after the policy change occurs. However, you must reset the neighbor to update existing outbound routes.

Any change to a policy is automatically applied to inbound routes that are learned after the policy change occurs. However, to apply the changes to existing inbound routes (those inbound routes that were learned before the policy change), you must reset the neighbors to update the routes using one of the following methods:

- Request the complete BGP4 route table from the neighbor or peer group. You can use this method if the neighbor supports the refresh capability (RFCs 2842 and 2858). Most devices today support this capability.
- Clear (reset) the session with the neighbor or peer group. This is the only method you can use if soft reconfiguration is enabled for the neighbor.

You also can clear and reset the BGP4 routes that have been installed in the IP route table. Refer to "Clearing and resetting BGP4 routes in the IP route table" on page 1096.

Using soft reconfiguration

The ***soft reconfiguration*** feature applies policy changes without resetting the BGP4 session. Soft reconfiguration does not request the neighbor or group to send the entire BGP4 table, nor does the feature reset the session with the neighbor or group. Instead, soft reconfiguration stores all the route updates received from the neighbor or group. When you request a soft reset of inbound routes, the software performs route selection by comparing the policies against the stored route updates, instead of requesting the neighbor BGP4 route table or resetting the session with the neighbor.

When you enable the soft reconfiguration feature, it sends a refresh message to the neighbor or group if the neighbor or group supports dynamic refresh. Otherwise, the feature resets the neighbor session. This step is required to ensure that the soft reconfiguration feature has a complete set of updates to use, and occurs only once, when you enable the feature. The feature accumulates all the route updates from the neighbor, eliminating the need for additional refreshes or resets when you change policies in the future.

To use soft reconfiguration:

- Enable the feature.
- Make the policy changes.
- Apply the changes by requesting a soft reset of the inbound updates from the neighbor or group.

Enabling soft reconfiguration

To configure a neighbor for soft reconfiguration, enter a command such as the following.

```
NetIron(config-bgp)# neighbor 10.10.200.102 soft-reconfiguration inbound
```

This command enables soft reconfiguration for updates received from 10.10.200.102. The software dynamically resets the session with the neighbor, then retains all route updates from the neighbor following the reset.

Syntax: [**no**] **neighbor** <*ip-addr*> | <*peer-group-name*> **soft-reconfiguration inbound**

NOTE
The syntax related to soft reconfiguration is shown. For complete command syntax, refer to "Configuring BGP4 neighbors" on page 1037 and "Configuring a BGP4 peer group" on page 1046.

Placing a policy change into effect

To place policy changes into effect, enter a command such as the following.

```
NetIron(config-bgp)# clear ip bgp neighbor 10.10.200.102 soft in
```

This command updates the routes by comparing the route policies against the route updates that the device has stored. The command does not request additional updates from the neighbor or otherwise affect the session with the neighbor.

Syntax: **clear ip bgp neighbor** <*ip-addr*> | <*peer-group-name*> **soft in**

NOTE
If you do not specify **in**, the command applies to both inbound and outbound updates.

NOTE
The syntax related to soft reconfiguration is shown. For complete command syntax, refer to "Dynamically refreshing routes" on page 1093.

Displaying the filtered routes received from the neighbor or peer group

When you enable soft reconfiguration, the device saves all updates received from the specified neighbor or peer group, including updates that contain routes that are filtered out by the BGP4 route policies in effect on the device. To display the routes that have been filtered out, enter the following command at any level of the CLI.

```
NetIron# show ip bgp filtered-routes
Searching for matching routes, use ^C to quit...
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED F:FILTERED
       Prefix             Next Hop        Metric     LocPrf     Weight Status
1      3.0.0.0/8          192.168.4.106              100        0      EF
         AS_PATH: 65001 4355 701 80
2      4.0.0.0/8          192.168.4.106              100        0      EF
         AS_PATH: 65001 4355 1
3      4.60.212.0/22      192.168.4.106              100        0      EF
         AS_PATH: 65001 4355 701 1 189
```

The routes displayed are the routes that were filtered out by the BGP4 policies on the device. The device did not place the routes in the BGP4 route table, but did keep the updates. If a policy change causes these routes to be permitted, the device does not need to request the route information from the neighbor, but instead uses the information in the updates.

Syntax: **show ip bgp filtered-routes** [<*ip-addr*>] | [**as-path-access-list** <*num*>] | [**detail**] | [**prefix-list** <*string*>]

The <*ip-addr*> parameter specifies the IP address of the destination network.

The **as-path-access-list** <*num*> parameter specifies an AS-path ACL. Only the routes permitted by the AS-path ACL are displayed.

The **detail** parameter displays detailed information for the routes. (The example shows summary information.) You can specify any of the other options after **detail** to further refine the display request.

The **prefix-list** <*string*> parameter specifies an IP prefix list. Only routes permitted by the prefix list are displayed.

NOTE
The syntax for displaying filtered routes is shown. For complete command syntax, refer to "Displaying the BGP4 route table" on page 1121.

Displaying all the routes received from the neighbor

To display all the route information received in route updates from a neighbor since you enabled soft reconfiguration, enter a command such as the following at any level of the CLI.

```
NetIron# show ip bgp neighbor 192.168.4.106 routes
       There are 97345 received routes from  neighbor 192.168.4.106
Searching for matching routes, use ^C to quit...
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED F:FILTERED
       Prefix             Next Hop        Metric     LocPrf     Weight Status
1      3.0.0.0/8          192.168.4.106              100        0      BE
         AS_PATH: 65001 4355 701 80
2      4.0.0.0/8          192.168.4.106              100        0      BE
         AS_PATH: 65001 4355 1
3      4.60.212.0/22      192.168.4.106              100        0      BE
         AS_PATH: 65001 4355 701 1 189
4      6.0.0.0/8          192.168.4.106              100        0      BE
```

Syntax: show ip bgp neighbors <*ip-addr*> **received-routes** [*detail*]

The **detail** parameter displays detailed information for the routes. This example shows summary information.

NOTE
The syntax for displaying received routes is shown. For complete command syntax, refer to "Displaying BGP4 neighbor information" on page 1109.

Dynamically requesting a route refresh from a BGP4 neighbor

You can easily apply changes to filters that control BGP4 routes received from or advertised to a neighbor, without resetting the BGP4 session between the device and the neighbor. For example, if you add, change, or remove a BGP4 IP prefix list that denies specific routes received from a neighbor, you can apply the filter change by requesting a route refresh from the neighbor. If the neighbor also supports dynamic route refreshes, the neighbor resends its Adj-RIB-Out, its table of BGP4 routes. Using the route refresh feature, you do not need to reset the session with the neighbor.

The route refresh feature is based on the following specifications:

- RFC 2842. This RFC specifies the Capability Advertisement, which a BGP4 device uses to dynamically negotiate a capability with a neighbor.
- RFC 2858 for Multi-protocol Extension.
- RFC 2918, which describes the dynamic route refresh capability

The dynamic route refresh capability is enabled by default and cannot be disabled. When the device sends a BGP4 OPEN message to a neighbor, the device includes a Capability Advertisement to inform the neighbor that the device supports dynamic route refresh.

NOTE
The option for dynamically refreshing routes received from a neighbor requires the neighbor to support dynamic route refresh. If the neighbor does not support this feature, the option does not take effect and the software displays an error message. The option for dynamically re-advertising routes to a neighbor does not require the neighbor to support dynamic route refresh.

Dynamically refreshing routes

The following sections describe how to refresh BGP4 routes dynamically to put new or changed filters into effect.

To request a dynamic refresh of all routes from a neighbor, enter a command such as the following.

```
NetIron(config-bgp)# clear ip bgp neighbor 192.168.1.170 soft in
```

This command asks the neighbor to send its BGP4 table (Adj-RIB-Out) again. The device applies its filters to the incoming routes and adds, modifies, or removes BGP4 routes as necessary.

Syntax: **clear ip bgp neighbor all** | <*ip-addr*> | <*peer-group-name*> | <*as-num*> [**soft-outbound** | **soft** [**in** | **out**]]

The **all** | <*ip-addr*> | <*peer-group-name*> | <*as-num*> parameters specify the neighbor. The <*ip-addr*> parameter specifies a neighbor by its IP interface with the device. The <*peer-group-name*> specifies all neighbors in a specific peer group. The <*as-num*> parameter specifies all neighbors within the specified AS. The **all** parameter specifies all neighbors.

The **soft-outbound** parameter updates all outbound routes by applying the new or changed filters, but sends only the existing routes affected by the new or changed filters to the neighbor.

The **soft** [**in** | **out**] parameter specifies whether you want to refresh the routes received from the neighbor or sent to the neighbor:

- **soft in** does one of the following:
  - If you enabled soft reconfiguration for the neighbor or peer group, **soft in** updates the routes by comparing the route policies against the route updates that the device has stored. Soft reconfiguration does not request additional updates from the neighbor or otherwise affect the session with the neighbor. Refer to "Using soft reconfiguration" on page 1090.
  - If you did not enable soft reconfiguration, **soft in** requests the entire BGP4 route table for the neighbor (Adj-RIB-Out), then applies the filters to add, change, or exclude routes.
  - If a neighbor does not support dynamic refresh, **soft in** resets the neighbor session.
- **soft out** updates all outbound routes, then sends the entire BGP4 router table for the device (Adj-RIB-Out) to the neighbor, after changing or excluding the routes affected by the filters.

If you do not specify **in** or **out**, the device performs both options.

NOTE
The **soft-outbound** parameter updates all outbound routes by applying the new or changed filters, but sends only the existing routes affected by the new or changed filters to the neighbor. The **soft out** parameter updates all outbound routes, then sends the entire BGP4 route table for the device (Adj-RIB-Out) to the neighbor, after changing or excluding the routes affected by the filters. Use **soft-outbound** if only the outbound policy is changed.

To dynamically resend all the device BGP4 routes to a neighbor, enter a command such as the following.

```
NetIron(config-bgp)# clear ip bgp neighbor 192.168.1.170 soft out
```

This command applies filters for outgoing routes to the device BGP4 route table (Adj-RIB-Out), changes or excludes routes accordingly, then sends the resulting Adj-RIB-Out to the neighbor.

NOTE
The device does not automatically update outbound routes using a new or changed outbound policy or filter when a session with the neighbor goes up or down. Instead, the device applies a new or changed policy or filter when a route is placed in the outbound queue (Adj-RIB-Out).

To place a new or changed outbound policy or filter into effect, you must enter a **clear ip bgp neighbor** command regardless of whether the neighbor session is up or down. You can enter the command without optional parameters or with the **soft out** or **soft-outbound** option. Either way, you must specify a parameter for the neighbor (<*ip-addr*>, <*as-num*>, <*peer-group-name*>, or **all**).

Displaying dynamic refresh information

You can use the **show ip bgp neighbors** command to display information for dynamic refresh requests. For each neighbor, the display lists the number of dynamic refresh requests the device has sent to or received from the neighbor and indicates whether the device received confirmation from the neighbor that the neighbor supports dynamic route refresh.

The RefreshCapability field indicates whether this device has received confirmation from the neighbor that the neighbor supports the dynamic refresh capability. The statistics in the Message Sent and Message Received rows under Refresh-Req indicate how many dynamic refreshes have been sent to and received from the neighbor. The statistic is cumulative across sessions.

```
NetIron(config-bgp)# show ip bgp neighbor 10.4.0.2
1   IP Address: 10.4.0.2, AS: 5 (EBGP), RouterID: 100.0.0.1
      Description: neighbor 10.4.0.2
    State: ESTABLISHED, Time: 0h1m0s, KeepAliveTime: 0, HoldTime: 0
      PeerGroup: pg1
      Mutihop-EBGP: yes, ttl: 1
      RouteReflectorClient: yes
      SendCommunity: yes
      NextHopSelf: yes
      DefaultOriginate: yes (default sent)
      MaximumPrefixLimit: 90000

Closing or resetting a neighbor session

You can close a neighbor session or resend route updates to a neighbor.

If you make changes to filters or route maps and the neighbor does not support dynamic route refresh, use the following methods to ensure that neighbors contain only the routes you want them to contain:

- If you close a neighbor session, the device and the neighbor clear all the routes they learned from each other. When the device and neighbor establish a new BGP4 session, they exchange route tables again. Use this method if you want the device to relearn routes from the neighbor and resend its own route table to the neighbor.
- If you use the soft-outbound option, the device compiles a list of all the routes it would normally send to the neighbor at the beginning of a session. However, before sending the updates, the device also applies the filters and route maps you have configured to the list of routes. If the filters or route maps result in changes to the list of routes, the device sends updates to advertise, change, or even withdraw routes on the neighbor as needed. This ensures that the neighbor receives only the routes you want it to contain. Even if the neighbor already contains a route learned from the device that you later decided to filter out, using the soft-outbound option removes that route from the neighbor.

You can specify a single neighbor or a peer group.

To close a neighbor session and thus flush all the routes exchanged by the device and the neighbor, enter the following command.

```
NetIron# clear ip bgp neighbor all
```

Syntax: clear ip bgp neighbor all | <*ip-addr*> | <*peer-group-name*> | <*as-num*> [**soft-outbound** | **soft** [**in** | **out**]]

The **all** | <*ip-addr*> | <*peer-group-name*> | <*as-num*> parameters specify the neighbor. The <*ip-addr*> parameter specifies a neighbor by its IP interface with the device. The <*peer-group-name*> specifies all neighbors in a specific peer group. The <*as-num*> parameter specifies all neighbors within an AS and has a range of 1 – 4294967295. The **all** keyword specifies all neighbors.

To resend routes to a neighbor without closing the neighbor session, enter a command such as the following.

```
NetIron# clear ip bgp neighbor 10.0.0.1 soft out
```

Clearing and resetting BGP4 routes in the IP route table

To clear BGP4 routes from the IP route table and reset the routes, enter a command such as the following.

```
NetIron# clear ip bgp routes
```

Syntax: clear ip bgp routes [<*ip-addr*>/<*prefix-length*>]

Clearing traffic counters

You can clear the counters (reset them to 0) for BGP4 messages.

To clear the BGP4 message counter for all neighbors, enter the following command.

```
NetIron# clear ip bgp traffic
```

Syntax: clear ip bgp traffic

To clear the BGP4 message counter for a specific neighbor, enter a command such as the following.

```
NetIron# clear ip bgp neighbor 10.0.0.1 traffic
```

To clear the BGP4 message counter for all neighbors within a peer group, enter a command such as the following.

```
NetIron# clear ip bgp neighbor PeerGroup1 traffic
```

Syntax: clear ip bgp neighbor all | <*ip-addr*> | <*peer-group-name*> | <*as-num*> **traffic**

The **all** | <*ip-addr*> | <*peer-group-name*> | <*as-num*> parameters specify the neighbor. The <*ip-addr*> parameter specifies a neighbor by its IP interface with the device. The <*peer-group-name*> specifies all neighbors in a specific peer group. The <*as-num*> parameter specifies all neighbors within the specified AS. The **all** parameter specifies all neighbors.

Clearing route flap dampening statistics

Clearing the dampening statistics for a route does not change the dampening status of the route.

To clear all the route dampening statistics, enter the following command at any level of the CLI.

```
NetIron# clear ip bgp flap-statistics
```

Syntax: **clear ip bgp flap-statistics** [**regular-expression** <*regular-expression*> | <*address*> <*mask*> | **neighbor** <*ip-addr*>]

The parameters are the same as those for the **show ip bgp flap-statistics** command (except the **longer-prefixes** option is not supported). Refer to "Displaying route flap dampening statistics" on page 1129.

NOTE
The **clear ip bgp damping** command not only clears statistics but also un-suppresses the routes. Refer to "Displaying route flap dampening statistics" on page 1129.

Removing route flap dampening

You can un-suppress routes by removing route flap dampening from the routes. The device allows you to un-suppress all routes at once or un-suppress individual routes.

To un-suppress all the suppressed routes, enter the following command at the Privileged EXEC level of the CLI.

```
NetIron# clear ip bgp damping
```

Syntax: **clear ip bgp damping** [<*ip-addr*> <*ip-mask*>]

The <*ip-addr*> parameter specifies a particular network.

The <*ip-mask*> parameter specifies the network's mask.

To un-suppress a specific route, enter a command such as the following:

```
NetIron# clear ip bgp damping 209.157.22.0 255.255.255.0
```

This command un-suppresses only the routes for network 209.157.22.0/24.

Clearing diagnostic buffers

The device stores the following BGP4 diagnostic information in buffers:

- The first 400 bytes of the last packet received that contained an error
- The last NOTIFICATION message either sent or received by the device

To display these buffers, use options with the **show ip bgp neighbors** command. Refer to "Displaying BGP4 neighbor information" on page 1109.

This information can be useful if you are working with Dell Technical Support to resolve a problem. The buffers do not identify the system time when the data was written to the buffer. If you want to ensure that diagnostic data in a buffer is recent, you can clear the buffers. You can clear the buffers for a specific neighbor or for all neighbors.

If you clear the buffer containing the first 400 bytes of the last packet that contained errors, all the bytes are changed to zeros. The Last Connection Reset Reason field of the BGP4 neighbor table also is cleared.

If you clear the buffer containing the last NOTIFICATION message sent or received, the buffer contains no data.

You can clear the buffers for all neighbors, for an individual neighbor, or for all the neighbors within a specific peer group.

To clear these buffers for neighbor 10.0.0.1, enter the following commands.

```
NetIron# clear ip bgp neighbor 10.0.0.1 last-packet-with-error
NetIron# clear ip bgp neighbor 10.0.0.1 notification-errors
```

Syntax: **clear ip bgp neighbor all** | <*ip-addr*> | <*peer-group-name*> | <*as-num*> **last-packet-with-error** | **notification-errors**

The **all** | <*ip-addr*> | <*peer-group-name*> | <*as-num*> parameters specify the neighbor. The <*ip-addr*> parameter specifies a neighbor by its IP interface with the device. The <*peer-group-name*> specifies all neighbors in a specific peer group. The <*as-num*> parameter specifies all neighbors within the specified AS. The **all** parameter specifies all neighbors.

Configuring BGP4 Restart

BGP4 Restart can be configured for a global routing instance or for a specified Virtual Routing and Forwarding (VRF) instance. The following sections describe how to enable the BGP4 Restart feature.

Configuring BGP4 restart for the global routing instance

Use the following command to enable the BGP4 restart feature globally on a device.

```
NetIron(config)# router bgp
NetIron(config-bgp)# graceful-restart
```

Syntax: [**no**] **graceful-restart**

Configuring BGP4 Restart for a VRF

Use the following command to enable the BGP4 restart feature for a specified VRF.

```
NetIron(config)# router bgp
NetIron(config-bgp)# address-family ipv4 unicast vrf blue
NetIron(config-bgp-ipv4u-vrf)# graceful-restart
```

Syntax: [**no**] **graceful-restart**

Configuring timers for BGP4 Restart (optional)

You can optionally configure the following timers to change their values from the default values:

- Restart Timer
- Stale Routes Timer
- Purge Timer

The <*seconds*> variable sets the maximum restart wait time advertised to neighbors. Possible values are 1– 3600 seconds. The default value is 120 seconds.

Configuring the restart timer for BGP4 Restart

Use the following command to specify the maximum amount of time a device will maintain routes from and forward traffic to a restarting device.

```
NetIron(config-bgp)# graceful-restart restart-timer 150
```

Syntax: [**no**] **graceful-restart restart-timer** <*seconds*>

The <*seconds*> variable sets the maximum restart wait time advertised to neighbors. Possible values are 1 - 3600 seconds. The default value is 120 seconds.

Configuring BGP4 Restart stale routes timer

Use the following command to specify the maximum amount of time a helper device will wait for an end-of-RIB message from a peer before deleting routes from that peer.

```
NetIron(config-bgp)# graceful-restart stale-routes-time 120
```

Syntax: [**no**] **graceful-restart stale-routes-time** <*seconds*>

The <*seconds*> variable sets the maximum time before a helper device cleans up stale routes. Possible values are 1 - 3600 seconds. The default value is 360 seconds.

Configuring BGP4 Restart purge timer

Use the following command to specify the maximum amount of time a device will maintain stale routes in its routing table before purging them.

```
NetIron(config-bgp)# graceful-restart purge-time 900
```

Syntax: [**no**] **graceful-restart purge-time** <*seconds*>

The <*seconds*> variable sets the maximum time before a restarting device cleans up stale routes. Possible values are 1 – 3600 seconds. The default value is 600 seconds.

For information about displaying BGP4 restart neighbor information, refer to "Displaying BGP4 restart neighbor information" on page 1131.

Configuring BGP4 null0 routing

BGP4 null0 routing is described in "BGP4 null0 routing" on page 1007. The following example configures a null0 routing application to stop denial of service attacks from remote hosts on the Internet.

Configuration steps

1. Select a device, for example, device 6, to distribute null0 routes throughout the BGP4 network.
2. Configure a route-map to match a particular tag (50) and set the next-hop address to an unused network address (192.168.0.1).
3. Set the local-preference to a value higher than any possible internal or external local-preference (50).

4. Complete the route map by setting origin to IGP.
5. On device 6, redistribute the static routes into BGP4, using route-map <*route-map-name*> (redistribute static route-map block user).
6. On device 1, (the device facing the Internet), configure a null0 route matching the next-hop address in the route-map (ip route 192.168.0.1/32 null0).
7. Repeat step 3 for all devices interfacing with the Internet (edge corporate devices). In this case, device 2 has the same null0 route as device 1.
8. On device 6, configure the network prefixes associated with the traffic you want to drop. The static route IP address references a destination address. You must point the static route to the egress port, (for example, Ethernet 3/7), and specify the tag 50, matching the route-map configuration.

Configuration examples

Device 6

The following configuration defines specific prefixes to filter:

```
NetIron(config)# ip route 110.0.0.40/29 ethernet 3/7 tag 50
NetIron(config)# ip route 115.0.0.192/27 ethernet 3/7 tag 50
NetIron(config)# ip route 120.014.0/23 ethernet 3/7 tag 50
```

The following configuration redistributes routes into BGP4.

```
NetIron(config)# router bgp
NetIron(config-bgp-router)# local-as 100
NetIron(config-bgp-router)# neighbor <router1_int_ip address> remote-as 100
NetIron(config-bgp-router)# neighbor <router2_int_ip address> remote-as 100
NetIron(config-bgp-router)# neighbor <router3_int_ip address> remote-as 100
NetIron(config-bgp-router)# neighbor <router4_int_ip address> remote-as 100
NetIron(config-bgp-router)# neighbor <router5_int_ip address> remote-as 100
NetIron(config-bgp-router)# neighbor <router7_int_ip address> remote-as 100
NetIron(config-bgp-router)# redistribute static route-map blockuser
NetIron(config-bgp-router)# exit
```

The following configuration defines the specific next hop address and sets the local preference to preferred.

```
NetIron(config)# route-map blockuser permit 10
NetIron(config-routemap blockuser)# match tag 50
NetIron(config-routemap blockuser)# set ip next-hop 192.168.0.1
NetIron(config-routemap blockuser)# set local-preference 1000000
NetIron(config-routemap blockuser)# set origin igp
NetIron(config-routemap blockuser)# exit
```

NOTE
A match tag can take up to 16 tags. During the execution of a route-map, a match on any tag value in the list is considered a successful match.

Device 1

The following configuration defines the null0 route to the specific next hop address. The next hop address 192.168.0.1 points to 128.178.1.101, which gets blocked.

```
NetIron(config)# ip route 192.168.0.1/32 null0
```

```
NetIron(config)# router bgp
local-as 100
NetIron(config-bgp-router)# neighbor <router2_int_ip address> remote-as 100
NetIron(config-bgp-router)# neighbor <router3_int_ip address> remote-as 100
NetIron(config-bgp-router)# neighbor <router4_int_ip address> remote-as 100
NetIron(config-bgp-router)# neighbor <router5_int_ip address> remote-as 100
NetIron(config-bgp-router)# neighbor <router6_int_ip address> remote-as 100
NetIron(config-bgp-router)# neighbor <router7_int_ip address> remote-as 100
```

Device 2

The following configuration defines a null0 route to the specific next hop address. The next hop address 192.168.0.1 points to 128.178.1.101, which gets blocked.

```
NetIron(config)# ip route 192.168.0.1/32 null0
NetIron(config)# router bgp
NetIron(config-bgp-router)# local-as 100
NetIron(config-bgp-router)# neighbor <router1_int_ip address> remote-as 100
NetIron(config-bgp-router)# neighbor <router3_int_ip address> remote-as 100
NetIron(config-bgp-router)# neighbor <router4_int_ip address> remote-as 100
NetIron(config-bgp-router)# neighbor <router5_int_ip address> remote-as 100
NetIron(config-bgp-router)# neighbor <router6_int_ip address> remote-as 100
NetIron(config-bgp-router)# neighbor <router7_int_ip address> remote-as 100
```

Show commands

After configuring the null0 application, you can display the output using **show** commands.

Device 6

Show ip route static output for device 6.

```
NetIron# show ip route static
Type Codes - B:BGP  D:Connected  S:Static  R:RIP  O:OSPF;   Cost - Dist/Metric
          Destination          Gateway         Port        Cost       Type
1       110.0.0.40/29          DIRECT          eth 3/7     1/1        S
2       115.0.0.192/27         DIRECT          eth 3/7     1/1        S

NetIron#
```

Generalized TTL Security Mechanism support

The device supports the Generalized TTL Security Mechanism (GTSM) as defined in RFC 3682. GTSM protects the device from attacks of invalid BGP4 control traffic that is sent to overload the CPU or hijack the BGP4 session. GTSM protection applies to EBGP neighbors only.

When GTSM protection is enabled, BGP4 control packets sent by the device to a neighbor have a Time To Live (TTL) value of 255. In addition, the device expects the BGP4 control packets received from the neighbor to have a TTL value of either 254 or 255. For multihop peers (where the **ebgp-multihop** option is configured for the neighbor), the device expects the TTL for BGP4 control packets received from the neighbor to be greater than or equal to 255, minus the configured number of hops to the neighbor. If the BGP4 control packets received from the neighbor do not have the anticipated value, the device drops them.

For more information on GTSM protection, see RFC 3682.

To enable GTSM protection for neighbor 192.168.9.210 (for example), enter the following command.

```
NetIron(config-bgp-router)# neighbor 192.168.9.210 ebgp-btsh
```

Syntax: [**no**] **neighbor** <*ip-addr*> | <*peer-group-name*> **ebgp-btsh**

NOTE
For GTSM protection to work properly, it must be enabled on both the device and the neighbor.

Displaying BGP4 information

You can display the following configuration information and statistics for BGP4 protocol:

- Summary BGP4 configuration information for the device
- Active BGP4 configuration information (the BGP4 information in the running configuration)
- Neighbor information
- Peer-group information
- Information about the paths from which BGP4 selects routes
- Summary BGP4 route information
- The device's BGP4 route table
- Route flap dampening statistics
- Active route maps (the route map configuration information in the running configuration)
- BGP4 Restart Neighbor Information
- AS4 support and asdot notation

Displaying summary BGP4 information

You can display the local AS number, the maximum number of routes and neighbors supported, and some BGP4 statistics. You can also display BGP4 memory usage for:

- BGP4 routes installed
- Routes advertising to all neighbors (aggregated into peer groups)
- Attribute entries installed

The **show ip bgp summary** command output has the following limitations:

- If a BGP4 peer is not configured for an address-family, the peer information is not displayed.
- If a BGP4 peer is configured for an address-family but not negotiated for an address-family after the BGP4 peer is in the established state, the **show ip bgp summary** command output shows (**NoNeg**) at the end of the line for this peer.
- If a BGP4 peer is configured and negotiated for that address-family, its display is the same as in previous releases.

To view summary BGP4 information for the device, enter the following command at any CLI prompt

```
NetIron# show ip bgp summary
  BGP4 Summary
  Router ID: 30.10.1.14 Local AS Number: 100
  Confederation Identifier: not configured
  Confederation Peers:
  Maximum Number of IP ECMP Paths Supported for Load Sharing: 1
  Number of Neighbors Configured: 67, UP: 67
  Number of Routes Installed: 258088, Uses 22195568 bytes
  Number of Routes Advertising to All Neighbors: 17,035844 (3,099146 entries),
Uses 192,147052 bytes
  Number of Attribute Entries Installed: 612223, Uses 55100070 bytes
  Neighbor Address  AS#   State   Time     Rt:Accepted Filtered Sent   ToSend
  100.0.100.2       100   ESTABp  0h28m24s    0        0        258087 0
  100.0.101.2       100   ESTAB   0h28m24s    0        0        258087 0

```

Syntax: show ip bgp summary

This display shows the following information.

TABLE 170 BGP4 summary information

This field...	Displays...
Router ID	The device's device ID.
Local AS Number	The BGP4 AS number for the device.
Confederation Identifier	The AS number of the confederation in which the device resides.
Confederation Peers	The numbers of the local ASs contained in the confederation. This list matches the confederation peer list you configure on the device.
Maximum Number of Paths Supported for Load Sharing	The maximum number of route paths across which the device can balance traffic to the same destination. The feature is enabled by default but the default number of paths is 1. You can increase the number from 2 – 8 paths. Refer to "Configuring BGP4 multipath load sharing" on page 1034.
Number of Neighbors Configured	The number of BGP4 neighbors configured on this device, and currently in established state.
Number of Routes Installed	The number of BGP4 routes in the device BGP4 route table and the route or path memory usage.
Number of Routes Advertising to All Neighbors	The total of the RtSent and RtToSend columns for all neighbors, the total number of unique ribout group entries, and the amount of memory used by these groups.
Number of Attribute Entries Installed	The number of BGP4 route-attribute entries in the device route-attributes table and the amount of memory used by these entries. To display the route-attribute table, refer to "Displaying BGP4 route-attribute entries" on page 1127.
Neighbor Address	The IP addresses of the BGP4 neighbors for this device.
AS#	The AS number.

TABLE 170 BGP4 summary information (Continued)

This field...	Displays...
State	The state of device sessions with each neighbor. The states are from this perspective of the device, not the neighbor. State values are based on the BGP4 state machine values described in RFC 1771 and can be one of the following for each device: • IDLE – The BGP4 process is waiting to be started. Usually, enabling BGP4 or establishing a neighbor session starts the BGP4 process. • ADMND – The neighbor has been administratively shut down. Refer to "Administratively shutting down a session with a BGP4 neighbor" on page 1049. • CONNECT – BGP4 is waiting for the connection process for the TCP neighbor session to be completed. • ACTIVE – BGP4 is waiting for a TCP connection from the neighbor. **Note**: If the state frequently changes between CONNECT and ACTIVE, there may be a problem with the TCP connection. • OPEN SENT – BGP4 is waiting for an Open message from the neighbor. • OPEN CONFIRM – BGP4 has received an Open message from the neighbor and is now waiting for either a KEEPALIVE or NOTIFICATION message. If the device receives a KEEPALIVE message from the neighbor, the state changes to Established. If the message is a NOTIFICATION, the state changes to Idle. • ESTABLISHED – BGP4 is ready to exchange UPDATE packets with the neighbor. **Operational States:** Additional information regarding the operational states of the BGP4 states described above may be added as described in the following: • **(+)** – is displayed if there is more BGP4 data in the TCP receiver queue. **Note**: If you display information for the neighbor using the **show ip bgp neighbor** <*ip-addr*> command, the TCP receiver queue value will be greater than 0. • **(-)** – indicates that the session has gone down and the software is clearing or removing routes. • **(*)** – indicates that the inbound or outbound policy is being updated for the peer. • **(s)** – indicates that the peer has negotiated restart, and the session is in a stale state. • **(r)** – indicates that the peer is restarting the BGP4 connection, through restart. • **(^)** – on the standby MP indicates that the peer is in the ESTABLISHED state and has received restart capability (in the primary MP). • **(<)** – indicates that the device is waiting to receive the "End of RIB" message the peer. • **(p)** – indicates that the neighbor ribout group membership change is pending or in progress
Time	The time that has passed since the state last changed.
Accepted	The number of routes received from the neighbor that this device installed in the BGP4 route table. Usually, this number is lower than the RoutesRcvd number. The difference indicates that this device filtered out some of the routes received in the UPDATE messages.
Filtered	The routes or prefixes that have been filtered out: • If soft reconfiguration is enabled, this field shows how many routes were filtered out (not placed in the BGP4 route table) but retained in memory. • If soft reconfiguration is not enabled, this field shows the number of BGP4 routes that have been filtered out.

TABLE 170 BGP4 summary information (Continued)

This field...	Displays...
Sent	The number of BGP4 routes the device has sent to the neighbor.
ToSend	The number of routes the device has queued to advertise and withdraw to a neighbor.

Displaying the active BGP4 configuration

To view the active BGP4 configuration information contained in the running configuration without displaying the entire running configuration, enter the following command at any level of the CLI.

```
NetIron# show ip bgp config
router bgp
  local-as 200
neighbor 102.102.1.1 remote-as 200
neighbor 102.102.1.1 ebgp-multihop
neighbor 102.102.1.1 update-source loopback 1
neighbor 192.168.2.1 remote-as 100
neighbor 200.200.2.2 remote-as 400
neighbor 1000:2::1:1 remote-as 200
neighbor 2000:1::1:2 remote-as 400
neighbor 4444::1 remote-as 300

address-family ipv4 unicast
no neighbor 1000:2::1:1 activate
no neighbor 2000:1::1:2 activate
no neighbor 4444::1 activate
exit-address-family

address-family ipv4 multicast
exit-address-family

address-family ipv6 unicast
redistribute static
neighbor 1000:2::1:1 activate
neighbor 2000:1::1:2 activate
neighbor 4444::1 activate
exit-address-family
end of BGP configuration
```

Syntax: show ip bgp config

Displaying summary neighbor information

The **show ip bgp neighbor** command output has the following limitations.

1. If BGP4 peer is not configured for an address-family, the peer information will NOT be displayed.
2. If BGP4 peer is configured for an address-family, it will display the same as in previous releases.

To display summary neighbor information, enter a command such as the following at any level of the CLI.

```
NetIron(config-bgp)# show ip bgp neighbor 192.168.4.211 routes-summary
1   IP Address: 192.168.4.211
Routes Accepted/Installed:1,  Filtered/Kept:11,  Filtered:11
   Routes Selected as BEST Routes:1
      BEST Routes not Installed in IP Forwarding Table:0
   Unreachable Routes (no IGP Route for NEXTHOP):0
   History Routes:0

NLRIs Received in Update Message:24,  Withdraws:0 (0),  Replacements:1
   NLRIs Discarded due to
      Maximum Prefix Limit:0, AS Loop:0
      Invalid Nexthop:0, Invalid Nexthop Address:0.0.0.0
      Duplicated Originator_ID:0, Cluster_ID:0

Routes Advertised:0,  To be Sent:0,  To be Withdrawn:0
NLRIs Sent in Update Message:0,  Withdraws:0,  Replacements:0

Peer Out of Memory Count for:
   Receiving Update Messages:0, Accepting Routes(NLRI):0
   Attributes:0, Outbound Routes(RIB-out):0
```

Syntax: show ip bgp neighbors [<*ip-addr*>] | [**route-summary**]

This display shows the following information.

TABLE 171 BGP4 route summary information for a neighbor

This field...	Displays...
IP Address	The IP address of the neighbor.
Routes Received	How many routes the device has received from the neighbor during the current BGP4 session: • Accepted or Installed – Number of received routes the device accepted and installed in the BGP4 route table. • Filtered or Kept – Number of routes that were filtered out, but were retained in memory for use by the soft reconfiguration feature. • Filtered – Number of received routes filtered out.
Routes Selected as BEST Routes	The number of routes that the device selected as the best routes to their destinations.
BEST Routes not Installed in IP Forwarding Table	The number of routes received from the neighbor that are the best BGP4 routes to their destinations, but were not installed in the IP route table because the device received better routes from other sources (such as OSPF, RIP, or static IP routes).
Unreachable Routes	The number of routes received from the neighbor that are unreachable because the device does not have a valid RIP, OSPF, or static route to the next-hop.
History Routes	The number of routes that are down but are being retained for route flap dampening purposes.
NLRIs Received in Update Message	The number of routes received in Network Layer Reachability (NLRI) format in UPDATE messages: • Withdraws – Number of withdrawn routes the device has received. • Replacements – Number of replacement routes the device has received.

TABLE 171 BGP4 route summary information for a neighbor (Continued)

This field...	Displays...
NLRIs Discarded due to	Indicates the number of times the device discarded an NLRI for the neighbor due to the following reasons: • Maximum Prefix Limit – The configured maximum prefix amount had been reached. • AS Loop – An AS loop occurred. An AS loop occurs when the BGP4 AS-path attribute contains the local AS number. • maxas-limit aspath – The number of route entries discarded because the AS path exceeded the configured maximum length or exceeded the internal memory limits. • Invalid Nexthop – The next-hop value was not acceptable. • Duplicated Originator_ID – The originator ID was the same as the local device ID. • Cluster_ID – The cluster list contained the local cluster ID, or the local device ID (see above) if the cluster ID is not configured.
Routes Advertised	The number of routes the device has advertised to this neighbor: • To be Sent – The number of routes queued to send to this neighbor. • To be Withdrawn – The number of NLRIs for withdrawing routes the device has queued to send to this neighbor in UPDATE messages.
NLRIs Sent in Update Message	The number of NLRIs for new routes the device has sent to this neighbor in UPDATE messages: • Withdraws – Number of routes the device has sent to the neighbor to withdraw. • Replacements – Number of routes the device has sent to the neighbor to replace routes the neighbor already has.
Peer Out of Memory Count for	Statistics for the times the device has run out of BGP4 memory for the neighbor during the current BGP4 session: • Receiving Update Messages – The number of times UPDATE messages were discarded because there was no memory for attribute entries. • Accepting Routes (NLRI) – The number of NLRIs discarded because there was no memory for NLRI entries. This count is not included in the Receiving Update Messages count. • Attributes – The number of times there was no memory for BGP4 attribute entries. • Outbound Routes (RIB-out) – The number of times there was no memory to place a “best” route into the neighbor route information base (Adj-RIB-Out) for routes to be advertised.

Displaying BGP4 neighbor information

You can display configuration information and statistics for BGP4 neighbors of the device.

To view BGP4 neighbor information, including the values for all the configured parameters, enter the following command.

NOTE
The display shows all the configured parameters for the neighbor. Only the parameters that have values different from their defaults are shown.

```
NetIron(config-bgp)# show ip bgp neighbor 10.4.0.2
    Total number of BGP neighbors:
1   IP Address: 10.4.0.2, AS: 5 (EBGP), RouterID: 100.0.0.1
       Description: neighbor 10.4.0.2
    Local AS: 101
    State: ESTABLISHED, Time: 0h1m0s, KeepAliveTime: 0, HoldTime: 0
       PeerGroup: pg1
       Multihop-EBGP: yes, ttl: 1
       RouteReflectorClient: yes
       SendCommunity: yes
       NextHopSelf: yes
       DefaultOriginate: yes (default sent)
       MaximumPrefixLimit: 90000
       RemovePrivateAs: : yes
       RefreshCapability: Received
    Route Filter Policies:
       Distribute-list: (out) 20
       Filter-list: (in) 30

       SendQue:           0  RcvQue:            0  CngstWnd:       1460
```

This example shows how to display information for a specific neighbor, by specifying the neighbor's IP address with the command. Since none of the other display options are used, all of the information is displayed for the neighbor. The number in the far left column indicates the neighbor for which information is displayed. When you list information for multiple neighbors, this number makes the display easier to read.

The TCP statistics at the end of the display show status for the TCP session with the neighbor. Most of the fields show information stored in the Transmission Control Block (TCB) for the TCP session between the device and the neighbor. These fields are described in detail in section 3.2 of RFC 793, "Transmission Control Protocol Functional Specification".

Syntax: **show ip bgp neighbors** [<*ip-addr*> [**advertised-routes** [**detail** [<*ip-addr*>[/<*mask-bits*>]]]] | [**attribute-entries** [**detail**]] | [**flap-statistics**] | [**last-packet-with-error**] | [**received prefix-filter**] |
[**received-routes**] | [**routes** [**best**] | [**detail** [**best**] | [**not-installed-best**] | [**unreachable**]] | [**rib-out-routes** [<*ip-addr*>/<*mask-bits*> | <*ip-addr*> <*net-mask*> | **detail**]] | [**routes-summary**]]

The <*ip-addr*> option lets you narrow the scope of the command to a specific neighbor.

The **advertised-routes** option displays only the routes that the device has advertised to the neighbor during the current BGP4 session.

The **attribute-entries** option shows the attribute-entries associated with routes received from the neighbor.

The **flap-statistics** option shows the route flap statistics for routes received from or sent to the neighbor.

The **last-packet-with-error** option displays the last packet from the neighbor that contained an error. The packet contents are displayed in decoded (human-readable) format.

The **received prefix-filter** option shows the Outbound Route Filters (ORFs) received from the neighbor. This option applies to cooperative route filtering.

The **received-routes** option lists all the route information received in route updates from the neighbor since the soft reconfiguration feature was enabled. Refer to "Using soft reconfiguration" on page 1090.

The **routes** option lists the routes received in UPDATE messages from the neighbor. You can specify the following additional options:

- **best** – Displays the routes received from the neighbor that the device selected as the best routes to their destinations.
- **not-installed-best** – Displays the routes received from the neighbor that are the best BGP4 routes to their destinations, but were not installed in the IP route table because the device received better routes from other sources (such as OSPF, RIP, or static IP routes).
- **unreachable** – Displays the routes that are unreachable because the device does not have a valid RIP, OSPF, or static route to the next hop.
- **detail** – Displays detailed information for the specified routes. You can refine your information request by also specifying one of the options (**best**, **not-installed-best**, or **unreachable**).

The **rib-out-routes** option lists the route information base (RIB) for outbound routes. You can display all routes or specify a network address.

The **routes-summary** option displays a summary of the following information:

- Number of routes received from the neighbor
- Number of routes accepted by this device from the neighbor
- Number of routes this device filtered out of the UPDATES received from the neighbor and did not accept
- Number of routes advertised to the neighbor
- Number of attribute entries associated with routes received from or advertised to the neighbor.

This display shows the following information.

TABLE 172 BGP4 neighbor information

This field...	Displays...
Total Number of BGP4 Neighbors	The number of BGP4 neighbors configured.
IP Address	The IP address of the neighbor.
AS	The AS the neighbor is in.

TABLE 172 BGP4 neighbor information (Continued)

This field...	Displays...
EBGP or IBGP	Whether the neighbor session is an IBGP session, an EBGP session, or a confederation EBGP session: • EBGP – The neighbor is in another AS. • EBGP_Confed – The neighbor is a member of another sub-AS in the same confederation. • IBGP – The neighbor is in the same AS.
RouterID	The neighbor device ID.
Description	The description you gave the neighbor when you configured it on the device.
Local AS	The value (if any) of the Local AS configured.
State	The state of the session with the neighbor. The states are from the device perspective, not the neighbor perspective. The state values are based on the BGP4 state machine values described in RFC 1771 and can be one of the following for each device: • IDLE – The BGP4 process is waiting to be started. Usually, enabling BGP4 or establishing a neighbor session starts the BGP4 process. • A minus sign (-) indicates that the session has gone down and the software is clearing or removing routes. • ADMND – The neighbor has been administratively shut down. Refer to "Administratively shutting down a session with a BGP4 neighbor" on page 1049. • A minus sign (-) indicates that the session has gone down and the software is clearing or removing routes. • CONNECT – BGP4 is waiting for the connection process for the TCP neighbor session to be completed. • ACTIVE – BGP4 is waiting for a TCP connection from the neighbor. **NOTE:** If the state frequently changes between CONNECT and ACTIVE, there may be a problem with the TCP connection. • OPEN SENT – BGP4 is waiting for an Open message from the neighbor. • OPEN CONFIRM – BGP4 has received an OPEN message from the neighbor and is now waiting for either a KEEPALIVE or NOTIFICATION message. If the device receives a KEEPALIVE message from the neighbor, the state changes to Established. If the message is a NOTIFICATION, the state changes to Idle. • ESTABLISHED – BGP4 is ready to exchange UPDATE messages with the neighbor. • If there is more BGP4 data in the TCP receiver queue, a plus sign (+) is also displayed. **NOTE:** If you display information for the neighbor using the **show ip bgp neighbor** <*ip-addr*> command, the TCP receiver queue value will be greater than 0.
Time	The amount of time this session has been in the current state.
KeepAliveTime	The keep alive time, which specifies how often this device sends keepalive messages to the neighbor. Refer to "Changing the Keep Alive Time and Hold Time" on page 1057.
HoldTime	The hold time, which specifies how many seconds the device will wait for a keepalive or update message from a BGP4 neighbor before deciding that the neighbor is not operational. Refer to "Changing the Keep Alive Time and Hold Time" on page 1057.
PeerGroup	The name of the peer group the neighbor is in, if applicable.

TABLE 172 BGP4 neighbor information (Continued)

This field...	Displays...
Multihop-EBGP	Whether this option is enabled for the neighbor.
RouteReflectorClient	Whether this option is enabled for the neighbor.
SendCommunity	Whether this option is enabled for the neighbor.
NextHopSelf	Whether this option is enabled for the neighbor.
DefaultOriginate	Whether this option is enabled for the neighbor.
MaximumPrefixLimit	Maximum number of prefixes the device will accept from this neighbor.
RemovePrivateAs	Whether this option is enabled for the neighbor.
RefreshCapability	Whether this device has received confirmation from the neighbor that the neighbor supports the dynamic refresh capability.
CooperativeFilteringCapability	Whether the neighbor is enabled for cooperative route filtering.
Distribute-list	Lists the distribute list parameters, if configured.
Filter-list	Lists the filter list parameters, if configured.
Prefix-list	Lists the prefix list parameters, if configured.
Route-map	Lists the route map parameters, if configured.
Messages Sent	The number of messages this device has sent to the neighbor. The display shows statistics for the following message types: • Open • Update • KeepAlive • Notification • Refresh-Req
Messages Received	The number of messages this device has received from the neighbor. The message types are the same as for the Message Sent field.
Last Update Time	Lists the last time updates were sent and received for the following: • NLRIs • Withdraws

TABLE 172 BGP4 neighbor information (Continued)

This field...	Displays...
Last Connection Reset Reason	The reason the previous session with this neighbor ended. The reason can be one of the following: Reasons described in the BGP4 specifications: • Message Header Error • Connection Not Synchronized • Bad Message Length • Bad Message Type • OPEN Message Error • Unsupported Version Number • Bad Peer AS Number • Bad BGP4 Identifier • Unsupported Optional Parameter • Authentication Failure • Unacceptable Hold Time • Unsupported Capability • UPDATE Message Error • Malformed Attribute List • Unrecognized Well-known Attribute • Missing Well-known Attribute • Attribute Flags Error • Attribute Length Error • Invalid ORIGIN Attribute • Invalid NEXT_HOP Attribute • Optional Attribute Error • Invalid Network Field • Malformed AS_PATH • Hold Timer Expired • Finite State Machine Error • Rcv Notification
Last Connection Reset Reason (cont.)	Reasons specific to the implementation: • Reset All Peer Sessions • User Reset Peer Session • Port State Down • Peer Removed • Peer Shutdown • Peer AS Number Change • Peer AS Confederation Change • TCP Connection KeepAlive Timeout • TCP Connection Closed by Remote • TCP Data Stream Error Detected

TABLE 172 BGP4 neighbor information (Continued)

This field...	Displays...

Notification Sent	If the device receives a notification message from the neighbor, the message contains an error code corresponding to one of the following errors. Some errors have subcodes that clarify the reason for the error. Where applicable, the subcode messages are listed underneath the error code messages.
	• Message Header Error:
	  • Connection Not Synchronized
	  • Bad Message Length
	  • Bad Message Type
	  • Unspecified
	• Open Message Error:
	  • Unsupported Version
	  • Bad Peer As
	  • Bad BGP4 Identifier
	  • Unsupported Optional Parameter
	  • Authentication Failure
	  • Unacceptable Hold Time
	  • Unspecified
	• Update Message Error:
	  • Malformed Attribute List
	  • Unrecognized Attribute
	  • Missing Attribute
	  • Attribute Flag Error
	  • Attribute Length Error
	  • Invalid Origin Attribute
	  • Invalid NextHop Attribute
	  • Optional Attribute Error
	  • Invalid Network Field
	  • Malformed AS Path
	  • Unspecified
	• Hold Timer Expired
	• Finite State Machine Error
	• Cease
	• Unspecified

Notification Received	See above.

TABLE 172 BGP4 neighbor information (Continued)

This field...	Displays...
TCP Connection state	The state of the connection with the neighbor. The connection can have one of the following states: • LISTEN – Waiting for a connection request. • SYN-SENT – Waiting for a matching connection request after having sent a connection request. • SYN-RECEIVED – Waiting for a confirming connection request acknowledgment after having both received and sent a connection request. • ESTABLISHED – Data can be sent and received over the connection. This is the normal operational state of the connection. • FIN-WAIT-1 – Waiting for a connection termination request from the remote TCP, or an acknowledgment of the connection termination request previously sent. • FIN-WAIT-2 – Waiting for a connection termination request from the remote TCP. • CLOSE-WAIT – Waiting for a connection termination request from the local user. • CLOSING – Waiting for a connection termination request acknowledgment from the remote TCP. • LAST-ACK – Waiting for an acknowledgment of the connection termination request previously sent to the remote TCP (which includes an acknowledgment of its connection termination request). • TIME-WAIT – Waiting for enough time to pass to be sure the remote TCP received the acknowledgment of its connection termination request. • CLOSED – There is no connection state.
Byte Sent	The number of bytes sent.
Byte Received	The number of bytes received.
Local host	The IP address of the device.
Local port	The TCP port the device is using for the BGP4 TCP session with the neighbor.
Remote host	The IP address of the neighbor.
Remote port	The TCP port the neighbor is using for the BGP4 TCP session with the device.
ISentSeq	The initial send sequence number for the session.
SendNext	The next sequence number to be sent.
TotUnAck	The number of sequence numbers sent by the device that have not been acknowledged by the neighbor.
TotSent	The number of sequence numbers sent to the neighbor.
ReTrans	The number of sequence numbers that the device retransmitted because they were not acknowledged.
UnAckSeq	The current acknowledged sequence number.
IRcvSeq	The initial receive sequence number for the session.
RcvNext	The next sequence number expected from the neighbor.
SendWnd	The size of the send window.
TotalRcv	The number of sequence numbers received from the neighbor.
DupliRcv	The number of duplicate sequence numbers received from the neighbor.
RcvWnd	The size of the receive window.

TABLE 172 BGP4 neighbor information (Continued)

This field...	Displays...
SendQue	The number of sequence numbers in the send queue.
RcvQue	The number of sequence numbers in the receive queue.
CngstWnd	The number of times the window has changed.

Displaying route information for a neighbor

You can display routes based on the following criteria:

- A summary of the routes for a specific neighbor.
- Routes received from the neighbor that the device selected as the best routes to their destinations.
- Routes received from the neighbor that are the best BGP4 routes to their destinations, but were not installed in the IP route table because the device received better routes from other sources (such as OSPF, RIP, or static IP routes).
- Routes that are unreachable because the device does not have a valid RIP, OSPF, or static route to the next hop.
- Routes for a specific network advertised by the device to the neighbor.
- The Routing Information Base (RIB) for a specific network advertised to the neighbor. You can display the RIB regardless of whether the device has already sent it to the neighbor.

Displaying summary route information

To display summary route information, enter a command such as the following at any level of the CLI.

```
NetIron(config-bgp)# show ip bgp neighbor 10.1.0.2 routes-summary
1   IP Address: 10.1.0.2
Routes Accepted/Installed:1,  Filtered/Kept:11,  Filtered:11
   Routes Selected as BEST Routes:1
      BEST Routes not Installed in IP Forwarding Table:0
   Unreachable Routes (no IGP Route for NEXTHOP):0
   History Routes:0

NLRIs Received in Update Message:24,  Withdraws:0 (0),  Replacements:1
   NLRIs Discarded due to
      Maximum Prefix Limit:0, AS Loop:0
      Invalid Nexthop:0, Invalid Nexthop Address:0.0.0.0
      Duplicated Originator_ID:0, Cluster_ID:0

Routes Advertised:0,  To be Sent:0,  To be Withdrawn:0

   Receiving Update Messages:0, Accepting Routes(NLRI):0
   Attributes:0, Outbound Routes(RIB-out):0
```

This display shows the following information.

TABLE 173 BGP4 route summary information for a neighbor

This field...	Displays...
Routes Received	How many routes the device has received from the neighbor during the current BGP4 session: • Accepted or Installed – Indicates how many of the received routes the device accepted and installed in the BGP4 route table. • Filtered – Indicates how many of the received routes the device did not accept or install because they were denied by filters on the device.
Routes Selected as BEST Routes	The number of routes that the device selected as the best routes to their destinations.
BEST Routes not Installed in IP Forwarding Table	The number of routes received from the neighbor that are the best BGP4 routes to their destinations, but were not installed in the IP route table because the device received better routes from other sources (such as OSPF, RIP, or static IP routes).
Unreachable Routes	The number of routes received from the neighbor that are unreachable because the device does not have a valid RIP, OSPF, or static route to the next hop.
History Routes	The number of routes that are down but are being retained for route flap dampening purposes.
NLRIs Received in Update Message	The number of routes received in Network Layer Reachability (NLRI) format in UPDATE messages: • Withdraws – The number of withdrawn routes the device has received. • Replacements – The number of replacement routes the device has received.
NLRIs Discarded due to	Indicates the number of times the device discarded an NLRI for the neighbor due to the following reasons: • Maximum Prefix Limit – The configured maximum prefix amount had been reached. • AS Loop – An AS loop occurred. An AS loop occurs when the BGP4 AS-path attribute contains the local AS number. • Invalid Nexthop – The next-hop value was not acceptable. • Duplicated Originator_ID – The originator ID was the same as the local device ID. • Cluster_ID – The cluster list contained the local cluster ID, or contained the local device ID (see above) if the cluster ID is not configured.
Routes Advertised	The number of routes the device has advertised to this neighbor: • To be Sent – Number of routes the device has queued to send to this neighbor. • To be Withdrawn –Number of NLRIs for withdrawing routes the device has queued up to send to this neighbor in update messages.

TABLE 173 BGP4 route summary information for a neighbor (Continued)

This field...	Displays...
NLRIs Sent in Update Message	The number of NLRIs for new routes the device has sent to this neighbor in UPDATE messages: • Withdraws – The number of routes the device has sent to the neighbor to withdraw. • Replacements – The number of routes the device has sent to the neighbor to replace routes the neighbor already has.
Peer Out of Memory Count for	Statistics for the times the device has run out of BGP4 memory for the neighbor during the current BGP4 session: • Receiving Update Messages – The number of times update messages were discarded because there was no memory for attribute entries. • Accepting Routes (NLRI) – The number of NLRIs discarded because there was no memory for NLRI entries. This count is not included in the Receiving Update Messages count. • Attributes – The number of times there was no memory for BGP4 attribute entries. • Outbound Routes (RIB-out) – The number of times there was no memory to place a "best" route into the neighbor route information base (Adj-RIB-Out) for routes to be advertised.

Displaying advertised routes

To display the routes the device has advertised to a specific neighbor for a specific network, enter a command such as the following at any level of the CLI.

```
NetIron# show ip bgp neighbors 192.168.4.211 advertised-routes
       There are 2 routes advertised to neighbor 192.168.4.211
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST I:IBGP L:LOCAL
       Network        Next Hop        Metric     LocPrf     Weight     Status
1      102.0.0.0/24   192.168.2.102   12                    32768      BL
2      200.1.1.0/24   192.168.2.102   0                     32768    BL
```

You also can enter a specific route.

```
NetIron# show ip bgp neighbors 192.168.4.211 advertised 200.1.1.0/24
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST I:IBGP L:LOCAL
       Network        Next Hop        Metric     LocPrf     Weight     Status
1      200.1.1.0/24   192.168.2.102   0                     32768      BL
```

Syntax: show ip bgp neighbor <*ip-addr*> **advertised-routes** [<*ip-addr*>/<*prefix*>]

For information about the fields in this display, refer to Table 173. The fields in this display also appear in the **show ip bgp** display.

Displaying the routes with destinations that are unreachable

To display BGP4 routes with destinations that are unreachable using any of the BGP4 paths in the BGP4 route table, enter a command such as the following at any level of the CLI:

```
NetIron(config-bgp)# show ip bgp neighbor 192.168.4.211 routes unreachable
```

Syntax: show ip bgp neighbor <*ip-addr*> **routes unreachable**

For information about the fields in this display, refer to Table 173. The fields in this display also appear in the **show ip bgp** display.

Displaying the Adj-RIB-Out for a neighbor

To display the current BGP4 Routing Information Base (Adj-RIB-Out) for a specific neighbor and a specific destination network, enter a command such as the following at any level of the CLI.

```
NetIron(config-bgp)# show ip bgp neighbor 192.168.4.211 rib-out-routes
192.168.1.0/24
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST I:IBGP L:LOCAL
       Prefix             Next Hop        Metric     LocPrf     Weight Status
1      200.1.1.0/24       0.0.0.0         0          101        32768  BL
```

The Adj-RIB-Out contains the routes that the device either has most recently sent to the neighbor or is about to send to the neighbor.

Syntax: show ip bgp neighbor <*ip-addr*> **rib-out-routes** [<*ip-addr*>/<*prefix*>]

For information about the fields in this display, refer to Table 173. The fields in this display also appear in the **show ip bgp** display.

Displaying peer group information

To display peer-group information, enter a command such as the following at the Privileged EXEC level of the CLI.

```
NetIron# show ip bgp peer-group pg1
1   BGP peer-group is pg
    Description: peer group abc
       SendCommunity: yes
       NextHopSelf: yes
       DefaultOriginate: yes
    Members:
       IP Address: 192.168.10.10, AS: 65111
```

Syntax: show ip bgp peer-group [<*peer-group-name*>]

Only the parameters that have values different from their defaults are listed.

Displaying summary route information

To display summary statistics for all the routes in the device's BGP4 route table, enter a command such as the following at any level of the CLI.

```
NetIron(config-bgp)# show ip bgp routes summary
  Total number of BGP routes (NLRIs) Installed     : 20
  Distinct BGP destination networks                : 20
  Filtered BGP routes for soft reconfig            : 100178
  Routes originated by this router                 : 2
  Routes selected as BEST routes                   : 19
  BEST routes not installed in IP forwarding table : 1
  Unreachable routes (no IGP route for NEXTHOP)    : 1
  IBGP routes selected as best routes              : 0
  EBGP routes selected as best routes              : 17
```

Syntax: show ip bgp routes summary

This display shows the following information.

TABLE 174 BGP4 summary route information

This field...	Displays...
Total number of BGP4 routes (NLRIs) Installed	Number of BGP4 routes the device has installed in the BGP4 route table.
Distinct BGP4 destination networks	Number of destination networks the installed routes represent. The BGP4 route table can have multiple routes to the same network.
Filtered BGP4 routes for soft reconfig	Number of route updates received from soft-reconfigured neighbors or peer groups that have been filtered out but retained. For information about soft reconfiguration, refer to "Using soft reconfiguration" on page 1090.
Routes originated by this device	Number of routes in the BGP4 route table that this device originated.
Routes selected as BEST routes	Number of routes in the BGP4 route table that this device has selected as the best routes to the destinations.
BEST routes not installed in IP forwarding table	Number of BGP4 routes that are the best BGP4 routes to their destinations but were not installed in the IP route table because the device received better routes from other sources (such as OSPF, RIP, or static IP routes).
Unreachable routes (no IGP route for NEXTHOP)	Number of routes in the BGP4 route table whose destinations are unreachable because the next-hop is unreachable.
IBGP routes selected as best routes	Number of "best" routes in the BGP4 route table that are IBGP routes.
EBGP routes selected as best routes	Number of "best" routes in the BGP4 route table that are EBGP routes.

Displaying the BGP4 route table

BGP4 uses filters that you define as well as the algorithm described in "How BGP4 selects a path for a route" on page 1000 to determine the preferred route to a destination. BGP4 sends only the preferred route to the IP table. To view all the learned BGP4 routes, you can display the BGP4 table.

To view the BGP4 route table, enter the following command.

```
NetIron(config-bgp)# show ip bgp routes
Total number of BGP Routes: 97371
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED
       Prefix             Next Hop        Metric     LocPrf     Weight Status
1      3.0.0.0/8          192.168.4.106               100        0      BE
         AS_PATH: 65001 4355 701 80
2      4.0.0.0/8          192.168.4.106               100        0      BE
         AS_PATH: 65001 4355 1
3      4.60.212.0/22      192.168.4.106               100        0      BE
         AS_PATH: 65001 4355 701 1 189
4      6.0.0.0/8          192.168.4.106               100        0      BE
         AS_PATH: 65001 4355 3356 7170 1455
5      8.8.1.0/24         192.168.4.106   0           100        0      BE
         AS_PATH: 65001
```

Syntax: show ip bgp routes [[**network**] <*ip-addr*>] | <*num*> | [**age** <*secs*>] | [**as-path-access-list** <*num*>] | [**best**] | [**cidr-only**] | [**community** <*num*> | **no-export** | **no-advertise** | **internet** |

local-as] | [**community-access-list** <*num*>] | [**community-list** <*num*> | [**detail** <*option*>] | [**filter-list** <*num, num,...*>] |[**next-hop** <*ip-addr*>] | [**no-best**] | [**not-installed-best**] | [**prefix-list** <*string*>] | [**regular-expression** <*regular-expression*>] | [**route-map** <*map-name*>] | [**summary**] | [**unreachable**]

The <*ip-addr*> option displays routes for a specific network. The **network** keyword is optional. You can enter the network address without entering **network** in front of it.

The <*num*> option specifies the table entry with which you want the display to start. For example, if you want to list entries beginning with table entry 100, specify 100.

The **age** <*secs*> parameter displays only the routes that have been received or updated more recently than the number of seconds you specify.

The **as-path-access-list** <*num*> parameter filters the display using the specified AS-path ACL.

The **best** parameter displays the routes received from the neighbor that the device selected as the best routes to their destinations.

The **cidr-only** option lists only the routes whose network masks do not match their class network length.

The **community** option lets you display routes for a specific community. You can specify **local-as**, **no-export**, **no-advertise**, **internet**, or a private community number. You can specify the community number as either two five-digit integer values of up to 1– 65535, separated by a colon (for example, 12345:6789) or a single long integer value.

The **community-access-list** <*num*> parameter filters the display using the specified community ACL.

The **community-list** option lets you display routes that match a specific community filter.

The **detail** option lets you display more details about the routes. You can refine your request by also specifying one of the other display options after the detail keyword.

The **filter-list** option displays routes that match a specific address filter list.

The **next-hop** <*ip-addr*> option displays the routes for a given next-hop IP address.

The **no-best** option displays the routes for which none of the routes to a given prefix were selected as the best route. The IP route table does not contain a BGP4 route for any of the routes listed by the command.

The **not-installed-best** option displays the routes received from the neighbor that are the best BGP4 routes to their destinations, but were not installed in the IP route table because the device received better routes from other sources (such as OSPF, RIP, or static IP routes).

The **prefix-list** <*string*> parameter filters the display using the specified IP prefix list.

The **regular-expression** <*regular-expression*> option filters the display based on a regular expression. Refer to "Using regular expressions" on page 1064.

The **route-map** <*map-name*> parameter filters the display by using the specified route map. The software displays only the routes that match the match clauses in the route map. Software disregards the route map's set clauses.

The **summary** option displays summary information for the routes.

The **unreachable** option displays the routes that are unreachable because the device does not have a valid RIP, OSPF, or static route to the next-hop.

Displaying the best BGP4 routes

To display all the BGP4 routes in the device's BGP4 route table that are the best routes to their destinations, enter a command such as the following at any level of the CLI

```
NetIron(config-bgp)# show ip bgp routes best
Searching for matching routes, use ^C to quit...
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED F:FILTERED
       Prefix             Next Hop        Metric     LocPrf     Weight Status
1      3.0.0.0/8          192.168.4.106              100        0      BE
         AS_PATH: 65001 4355 701 80
2      4.0.0.0/8          192.168.4.106              100        0      BE
         AS_PATH: 65001 4355 1
3      4.60.212.0/22      192.168.4.106              100        0      BE
         AS_PATH: 65001 4355 701 1 189
4      6.0.0.0/8          192.168.4.106              100        0      BE
         AS_PATH: 65001 4355 3356 7170 1455
5      9.2.0.0/16         192.168.4.106              100        0      BE
         AS_PATH: 65001 4355 701
```

Syntax: show ip bgp routes best

For information about the fields in this display, refer to Table 173. The fields in this display also appear in the **show ip bgp** display.

Displaying BGP4 routes whose destinations are unreachable

To display BGP4 routes whose destinations are unreachable using any of the BGP4 paths in the BGP4 route table, enter a command such as the following at any level of the CLI.

```
NetIron(config-bgp)# show ip bgp routes unreachable
Searching for matching routes, use ^C to quit...
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED
       Prefix      Next Hop        Metric     LocPrf     Weight Status
1      8.8.8.0/24  192.168.5.1     0          101        0
         AS_PATH: 65001 4355 1
```

Syntax: show ip bgp routes unreachable

For information about the fields in this display, refer to Table 173. The fields in this display also appear in the **show ip bgp** display.

Displaying information for a specific route

To display BGP4 network information by specifying an IP address within the network, enter a command such as the following at any level of the CLI.

```
NetIron(config-bgp)# show ip bgp 9.3.4.0
Number of BGP Routes matching display condition : 1
Status codes: s suppressed, d damped, h history, * valid, > best, i internal
Origin codes: i - IGP, e - EGP, ? - incomplete
    Network            Next Hop        Metric LocPrf Weight Path
*>  9.3.4.0/24         192.168.4.106          100    0      65001 4355 1 1221 ?
       Last update to IP routing table: 0h11m38s, 1 path(s) installed:
         Gateway           Port
         192.168.2.1       2/1
       Route is advertised to 1 peers:
        20.20.20.2(65300)
```

Syntax: show ip bgp [**route**] <*ip-addr*>/<*prefix*> [**longer-prefixes**] | <*ip-addr*>

If you use the **route** option, the display for the information is different, as shown in the following example.

```
NetIron(config-bgp)# show ip bgp route 9.3.4.0
Number of BGP Routes matching display condition : 1
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED F:FILTERED
       Prefix             Next Hop        Metric     LocPrf     Weight Status
1      9.3.4.0/24         192.168.4.106              100        0      BE
         AS_PATH: 65001 4355 1 1221
       Last update to IP routing table: 0h12m1s, 1 path(s) installed:
         Gateway           Port
         192.168.2.1       2/1
       Route is advertised to 1 peers:
        20.20.20.2(65300)
```

These displays show the following information.

TABLE 175 BGP4 network information

This field...	Displays...
Number of BGP4 Routes matching display condition	The number of routes that matched the display parameters you entered. This is the number of routes displayed by the command.
Status codes	A list of the characters the display uses to indicate the route's status. The status code appears in the left column of the display, to the left of each route. The status codes are described in the command's output. **NOTE:** This field appears only if you *do not* enter the **route** option.
Prefix	The network address and prefix.
Next Hop	The next-hop device for reaching the network.
Metric	The value of the route's MED attribute. If the route does not have a metric, this field is blank.
LocPrf	The degree of preference for this route relative to other routes in the local AS. When the BGP4 algorithm compares routes on the basis of local preferences, the route with the higher local preference is chosen. The preference can have a value from 0 – 4294967295.
Weight	The value that this device associates with routes from a specific neighbor. For example, if the device receives routes to the same destination from two BGP4 neighbors, the device prefers the route from the neighbor with the larger weight.

TABLE 175 BGP4 network information (Continued)

This field...	Displays...
Path	The route AS path. **NOTE:** This field appears only if you *do not* enter the **route** option.
Origin code	A character that indicates the route origin. The origin code appears to the right of the AS path (Path field). The origin codes are described in the command output. **NOTE:** This field appears only if you *do not* enter the **route** option.
Status	The route status, which can be one or more of the following: • A – AGGREGATE.The route is an aggregate route for multiple networks. • B – BEST. BGP4 has determined that this is the optimal route to the destination. **NOTE:** If the "b" is lowercase, the software was not able to install the route in the IP route table. • b – NOT-INSTALLED-BEST. The routes received from the neighbor are the best BGP4 routes to their destinations, but were not installed in the IP route table because the device received better routes from other sources (such as OSPF, RIP, or static IP routes). • C – CONFED_EBGP. The route was learned from a neighbor in the same confederation and AS, but in a different sub-AS within the confederation. • D – DAMPED. This route has been dampened (by the route dampening feature), and is currently unusable. • H – HISTORY. Route dampening is configured for this route, and the route has a history of flapping and is unreachable now. • I – INTERNAL. The route was learned through BGP4. • L – LOCAL. The route originated on this device. • M – MULTIPATH. BGP4 load sharing is enabled and this route was selected as one of the best ones to the destination. The best route among the multiple paths also is marked with "B". **NOTE:** If the "m" is lowercase, the software was not able to install the route in the IP route table. • S – SUPPRESSED. This route was suppressed during aggregation and thus is not advertised to neighbors. **NOTE:** This field appears only if you enter the **route** option.

Displaying route details

This example shows the information displayed when you use the **detail** option. In this example, the information for one route is shown.

```
NetIron# show ip bgp routes detail
Total number of BGP Routes: 2
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED
1       Prefix: 10.5.0.0/24,  Status: BME,  Age: 0h28m28s
         NEXT_HOP: 201.1.1.2,  Learned from Peer: 10.1.0.2 (5)
          LOCAL_PREF: 101,  MED: 0,  ORIGIN: igp,  Weight: 10
           AS_PATH: 5
            Adj_RIB_out count: 4,  Admin distance 20
```

Syntax: show ip bgp routes detail

These displays show the following information.

TABLE 176 BGP4 route information

This field...	Displays...
Total number of BGP4 Routes	The number of BGP4 routes.
Status codes	A list of the characters that indicate route status. The status code is appears in the left column of the display, to the left of each route. The status codes are described in the command's output.
Prefix	The network prefix and mask length.
Status	The route status, which can be one or more of the following: • A – AGGREGATE.The route is an aggregate route for multiple networks. • B – BEST. BGP4 has determined that this is the optimal route to the destination. **NOTE:** If the "b" is lowercase, the software was not able to install the route in the IP route table. • b – NOT-INSTALLED-BEST. The routes received from the neighbor are the best BGP4 routes to their destinations, but were not installed in the IP route table because the device received better routes from other sources (such as OSPF, RIP, or static IP routes). • C – CONFED_EBGP. The route was learned from a neighbor in the same confederation and AS, but in a different sub-AS within the confederation. • D – DAMPED. This route has been dampened (by the route dampening feature), and is currently unusable. • H – HISTORY. Route dampening is configured for this route, and the route has a history of flapping and is unreachable now. • I – INTERNAL. The route was learned through BGP4. • L – LOCAL. The route originated on this device. • M – MULTIPATH. BGP4 load sharing is enabled and this route was selected as one of the best ones to the destination. The best route among the multiple paths also is marked with "B". **NOTE:** If the "m" is lowercase, the software was not able to install the route in the IP route table. • S – SUPPRESSED. This route was suppressed during aggregation and thus is not advertised to neighbors.
Age	The last time an update occurred.
Next_Hop	The next-hop device for reaching the network.
Learned from Peer	The IP address of the neighbor that sent this route.
Local_Pref	The degree of preference for this route relative to other routes in the local AS. When the BGP4 algorithm compares routes on the basis of local preferences, the route with the higher local preference is chosen. The preference can have a value from 0 – 4294967295.
MED	The route metric. If the route does not have a metric, this field is blank.

TABLE 176 BGP4 route information (Continued)

This field...	Displays...
Origin	The source of the route information. The origin can be one of the following: • EGP – The routes with these attributes came to BGP4 through EGP. • IGP – The routes with these attributes came to BGP4 through IGP. • INCOMPLETE – The routes came from an origin other than one of the above. For example, they may have been redistributed from OSPF or RIP. When BGP4 compares multiple routes to select the best route, IGP is preferred over EGP and both are preferred over INCOMPLETE.
Weight	The value this device associates with routes from a specific neighbor. For example, if the device receives routes to the same destination from two BGP4 neighbors, the device prefers the route from the neighbor with the larger weight.
Atomic	Whether network information in this route has been aggregated and this aggregation has resulted in information loss. **NOTE:** Information loss under these circumstances is a normal part of BGP4 and does not indicate an error.
Aggregation ID	The device that originated this aggregation.
Aggregation AS	The AS in which the network information was aggregated. This value applies only to aggregated routes and is otherwise 0.
Originator	The originator of the route in a route reflector environment.
Cluster List	The route-reflector clusters through which this route has passed.
Learned From	The IP address of the neighbor from which the device learned the route.
Admin Distance	The administrative distance of the route.
Adj_RIB_out	The number of neighbors to which the route has been or will be advertised. This is the number of times the route has been selected as the best route and placed in the Adj-RIB-Out (outbound queue) for a BGP4 neighbor.
Communities	The communities the route is in.

Displaying BGP4 route-attribute entries

The route-attribute entries table lists the sets of BGP4 attributes stored in device memory. Each set of attributes is unique and can be associated with one or more routes. In fact, the device typically has fewer route attribute entries than routes.

To display the IP route table, enter the following command.

```
NetIron# show ip bgp attribute-entries
```

Syntax: show ip bgp attribute-entries

This example shows the information displayed by this command. A zero value indicates that the attribute is not set.

```
NetIron# show ip bgp attribute-entries
        Total number of BGP Attribute Entries: 7753
1       Next Hop  :192.168.11.1       Metric   :0                Origin:IGP
        Originator:0.0.0.0            Cluster List:None
         Aggregator:AS Number :0         Router-ID:0.0.0.0          Atomic:FALSE
        Local Pref:100                Communities:Internet
        AS Path   :(65002) 65001 4355 2548 3561 5400 6669 5548
2       Next Hop  :192.168.11.1       Metric   :0                Origin:IGP
        Originator:0.0.0.0            Cluster List:None
         Aggregator:AS Number :0         Router-ID:0.0.0.0          Atomic:FALSE
        Local Pref:100                Communities:Internet
        AS Path   :(65002) 65001 4355 2548
```

This display shows the following information.

TABLE 177 BGP4 route-attribute entries information

This field...	Displays...
Total number of BGP4 Attribute Entries	The number of routes contained in this BGP4 route table.
Next Hop	The IP address of the next-hop device for routes that have this set of attributes.
Metric	The cost of the routes that have this set of attributes.
Origin	The source of the route information. The origin can be one of the following: • EGP – The routes with these attributes came to BGP4 through EGP. • IGP – The routes with these attributes came to BGP4 through IGP. • INCOMPLETE – The routes came from an origin other than one of the above. For example, they may have been redistributed from OSPF or RIP. When BGP4 compares multiple routes to a destination to select the best route, IGP is preferred over EGP and both are preferred over INCOMPLETE.
Originator	The originator of the route in a route reflector environment.
Cluster List	The route-reflector clusters through which this set of attributes has passed.
Aggregator	Aggregator information: • AS Number shows the AS in which the network information in the attribute set was aggregated. This value applies only to aggregated routes and is otherwise 0. • Router-ID shows the device that originated this aggregator.
Atomic	Whether the network information in this set of attributes has been aggregated *and* this aggregation has resulted in information loss. • TRUE – Indicates information loss has occurred • FALSE – Indicates no information loss has occurred **NOTE:** Information loss under these circumstances is a normal part of BGP4 and does not indicate an error.
Local Pref	The degree of preference for routes that use these attributes relative to other routes in the local AS.
Communities	The communities to which routes with these attributes belong.
AS Path	The ASs through which routes with these attributes have passed. The local AS is shown in parentheses.

Displaying the routes BGP4 has placed in the IP route table

The IP route table indicates the routes it has received from BGP4 by listing “BGP” as the route type.

To display the IP route table, enter the following command.

```
NetIron# show ip route
```

Syntax: show ip route [<*ip-addr*> | <*num*> | **bgp** | **ospf** | **rip** | **isis**]

This example shows the information displayed by this command. Notice that most of the routes in this example have type “B”, indicating that their source is BGP4.

```
NetIron# show ip route
Type Codes - B:BGP D:Connected I:ISIS S:Static R:RIP O:OSPF; Cost - Dist/Metric
       Destination         Gateway       Port     Cost    Type
1      130.130.130.0/24    11.11.11.1    ve 1     200/0   B
2      130.130.131.0/24    11.11.11.1     ve 1    200/0   B
```

Displaying route flap dampening statistics

To display route dampening statistics or all the dampened routes, enter the following command at any level of the CLI.

```
NetIron# show ip bgp flap-statistics
Total number of flapping routes: 414
    Status Code  >:best d:damped h:history *:valid
    Network            From            Flaps Since    Reuse    Path
h>  192.50.206.0/23    166.90.213.77   1     0 :0 :13 0 :0 :0  65001 4355 1 701
h>  203.255.192.0/20   166.90.213.77   1     0 :0 :13 0 :0 :0  65001 4355 1 7018
h>  203.252.165.0/24   166.90.213.77   1     0 :0 :13 0 :0 :0  65001 4355 1 7018
h>  192.50.208.0/23    166.90.213.77   1     0 :0 :13 0 :0 :0  65001 4355 1 701
h>  133.33.0.0/16      166.90.213.77   1     0 :0 :13 0 :0 :0  65001 4355 1 701
*>  204.17.220.0/24    166.90.213.77   1     0 :1 :4  0 :0 :0  65001 4355 701 62
```

Syntax: show ip bgp flap-statistics [**regular-expression** <*regular-expression*> | <*address*> <*mask*> [longer-prefixes] | **neighbor** <*ip-addr*> | **filter-list** <*num*>...]

The **regular-expression** <*regular-expression*> parameter is a regular expression. The regular expressions are the same ones supported for BGP4 AS-path filters. Refer to “Using regular expressions” on page 1064.

The <*address*> <*mask*> parameters specify a particular route. If you also use the optional **longer-prefixes** parameter, all statistics for routes that match the specified route or have a longer prefix than the specified route are displayed. For example, if you specify **209.157.0.0 longer**, all routes with the prefix 209.157 or that have a longer prefix (such as 209.157.22) are displayed.

The **neighbor** <*ip-addr*> parameter displays route flap dampening statistics only for routes learned from the specified neighbor. You can also display route flap statistics for routes learned from a neighbor by entering the **show ip bgp neighbor** <*ip-addr*> **flap-statistics**.command.

The **filter-list** <*num*> parameter specifies one or more filters. Only routes that have been dampened and that match the specified filters are displayed.

This display shows the following information.

TABLE 178 Route flap dampening statistics

This field...	Displays...
Total number of flapping routes	The total number of routes in the BGP4 route table that have changed state and have been marked as flapping routes.
Status code	The dampening status of the route, which can be one of the following: • > – This is the best route among those in the BGP4 route table to the route destination. • d – This route is currently dampened, and thus unusable. • h – The route has a history of flapping and is unreachable now. • * – The route has a history of flapping but is currently usable.
Network	The destination network of the route.
From	The neighbor that sent the route to this device.
Flaps	The number of flaps (state changes) the route has experienced.
Since	The amount of time since the first flap of this route.
Reuse	The amount of time remaining until this route will be un-suppressed and thus be usable again.
Path	The AS-path information for the route.

You can display all dampened routes by entering the **show ip bgp dampened-paths**.command.

Displaying the active route map configuration

You can view the active route map configuration (contained in the running configuration) without displaying the entire running configuration.by entering the following command at any level of the CLI.

```
NetIron# show route-map
route-map permitnet4 permit 10
 match ip address prefix-list plist1
route-map permitnet1 permit 1
 match ip address prefix-list plist2
route-map setcomm permit 1
 set community 1234:2345 no-export
route-map test111 permit 111
 match address-filters 11
 set community 11:12 no-export
route-map permit1122 permit 12
 match ip address 11
route-map permit1122 permit 13
 match ip address std_22
```

This example shows that the running configuration contains six route maps. Notice that the match and set statements within each route map are listed beneath the command for the route map itself. In this simplified example, each route map contains only one match or set statement.

To display the active configuration for a specific route map, enter a command such as the following, which specifies a route map name.

```
NetIron# show route-map setcomm
route-map setcomm permit 1
 set community 1234:2345 no-export
```

This example shows the active configuration for a route map named “setcomm“.

Syntax: **show route-map** [<*map-name*>]

Displaying BGP4 restart neighbor information

To display BGP4 restart information for BGP4 neighbors, enter the **show ip bgp neighbors** command.

```
NetIron# show ip bgp neighbors
    Total number of BGP Neighbors: 6
1   IP Address: 50.50.50.10, AS: 20 (EBGP), RouterID: 10.10.10.20, VRF: default
    State: ESTABLISHED, Time: 0h0m18s, KeepAliveTime: 60, HoldTime: 180
       KeepAliveTimer Expire in 34 seconds, HoldTimer Expire in 163 seconds
       Minimum Route Advertisement Interval: 0 seconds
       RefreshCapability: Received
       GracefulRestartCapability: Received
           Restart Time 120 sec, Restart bit 0
           afi/safi 1/1, Forwarding bit 0
       GracefulRestartCapability: Sent
           Restart Time 120 sec, Restart bit 0
           afi/safi 1/1, Forwarding bit 1
    Messages:    Open    Update  KeepAlive Notification Refresh-Req
```

The text in bold is the BGP4 restart information for the specified neighbor.

Displaying AS4 details

This section describes the use of the following **show** commands, which produce output that includes information about AS4s. Information that reflects AS4s appears in **bold**.

- **show ip bgp neighbor** shows whether the AS4 capability is enabled.
- **show ip bgp attribute-entries** shows AS4 path values and extended community values.
- **show ip bgp** shows the route entries with two and AS4 path information.
- **show ip extcommunity-list** shows the members of the extended community.
- **show route-map** shows the presence of any AS4 configuration data.
- **show ip as-path-access-lists** shows the presence of any AS4 configuration data.
- **show ip bgp config** shows the presence of any AS4 configuration data.

Route entries with four-byte path information

The **show ip bgp** command without of any optional parameters display AS4 path information, as indicated by the bold text in this example.

```
NetIron-mu2(config)#show ip bgp
Total number of BGP Routes: 1
Status codes: s suppressed, d damped, h history, * valid, > best, i internal, S
stale
Origin codes: i - IGP, e - EGP, ? - incomplete
    Network            Next Hop        Metric LocPrf Weight Path
*>  47.1.1.0/24        192.168.1.5     1      100    0      90000 100 200 65535
65536 65537 65538 65539 75000
```

Syntax: **show ip bgp**

Current AS numbers

To display current AS numbers, use the **show ip bgp neighbors** command at any level of the CLI.

```
NetIron-mu2#show ip bgp neighbors
  neighbors              Details on TCP and BGP neighbor connections
    Total number of BGP Neighbors: 1
1   IP Address: 192.168.1.1, AS: 7701000 (IBGP), RouterID: 192.168.1.1, VRF:

       SendQue:           0  RcvQue:            0  CngstWnd:       5840
```

Syntax: show ip bgp neighbors

The information related to AS4s is highlighted in bold text.

Attribute entries

Use the **show ip bgp attribute-entries** command to see AS4 path values and extended community values, as the following example illustrates.The extended community values in bold reflect AS4s.

```
NetIron-mu2#show ip bgp attribute-entries
        Total number of BGP Attribute Entries: 18 (0)
1       Next Hop  :192.168.1.6        Metric   :1              Origin:INCOMP
        Originator:0.0.0.0            Cluster List:None
        Aggregator:AS Number :0      Router-ID:0.0.0.0         Atomic:None
        Local Pref:100               Communities:Internet
        Extended Community: SOO 300000:3
        AS Path   :90000 80000 (length 11)
        Address: 0x10e4e0c4  Hash:489 (0x03028536), PeerIdx 0
        Links: 0x00000000, 0x00000000, nlri: 0x10f4804a
        Reference Counts: 1:0:1, Magic: 51
2       Next Hop  :192.168.1.5        Metric   :1              Origin:INCOMP
        Originator:0.0.0.0            Cluster List:None
        Aggregator:AS Number :0      Router-ID:0.0.0.0         Atomic:None
        Local Pref:100               Communities:Internet
        Extended Community: RT 200000:2
        AS Path   :90000 75000 (length 11)
        Address: 0x10e4e062  Hash:545 (0x0301e8f6), PeerIdx 0
        Links: 0x00000000, 0x00000000, nlri: 0x10f47ff0
        Reference Counts: 1:0:1, Magic: 49
```

Syntax: show ip bgp attribute-entries

Extended community

Support for AS4s is reflected in the values for extended community, as shown by the bold text in this output for the **show ip extcommunity-list** command.

```
NetIron-mu2#show ip extcommunity-list
ip extcommunity access list 1:
  permit RT 100000:123 SOO 150000:456
mu2#show route-map
route-map test permit 1
 match extcommunity 1
 set ip next-hop 192.168.1.15
route-map test permit 2
 set ip next-hop 192.168.1.101
```

Syntax: show ip extcommunity-list

AS-path prepend and extended community information

The AS-path prepend and extended community information is shown in this example of the **show route-map** command.

```
NetIron(config)# show route-map
route-map test permit 1
 match ip address  1
 set as-path prepend  75000
 set extcommunity RT 100000:123
 set extcommunity SOO 150000:456
route-map test permit 2
 match ip address  2
 set as-path prepend 80000
```

Syntax: show route-map [<*name*>]

The optional <*name*> parameter lets you name a specific route.

Running configuration

AS4s appear in the display of a running configuration, as shown.

```
NetIron(config-bgp)# show ip bgp config
Current BGP configuration:
router bgp
 local-as 7701000
 confederation identifier 120000
 confederation peers 80000
 neighbor 192.168.1.2 remote-as 80000
```

Access lists that contain AS4s

AS4s that exist in access lists are displayed by the command, as shown.

```
NetIron-mu2# show ip as-path-access-lists
ip as-path access list abc: 1 entries
     seq 10 permit _75000_
ip as-path access list def: 1 entries
     seq 5 permit _80000_
```

Formats of AS4s in show command output

To display the asdot and asdot+ notation for AS4s, enter the **as-format asdot** or **as-format asdot+** commands before you enter the **show ip bgp** command..

```
NetIron-mu2(config)# as-format asdot
NetIron-mu2(config)# show ip bgp
Total number of BGP Routes: 1
Status codes: s suppressed, d damped, h history, * valid, > best, i internal, S
stale
Origin codes: i - IGP, e - EGP,? - incomplete
    Network            Next Hop        Metric LocPrf Weight Path
*> 47.1.1.0/24        192.168.1.5     1      100    0      1.24464 100 200 655
5 1.0 1.1 1.2 1.3 1.9464 ?
```

Syntax: as-format asdot

```
NetIron-mu2(config)# as-format asdot+
NetIron-mu2(config)# show ip bgp
Total number of BGP Routes: 1
Status codes: s suppressed, d damped, h history, * valid, > best, i internal, S
stale
Origin codes: i - IGP, e - EGP, ? - incomplete
    Network            Next Hop        Metric LocPrf Weight Path
*>  47.1.1.0/24        192.168.1.5     1      100    0      1.24464 0.100 0.200
0.65535 1.0 1.1 1.2 1.3 1.9464?
```

Syntax: as-format asdot

Displaying route-map continue clauses

This section contains examples of route-map continuation clauses. Both the route map and the routes to which it applies are described.

This example is a simple illustration of route-map continue clauses. If the match clause of either route map instance 5 or 10 matches, the route map traversal continues at instance 100.

```
route-map test permit 5
 match community my_community1
 set comm-list delete my_community1
 continue 100
route-map test permit 10
 match community my_community2
 set comm-list delete my_community2
 continue 100
route-map test permit 100
 match as-path my_aspath
 set community 1234:5678 additive
```

The following example shows the route map “test.” The **show ip bgp route** output shows the consequences of the action in instance 1 (set weight = 10); instance 2 (metric becomes 20); and instance 5 (prepend as_path 300).

```
NetIron(config-routemap test)# show route-map test
route-map test permit 1
 set weight 10
 continue 2
route-map test permit 2
 set metric 20
 continue 3
route-map test permit 3
 set community 10:20
 continue 4
route-map test permit 4
 set community 30:40
 continue 5
route-map test permit 5
 set as-path prepend 300
 continue 6

NetIron(config-routemap test)# show ip bgp route
Total number of BGP Routes: 1
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH m:NOT-INSTALLED-MULTIPATH
       S:SUPPRESSED F:FILTERED s:STALE
       Prefix             Next Hop        Metric     LocPrf     Weight Status
1      8.8.8.0/24         8.8.8.3         20         100        10     BE
         AS_PATH: 300 200
```

Syntax: show route-map <*map-name*>

The <*map-name*> is the name of the route map.

Syntax: show ip bgp route

In the following example, the continue clause of instance 1 has been changed so that program flow jumps to instance 5. The resulting BGP4 route only has the weight updated and as-path prepended. These changes show route-map <*route name*>

Syntax: route-map

Syntax: [**no**] **continue** <*instance number*>

Syntax: show ip bgp route

In this example, a match clause has been added to instance 8. Because the match clause of instance 8 does not get fired, the search for the next instance continues to the end of the route-map. The set statements set the weight to 10, prepend 300, prepend 100 to the as-path, set the community to none, and set the local preference to 70. The results of this route-map traversal appear in the output of the **show ip bgp route** command.

```
NetIron(config-routemap test)# show route-map test
route-map test permit 1
 set weight 10
 continue 5
route-map test permit 2
 set metric 20
 continue 3
route-map test permit 3
 set community 10:20
 continue 4
route-map test permit 4
 set community 30:40
 continue 5
route-map test permit 5
 set as-path prepend 300
 continue 6
route-map test permit 6
 set as-path prepend 100
 continue 7

NetIron(config-routemap test)#show ip bgp route
```

BGP Routing Table is empty

Syntax: show route-map <*map-name*>

Configuring IP Multicast Protocols 27

Overview

The following displays the IP Multicast features supported by PowerConnect B-MLXe.

- IGMP (V1 and V2)
- IGMP (V1 and V2) Snooping
- IGMP v2 Fast-Leave
- IGMP v3
- IGMP v3 Snooping
- Multicast Routing PIM
- DVMRP
- PMRI
- PIM-SSM
- Multicast over Multi-VRF
- IP Multicast Boundaries
- PIM Dense
- PIM Sparse
- Modifying the TTL threshold
- Multicast Source Discovery Protocol (MSDP)
- MSDP Mesh Groups
- MSDP Anycast RP
- PIM Anycast RP
- Static Multicast Routes
- Optimization of Multicast Replication and Platform Independence
- Concurrent Support for Multicast Routing and Snooping
- Modifying the Prune Wait Timer
- Configuring PIM-SM (*,g) Forwarding
- IPv6 Support

This chapter describes how to configure devices for the following IP multicast protocol and versions:

- Internet Group Management Protocol (IGMP) V1 and V2
- Protocol Independent Multicast Dense mode (PIM DM) V1 (draft-ietf-pim-dm-05) and V2 (draft-ietf-pim-v2-dm-03)
- PIM Sparse mode (PIM SM) V2 (RFC 2362)
- Distance Vector Multicast Routing Protocol (DVMRP) V2 (RFC 1075)

NOTE
Each multicast protocol uses IGMP. IGMP is automatically enabled on an interface when you configure PIM or DVMRP, and is disabled on the interface if you disable PIM or DVMRP.

Overview of IP multicasting

Multicast protocols allow a group or channel to be accessed over different networks by multiple stations (clients) for the receipt and transmission of multicast data.

Distribution of stock quotes, video transmissions such as news services and remote classrooms, and video conferencing are all examples of applications that use multicast routing.

Dell devices support two multicast routing protocols—Distance Vector Multicast Routing Protocol (DVMRP) and Protocol-Independent Multicast (PIM) protocol, along with the Internet Group Membership Protocol (IGMP).

PIM and DVMRP are broadcast and pruning multicast protocols that deliver IP multicast datagrams. These protocols employ reverse path lookup check and pruning to allow source-specific multicast delivery trees to reach all group members. DVMRP and PIM build a different multicast tree for each source and destination host group.

Both DVMRP and PIM can concurrently operate on different ports of a device. The CAM can hold up to 1535 IPv4 multicast entries.

Multicast terms

The following terms are commonly used in discussing multicast-capable devices. These terms are used throughout this chapter:

Node: Refers to a device.

Root Node: The node that initiates the tree building process. It is also the device that sends the multicast packets down the multicast delivery tree.

Upstream: Represents the direction from which a device receives multicast data packets. An upstream device is a node that sends multicast packets.

Downstream: Represents the direction to which a device forwards multicast data packets. A **downstream** device is a node that receives multicast packets from upstream transmissions.

Group Presence: Means that a multicast group has been learned from one of the directly connected interfaces. Members of the multicast group are present on the device.

Intermediate nodes: Devices that are in the path between source devices and leaf devices.

Leaf nodes: Devices that do not have any downstream devices.

Multicast Tree: A unique tree is built for each source group (S,G) pair. A multicast tree is comprised of a root node and one or more nodes that are leaf or intermediate nodes.

Changing global IP multicast parameters

The following sections apply to PIM-DM, PIM-SM, IGMP, and DVMRP.

Concurrent support for multicast routing and snooping

Multicast routing and multicast snooping instances work concurrently on the same device. For example, you can configure PIM routing on certain VEs interfaces and snooping on other VEs or VLANs. The limitation is that either multicast snooping or routing can be enabled on a VE interface or VLAN, but not on both. This is because all of the multicast data and control packets (IGMP, PIM) received on the snooping VLAN are handled by multicast snooping and do not reach the multicast routing component. Similarly, any multicast data or control packets received on a VE interface enabled with PIM or DVMRP routing are handled by the PIM or DVMRP routing component and are not seen by the IGMP or PIM snooping component.

The following considerations apply when configuring concurrent operation of Multicast Routing and Snooping.

1. Either multicast snooping or routing can be enabled on a VE or VLAN but not both.
2. Snooping can be enabled globally (**ip multicast** <*active* | *passive*>) as can multicast routing (**ip multicast-routing**).
3. The global snooping configuration is inherited by all current VLANs that are not enabled for multicast routing.
4. The global snooping configuration is also inherited by all new VLANs. Enabling multicast routing on a newly created VLAN or VE automatically disables snooping on the VLAN or VE.
5. When a VLAN-level snooping is configured, it is displayed.

Defining the maximum number of DVMRP cache entries

You can use the following run-time command to define the maximum number of repeated DVMRP traffic being sent from the same source address and being received by the same destination address. The maximum number of multicast cache entries for DVMRP can be defined for the default VRF using the following command.

```
NetIron(config)# router dvmrp
NetIron(config-dvmrp-router)# max-mcache 500
```

Syntax: [no] max-mcache <*num*>

The <*num*> variable specifies the maximum number of multicast cache entries for DVMRP. If not defined by this command, the maximum value is determined by available system resources.

The maximum number of multicast cache entries for DVMRP for a specified Virtual Routing Instance (VRF) can be defined using the following command.

```
NetIron(config)# router dvmrp vrf vpn1
NetIron(config-dvmrp-router-vrf-vpn1)# max-mcache 500
```

Syntax: [no] router dvmrp [vrf <*vrf-name*>]

Syntax: [no] max-mcache <*num*>

The **vrf** parameter specified with the **router dvmrp** command allows you to configure the **max-mcache** command for a virtual routing instance (VRF) specified by the variable <*vrf-name*>.

The <*num*> variable specifies the maximum number of multicast cache entries for DVMRP in the specified VRF. If not defined by this command, the maximum value is determined by available system resources

Defining the maximum number of DVMRP routes

You can use the following run-time command to set the maximum number of DVMRP routes. The maximum number of DVMRP routes can be defined for the default VRF using the following command.

```
NetIron(config)# router dvmrp
NetIron(config-dvmrp-router)# max-route 500
```

The maximum number of DVMRP routes can be defined for a specified VRF using the following command.

```
NetIron(config)# router dvmrp vrf vpn1
NetIron(config-dvmrp-router-vrf-vpn1)# max-route 500
```

Syntax: [no] router dvmrp [vrf <*vrf-name*>]

Syntax: [no] max-route <*num*>

The **vrf** parameter specified with the **router dvmrp** command allows you to configure the **max-route** command for a virtual routing instance (VRF) specified by the variable <*vrf-name*>.

The <*num*> parameter specifies the maximum number of DVMRP routes. If not defined by this command, the maximum value is determined by available system resources.

Defining the maximum number of PIM cache entries

You can use the following run-time command to define the maximum number of repeated PIM traffic being sent from the same source address and being received by the same destination address. To define this maximum for the default VRF, enter the following commands.

```
NetIron(config)# router pim
NetIron(config-pim-router)# max-mcache 999
```

Syntax: [no] max-mcache <*num*>

The <*num*> variable specifies the maximum number of multicast cache entries for PIM in the default VRF. If not defined by this command, the maximum value is determined by available system resources.

To define the maximum number of PIM Cache entries for a specified VRF, use the following command.

```
NetIron(config)# router pim vrf vpn1
NetIron(config-pim-router-vrf-vpn1)# max-mcache 999
```

Syntax: [no] router pim [vrf <*vrf-name*>]

Syntax: [no] max-mcache <*num*>

The **vrf** parameter specified with the **router pim** command allows you to configure the **max-mcache** command for a virtual routing instance (VRF) specified by the variable <*vrf-name*>.

The <*num*> variable specifies the maximum number of multicast cache entries for PIM in the specified VRF. If not defined by this command, the maximum value is determined by available system resources.

Defining the maximum number of multicast VRF CAM entries

To use a run time command to set the maximum values for multicast VRF CAM entries for all VRFs or for a specified VRF.

Defining the maximum number of multicast VRF CAM entries for all VRFs

You can use the following run-time command to define the maximum number of multicast VRF CAM entries by entering a command such as the following.

```
NetIron(config)# ip multicast-max-all-vrf-cam 3072
```

Syntax: [no] ip multicast-max-all-vrf-cam <*num*>

The <*num*> variable specifies the maximum number of multicast VRF CAM entries for all VRFs. This setting does not effect the default VRF. The maximum possible value is 8000 and the default value is 2048.

Defining the maximum number of multicast VRF CAM entries for a specified VRF

You can use the following run-time command to define the maximum number of multicast VRF CAM entries for a specified VRF by entering commands such as the following.

```
NetIron(config)# ip vrf vpn1
NetIron(config-vrf-vpn1)# ip multicast-max-cam 3072
```

Syntax: [no] ip vrf <*vrf-name*>

Syntax: [no] ip multicast-max-cam <*num*>

The **ip vrf** parameter specifies the virtual routing instance (VRF) specified by the variable <*vrf-name*>.

The <*num*> variable specifies the maximum number of multicast VRF CAM entries for the specified VRF. This setting can be any number up to the limit set using the **ip multicast-max-all-vrf-cam** command .

Defining the maximum number of IGMP group addresses

You can use the following run-time command to set the maximum number of IGMP addresses for the default VRF or for a specified VRF. To define this maximum for the default VRF, enter the following command.

```
NetIron(config)# ip igmp max-group-address 1000
```

Syntax: [no] ip igmp max-group-address <*num*>

The <*num*> variable specifies the maximum number of IGMP group addresses you want to make available for the default VRF. If not defined by this command, the maximum value is determined by available system resources.

To define this maximum for a specified VRF, enter the following commands.

```
NetIron(config)# ip vrf vpn1
NetIron(config-vrf-vpn1)# ip igmp max-group-address 1000
```

Syntax: [no] ip vrf <*vrf-name*>

Syntax: [no] ip igmp max-group-address <*num*>

The **ip vrf** parameter specifies the virtual routing instance (VRF) specified by the variable <*vrf-name*>.

The <*num*> parameter specifies the number of IGMP group addresses that you want to make available for the specified VRF. If not defined by this command, the maximum value is determined by available system resources.

Changing IGMP V1 and V2 parameters

IGMP allows Dell devices to limit the multicast of IGMP packets to only those ports on the device that are identified as IP Multicast members.

The device actively sends out host queries to identify IP Multicast groups on the network, inserts the group information in an IGMP packet, and forwards the packet to IP Multicast neighbors.

The following IGMP V1 and V2 parameters apply to PIM and DVMRP:

- **IGMP query interval** – Specifies how often the PowerConnect queries an interface for group membership. Possible values are 2 – 3600. The default is 125.
- **IGMP group membership time** – Specifies how many seconds an IP Multicast group can remain on a PowerConnect interface in the absence of a group report. Possible values are 5 – 26000. The default is 260.
- **IGMP maximum response time** – Specifies how many seconds the device will wait for an IGMP response from an interface before concluding that the group member on that interface is down and removing the interface from the group. Possible values are 1 – 25. The default is 10.

To change these parameters, you must first enable IP multicast routing by entering the following CLI command at the global CLI level.

```
NetIron(config)# ip multicast-routing
```

Syntax: [no] ip multicast-routing

NOTE
You must enter the **ip multicast-routing** command before changing the global IP Multicast parameters. Otherwise, the changes do not take effect and the software uses the default values. Also, entering **no ip multicast-routing** will reset all parameters to their default values.

Modifying IGMP (V1 and V2) query interval period

The IGMP query interval period defines how often a device will query an interface for group membership. Possible values are 2 – 3600 seconds and the default value is 125 seconds.

To modify the default value for the IGMP (V1 and V2) query interval, enter the following.

```
NetIron(config)# ip igmp query-interval 120
```

Syntax: [no] ip igmp query-interval <*num*>

The <*num*> variable specifies the number of seconds and can be a value from 2 - 3600.

The default value is 125.

Modifying IGMP (V1 and V2) membership time

Group membership time defines how long a group will remain active on an interface in the absence of a group report. Possible values are from 5 – 26000 seconds and the default value is 260 seconds.

To define an IGMP (V1 and V2) membership time of 240 seconds, enter the following.

```
NetIron(config)# ip igmp group-membership-time 240
```

Syntax: [no] ip igmp group-membership-time <*num*>

The <*num*> variable specifies the number of seconds and can be a value from 5 - 26000.

The default value is 260.

Modifying IGMP (V1 and V2) maximum response time

Maximum response time defines how long the PowerConnect will wait for an IGMP (V1 and V2) response from an interface before concluding that the group member on that interface is down and removing the interface from the group. Possible values are 1 – 25. The default is 10.

To change the IGMP (V1 and V2) maximum response time, enter a command such as the following at the global CONFIG level of the CLI.

```
NetIron(config)# ip igmp max-response-time 8
```

Syntax: [no] ip igmp max-response-time <*num*>

The <*num*> variable specifies the number of seconds and can be a value from 1 – 25. The default is 10.

Security Enhancement for IGMP

A security enhancement has been made to IGMPv2 to adhere to the following recommendation of RFC 2236: “Ignore the Report if you cannot identify the source address of the packet as belonging to a subnet assigned to the interface on which the packet was received.”

NOTE
When used in applications such as IP-TV (or any multicast application in general), the administrator should ensure that the set-top box (or multicast client) is configured on the same subnet as the v.e. configured on the device. This is typically the case but is emphasized here to ensure correct operation. Without this configuration, IGMP messages received by the device are ignored which causes an interruption in any multicast traffic directed towards the set-top box (multicast client).

Support for Multicast Multi-VRF

Multicast Multi-VRF support for the PowerConnect includes the following:

- **Static Mroute** – As described in "Configuring a static multicast route within a VRF" on page 1220 you can configure static multicast route from within a specified VRF.
- **PIM (PIM-SM and PIM-DM)** – The procedure for configuring PIM within a VRF instance is described in "Enabling PIM for a specified VRF" on page 1157 and "Enabling PIM Sparse for a specified VRF" on page 1166.
- **DVMRP** – The procedure for configuring DVMRP within a VRF instance is described in "Enabling DVMRP for a specified VRF" on page 1208.

System max parameter changes

Several changes to the system max commands have been made in support of Multicast Multi-VRF. That includes retiring the following system max commands:

system-max multicast-route

system-max dvmrp-mcache

system-max dvmrp-route

system-max pim-mcache

system-max igmp-max-group-address

These commands which require a system reload to take effect have been replaced by the following runtime commands:

ip max-mroute – This command replaces the **system-max multicast-route** command.

max-mcache – This command described in "Defining the maximum number of DVMRP cache entries" on page 1141 replaces the **system-max dvmrp-mcache** command.

max-mroute – This command described in "Defining the maximum number of DVMRP routes" on page 1142 replaces the **system-max dvmrp-route** command.

max-mcache – This command described in "Defining the maximum number of PIM cache entries" on page 1142 replaces the **system-max pim-mcache** command.

ip igmp max-group-address – This command described in "Defining the maximum number of IGMP group addresses" on page 1143 replaces the **system-max igmp-max-group-address** command.

NOTE
If the retired system-max commands are used, the new runtime commands will be substituted in the running config.

Additionally, you can set a maximum value for multicast VRF CAM entries as described in "Defining the maximum number of multicast VRF CAM entries" on page 1143.

show and clear command support

The following show and clear commands have been introduced or enhanced to support Multicast Multi-VRF:

- "clear ip dvmrp [vrf <vrf-name>] cache"
- "show ip dvmrp [vrf <vrf-name>] interface"
- "show ip dvmrp [vrf <vrf-name>] mcache"
- "clear ip igmp [vrf <vrf-name>] cache"
- "clear ip igmp [vrf <vrf-name>] traffic"
- "show ip igmp [vrf <vrf-name>] group [<group-address> [detail] [tracking]]"
- "show ip igmp [vrf <vrf-name>] interface [ve <number> | ethernet <slot/port> | pos <slot/port> | tunnel <num>]"
- "show ip igmp [vrf <vrf-name>] settings"
- "show ip igmp [vrf <vrf-name>] traffic"

Adding an interface to a multicast group

You can manually add an interface to a multicast group. This is useful in the following cases:

- Hosts attached to the interface are unable to add themselves as members of the group using IGMP.
- There are no members for the group attached to the interface.

When you manually add an interface to a multicast group, the device forwards multicast packets for the group but does not itself accept packets for the group.

You can manually add a multicast group to individual ports only. If the port is a member of a virtual routing interface, you must add the ports to the group individually.

To manually add a port to a multicast group, enter a command such as the following at the configuration level for the port.

```
NetIron(config-if-e10000-1/1)# ip igmp static-group 224.2.2.2
```

This command adds port 1/1 to multicast group 224.2.2.2.

To add a port that is a member of a virtual routing interface to a multicast group, enter a command such as the following at the configuration level for the virtual routing interface.

```
NetIron(config-vif-1)# ip igmp static-group 224.2.2.2 ethernet 5/2
```

This command adds port 5/2 in virtual routing interface 1 to multicast group 224.2.2.2.

Syntax: [no] ip igmp static-group <*ip-addr*> [ethernet <*slot*>/<*portnum*>]

The <*ip-addr*> parameter specifies the group number.

The **ethernet** <*slot*>/<*portnum*> parameter specifies the port number. Use this parameter if the port is a member of a virtual routing interface, and you are entering this command at the configuration level for the virtual routing interface.

Manually added groups are included in the group information displayed by the following commands:

- show ip igmp group
- show ip pim group

Multicast non-stop routing

Multicast non-stop routing (NSR) provides hitless upgrade and switchover support for all IPv4 multicast, including default and non-default VRFs for IPv4 PIM-DM, PIM-SM, and PIM-SSM. Multicast NSR is not supported for IPv6 multicast and DVMRP. The software multicast state is kept in sync between the active and standby MPs. As the PowerConnect system enters a hitless upgrade or switchover state, the standby MP will take over as the new active MP. The new active MP will carry a pre-installed multicast state that was originally supported by the previous MP. The new active MP will revalidate the pre-installed multicast state, and pick up any new changes as needed before marking the multicast state as operational. When the LP is ready to complete the hitless upgrade or switchover process, the operational multicast state will be downloaded to the LP CPU. When the LP resets, and the outage of the LP CPU occurs, pre-existing hardware forwarding multicast traffic will continue to flow without disruption, and the hardware multicast forwarding state is retained in the LP hardware.

Multicast NSR is globally enabled across all VRFs by configuring the **ip multicast-nonstop-routing** command. For more information on configuring the **ip multicast-nonstop-routing** command, refer to "Configuring multicast non-stop routing" on page 1148.

NOTE
During hitless reload, if any changes occur to the existing multicast forwarding records, then multicast receivers of the same forwarding records may see traffic loss.

Configuration considerations

- Multicast NSR is not supported for IPv6 multicast, DVMRP, and layer 2 multicast.
- When multicast NSR is turned on, unicast routing must be protected by NSR or graceful restart on all multicast VRFs.
- Any multicast flow that does not have a hardware CAM entry programmed prior to hitless upgrade or switchover will not be protected under multicast NSR. The multicast entry for such a flow shall be recreated upon the completion of the NSR process.

Configuring multicast non-stop routing

To globally enable multicast non-stop routing for all VRFs, enter the **ip multicast-nonstop-routing** command on the CLI as shown in the example below.

```
NetIron(config)#ip multicast-nonstop-routing
```

Syntax: ip multicast-nonstop-routing

During a hitless upgrade and switchover on the MP, the following syslog message is generated on the CLI.

```
Feb  3 14:09:58 Mcastv4 detected MP switchover, set switchover in progress to TRUE
Feb  3 14:10:07 Mcastv4 confirms unicast RTM is ready
Feb  3 14:10:07 Mcastv4 switchover done, set switchover in progress mode to FALSE
```

The syslog message displayed above shows the state transition of multicast NSR as the standby MP takes over as the active MP. The multicast data traffic will continue to flow during state transition.

Displaying the multicast NSR status

To display the multicast NSR status, enter the following command.

```
NetIron#show ip pim nsr
Global Mcast NSR Status
  NSR: ON
  Switchover In Progress Mode: FALSE
  Dy-Sync Postpone Flag: FALSE
```

The following table displays the output from the **show ip pim nsr** command.

TABLE 179 Output from the show ip pim nsr

This field...	Displays...
NSR	The NSR field indicates if the **ip multicast-nonstop-routing** command is enabled (ON) or disabled (OFF).
Switchover in Progress Mode	The Switchover in Progress Mode field indicates if the multicast traffic is in the middle of a switchover (displaying a TRUE status), or not (displaying a FALSE status).
Dy-Sync Postpone Flag	After the current switchover or hitless upgrade is complete, an update to the batched dy-sync may or may not need posting.

Displaying counter and statistic information for multicast NSR

To display multicast NSR counter and statistic information from the MP, enter the following command.

```
NetIron#show ip pim counter nsr
Mcache sync (entity id: 203)
  pack: 0
  unpack: 0
  ack: 0
RPset sync (entity id: 201)
  pack: 0
  unpack: 0
  ack: 0
BSR status (entity id: 202)
  pack: 1
  unpack: 0
  ack: 1
```

Syntax: show ip pim [vrf<*vrf_name*>] counter nsr

The **vrf** parameter allows you to display IP PIM counters for the VRF instance specified by the <*vrf-name*> variable.

The following table displays the output from the **show ip pim counter nsr** command.

TABLE 180 Output from the **show ip pim counter nsr** command

This field...	Displays...
Mcache sync	The mcache NSR sync queue that carries the NSR sync message for mcache updates.
pack	The number of NSR sync messages that are packed from current MP to the other MP.
unpack	The number of NSR sync messages that are received and unpacked by the current MP.
ack	The number of NSR sync acknowledgement the current MP received.
RPset sync	The RPset sync queue that carries the NSR sync message for RPset update.
BSR status	The BSR status sync queue that carries the NSR sync message for BSR information update.

Passive Multicast Route Insertion (PMRI)

To prevent unwanted multicast traffic from being sent to the CPU, PIM Routing and Passive Multicast Route Insertion (PMRI) can be used together to ensure that multicast streams are only forwarded out ports with interested receivers and unwanted traffic is dropped in hardware on Layer 3 Switches. This feature does not apply to DVMRP traffic.

PMRI enables a Layer 3 switch running PIM Sparse to create an entry for a multicast route (e.g., (S,G)), with no directly attached clients or when connected to another PIM device (transit network).

When a multicast stream has no output interfaces, the Layer 3 Switch can drop packets in hardware if the multicast traffic meets either of the following conditions:

In PIM-SM:

- The route has no OIF *and*
- If directly connected source passed source RPF check *and* completed data registration with RP *or*
- If non directly connected source passed source RPF check.

In PIM-DM:

- The route has no OIF *and*
- passed source RPF check *and*
- Device has no downstream PIM neighbor.

If the OIF is inserted after the hardware-drop entries are installed, the hardware entries will be updated to include the OIFs.

NOTE
Disabling hardware-drop does not immediately take away existing hardware-drop entries, they will go through the normal route aging processing when the traffic stops.

Configuring PMRI

PMRI is enabled by default. To disable PMRI, enter commands such as the following.

```
NetIron(config)# router pim
NetIron(config-pim-router)# hardware-drop-disable
```

Syntax: [no] hardware-drop-disable

Displaying hardware-drop

Use the **show ip pim sparse** command to display if the hardware-drop feature has been enabled or disabled.

```
NetIron(config)#show ip pim sparse
Global PIM Sparse Mode Settings
  Hello interval        : 30          Neighbor timeout                    : 105
  Bootstrap Msg interval: 60          Candidate-RP Advertisement interval: 60
  Join/Prune interval   : 60          SPT Threshold                       : 1
  Inactivity interval   : 180         SSM Enabled                         : No
  Hardware Drop Enabled : Yes
  show ip pim sparse
```

IP multicast boundaries

The Multicast Boundary feature is designed to selectively allow or disallow multicast flows to configured interfaces.

The **ip multicast-boundary** command allows you to configure a boundary on PIM enabled interface by defining which multicast groups may not forward packets over a specified interface. This includes incoming and outgoing packets. By default, all interfaces that are enabled for multicast are eligible to participate in a multicast flow provided they meet the multicast routing protocol's criteria for participating in a flow.

Configuration considerations

The configuration considerations are as follows:

- Only one ACL can be bound to any interface.
- Normal ACL restrictions apply as to how many software ACLs can be created, but there is no hardware restrictions on ACLs with this feature.
- Creation of a static IGMP client is allowed for a group on a port that may be prevented from participation in the group on account of an ACL bound to the port's interface. In such a situation, the ACL would prevail and the port will not be added to the relevant entries.
- Either standard or extended ACLs can be used with the multicast boundary feature. When a standard ACL is used, the address specified is treated as a group address and NOT a source address.
- When a boundary is applied to an ingress interface, all packets destined to a multicast group that is filtered out will be dropped by software. Currently, there is no support to drop such packets in hardware.

- The **ip multicast-boundary** command may not stop clients from receiving multicast traffic if the filter is applied on the egress interface up-stream from RP.

Configuring multicast boundaries

Multicast boundaries can be configured for IPv4 or IPv6.

To define boundaries for PIM enabled interfaces, enter a commands such as the following.

```
NetIron(config)# interface ve 40
NetIron(config-vif-40)#ip multicast-boundary DellAccessList
```

Multicast boundaries can be configured for IPv6 as shown in the following.

```
NetIron(config)# interface ethernet 1/2
NetIron(config-if-e1000-1/2)#ipv6 multicast-boundary DellAccessList
```

Syntax: [no] ip multicast-boundary <*acl-spec*>

Syntax: [no] ipv6 multicast-boundary <*acl-spec*>

Use the **acl-spec** parameter to define the number or name identifying an access list that controls the range of group addresses affected by the boundary.

Use the **no ip multicast boundary** command to remove the boundary on a PIM enabled interface.

The ACL, DellAccessList can be configured using standard ACL syntax. ACLs are described in Chapter 20, “Layer 2 Access Control Lists,” however, some examples of how ACLs can be used to filter multicast traffic are provided below:

Standard ACL to permit multicast traffic

To permit multicast traffic for group 225.1.0.2 and deny all other traffic, enter the following command.

```
NetIron(config)# access-list 10 permit host 225.1.0.2
NetIron(config)# access-list 10 deny any
```

Extended ACL to deny multicast traffic

To deny multicast data traffic from group 225.1.0.1 and permit all other traffic,

```
NetIron(config)# access-list 101 deny ip any host 225.1.0.1
NetIron(config)# access-list 101 permit ip any any
```

Extended ACL to permit multicast traffic

To permit multicast data traffic from source 97.1.1.50 for group 225.1.0.1 and deny all other traffic,

```
NetIron(config)# access-list 102 permit ip host 97.1.1.50 host 225.1.0.1
NetIron(config)# access-list 102 deny ip any any
```

Displaying multicast boundaries

To display multicast boundary information, use the **show ip pim interface** command.

```
NetIron# show ip pim interface
---------+------------+----+---+-----------------+---+---------+-------+-------
Interface|Local       |Mode|Ver|Designated Router |TTL|Multicast| VRF   | DR
         |Address     |    |   |Address       Port|Thr|Boundary |       | Prio
---------+------------+----+---+-----------------+---+---------+-------+-------
     v10   10.1.2.1       SM  V2  Itself             1  None     default  30
     v30  123.1.1.2       SM  V2  Itself             1  None
     v40  124.1.1.2       SM  V2  Itself             1  101
```

Syntax: show ip pim [vrf <*vrf-name*>] interface [ethernet <*slot*>/<*portnum*> | ve <*num*> | tunnel <*num*>]

The **vrf** option allows you to display multicast boundary information for the VRF instance identified by the <*vrf-name*> variable.

The **ethernet** <*port-number*> parameter specifies the physical port.

The **ve** <*num*> parameter specifies a virtual interface.

The **tunnel** <*num*> parameter specifies a GRE tunnel interface that is being configured. The GRE tunnel interface is enabled under the device PIM configuration.

PIM Dense

NOTE
This section describes the "dense" mode of PIM, described in RFC 3973. Refer to "PIM Sparse" on page 1163 for information about PIM Sparse.

PIM was introduced to simplify some of the complexity of the routing protocol at the cost of additional overhead tied with a greater replication of forwarded multicast packets. PIM is similar to DVMRP in that PIM builds source-routed multicast delivery trees and employs reverse path check when forwarding multicast packets.

There are two modes in which PIM operates: Dense and Sparse. The Dense Mode is suitable for densely populated multicast groups, primarily in the LAN environment. The Sparse Mode is suitable for sparsely populated multicast groups with the focus on WAN.

PIM primarily differs from DVMRP by using the IP routing table instead of maintaining its own, thereby being routing protocol independent.

Initiating PIM multicasts on a network

Once PIM is enabled on each device, a network user can begin a video conference multicast from the server on R1 as shown in Figure 154. When a multicast packet is received on a PIM-capable device interface, the interface checks its IP routing table to determine whether the interface that received the message provides the shortest path back to the source. If the interface does provide the shortest path back to the source, the multicast packet is then forwarded to all neighboring PIM devices. Otherwise, the multicast packet is discarded and a prune message is sent back upstream.

In Figure 154, the root node (R1) is forwarding multicast packets for group 229.225.0.1, which it receives from the server, to its downstream nodes, R2, R3, and R4. Device R4 is an intermediate device with R5 and R6 as its downstream devices. Because R5 and R6 have no downstream interfaces, they are leaf nodes. The receivers in this example are those workstations that are resident on devices R2, R3, and R6.

Pruning a multicast tree

As multicast packets reach these leaf devices, the devices check their IGMP databases for the group. If the group is not in the IGMP database of the device, the device discards the packet and sends a prune message to the upstream device. The device that discarded the packet also maintains the prune state for the source, group (S,G) pair. The branch is then pruned (removed) from the multicast tree. No further multicast packets for that specific (S,G) pair will be received from that upstream device until the prune state expires. You can configure the PIM Prune Timer (the length of time that a prune state is considered valid).

For example, in Figure 154 the sender with address 207.95.5.1 is sending multicast packets to the group 229.225.0.1. If a PIM device receives any groups other than that group, the device discards the group and sends a prune message to the upstream PIM device.

In Figure 155, device R5 is a leaf node with no group members in its IGMP database. Therefore, the device must be pruned from the multicast tree. R5 sends a prune message upstream to its neighbor device R4 to remove itself from the multicast delivery tree and install a prune state, as seen in Figure 155. Device 5 will not receive any further multicast traffic until the prune age interval expires.

When a node on the multicast delivery tree has all of its downstream branches (downstream interfaces) in the prune state, a prune message is sent upstream. In the case of R4, if both R5 and R6 are in a prune state at the same time, R4 becomes a leaf node with no downstream interfaces and sends a prune message to R1. With R4 in a prune state, the resulting multicast delivery tree would consist only of leaf nodes R2 and R3.

FIGURE 154 Transmission of multicast packets from the source to host group members

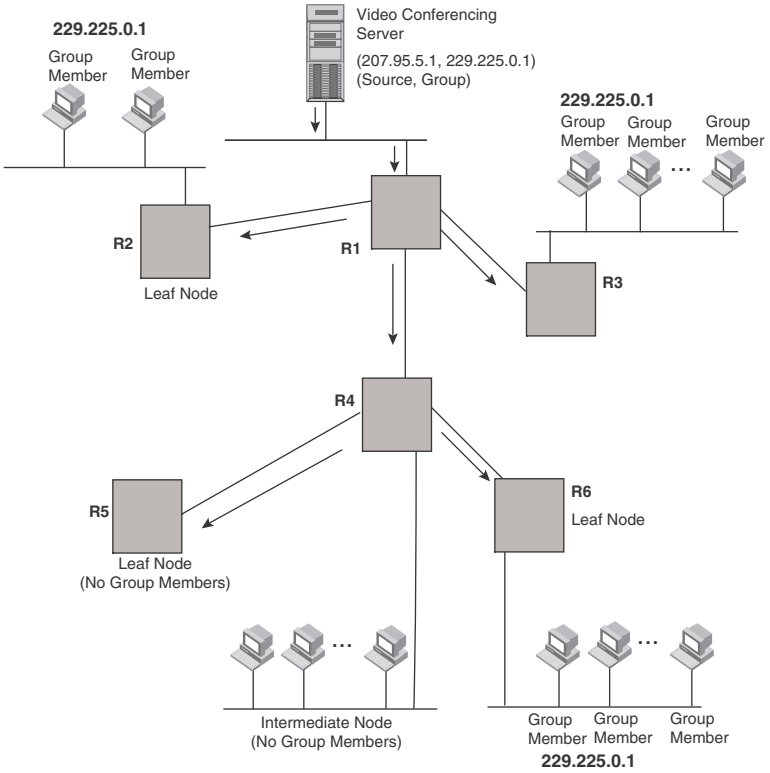

FIGURE 155 Pruning leaf nodes from a multicast tree

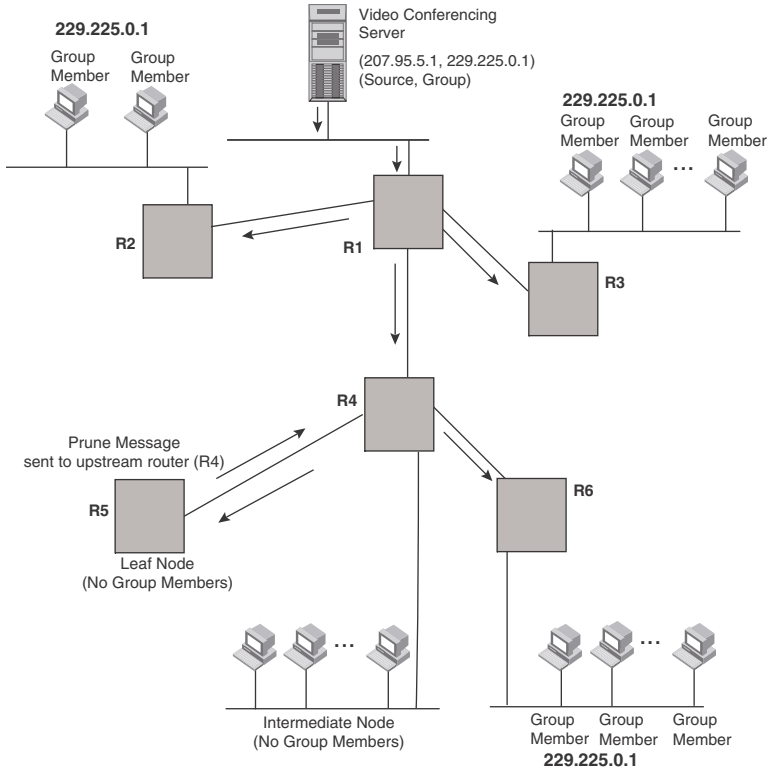


Grafts to a multicast tree

A PIM device restores pruned branches to a multicast tree by sending graft messages towards the upstream device. Graft messages start at the leaf node and travel up the tree, first sending the message to its neighbor upstream device.

In the example above, if a new 229.255.0.1 group member joins on device R6, which was previously pruned, a graft is sent upstream to R4. Since the forwarding state for this entry is in a prune state, R4 sends a graft to R1. Once R4 has joined the tree, R4 along with R6 once again receive multicast packets.

Prune and graft messages are continuously used to maintain the multicast delivery tree. No configuration is required on your part.

PIM DM versions

The device supports PIM DM V1 and V2. The default is V2. You can specify the version on an individual interface basis.

The primary difference between PIM DM V1 and V2 is the methods the protocols use for messaging:

- PIM DM V1 – uses the IGMP to send messages.
- PIM DM V2 – sends messages to the multicast address 224.0.0.13 (ALL-PIM-ROUTERS) with protocol number 103.

The CLI commands for configuring and managing PIM DM are the same for V1 and V2. The only difference is the command you use to enable the protocol on an interface.

NOTE
If you want to continue to use PIM DM V1 on an interface, you must change the version, then save the configuration.

NOTE
The note above does not mean you can run different PIM versions on devices that are connected to each other. The devices must run the same version of PIM. If you want to connect a device running PIM to a device that is running PIM V1, you must change the PIM version on the device to V1 (or change the version on the device to V2, if supported).

Configuring PIM DM

NOTE
This section describes how to configure the “dense” mode of PIM, described in RFC 1075. Refer to “Configuring PIM Sparse” on page 1165 for information about configuring PIM Sparse.

Enabling PIM on the device and an interface

By default, PIM is disabled. To enable PIM:

- Enable the feature globally.
- Configure the IP interfaces that will use PIM.

- Enable PIM locally on the ports that have the IP interfaces you configured for PIM.

Suppose you want to initiate the use of desktop video for fellow users on a sprawling campus network. All destination workstations have the appropriate hardware and software but the devices that connect the various buildings need to be configured to support PIM multicasts from the designated video conference server as shown in Figure 154 on page 1155.

PIM is enabled on each of the devices shown in Figure 154, on which multicasts are expected. You can enable PIM on each device independently or remotely from one of the devices with a Telnet connection. Follow the same steps for each device. All changes are dynamic.

Globally enabling and disabling PIM

To globally enable PIM, enter the following command.

```
NetIron(config)# device pim
```

Syntax: [**no**] **router pim**

NOTE
When PIM routing is enabled, the line rate for receive traffic is reduced by about 5%. The reduction occurs due to overhead from the VLAN multicasting feature, which PIM routing uses. This behavior is normal and does not indicate a problem with the device.

The [**no**] **router pim** command behaves in the following manner:

- Entering **router pim** command to enable PIM does not require a software reload.
- Entering a **no router pim** command removes all configuration for PIM multicast on a device (**router pim** level) only.

Enabling PIM for a specified VRF

To enable PIM for the VRF named “blue”, use the following commands.

```
NetIron(config)# router pim vrf blue
```

Syntax: [**no**] **router pim** [**vrf** <*vrf-name*>]

The **vrf** parameter allows you to configure PIM (PIM-DM and PIM-SM) on the virtual routing instance (VRF) specified by the <*vrf-name*> variable. All PIM parameters available for the default device instance are configurable for a VRF-based PIM instance.

The [**no**] **router pim vrf** command behaves in the following manner:

- Entering the **router pim vrf** command to enable PIM does not require a software reload.
- Entering a **no router pim vrf** command removes all configuration for PIM multicast on the specified VRF.

Enabling a PIM version

To enable PIM on an interface, globally enable PIM, then enable PIM on interface 3, enter the following commands.

```
NetIron(config)# router pim
NetIron(config)# int e 1/3
NetIron(config-if-e10000-1/3)# ip address 207.95.5.1/24
NetIron(config-if-e10000-1/3)# ip pim
NetIron(config-if-e10000-1/3)# write memory
NetIron(config-if-e10000-1/3)# end
```

Syntax: [**no**] **ip pim** [**version 1** | **2**]

The **version 1 | 2** parameter specifies the PIM DM version. The default version is 2.

If you have enabled PIM version 1 but need to enable version 2 instead, enter either of the following commands at the configuration level for the interface.

```
NetIron(config-if-e10000-1/1)# ip pim version 2
NetIron(config-if-e10000-1/1)# no ip pim version 1
```

To disable PIM DM on the interface, enter the following command.

```
NetIron(config-if-e10000-1/1)# no ip pim
```

Modifying PIM global parameters

PIM global parameters come with preset values. The defaults work well in most networks, but you can modify the following parameters if necessary:

- Neighbor timeout
- Hello timer
- Prune timer
- Prune wait timer
- Graft retransmit timer
- Inactivity timer

Modifying neighbor timeout

Neighbor timeout is the interval after which a PIM device will consider a neighbor to be absent. Absence of PIM hello messages from a neighboring device indicates that a neighbor is not present.

The default value is 105 seconds.

To apply a PIM neighbor timeout value of 360 seconds to all ports on the device operating with PIM, enter the following.

```
NetIron(config)# router pim
NetIron(config-pim-router)# nbr-timeout 360
```

Syntax: [**no**] **nbr-timeout** <*seconds*>

The default is 105 seconds. The range is 60-8000 seconds.

Modifying hello timer

This parameter defines the interval at which periodic hellos are sent out PIM interfaces. Devices use hello messages to inform neighboring devices of their presence. The default rate is 30 seconds.

To apply a PIM hello timer of 120 seconds to all ports on the device operating with PIM, enter the following.

```
NetIron(config)# router pim
NetIron(config-pim-router)# hello-timer 120
```

Syntax: [no] hello-timer <*10-3600*>

The default is 30 seconds.

Modifying prune timer

This parameter defines how long a PIM device will maintain a prune state for a forwarding entry.

The first received multicast interface is forwarded to all other PIM interfaces on the device. If there is no presence of groups on that interface, the leaf node sends a prune message upstream and stores a prune state. This prune state travels up the tree and installs a prune state.

A prune state is maintained until the prune timer expires or a graft message is received for the forwarding entry. The default value is 180 seconds.

To set the PIM prune timer to 90, enter the following.

```
NetIron(config)# router pim
NetIron(config-pim-router)# prune-timer 90
```

Syntax: [**no**] **prune-timer** <*seconds*>

The default is 180 seconds. The range is 60-3600 seconds.

Modifying the prune wait timer

The **prune-wait** command allows you to configure the amount of time a PIM device will wait before stopping traffic to neighbor devices that do not want the traffic. The value can be from zero to fifteen seconds. The default is three seconds. A smaller prune wait value reduces flooding of unwanted traffic.

A prune wait value of zero causes the PIM device to stop traffic immediately upon receiving a prune message. If there are two or more neighbors on the physical port, then the prune-wait command should not be used because one neighbor may send a prune message while the other sends a join message at the same time, or within less than three seconds.

To set the prune wait time to zero, enter the following commands.

```
NetIron(config)#router pim
NetIron(config-pim-router)#prune-wait 0
```

Syntax: [**no**] **prune-wait** <seconds>

The <*seconds*> can be 0 - 15. A value of 0 causes the PIM device to stop traffic immediately upon receiving a prune message. The default is 3 seconds.

To view the currently configured prune wait time, enter the **show ip pim dense** command as described in "Displaying basic PIM Dense configuration information" on page 1161.

Modifying graft retransmit timer

The graft retransmit timer defines the interval between the transmission of graft messages.

A graft message is sent by a device to cancel a prune state. When a device receives a graft message, the device responds with a Graft Ack (acknowledge) message. If this Graft Ack message is lost, the device that sent the graft message will resend it.

To change the graft retransmit timer from the default of 180 to 90 seconds, enter the following.

```
NetIron(config)# router pim
NetIron(config-pim-router)# graft-retransmit-timer 90
```

Syntax: [**no**] **graft-retransmit-timer** <*seconds*>

The default is 180 seconds. The range is from 60-3600 seconds.

Modifying inactivity timer

The device deletes a forwarding entry if the entry is not used to send multicast packets. The PIM inactivity timer defines how long a forwarding entry can remain unused before the device deletes it.

To apply a PIM inactivity timer of 90 seconds to all PIM interfaces, enter the following.

```
NetIron(config)# router pim
NetIron(config-pim-router)# inactivity-timer 90
```

Syntax: [no] **inactivity-timer** <*seconds*>

The default is 180 seconds. The range is from 60-3600 seconds.

Selection of shortest path back to source

By default, when a multicast packet is received on a PIM-capable interface in a multi-path topology, the interface checks its IP routing table to determine the shortest path back to the source. If the alternate paths have the same cost, the first alternate path in the table is picked as the path back to the source. For example, in the following example, the first four routes have the same cost back to the source. However, 137.80.127.3 is chosen as the path to the source since it is the first one on the list. The device rejects traffic from any port other than Port V11 on which 137.80.127.3 resides

```
Total number of IP routes: 19
Type Codes - B:BGP D:Connected I:ISIS S:Static R:RIP O:OSPF Cost - Dist/Metric
     Destination     Gateway         Port       Cost      Type
       ..
     172.17.41.4     137.80.127.3    v11        2          O
     172.17.41.4     137.80.126.3    v10        2          O
     172.17.41.4     137.80.129.1    v13        2          O
     172.17.41.4     137.80.128.3    v12        2          O
     172.17.41.8     0.0.0.0         1/2        1          D
```

Failover time in a multi-path topology

When a port in a multi-path topology fails, multicast devices, depending on the routing protocol being used, take a few seconds to establish a new path, if the failed port is the input port of the downstream device.

Modifying the TTL threshold

The TTL threshold defines the minimum value required in a packet for it to be forwarded OUT of the interface AFTER the TTL has been decremented.

For example, if the TTL for an interface is set at 10, only those packets that enter with a TTL value of 11 or more are forwarded through the TTL-10 interface. With a default TTL threshold of 1, only packets ingressing with a TTL of 2 or greater are forwarded. The TTL threshold only applies to routed interfaces and is ignored by switched interfaces. Possible TTL values are 1 to 64. The default TTL value is 1.

To configure a TTL of 45, enter a command such as the following.

```
NetIron(config-if-e10000-3/24)# ip pim ttl-threshold 45
```

Syntax: [no] **ip pim ttl-threshold** <*1-64*>

Configuring a DR priority

The DR priority option lets you give preference to a particular device in the DR election process by assigning it a numerically higher DR priority. This value can be set for IPv4 and IPv6 interfaces. To set a DR priority higher than the default value of 1, use the **ip pim dr-priority** command as shown:

For IPv4.

```
NetIron(config-if-e10000-3/24)# ip pim dr-priority 50
```

For IPv6.

```
NetIron(config-if-e10000-3/24)# ipv6 pim dr-priority 50
```

Syntax: [**no**] **ip pim dr-priority** <*priority-value*>

Syntax: [**no**] *ipv6* **pim dr-priority** <*priority-value*>

The <*priority-value*> variable is the value that you want to set for the DR priority. Optional values are: 0 - 65535. The default value is 1.

The **no** option removes the command and sets the DR priority back to the default value of 1.

The following information may be useful for troubleshooting.

1. If more than one device has the same DR priority on a subnet (as in the case of default DR priority on all), the device with the numerically highest IP address on that subnet is elected as the DR.
2. The DR priority information is used in the DR election ONLY IF ALL the PIM devices connected to the subnet support the DR priority option. If there is at least one PIM device on the subnet that does not support this option, then the DR election falls back to the backwards compatibility mode in which the device with the numerically highest IP address on the subnet is declared the DR regardless of the DR priority values.

Displaying basic PIM Dense configuration information

To display PIM Dense configuration information, enter the following command at any CLI level.

```
NetIron(config)# show ip pim dense
Global PIM Dense Mode Settings
  Maximum Mcache            : 0        Current Count                    : 0
  Hello interval            : 30       Neighbor timeout                 : 105
  Join/Prune interval       : 60       Inactivity interval              : 180
  Graft Retransmit interval : 180      Prune Age                        : 180
  Hardware Drop Enabled     : Yes      Prune Wait Interval              : 3
  Route Precedence          : mc-non-default mc-default uc-non-default uc-default
---------+--------------+----+---+--------------------+---+---------+-------+-
Interface|Local        |Mode|Ver|  Designated Router  |TTL|Multicast|  VRF  | DR
         |Address       |    |   |Address         Port|Thr|Boundary |       | Prio
---------+--------------+----+---+--------------------+---+---------+-------+-
     e1/2 65.19.11.1       DM  V2  Itself                1 None      default 1
     e1/4 97.47.11.1       DM  V2  Itself                1 None      default 1
    e2/13 65.29.11.1       DM  V2  Itself               1 None      default 1
    e2/18 97.49.11.1       DM  V2  Itself               1 None      default 1
     p3/1 65.30.12.1       DM  V2  Itself               1 None      default 1
```

Syntax: show ip pim [**vrf** <*vrf-name*>] **dense**

The **vrf** option allows you to display PIM dense configuration information for the VRF instance identified by the <*vrf-name*> variable.

This display shows the following information.

Table 0.1:

This field...	Displays...
Maximum Mcache	The maximum number multicast cache entries allowed on the device.
Current Count	The number of multicast cache entries currently used.
Hello interval	How frequently the device sends hello messages out the PIM dense interfaces.
Neighbor timeout	The interval after which a PIM device will consider a neighbor to be absent.
Graft or Retransmit interval	How interval between the transmission of graft messages.
Inactivity interval	How long a forwarding entry can remain unused before the device deletes it.
Join or Prune interval	How long a PIM device will maintain a prune state for a forwarding entry..
Prune Age	The number of packets the device sends using the path through the RP before switching to using the SPT path.
Hardware Drop Enabled	Displays Yes if the Passive Multicast Route Insertion feature is enable and No if it is not.
Prune Wait Interval	The amount of time a PIM device waits before stopping traffic to neighbor devices that do not want the traffic. The value can be from zero to three seconds. The default is three seconds.
Route Precedence	The route precedence configured to control the selection of routes based on the route types. There are four different types of routes: • Non-default route from the mRTM • Default route from the mRTM • Non-default route from the uRTM • Default route from the uRTM
Interface	The type of interface and the interface number.
Local Address	Indicates the IP address configured on the port or virtual interface.
Mode	Either DM for Dense Mode or SM for Sparse Mode.
Ver	The version of PIM Dense mode.
Designated Router	The IP address and port for the PIM designated device.
TTL Threshold	The minimum value required in a packet for it to be forwarded out of the interface.
Multicast Boundary	The multicast boundary enabled (if any) for PIM interfaces .
VRF	If the PIM Dense instance is configured within a VRF, this field will contain the name.
DR Prio	The priority of the designated device.

Displaying all multicast cache entries in a pruned state

You can use the following command to display all multicast cache entries that are currently in a pruned state and have not yet aged out.

```
NetIron(config-if-e10000-1/1)#show ip pim vrf med prune
Index Port    PhyPort SourceNet       Group           Nbr             Age
                                                                      sec
    1 v12     1/1     130.47.2.10     228.172.0.77    0.0.0.0         40
    2 v12     1/1     130.47.2.10     228.172.0.73    0.0.0.0         40
    3 v12     1/1     130.47.2.10     228.172.0.69    0.0.0.0         40
    4 v12     1/1     130.47.2.10     228.172.0.65    0.0.0.0         40
    5 v12     1/1     130.47.2.10     228.172.0.61    0.0.0.0         40
    6 v12     1/1     130.47.2.10     228.172.0.57    0.0.0.0         40
    7 v12     1/1     130.47.2.10     228.172.0.53    0.0.0.0         40
    8 v12     1/1     130.47.2.10     228.172.0.49    0.0.0.0         40
    9 v12     1/1     130.47.2.10     228.172.0.45    0.0.0.0         40
   ---------------------------------------
Total Prune entries: 9
```

Syntax: show ip pim [vrf <*vrf-name*>] prune

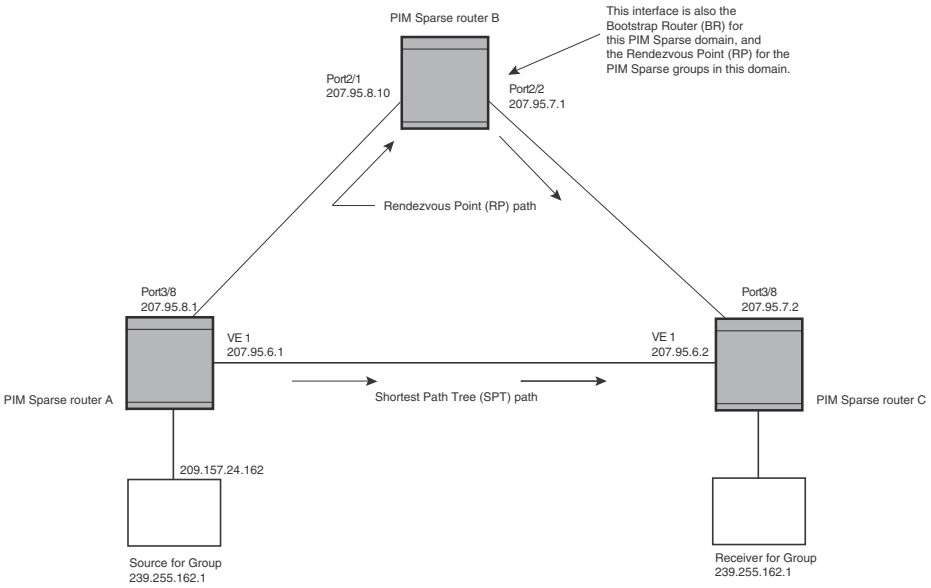
PIM Sparse

Dell devices support Protocol Independent Multicast (PIM) Sparse version 2. PIM Sparse provides multicasting that is especially suitable for widely distributed multicast environments. The Dell implementation is based on RFC 2362.

In a PIM Sparse network, a PIM Sparse device that is connected to a host that wants to receive information for a multicast group must explicitly send a join request on behalf of the receiver (host).

PIM Sparse devices are organized into domains. A PIM Sparse domain is a contiguous set of devices that all implement PIM and are configured to operate within a common boundary. Figure 156 shows a simple example of a PIM Sparse domain. This example shows three devices configured as PIM Sparse devices. The configuration is described in detail following the figure.

FIGURE 156 Example PIM Sparse domain



PIM Sparse device types

Devices that are configured with PIM Sparse interfaces also can be configured to fill one or more of the following roles:

- **PMBR** – A PIM device that has some interfaces within the PIM domain and other interface outside the PIM domain. PBMRs connect the PIM domain to the Internet.
- **BSR** – The Bootstrap Router (BSR) distributes RP information to the other PIM Sparse devices within the domain. Each PIM Sparse domain has one active BSR. For redundancy, you can configure ports on multiple devices as candidate BSRs. The PIM Sparse protocol uses an election process to select one of the candidate BSRs as the BSR for the domain. The BSR with the highest BSR priority (a user-configurable parameter) is elected. If the priorities result in a tie, then the candidate BSR interface with the highest IP address is elected. In the example in Figure 156, PIM Sparse device B is the BSR. Port 2/2 is configured as a candidate BSR.
- **RP** – The RP is the meeting point for PIM Sparse sources and receivers. A PIM Sparse domain can have multiple RPs, but each PIM Sparse multicast group address can have only one active RP. PIM Sparse devices learn the addresses of RPs and the groups for which they are responsible from messages that the BSR sends to each of the PIM Sparse devices. In the example in Figure 156, PIM Sparse device B is the RP. Port 2/2 is configured as a candidate Rendezvous Point (RP).

  To enhance overall network performance, the device uses the RP to forward only the first packet from a group source to the group's receivers. After the first packet, the device calculates the shortest path between the receiver and source (the Shortest Path Tree, or SPT) and uses the SPT for subsequent packets from the source to the receiver. The device calculates a separate SPT for each source-receiver pair.

NOTE
It is recommended that you configure the same ports as candidate BSRs and RPs.

RP paths and SPT paths

Figure 156 shows two paths for packets from the source for group 239.255.162.1 and a receiver for the group. The source is attached to PIM Sparse device A and the recipient is attached to PIM Sparse device C. PIM Sparse device B in is the RP for this multicast group. As a result, the default path for packets from the source to the receiver is through the RP. However, the path through the RP sometimes is not the shortest path. In this case, the shortest path between the source and the receiver is over the direct link between device A and device C, which bypasses the RP (device B).

To optimize PIM traffic, the protocol contains a mechanism for calculating the Shortest Path Tree (SPT) between a given source and receiver. PIM Sparse devices can use the SPT as an alternative to using the RP for forwarding traffic from a source to a receiver. By default, the device forwards the first packet they receive from a given source to a given receiver using the RP path, but forward subsequent packets from that source to that receiver through the SPT. In Figure 156, device A forwards the first packet from group 239.255.162.1's source to the destination by sending the packet to device B, which is the RP. Device B then sends the packet to device C. For the second and all future packets that device A receives from the source for the receiver, device A forwards them directly to device C using the SPT path.

Configuring PIM Sparse

To configure a PowerConnect for PIM Sparse, perform the following tasks:

- Configure the following global parameter:
  - Enable the PIM Sparse mode of multicast routing.
- Configure the following interface parameters:
  - Configure an IP address on the interface
  - Enable PIM Sparse.
  - Identify the interface as a PIM Sparse border, if applicable.
- Configure the following PIM Sparse global parameters:
  - Identify the PowerConnect as a candidate PIM Sparse Bootstrap Router (BSR), if applicable.
  - Identify the PowerConnect as a candidate PIM Sparse Rendezvous Point (RP), if applicable.
  - Specify the IP address of the RP (if you want to statically select the RP).

NOTE
It is recommended that you configure the same PowerConnect as both the BSR and the RP.

Current limitations

The implementation of PIM Sparse in the current software release has the following limitations:

- PIM Sparse and regular PIM (dense mode) cannot be used on the same interface.
- You cannot configure or display PIM Sparse information using the Web Management Interface. (You can display some general PIM information, but not specific PIM Sparse information.)

Configuring global PIM Sparse parameters

To configure basic global PIM Sparse parameters, enter commands such as the following on each device within the PIM Sparse domain.

```
NetIron(config)# router pim
```

Syntax: [**no**] **router pim**

NOTE
You do not need to globally enable IP multicast routing when configuring PIM Sparse.

The command in this example enables IP multicast routing, and enables the PIM Sparse mode of IP multicast routing. The command does not configure the PowerConnect as a candidate PIM Sparse Bootstrap Router (BSR) and candidate Rendezvous Point (RP). You can configure a device as a PIM Sparse device without configuring the PowerConnect as a candidate BSR and RP. However, if you do configure the device as one of these, it is recommended that you configure the device as both of these. Refer to "Configuring BSRs" on page 1167.

Entering a **[no] router pim** command does the following:

- Disables PIM or DVMRP.
- Removes all configuration for PIM multicast on a PowerConnect (**router pim** level) only.

Enabling PIM Sparse for a specified VRF

To enable PIM for the VRF named "blue", use the following commands.

```
NetIron(config)# router pim vrf blue
```

Syntax: [**no**] **router pim** [**vrf** <*vrf-name*>]

The **vrf** parameter allows you to configure PIM (PIM-DM and PIM-SM) on the virtual routing instance (VRF) specified by the <*vrf-name*> variable. All PIM parameters available for the default router instance are configurable for a VRF-based PIM instance.

The [**no**] **router pim vrf** command behaves in the following manner:

- Entering the **router pim vrf** command to enable PIM does not require a software reload.
- Entering a **no router pim vrf** command removes all configuration for PIM multicast on the specified VRF.

Configuring PIM interface parameters

After you enable IP multicast routing and PIM Sparse at the global level, you must enable it on the individual interfaces connected to the PIM Sparse network.

To enable PIM Sparse mode on an interface, enter commands such as the following.

```
NetIron(config)# interface ethernet 2/2
NetIron(config-if-e10000-2/2)# ip address 207.95.7.1 255.255.255.0
NetIron(config-if-e10000-2/2)# ip pim-sparse
```

Syntax: [**no**] **ip pim-sparse**

The commands in this example add an IP interface to port 2/2, then enable PIM Sparse on the interface.

If the interface is on the border of the PIM Sparse domain, you also must enter the following command.

```
NetIron(config-if-e10000-2/2)# ip pim border
```

Syntax: [no] ip pim border

Configuring BSRs

In addition to the global and interface parameters described in the previous sections, you need to identify an interface on at least one device as a candidate PIM Sparse Bootstrap router (BSR) and candidate PIM Sparse Rendezvous Point (RP).

NOTE
It is possible to configure the device as only a candidate BSR or RP, but it is recommended that you configure the same interface on the same device as both a BSR and an RP.

This section describes how to configure BSRs. Refer to "Configuring RPs" on page 1167 for instructions on how to configure RPs.

To configure the device as a candidate BSR, enter commands such as the following.

```
NetIron(config)# router pim
NetIron(config-pim-router)# bsr-candidate ethernet 2/2 30 255
BSR address: 207.95.7.1, hash mask length: 30, priority: 255
```

These commands configure the PIM Sparse interface on port 2/2 as a BSR candidate, with a hash mask length of 30 and a priority of 255. The information shown in italics above is displayed by the CLI after you enter the candidate BSR configuration command.

Syntax: [no] bsr-candidate ethernet <*slot*>/<*portnum*> | loopback <*num*> | tunnel <*num*> | ve <*num*><*hash-mask-length*> [<*priority*>]

The ethernet <*slot*>/<*portnum*> | loopback <*num*> | ve <*num*> parameters specify the interface. The device will advertise the IP address of the specified interface as a candidate BSR.

- Enter ethernet <*slot*>/<*portnum*> for a physical interface (port).
- Enter ve <*num*> for a virtual interface.
- Enter loopback <*num*> for a loopback interface.
- Enter tunnel <*num*> for a GRE tunnel interface to be configured. The GRE tunnel interface is enabled under the router PIM configuration.

The <*hash-mask-length*> parameter specifies the number of bits in a group address that are significant when calculating the group-to-RP mapping. You can specify a value from 1–32.

NOTE
it is recommended that you specify 30 for IP version 4 (IPv4) networks.

The <*priority*> specifies the BSR priority. You can specify a value from 0 – 255. When the election process for BSR takes place, the candidate BSR with the highest priority becomes the BSR. The default is 0.

Configuring RPs

Enter a command such as the following to configure the device as a candidate RP.

```
NetIron(config-pim-router)# rp-candidate ethernet 2/2
```

Syntax: [**no**] **rp-candidate ethernet** <*slot*>/<*portnum*> | **loopback** <*num*> | **tunnel** <*num*> | **ve** <*num*>

The **ethernet** <*slot*>/<*portnum*> | **loopback** <*num*> | **ve** <*num*> parameters specify the interface. The device will advertise the IP address of the specified interface as a candidate RP.

- Enter **ethernet** <*slot*>/<*portnum*> for a physical interface (port).
- Enter **ve** <*num*> for a virtual interface.
- Enter **loopback** <*num*> for a loopback interface.
- Enter **tunnel** <*num*> for a GRE tunnel interface to be configured. The GRE tunnel interface is enabled under the router PIM configuration.

By default, this command configures the device as a candidate RP for all group numbers beginning with 224. As a result, the device is a candidate RP for all valid PIM Sparse group numbers. You can change this by adding or deleting specific address ranges. The following example narrows the group number range for which the device is a candidate RP by explicitly adding a range.

```
NetIron(config-pim-router)# rp-candidate add 224.126.0.0 16
```

Syntax: [**no**] **rp-candidate add** <*group-addr*> <*mask-bits*>

The <*group-addr*> <*mask-bits*> specifies the group address and the number of significant bits in the subnet mask. In this example, the device is a candidate RP for all groups that begin with 224.126. When you add a range, you override the default. The device then becomes a candidate RP only for the group address ranges you add.

You also can delete the configured rp-candidate group ranges by entering the following command.

```
NetIron(config-pim-router)# rp-candidate delete 224.126.22.0 24
```

Syntax: [**no**] **rp-candidate delete** <*group-addr*> <*mask-bits*>

The usage of the <*group-addr*> <*mask-bits*> parameter is the same as for the **rp-candidate add** command.

.Updating PIM-Sparse forwarding entries with new RP configuration

If you make changes to your static RP configuration, the entries in the PIM-Sparse multicast forwarding table continue to use the old RP configuration until they are aged out.

The **clear pim rp-map** command allows you to update the entries in the static multicast forwarding table immediately after making RP configuration changes. This command is meant to be used with **rp-address** command.

To update the entries in a PIM sparse static multicast forwarding table with new RP configuration, enter the following command at the privileged EXEC level of the CLI.

```
NetIron(config)# clear ip pim rp-map
```

Syntax: clear ip pim [**vrf** <*vrf-name*>] **rp-map**

Use the **vrf** option to clear the PIM sparse static multicast forwarding table for a VRF instance specified by the <*vrf-name*> variable.

Statically specifying the RP

It is recommended that you use the PIM Sparse protocol's RP election process so that a backup RP can automatically take over if the active RP router becomes unavailable. However, if you do not want the RP to be selected by the RP election process but instead you want to explicitly identify the RP by P address, use the **rp-address** command.

If you explicitly specify the RP, the device uses the specified RP for all group-to-RP mappings and overrides the set of candidate RPs supplied by the BSR.

NOTE
Specify the same IP address as the RP on all PIM Sparse devices within the PIM Sparse domain. Make sure the device is on the backbone or is otherwise well connected to the rest of the network.

To specify the IP address of the RP, enter commands such as the following.

```
NetIron(config)# router pim
NetIron(config-pim-router)# rp-address 207.95.7.1
```

Syntax: [**no**] **rp-address** <*ip-addr*>

The <*ip-addr*> parameter specifies the IP address of the RP.

The command in this example identifies the device interface at IP address 207.95.7.1 as the RP for the PIM Sparse domain. The device uses the specified RP and ignore group-to-RP mappings received from the BSR.

ACL based RP assignment

The **rp-address** command allows multiple static RP configurations. For each static RP, an ACL can be given as an option to define the multicast address ranges that the static RP permit or deny to serve.

A static RP by default serves the range of 224.0.0.0/4 if the RP is configured without an ACL name. If an ACL name is given but the ACL is not defined, the static RP is set to inactive mode and it will not cover any multicast group ranges.

The optional static RP ACL can be configured as a standard ACL or as an extended ACL. For an extended ACL, the destination filter will be used to derive the multicast group range and all other filters are ignored. The content of the ACL needs to be defined in the order of prefix length; the longest prefix must be placed at the top of the ACL definition.

If there are overlapping group ranges among the static RPs, the static RP with the longest prefix match is selected. If more than one static RP covers the exact same group range, the highest IP static RP will be used.

Configuration considerations:

- The Static RP has higher precedence over RP learnt from the BSR.
- There is a limit of 64 static RPs in the systems.

Configuring an ACL based RP assignment

To configure an ACL based RP assignment, enter commands such as the following.

```
NetIron(config)# router pim
NetIron(config-pim-router)# rp-address 130.1.1.1 acl1
```

Syntax: [**no**] **rp-address** <*ip_address*> [<*acl_name_or_id*>] [**vrf** <*vrf-name*>]

Use the **ip address** parameter to specify the IP address of the device you want to designate as an RP device.

Use the **acl name** or **id** (optional) parameter to specify the name or ID of the ACL that specifies which multicast groups use this RP.

Use the **vrf** parameter to specify a VRF instance.

Displaying the static RP

Use the **show ip pim rp-set** command to display static RP and the associated group ranges.

```
NetIron(config)# show ip pim rp-set
Static RP and associated group ranges
-------------------------------------
Static RP count: 4
130.1.1.1
   permit 238.1.1.0/24
   permit 239.1.0.0/16
   permit 235.0.0.0/8
120.1.1.1
   deny all
120.2.1.1
   deny all
124.1.1.1
   permit 224.0.0.0/4
Number of group prefixes Learnt from BSR: 0
No RP-Set present.
```

Use the **show ip pim rp-map** command to display all current multicast group addresses to RP address mapping.

```
NetIron(config)# show ip pim rp-map
Number of group-to-RP mappings: 5
      Group address     RP address
--------------------------------------
1     230.0.0.1         100.1.1.1
2     230.0.0.2         100.1.1.1
3     230.0.0.3         100.1.1.1
4     230.0.0.4         100.1.1.1
5      230.0.0.5          100.1.1.1
```

Route selection precedence for multicast

The **route-precedence** command lets you specify a precedence table that dictates how routes are selected for multicast.

Configuration considerations:

PIM must be enabled at the global level.

Configuring route precedence by specifying route types

The **route precedence** command lets you control the selection of routes based on the following route types:

- Non-default route from the mRTM
- Default route from the mRTM
- Non-default route from the uRTM
- Default route from the uRTM

Use this command to specify an option for all of the precedence levels.

Example

To specify a non-default route from the mRTM, then a non-default route from the uRTM, then a default route from the mRTM, and then a default route from the uRTM, enter commands such as the following.

```
NetIron(config)# router pim
NetIron(config-pim-router)# route-precedence mc-non-default uc-non-default
mcdefault uc-default
```

The **none** option may be used to fill up the precedence table in order to ignore certain types of routes. To use the unicast default route for multicast, enter commands such as the following.

```
NetIron(config)# router pim
NetIron(config-pim-router)# route-precedence mc-non-default mc-default
uc-non-default none
```

Syntax: [**no**] **route-precedence** [**mc-non-default** | **mc-default** | **uc-non-default** | **uc-default** | **none**]

Default value: **route-precedence mc-non-default mc-default uc-non-default uc-default**

Use the **mc-non-default** parameter to specify a multicast non-default route.

Use the **mc-default** parameter to specify a multicast default route.

Use the **uc-non-default p**arameter to specify a unicast non-default route.

Use the **uc-default** parameter to specify a unicast default route.

Use the **none** parameter to ignore certain types of routes.

The **no** form of this command removes the configuration.

Displaying the route selection

Use the **show ip pim sparse** command to display the current route selection. This example shows the default route precedence selection.

```
NetIron(config)#show ip pim sparse
Global PIM Sparse Mode Settings
  Hello interval : 30 Neighbor timeout : 105
  Bootstrap Msg interval: 60 Candidate-RP Advertisement interval: 60
  Join/Prune interval : 60 SPT Threshold : 1
  Inactivity interval : 180 SSM Enabled : No
  Hardware Drop Enabled : Yes
  Route Selection : mc-non-default mc-default uc-non-default uc-default
---------+---------------+----+---+----------------------+------+-------------+
Interface|Local          |Mode|Ver| Designated Router    |TTL   |Multicast    |
         |Address        |    |   |Address         Port  |Thresh|Boundary     |
---------+---------------+----+---+----------------------+------+-------------+
      v12 100.4.8.2        SM  V2  Itself                    1 None
      v13 100.16.8.2       SM  V2  Itself                    1 None
     v124 124.0.0.1        SM  V2  Itself                    1 None
     v125 125.0.0.1        SM  V2  Itself                    1 None
     v126 126.0.0.1        SM  V2  Itself                    1 None
     v127 127.0.0.1        SM  V2  Itself                    1 None
        l1 1.0.8.1         SM  V2   Itself                   1 None
```

In this example, the route precedence selection is multicast non-default, then unicast non-default, then multicast default, and then unicast default.

Changing the Shortest Path Tree (SPT) threshold

In a typical PIM Sparse domain, there may be two or more paths from a DR (designated router) for a multicast source to a PIM group receiver:

- **Path through the RP** – This is the path the device uses the first time it receives traffic for a PIM group. However, the path through the RP may not be the shortest path from the device to the receiver.
- **Shortest Path** – Each PIM Sparse device that is a DR for a multicast source calculates a shortest path tree (SPT) to all the PIM Sparse group receivers within the domain, with the device itself as the root of the tree. The first time a device configured as a PIM router receives a packet for a PIM receiver, the device sends the packet to the RP for the group. The device also calculates the SPT from itself to the receiver. The next time the device receives a PIM Sparse packet for the receiver, the device sends the packet toward the receiver using the shortest route, which may not pass through the RP.

By default, the device switches from the RP to the SPT after receiving the first packet for a given PIM Sparse group. The device maintains a separate counter for each PIM Sparse source-group pair.

After the device receives a packet for a given source-group pair, it starts a PIM data timer for that source-group pair. If the device does not receive another packet for the source-group pair before the timer expires, it reverts to using the RP for the next packet received for the source-group pair. In accordance with the PIM Sparse RFC recommendation, the timer is 210 seconds and is not configurable. The counter is reset to zero each time the device receives a packet for the source-group pair.

You can change the number of packets that the device sends using the RP before switching to using the SPT by entering commands such as the following.

```
NetIron(config)# router pim
NetIron(config-pim-router)# spt-threshold 1000
```

Syntax: [**no**] **spt-threshold infinity** | <*num*>

The **infinity** | <*num*> parameter specifies the number of packets. If you specify **infinity**, the device sends packets using the RP indefinitely and does not switch over to the SPT. If you enter a specific number of packets, the device does not switch over to using the SPT until it has sent the number of packets you specify using the RP.

Configuring PIM-SM (*,g) forwarding

By default, the device supports only (s,g) hardware routing. This is adequate in network topologies where there a limited number of multicast flows, and most SPT and RPF paths diverge from the PIM Last Hop (PIM LH) from the PIM First Hop (PIM FH).

If however, the RPF path from a PIM LH to the PIM RP and the source is the same, the intermediate devices between RP and LH can be optimized to aggregate multicast flows destined to the same group address to use a single (*,g) CAM entry, instead of consuming an (s,g) hardware entry for each flow. This reduces CAM usage as well as the number of IPCs between the interface and managment modules to manage the individual (s,g) states.

For example, where a service provider is provisioning multicast service, with only the route of PIM RP being visible to customers, and routes to the sources are all default, the (*,g) hardware entry can help optimize system resources by keeping the traffic on the shared tree.

NOTE
It is recommended to configure the **spt-threshold infinity** command beginning from the PIM LH router, then to the intermediate PIM routers and finally to the PIM RP.

Configuration details

To enable this feature, you must explicitly configure the **spt-threshold infinity** command on all multicast nodes, as shown in the following example.

```
NetIron(config)# router pim
NetIron(config-pim-router)# spt-threshold infinity
```

Syntax: [**no**] **spt-threshold infinity**

This configuration option forces PIM-SM to distribute multicast traffic on the share tree only. PIM devices from RP to LH maintain only (*,g) states, regardless of the source location in the network topology. PIM LH will not initiate (s,g) SPT switchover, so there are no (s,g) joins generated from LH. Devices in the share tree, eg, devices downstream from RP, create a (*,g) hardware forwarding state to switch multicast flows for the group.

Changing the PIM Join and Prune message interval

By default, the device sends PIM Sparse Join or Prune messages every 60 seconds. These messages inform other PIM Sparse devices about clients who want to become receivers (Join) or stop being receivers (Prune) for PIM Sparse groups.

NOTE
Use the same Join or Prune message interval on all the PIM Sparse devices in the PIM Sparse domain. If the devices do not all use the same timer interval, the performance of PIM Sparse can be adversely affected.

To change the Join or Prune interval, enter commands such as the following.

```
NetIron(config)# router pim
NetIron(config-pim-router)# message-interval 30
```

Syntax: [**no**] **message-interval** <*num*>

The <*num*> parameter specifies the number of seconds and can from 1 – 65535. The default is 60.

Multicast Outgoing Interface (OIF) list optimization

Each multicast route entry maintains a list of outgoing interfaces (OIF List) to which an incoming multicast data packet matching the route is replicated. In hardware-forwarded route entries, these OIF lists are stored inside the hardware in replication tables which are limited in size. In many deployment scenarios, more than one multicast route can have identical OIF lists and can optimize usage of the replication table entries by sharing them across multiple multicast routes. Multicast OIF list optimization keeps track of all the OIF lists in the system. It manages the hardware replication resources optimally, in real time, by dynamically assigning or re-assigning resources to multicast route entries to suit their current OIF list requirements, while maximizing resource sharing.

Displaying PIM Sparse configuration information and statistics

You can display the following PIM Sparse information:

- Basic PIM Sparse configuration information
- Group information
- BSR information
- Candidate RP information
- RP-to-group mappings
- RP information for a PIM Sparse group
- RP set list
- PIM neighbor information
- The PIM flow cache
- The PIM multicast cache
- PIM traffic statistics
- PIM counter statistics

Displaying basic PIM Sparse configuration information

To display PIM Sparse configuration information, enter the following command at any CLI level.

```
NetIron# show ip pim sparse
Global PIM Sparse Mode Settings
  Hello interval        : 30          Neighbor timeout                  : 105
  Bootstrap Msg interval: 60          Candidate-RP Advertisement interval: 60
  Join/Prune interval   : 60          SPT Threshold                     : 1
  Inactivity interval   : 180
  SSM Enabled: Yes
  SSM Group Range: 226.0.0.0/8
---------+---------------+----+---+----------------------+------
Interface|Local           |Mode|Ver|  Designated Router   |TTL
         |Address         |    |   |Address          Port |Thresh
---------+---------------+----+---+----------------------+------
     e6/3 10.2.0.10         SM  V2  Itself                     1
     e6/4 10.3.0.10         SM  V2  Itself                     1
      v30 10.10.10.10       SM  V2  Itself                     1
```

Syntax: show ip pim [**vrf** <*vrf-name*>] **sparse**

The **vrf** option allows you to display PIM sparse configuration information for the VRF instance identified by the <*vrf-name*> variable.

This example shows the PIM Sparse configuration information on PIM Sparse device A in Figure 156.

Table 181 shows the information displayed by the **show ip pim sparse** command..

TABLE 181 Output of the **show ip pim sparse** command

This field...	Displays...
Global PIM Sparse mode settings	
Hello interval	How frequently the device sends PIM Sparse hello messages to its PIM Sparse neighbors. This field also shows the number of seconds between hello messages. PIM Sparse devices use hello messages to discover each another.
Neighbor timeout	How many seconds the device waits for a hello message from a neighbor before determining that the neighbor is no longer present and removing cached PIM Sparse forwarding entries for the neighbor.
Bootstrap Msg interval	How frequently the BSR configured on the device sends the RP set to the RPs within the PIM Sparse domain. The RP set is a list of candidate RPs and their group prefixes. A candidate RP group prefix indicates the range of PIM Sparse group numbers for which it can be an RP. **NOTE:** This field contains a value only if an interface on the device is elected to be the BSR. Otherwise, the field is blank.
Candidate-RP Advertisement interval	How frequently the candidate PR configured on the device sends candidate RP advertisement messages to the BSR. **NOTE:** This field contains a value only if an interface on the device is configured as a candidate RP. Otherwise, the field is blank.
Join or Prune interval	How frequently the device sends PIM Sparse Join or Prune messages for the multicast groups it is forwarding. This field also shows the number of seconds between Join or Prune messages. The device sends Join or Prune messages on behalf of multicast receivers who want to join or leave a PIM Sparse group. When forwarding packets from PIM Sparse sources, the device sends the packets only on the interfaces on which it has received join requests in Join or Prune messages for the source group. You can change the Join or Prune interval. Refer to "Changing the PIM Join and Prune message interval" on page 1173.
SPT Threshold	The number of packets the device sends using the path through the RP before switching to using the SPT path.
Inactivity Interval	
SSM Enabled	If yes, source-specific multicast is configured globally on this device.
SSM Group Range	The SSM range of IP multicast addresses. By default this range will be 232/8 as assigned by the Internet Assigned Numbers Authority (IANA) for use with SSM. Other values can be configured.
PIM Sparse interface information **NOTE:** You also can display IP multicast interface information using the **show ip pim interface** command. However, this command lists all IP multicast interfaces, including regular PIM (dense mode) and DVMRP interfaces. The **show ip pim sparse** command lists only the PIM Sparse interfaces.	
Interface	The type of interface and the interface number. The interface type can be one of the following: • Ethernet • VE The number is either a port number (and slot number if applicable) or the virtual interface (VE) number.
TTL Threshold	Following the TTL threshold value, the interface state is listed. The interface state can be one of the following: • Disabled • Enabled

TABLE 181 Output of the **show ip pim sparse** command (Continued)

This field...	Displays...
Local Address	Indicates the IP address configured on the port or virtual interface.
Mode	
Version	
Designated Router	

Displaying a list of multicast groups

To display PIM group information, enter the following command at any CLI level.

```
NetIron# show ip pim group

Total number of Groups: 2
Index 1         Group 239.255.162.1       Ports e3/11
```

Syntax: show ip pim [**vrf** <*vrf-name*>] **group**

The **vrf** option allows you to display PIM group information for the VRF instance identified by the <*vrf-name*> variable.

Table 182 describes the output from this command.

TABLE 182 Output from the **show ip pim vrf group** command

This field...	Displays...
Total number of Groups	Lists the total number of IP multicast groups the device is forwarding. **NOTE:** This list can include groups that are not PIM Sparse groups. If interfaces on the device are configured for regular PIM (dense mode) or DVMRP, these groups are listed too.
Index	The index number of the table entry in the display.
Group	The multicast group address
Ports	The device ports connected to the receivers of the groups.

Displaying BSR information

To display BSR information, enter the following command at any CLI level.

```
NetIron# show ip pim bsr

PIMv2 Bootstrap information

This system is the elected Bootstrap Router (BSR)
  BSR address: 207.95.7.1
  Uptime: 00:33:52, BSR priority: 5, Hash mask length: 32
  Next bootstrap message in 00:00:20

Next Candidate-RP-advertisement in 00:00:10
  RP: 207.95.7.1
    group prefixes:
    224.0.0.0 / 4
Candidate-RP-advertisement period: 60
```

This example shows information displayed on a device that has been elected as the BSR. The next example shows information displayed on a device that is not the BSR. Notice that some fields shown in the example above do not appear in the example below.

```
NetIron# show ip pim bsr

PIMv2 Bootstrap information
 BSR address  = 207.95.7.1
 BSR priority = 5
```

Syntax: show ip pim [**vrf** <*vrf-name*>] **bsr**

The **vrf** option allows you to display BSR information for the VRF instance identified by the <*vrf-name*> variable.

Table 183 describes the output from this command.

TABLE 183 Output from the **show ip pim bsr** command

This field...	Displays...
BSR address	The IP address of the interface configured as the PIM Sparse Bootstrap Router (BSR).
Uptime	The amount of time the BSR has been running. **NOTE:** This field appears only if this device is the BSR.
BSR priority	The priority assigned to the interface for use during the BSR election process. During BSR election, the priorities of the candidate BSRs are compared and the interface with the highest BSR priority becomes the BSR.
Hash mask length	The number of significant bits in the IP multicast group comparison mask. This mask determines the IP multicast group numbers for which the device can be a BSR. The default is 32 bits, which allows the device to be a BSR for any valid IP multicast group number. **NOTE:** This field appears only if this device is a candidate BSR.
Next bootstrap message in	Indicates how many seconds will pass before the BSR sends the next bootstrap message. **NOTE:** This field appears only if this device is the BSR.
Next Candidate-RP-advertisement message in	Indicates how many seconds will pass before the BSR sends the next candidate PR advertisement message. **NOTE:** This field appears only if this device is a candidate BSR.
RP	Indicates the IP address of the Rendezvous Point (RP). **NOTE:** This field appears only if this device is a candidate BSR.
group prefixes	Indicates the multicast groups for which the RP listed by the previous field is a candidate RP. **NOTE:** This field appears only if this device is a candidate BSR.
Candidate-RP-advertisement period	Indicates how frequently the BSR sends candidate RP advertisement messages. **NOTE:** This field appears only if this device is a candidate BSR.

Displaying candidate RP information

To display candidate RP information, enter the following command at any CLI level.

```
NetIron# show ip pim rp-candidate

Next Candidate-RP-advertisement in 00:00:10
  RP: 207.95.7.1
    group prefixes:
    224.0.0.0 / 4

  Candidate-RP-advertisement period: 60
```

This example show information displayed on a device that is a candidate RP. The next example shows the message displayed on a device that is not a candidate RP.

```
NetIron# show ip pim rp-candidate
```

This system is not a Candidate-RP.

Syntax: show ip pim rp-candidate <*vrf-name*>

This command displays candidate RP information for the VRF instance identified by the <*vrf-name*> variable.

Table 184 describes the output from this command.

TABLE 184 Output from the **show ip pim rp-candidate** command

This field...	Displays...
Candidate-RP-advertisement in	Indicates how many seconds will pass before the BSR sends the next RP message. **NOTE:** This field appears only if this device is a candidate RP.
RP	Indicates the IP address of the Rendezvous Point (RP). **NOTE:** This field appears only if this device is a candidate RP.
group prefixes	Indicates the multicast groups for which the RP listed by the previous field is a candidate RP. **NOTE:** This field appears only if this device is a candidate RP.
Candidate-RP-advertisement period	Indicates how frequently the BSR sends candidate RP advertisement messages. **NOTE:** This field appears only if this device is a candidate RP.

Displaying RP-to-group mappings

To display RP-to-group-mappings, enter the following command at any CLI level.

```
NetIron# show ip pim rp-map
Number of group-to-RP mappings: 6

Group address        RP address
------------------------------
1 239.255.163.1  99.99.99.5
2 239.255.163.2  99.99.99.5
3 239.255.163.3  99.99.99.5
4 239.255.162.1  99.99.99.5
5 239.255.162.2  43.43.43.1
6 239.255.162.3  99.99.99.5
```

Syntax: show ip pim [**vrf** <*vrf-name*>] **rp-map**

The **vrf** option allows you to display candidate RP-to-group mappings for the VRF instance identified by the <*vrf-name*> variable.

This display shows the following information.

TABLE 185 Output of the **show ip pim rp-map** command

This field...	Displays...
Group address	Indicates the PIM Sparse multicast group address using the listed RP.
RP address	Indicates the IP address of the Rendezvous Point (RP) for the listed PIM Sparse group.

Displaying RP Information for a PIM Sparse group

To display RP information for a PIM Sparse group, enter the following command at any CLI level.

```
NetIron# show ip pim rp-hash 239.255.162.1

  RP: 207.95.7.1, v2
    Info source: 207.95.7.1, via bootstrap
```

Syntax: show ip pim [**vrf** <*vrf-name*>] **rp-hash** <*group-addr*>

The **vrf** option allows you to display RP information for the VRF instance identified by the <*vrf-name*> variable.

The <*group-addr*> parameter is the address of a PIM Sparse IP multicast group.

Table 186 describes the output from this command.

TABLE 186 Output from the **show ip pim** command

This field...	Displays...
RP	Indicates the IP address of the Rendezvous Point (RP) for the specified PIM Sparse group, followed by the port or virtual interface through which this device learned the identity of the RP.
Info source	Indicates the IP address on which the RP information was received, followed by the IP address through which this device learned the identity of the RP.

Displaying the RP set list

To display the RP set list, enter the following command at any CLI level.

```
NetIron# show ip pim rp-set
Group address Static-RP-address Override
-------------------------------------------------
Access-List 44 99.99.99.5 On
Number of group prefixes Learnt from BSR: 1
Group prefix = 239.255.162.0/24 # RPs expected: 1
# RPs received: 1
RP 1: 43.43.43.1 priority=0 age=0
```

Syntax: show ip pim [**vrf** <*vrf-name*>] **rp-set**

The **vrf** option allows you to display the RP set list for the VRF instance identified by the <*vrf-name*> variable.

Table 187 describes the output from this command.

TABLE 187 Output from the **show ip pim vrf rp-set** command

This field...	Displays...
Number of group prefixes	The number of PIM Sparse group prefixes for which the RP is responsible.
Group prefix	Indicates the multicast groups for which the RP listed by the previous field is a candidate RP.
RPs expected or received	Indicates how many RPs were expected and received in the latest bootstrap message.
RP <*num*>	Indicates the RP number. If there are multiple RPs in the PIM Sparse domain, a line of information for each RP is listed, in ascending numerical order.
priority	The RP priority of the candidate RP. During the election process, the candidate RP with the highest priority is elected as the RP.
age	The age (in seconds) of this RP-set. **NOTE:** If this device is not a BSR, this field contains zero. Only the BSR ages the RP-set.

Displaying multicast neighbor information

To display information about PIM neighbors, enter the following command at any CLI level.

```
NetIron# show ip pim nbr

Port   Phy_Port Neighbor      Holdtime  Age    UpTime  VRF          Priority
                              sec       sec    sec
e1/8   e1/3     207.95.8.10   105       30     900     default-VRF   1
e2/4   e2/4     65.31.11.1    105       30     60      default-VRF   10
p3/1   e3/      165.31.11.1   105       30     300     default-VRF   N/A
```

Syntax: show ip pim [**vrf** <*vrf-name*>] **nbr**

The **vrf** option allows you to display information about the PIM neighbors for the VRF instance identified by the <*vrf-name*> variable.

Table 188 describes the output from this command.

TABLE 188 Output from the **show ip pim vrf nbr** command

This field...	Displays...
Port	The interface through which the device is connected to the neighbor.
Neighbor	The IP interface of the PIM neighbor.
Holdtime sec	Indicates how many seconds the neighbor wants this device to hold the entry for this neighbor in memory. The neighbor sends the Hold Time in Hello packets: • If the device receives a new Hello packet before the Hold Time received in the previous packet expires, the device updates its table entry for the neighbor. • If the device does not receive a new Hello packet from the neighbor before the Hold time expires, the device assumes the neighbor is no longer available and removes the entry for the neighbor.
Age sec	The number of seconds since the device received the last hello message from the neighbor.
UpTime sec	The number of seconds the PIM neighbor has been up. This timer starts when the device receives the first Hello messages from the neighbor.

TABLE 188 Output from the **show ip pim vrf nbr** command (Continued)

This field...	Displays...
VRF	The VRF in which the interface is configured. This can be a VRF that the port was assigned to or the default VRF of the device.
Priority	The DR priority that is used in the DR election process. This can be a configured value or the default value of 1.

Displaying the PIM multicast cache

To display the PIM multicast cache, enter the following command at any CLI level.

```
NetIron# show ip pim mcache
Total 6 entries

```

Syntax: show ip pim [**vrf** <*vrf-name*>] **mcache**

The **vrf** option allows you to display the PIM multicast cache for the VRF instance identified by the <*vrf-name*> variable.

Displaying the PIM multicast cache for MVID

To display the PIM multicast cache for a specified mvid, enter the following command at any CLI level.

```
NetIron# show ip pim mcache mvid 1
Total 8 entries
1    (1.1.1.100, 239.1.1.1) in e3/1 (e3/1), cnt=0
     Sparse Mode, RPT=0 SPT=1 Reg=0 L2Reg=0 RegSupp=0 LSrc=1 LRcv=1

     age=0 fid: 0x8008  mvid: 0x0001

Total number of mcache entries 2
```

Syntax: show ip pim mcache mvid <*mvid*>

The <*mvid*> variable allows you to display an entry that matches a specified mvid.

Displaying the PIM multicast cache for FID

To display the PIM multicast cache for a specified fid, enter the following command at any CLI level

```
NetIron# show ip pim mcache fid 8009
Total 8 entries
1    (1.1.1.100, 239.1.1.2) in e3/1 (e3/1), cnt=0
     Sparse Mode, RPT=0 SPT=1 Reg=0 L2Reg=0 RegSupp=0 LSrc=1 LRcv=1
     Source is directly connected. RP 100.2.1.1
     num_oifs = 3
     L3 (HW) 3: e3/15(VL10 VL20 VL30)
     Flags (0x004680a1)
        sm=1 ssm=0 fast=1 slow=0 leaf=0 prun=0 frag=0 tag=1 needRte=0 msdp_adv=1
     age=0 fid: 0x8009  mvid: 0x0000
2    (1.1.1.100, 239.1.1.3) in e3/1 (e3/1), cnt=0
     Sparse Mode, RPT=0 SPT=1 Reg=0 L2Reg=0 RegSupp=0 LSrc=1 LRcv=1
     Source is directly connected. RP 100.2.1.1
     num_oifs = 2
     L3 (HW) 2: e3/15(VL10 VL20)

     age=0 fid: 0x8009  mvid: 0x0001

Total number of mcache entries 2
```

Syntax: show ip pim mcache fid <*fid-id*>

The <*fid-id*> variable allows you to display an entry that matches a specified fid.

Clearing the PIM forwarding cache

You can clear the PIM forwarding cache using the following command.

```
NetIron# clear ip pim cache
```

Syntax: clear ip pim [**vrf** <*vrf-name*>] **cache**

Use the **vrf** option to clear the PIM forwarding cache for a VRF instance specified by the <*vrf-name*> variable.

Displaying PIM traffic statistics

To display PIM traffic statistics, enter the following command at any CLI level.

```
NetIron# show ip pim traffic

Port    Hello           J/P          Register       RegStop          Assert
     [Rx     Tx]    [Rx     Tx]    [Rx     Tx]    [Rx     Tx]    [Rx     Tx]
e3/8   19     19      32     0       0      0       37     0       0      0
v1     18     19      0      20      0      0       0      0       0      0
v2     0      19      0      0       0      16      0      0       0      0

Total 37      57     32      0       0      0       0      0       0      0
IGMP Statistics:
  Total Recv/Xmit 85/110
  Total Discard/chksum  0/0
```

Syntax: show ip pim [**vrf** <*vrf-name*>] **traffic**

The **vrf** option allows you to display the PIM traffic statistics for the VRF instance identified by the <*vrf-name*> variable.

NOTE
If you have configured interfaces for standard PIM (dense mode) on the device, statistics for these interfaces are listed first by the display.

Table 189 describes the output from this command.

TABLE 189 Output from the **show ip pim vrf traffic** command

This field...	Displays...
Port	The port or virtual interface on which the PIM interface is configured.
Hello	The number of PIM Hello messages sent or received on the interface.
J or P	The number of Join or Prune messages sent or received on the interface. **NOTE:** Unlike PIM dense, PIM Sparse uses the same messages for Joins and Prunes.
Register	The number of Register messages sent or received on the interface.
RegStop	The number of Register Stop messages sent or received on the interface.
Assert	The number of Assert messages sent or received on the interface.

TABLE 189 Output from the **show ip pim vrf traffic** command (Continued)

This field...	Displays...
Total Recv or Xmit	The total number of IGMP messages sent and received by the device.
Total Discard or chksum	The total number of IGMP messages discarded, including a separate counter for those that failed the checksum comparison.

Clearing the PIM message counters

You can clear the PIM message counters using the following command.

```
NetIron# clear ip pim traffic
```

Syntax: clear ip pim [**vrf** <*vrf-name*>] **traffic**

Use the **vrf** option to clear the PIM message counters for a VRF instance specified by the <*vrf-name*> variable.

Displaying PIM RPF

The **show ip pim rfp** command displays what PIM sees as the reverse path to the source as shown in the following. While there may be multiple routes back to the source, the one displayed by this command is the one that PIM thinks is best.

```
NetIron# show ip pim vrf eng rpf 130.50.11.10
Source 130.50.11.10 directly connected on e4/1
```

Syntax: show ip pim [**vrf** <*vrf-name*>] **rpf** <*ip-address*>

The <*ip-address*> variable specifies the source address for RPF check.

The **vrf** option to display what PIM sees as the reverse path to the source for a VRF instance specified by the <*vrf-name*> variable.

Displaying PIM counters

You can display the number of default-vlan-id changes that have occurred since the applicable VRF was created, and how many times a tagged port was placed in a VLAN since the applicable VRF was created as shown.

```
NetIron(config)# show ip pim vrf eng counter
Event Callback:
   DFTVlanChange :          2               VlanPort:          13
```

Syntax: show ip pim [**vrf** <*vrf-name*>] **counter**

Table 190 describes the output from this command.

TABLE 190 Output from the **show ip pim vrf counter** command

This field...	Displays...
DFTVlanChange	The number of default-vlan-id changes that have occurred since the applicable VRF was created.
VlanPort	The number of times that a tagged port was placed in a VLAN since the applicable VRF was created.

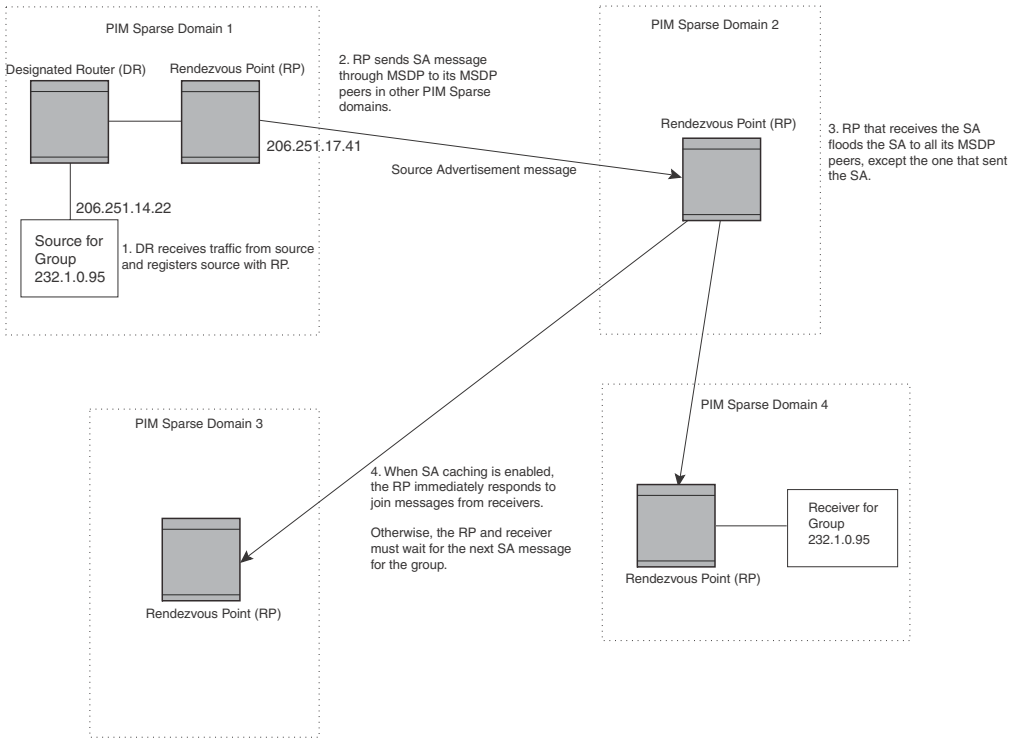
NOTE
Since VLANs are not VRF-aware, any changes to default-vlan or tagged port moves is counted by all VRFs in existence at the time, including the default VRF.

Configuring Multicast Source Discovery Protocol (MSDP)

The Multicast Source Discovery Protocol (MSDP) is used by Protocol Independent Multicast (PIM) Sparse devices to exchange source information across PIM Sparse domains. Devices running MSDP can discover PIM Sparse sources in other PIM Sparse domains.

Figure 157 shows an example of some PIM Sparse domains. For simplicity, this example shows one Designated Router (DR), one group source, and one receiver for the group. Only one PIM Sparse device within each domain needs to run MSDP.

FIGURE 157 PIM Sparse domains joined by MSDP devices



In this example, the source for PIM Sparse multicast group 232.0.1.95 is in PIM Sparse domain 1. The source sends a packet for the group to its directly attached DR. The DR sends a Group Advertisement message for the group to the RP for the domain. The RP is configured for MSDP, which enables the RP to exchange source information with other PIM Sparse domains by communicating with RPs in other domains that are running MSDP.

The RP sends the source information to each peer through a Source Active message. The message contains the IP address of the source, the group address to which the source is sending, and the IP address of the RP.

In this example, the Source Active message contains the following information:

- Source address: 206.251.14.22
- Group address: 232.1.0.95
- RP address: 206.251.17.41

Figure 157 shows only one peer for the MSDP device (which is also the RP here) in domain 1, so the Source Active message goes to only that peer. When an MSDP device has multiple peers, it sends a Source Active message to each of those peers. Each peer sends the Source Advertisement to other MSDP peers. The RP that receives the Source Active message also sends a Join message to the source if the RP that received the message has receivers for the group and source.

Peer Reverse Path Forwarding (RPF) flooding

When the MSDP device (also the RP) in domain 2 receives the Source Active message from the peer in domain 1, the MSDP device in domain 2 forwards the message to all other peers. This propagation process is sometimes called "peer Reverse Path Forwarding (RPF) flooding". In Figure 157, the MSDP device floods the Source Active message it receives from the peer in domain 1 to peers in domains 3 and 4.

The MSDP device in domain 2 does not forward the Source Active back to the peer in domain 1, because that is the peer from which the device received the message. An MSDP device never sends a Source Active message back to the peer that sent it. The peer that sent the message is sometimes called the "RPF peer". The MSDP device uses the unicast routing table for its Exterior Gateway Protocol (EGP) to identify the RPF peer by looking for the route entry that is the next hop toward the source. Often, the EGP protocol is Border Gateway Protocol (BGP) version 4.

NOTE
MSDP depends on BGP and MBGP for inter-domain operations.

The MSDP routers in domains 3 and 4 also forward the Source Active message to all peers except the ones that sent them the message. Figure 157 does not show additional peers.

Source Active caching

When an MSDP device that is also an RP and source receives a Source Active message, the RP and source checks the PIM Sparse multicast group table for receivers for the group. If the DR has a receiver for the group being advertised in the Source Active message, the RP sends a Join message towards that source.

In Figure 157, if the MSDP device and RP in domain 4 has a table entry for the receiver, the RP sends a Join message on behalf of the receiver back through the RPF tree to the source, in this case the source in domain 1.

Source Active caching is enabled in MSDP on Dell devices. The RP caches the Source Active messages it receives even if the RP does not have a receiver for the group. Once a receiver arrives, the RP can then send a Join to the cached source immediately.

The size of the cache used to store MSDP Source Active messages is 32K.

Configuring MSDP

To configure MSDP, perform the following tasks:

- Enable MSDP.
- Configure the MSDP peers.

NOTE
The PIM Sparse Rendezvous Point (RP) is also an MSDP peer.

NOTE
Devices that run MSDP usually also run BGP. The source address used by the MSDP device is normally configured to be the same source address used by BGP.

Enabling MSDP

To enable MSDP, enter the following command.

```
NetIron(config)# router msdp
```

Syntax: [no] router msdp

Enabling MSDP for a specified VRF

The **vrf** parameter allows you to configure MSDP on the virtual routing instance (VRF) specified by the <*vrf-name*> variable. All MSDP parameters available for the default router instance are configurable for a VRF-based MSDP instance.

To enable MSDP for the VRF named “blue”, enter the following commands.

```
NetIron(config)# router msdp vrf blue
NetIron(config-msdp-router-vrf-blue)
```

Syntax: [no] router msdp [vrf <*vrf-name*>]

The **vrf** parameter allows you to configure MSDP on the virtual routing instance (VRF) specified by the <*vrf-name*> variable.

Entering a **no router msdp vrf** command removes the MSDP configuration from the specified VRF only.

Assigning a Route Distinguisher to a VRF

Each instance of a VRF must be assigned a unique Route Distinguisher (RD). The RD is prepended on any address being routed or advertised. The RD can be defined as either ASN-relative or IP address-relative. Since the RD is unique to an instance of a VRF, it allows the same IP address to be used in different VPNs without creating any conflict.

To assign a Route Distinguisher (RD) for a VRF based on the AS number 3 and the arbitrary identification number 6, enter the following command.

```
NetIron(config)# router msdp vrf blue
NetIron(config-msdp-router-vrf-blue)# rd 3:6
NetIron(config-msdp-router-vrf-blue) exit
```

Syntax: [no] rd <*route_distinguisher*>

The <*route_distinguisher*> variable specifies a route distinguisher for a VRF that gives a unique identity to a route associated with the VRF. The RD is prepended on the address being advertised. The RD allows the same IP address to be used in different VPNs without creating any conflicts. It can also be used with the **route-target** command to constrain distribution of routes to or from a VPN. The <*route_distinguisher*> parameter can be either ASN-relative or IP address-relative.

ASN-relative – Composed of the local ASN number followed by a “:” and a unique arbitrary number. For example: 3:6

IP address-relative – Composed of the local IP address followed by a ":" and a unique arbitrary number.

Configuring MSDP peers

To configure an MSDP peer, enter a command such as the following at the MSDP configuration level.

```
NetIron(config-msdp-router)# msdp-peer 205.216.162.1
```

To configure an MSDP peer on a VRF, enter the following commands at the MSDP VRF configuration level.

```
NetIron(config)# router msdp vrf blue
NetIron(config-msdp-router-vrf-blue)# msdp-peer 205.216.162.1
```

Syntax: [**no**] **msdp-peer** <*ip-addr*> [**connect-source loopback** <*num*>]

The <*ip-addr*> parameter specifies the IP address of the neighbor.

The **connect-source loopback** <*num*> parameter specifies the loopback interface you want to use as the source for sessions with the neighbor and must be reachable within the VRF.

NOTE
It is strongly recommended that you use the connect-source loopback <*num*> parameter when issuing the **msdp-peer** command. If you do not use this parameter, the device uses the IP address of the outgoing interface. You should also make sure the IP address of the connect-source loopback is the source IP address used by the PIM-RP, and the BGP device.

The commands in the following example add an MSDP neighbor and specify a loopback interface as the source interface for sessions with the neighbor. By default, the device uses the subnet address configured on the physical interface where you configure the neighbor as the source address for sessions with the neighbor.

```
NetIron(config)# interface loopback 1
NetIron(config-lbif-1)# ip address 9.9.9.9/32
NetIron(config)# router msdp
NetIron(config-msdp-router)# msdp-peer 2.2.2.99 connect-source loopback 1
```

Disabling an MSDP peer

To disable an MSDP peer, enter the following command at the configure MSDP router level.

```
NetIron(config-msdp-router)# msdp-peer 205.216.162.1 shutdown
```

To disable the MSDP VRF peer named "blue", enter the following commands.

```
NetIron(config)# router msdp vrf blue
NetIron(config-msdp-router-vrf-blue)# no msdp-peer 205.216.162.1
```

Syntax: [**no**] **msdp-peer** <*ip-addr*> **shutdown**

The <*ip-addr*> parameter specifies the IP address of the MSDP peer that you want to disable.

Designating the interface IP address as the RP IP address

When an RP receives a Source Active message, it checks its PIM Sparse multicast group table for receivers for the group. If a receiver exists the RP sends a Join to the source.

By default, the IP address included in the RP address field of the SA message is the IP address of the originating RP. An SA message can use the IP address of any interface on the originating RP. (The interface is usually a loopback interface.)

To designate an interface IP address to be the IP address of the RP, enter commands such as the following.

```
NetIron(config)# interface loopback 2
NetIron(config-lbif-2)# ip address 2.2.1.99/32
NetIron(config)# router msdp
NetIron(config-msdp-router)# originator-id loopback 2
NetIron(config-msdp-router)# exit
```

To specify VRF information, enter the following commands at the MSDP VRF configuration level.

```
NetIron(config)# interface loopback 2
NetIron(config-lbif-2)# ip address 2.2.1.99/32
NetIron(config)# router msdp vrf blue
NetIron(config-msdp-router-vrf blue)# originator-id loopback 2
NetIron(config-msdp-router-vrf blue)# exit
```

Syntax: [no] originator-id <*type*> <*number*>

The originator-id parameter instructs MSDP to use the specified interface IP address as the IP address of the RP in an SA message. This address must be the address of the interface used to connect the RP to the source. The default address used is the RP IP address.

The <*type*> parameter indicates the type of interface used by the RP. Ethernet, loopback and virtual routing interfaces (ve) can be used.

The <*number*> parameter specifies the interface number (for example: loopback number, port number or virtual routing interface number.)

Filtering MSDP source-group pairs

You can filter individual source-group pairs in MSDP Source-Active messages:

- sa-filter in – Filters source-group pairs received in Source-Active messages from an MSDP neighbor.
- sa-filter originate – Filters self-originated source-group pairs in outbound Source-Active messages sent to an MSDP neighbor
- sa-filter out – Filters self-originated and forwarded source-group pairs in outbound Source-Active messages sent to an MSDP neighbor

Filtering incoming and outgoing Source-Active messages

The following example configures filters for incoming Source-Active messages from three MSDP neighbors:

- For peer 2.2.2.99, all source-group pairs in Source-Active messages from the neighbor are filtered (dropped).
- For peer 2.2.2.97, all source-group pairs except those with source address matching 10.x.x.x and group address of 235.10.10.1 are permitted.
- For peer 2.2.2.96, all source-group pairs except those associated with RP 2.2.42.3 are permitted.

To configure filters for incoming Source-Active messages, enter commands at the MSDP VRF configuration level.

To configure filters for outbound Source-Active messages, enter the optional out keyword.

Example

The following commands configure extended ACLs. The ACLs will be used in route maps, which will be used by the Source-Active filters.

```
NetIron(config)# access-list 123 permit ip 10.0.0.0 0.255.255.255 host
235.10.10.1
NetIron(config)# access-list 124 permit ip host 2.2.42.3 any
NetIron(config)# access-list 125 permit ip any any
```

The following commands configure the route maps.

```
NetIron(config)# route-map msdp_map deny 1
NetIron(config-routemap msdp_map)# match ip address 123
NetIron(config-routemap msdp_map)# exit
NetIron(config)# route-map msdp_map permit 2
NetIron(config-routemap msdp_map)# match ip address 125
NetIron(config-routemap msdp_map)# exit
NetIron(config)# route-map msdp2_map permit 1
NetIron(config-routemap msdp2_map)# match ip address 125
NetIron(config-routemap msdp2_map)# exit
NetIron(config)# route-map msdp2_rp_map deny 1
NetIron(config-routemap msdp2_rp_map)# match ip route-source 124
NetIron(config-routemap msdp2_rp_map)# exit
NetIron(config)# route-map msdp2_rp_map permit 2
NetIron(config-routemap msdp2_rp_map)# match ip route-source 125
NetIron(config-routemap msdp2_rp_map)# exit
```

To specify VRF information, enter the following commands at the MSDP VRF configuration level.

```
NetIron(config)# router msdp vrf blue
NetIron(config-msdp-router-vrf blue)# sa-filter in 2.2.2.99
NetIron(config-msdp-router-vrf blue)# sa-filter in 2.2.2.97 route-map msdp_map
NetIron(config-msdp-router-vrf blue)# sa-filter in 2.2.2.96 route-map msdp2_map
rp-route-map msdp2_rp_map
```

The **sa-filter** commands configure the following filters:

- **sa-filter in 2.2.2.99** – This command drops all source-group pairs received from neighbor 2.2.2.99.

  NOTE
  The default action is to deny all source-group pairs from the specified neighbor. If you want to permit some pairs, use route maps.

- **sa-filter in 2.2.2.97 route-map msdp_map** – This command drops source-group pairs received from neighbor 2.2.2.97 if the pairs have source addresses matching 10.x.x.x and group address 235.10.10.1.
- **sa-filter in 2.2.2.96 route-map msdp2_map rp-route-map msdp2_rp_map** – This command accepts all source-group pairs except those associated with RP 2.2.42.3.

Syntax: [**no**] **sa-filter in** | **originate** | **out** <*ip-addr*> [**route-map** <*map-tag*>] [**rp-route-map** <*rp-map-tag*>]

Selecting the **in** option applies the filter to incoming Source-Active messages.

Selecting the **originate** option applies the filter to self-originated outbound Source-Active messages.

Selecting the **out** option applies the filter to self-originated and forwarded outbound Source-Active messages.

The <*ip-addr*> parameter specifies the IP address of the MSDP neighbor. The filters apply to Source-Active messages received from or sent to this neighbor.

The **route-map** <*map-tag*> parameter specifies a route map. The device applies the filter to source-group pairs that match the route map. Use the **match ip address** <*acl-id*> command in the route map to specify an extended ACL that contains the source addresses.

The **rp-route-map** <*rp-map-tag*> parameter specifies a route map to use for filtering based on Rendezvous Point (RP) address. Use this parameter if you want to filter Source-Active messages based on their originating RP. Use the **match ip route-source** <*acl-id*> command in the route map to specify an extended ACL that contains the RP address.

NOTE
The default filter action is deny. If you want to permit some source-group pairs, use a route map.

Filtering advertised Source-Active messages

The following example configures the device to advertise all source-group pairs except the ones that have source address 10.x.x.x.

Example

The following commands configure extended ACLs to be used in the route map definition.

```
NetIron(config)# access-list 123 permit ip 10.0.0.0 0.255.255.255 any
NetIron(config)# access-list 125 permit ip any any
```

The following commands use the above ACLs to configure a route map which denies source-group with source address 10.x.x.x and any group address, while permitting everything else.

```
NetIron(config)# route-map msdp_map deny 1
NetIron(config-routemap msdp_map)# match ip address 123
NetIron(config-routemap msdp_map)# exit
NetIron(config)# route-map msdp_map permit 2
NetIron(config-routemap msdp_map)# match ip address 125
NetIron(config-routemap msdp_map)# exit
```

The following commands configure the Source-Active filter.

```
NetIron(config)# router msdp
NetIron(config-msdp-router)# sa-filter originate route-map msdp_map
```

To specify VRF information, enter the following commands at the MSDP VRF configuration level.

```
NetIron(config)# router msdp vrf blue
NetIron(config-msdp-router-vrf blue)# sa-filter originate route-map msdp_map
```

Syntax: [**no**] **sa-filter originate** [**route-map** <*map-tag*>]

The **route-map** <*map-tag*> parameter specifies a route map. The router applies the filter to source-group pairs that match the route map. Use the **match ip address** <*acl-id*> command in the route map to specify an extended ACL that contains the source and group addresses.

NOTE
The default filter action is deny. If you want to permit some source-group pairs, use a route map. A permit action in the route map allows the device to advertise the matching source-group pairs. A deny action in the route map drops the source-group pairs from advertisements.

Displaying MSDP information

You can display the following MSDP information:

- **Summary information** – the IP addresses of the peers, the state of the device MSDP session with each peer, and statistics for keepalive, source active, and notification messages sent to and received from each of the peers
- **VRF Information** – Summary information for a specific VRF
- **Peer information** – the IP address of the peer, along with detailed MSDP and TCP statistics
- **Source Active cache entries** – the source active messages cached by the router.

Displaying summary information

To display summary MSDP information, enter the CLI command.

```
NetIron# show ip msdp vrf blue summary

MSDP Peer Status Summary
 KA: Keepalive SA:Source-Active NOT: Notification
 Peer Address     State          KA          SA          NOT
                              In     Out   In    Out   In   Out
 206.251.17.30    ESTABLISH   3      3     0     640   0     0
 206.251.17.41    ESTABLISH   0      3     651   0     0     0
```

Syntax: show ip msdp summary

Table 191 describes the output from this command.

TABLE 191 MSDP summary information

This field...	Displays...
Peer address	The IP address of the peer interface with the device
State	The state of the MSDP device connection with the peer. The state can be one of the following: • CONNECTING – The session is in the active open state. • ESTABLISHED – The MSDP session is fully up. • INACTIVE – The session is idle. • LISTENING – The session is in the passive open state.
KA In	The number of MSDP keepalive messages the MSDP device has received from the peer
KA Out	The number of MSDP keepalive messages the MSDP device has sent to the peer
SA In	The number of source active messages the MSDP device has received from the peer
SA Out	The number of source active messages the MSDP device has sent to the peer
NOT In	The number of notification messages the MSDP router has received from the peer
NOT Out	The number of notification messages the MSDP router has sent to the peer

Displaying peer information

To display MSDP peer information, enter the following command.

```
NetIron# show ip msdp vrf blue peer

        Total number of MSDP Peers: 2

        IP Address           State
1       206.251.17.30        ESTABLISHED
        Keep Alive Time  Hold Time
        60               90

                             Message Sent         Message Received
        Keep Alive           2                    3
        Notifications        0                    0
        Source-Active        0                    640
        Last Connection Reset Reason:Reason Unknown
        Notification Message Error Code Received:Unspecified
        Notification Message Error SubCode Received:Not Applicable
        Notification Message Error Code Transmitted:Unspecified
        Notification Message Error SubCode Transmitted:Not Applicable
        TCP Connection state: ESTABLISHED
          Local host:  206.251.17.29, Local  Port: 8270
          Remote host: 206.251.17.30, Remote Port: 639
          ISentSeq:      16927  SendNext:     685654  TotUnAck:          0
          SendWnd:       16384  TotSent:      668727  ReTrans:           1
          IRcvSeq:    45252428  RcvNext:    45252438  RcvWnd:        16384
          TotalRcv:         10  RcvQue:            0  SendQue:           0
```

Syntax: show ip msdp peer

Table 192 describes the output from this command.

TABLE 192 MSDP peer information

This field...	Displays...
Total number of MSDP peers	The number of MSDP peers configured on the device
IP Address	The IP address of the peer's interface with the device
State	The state of the MSDP device connection with the peer. The state can be one of the following: • CONNECTING – The session is in the active open state. • ESTABLISHED – The MSDP session is fully up. • INACTIVE – The session is idle. • LISTENING – The session is in the passive open state.
Keep Alive Time	The keepalive time, which specifies how often this MSDP device sends keep alive messages to the neighbor. The keep alive time is 60 seconds and is not configurable.
Hold Time	The hold time, which specifies how many seconds the MSDP device will wait for a KEEPALIVE or UPDATE message from an MSDP neighbor before deciding that the neighbor is dead. The hold time is 90 seconds and is not configurable.
Keep Alive Message Sent	The number of keepalive messages the MSDP device has sent to the peer.

TABLE 192 MSDP peer information (Continued)

This field...	Displays...
Keep Alive Message Received	The number of keepalive messages the MSDP device has received from the peer.
Notifications Sent	The number of notification messages the MSDP device has sent to the peer.
Notifications Received	The number of notification messages the MSDP device has received from the peer.
Source-Active Sent	The number of source active messages the MSDP device has sent to the peer.
Source-Active Received	The number of source active messages the MSDP device has received from the peer.
Last Connection Reset Reason	The reason the previous session with this neighbor ended.
Notification Message Error Code Received	The MSDP device has received a notification message from the neighbor that contains an error code corresponding to one of the following errors. Some errors have subcodes that clarify the reason for the error. Where applicable, the subcode messages are listed underneath the error code messages: • 1 – Message Header Error • 2 – SA-Request Error • 3 – SA-Message or SA-Response Error • 4 – Hold Timer Expired • 5 – Finite State Machine Error • 6 – Notification • 7 – Cease For information about these errors, refer to section 17 in the Internet draft describing MSDP, “draft-ietf-msdp-spec”.
Notification Message Error SubCode Received	See above.
Notification Message Error Code Transmitted	The error message corresponding to the error code in the NOTIFICATION message this MSDP router sent to the neighbor. See the description for the Notification Message Error Code Received field for a list of possible codes.
Notification Message Error SubCode Transmitted	See above.
TCP Statistics	

TABLE 192 MSDP peer information (Continued)

This field...	Displays...
TCP connection state	The state of the connection with the neighbor. Can be one of the following: • LISTEN – Waiting for a connection request. • SYN-SENT – Waiting for a matching connection request after having sent a connection request. • SYN-RECEIVED – Waiting for a confirming connection request acknowledgment after having both received and sent a connection request. • ESTABLISHED – Data can be sent and received over the connection. This is the normal operational state of the connection. • FIN-WAIT-1 – Waiting for a connection termination request from the remote TCP, or an acknowledgment of the connection termination request previously sent. • FIN-WAIT-2 – Waiting for a connection termination request from the remote TCP. • CLOSE-WAIT – Waiting for a connection termination request from the local user. • CLOSING – Waiting for a connection termination request acknowledgment from the remote TCP. • LAST-ACK – Waiting for an acknowledgment of the connection termination request previously sent to the remote TCP (includes an acknowledgment of the connection termination request). • TIME-WAIT – Waiting for enough time to pass to be sure the remote TCP received the acknowledgment of the connection termination request. • CLOSED – There is no connection state.
Local host	The IP address of the MSDP device interface with the peer.
Local port	The TCP port the MSDP router is using for the BGP4 TCP session with the neighbor.
Remote host	The IP address of the neighbor.
Remote port	The TCP port number of the peer end of the connection.
ISentSeq	The initial send sequence number for the session.
SendNext	The next sequence number to be sent.
TotUnAck	The number of sequence numbers sent by the MSDP device that have not been acknowledged by the neighbor.
SendWnd	The size of the send window.
TotSent	The number of sequence numbers sent to the neighbor.
ReTrans	The number of sequence numbers the MSDP device retransmitted because they were not acknowledged.
IRcvSeq	The initial receive sequence number for the session.
RcvNext	The next sequence number expected from the neighbor.
RcvWnd	The size of the receive window.
TotalRcv	The number of sequence numbers received from the neighbor.
RcvQue	The number of sequence numbers in the receive queue.
SendQue	The number of sequence numbers in the send queue.

Displaying Source Active cache information

To display the Source Actives in the MSDP cache, use the following command.

```
NetIron# show ip msdp vrf blue sa-cache
Total of 10 SA cache entries
Index  RP address       (Source, Group)                    Orig Peer        Age
1      2.2.2.2          (192.6.1.10, 227.1.1.1)            192.1.1.2        0
2      2.2.2.2          (192.6.1.10, 227.1.1.2)            192.1.1.2        0
3      2.2.2.2          (192.6.1.10, 227.1.1.3)            192.1.1.2        0
4      2.2.2.2          (192.6.1.10, 227.1.1.4)            192.1.1.2        0
5      2.2.2.2          (192.6.1.10, 227.1.1.5)            192.1.1.2        0
6      2.2.2.2          (192.6.1.10, 227.1.1.6)            192.1.1.2        0
7      2.2.2.2          (192.6.1.10, 227.1.1.7)            192.1.1.2        0
8      2.2.2.2          (192.6.1.10, 227.1.1.8)            192.1.1.2        0
9      2.2.2.2          (192.6.1.10, 227.1.1.9)            192.1.1.2        0
10     2.2.2.2          (192.6.1.10, 227.1.1.10)           192.1.1.2        0
```

Syntax: show ip msdp sa-cache

Table 193 describes the output from this command.

TABLE 193 MSDP source active cache

This field...	Displays...
Total	The number of entries the cache currently contains.
Index	The cache entry number.
RP	The RP through which receivers can access the group traffic from the source
SourceAddr	The IP address of the multicast source.
GroupAddr	The IP multicast group to which the source is sending information.
Orig Peer	The peer from which this source-active entry was received.
Age	The number of seconds the entry has been in the cache

Clearing MSDP information

You can clear the following MSDP information:

- Peer information
- Source active cache
- MSDP statistics

Clearing peer information

To clear MSDP peer information, enter the following command at the Privileged EXEC level of the CLI.

```
NetIron# clear ip msdp peer 205.216.162.1
```

Syntax: clear ip msdp peer <*ip-addr*>

The command in this example clears the MSDP peer connection with MSDP router 205.216.162.1. The CLI displays a message to indicate when the connection has been successfully closed. To clear all the peers, omit the <*ip-addr*> variable from the command.

Clearing peer information on a VRF

To clear the MSDP VRF peers, enter the following command at the MSDP VRF configuration level.

```
NetIron#clear ip msdp vrf blue peer 207.207.162.5
```

Clearing the source active cache

To clear the source active cache, enter the following command at the Privileged EXEC level of the CLI.

```
NetIron# clear ip msdp sa-cache
```

Syntax: clear ip msdp sa-cache <*ip-addr*>

The command in this example clears all the cache entries. Use the <*ip-addr*> variable to clear only the entries matching either a source or a group.

Clearing the source active cache for a VRF

To clear the MSDP VRF source active cache by entering the following command at the MSDP VRF configuration level.

```
NetIron#clear ip msdp sa-cache vrf blue
```

Syntax: clear ip msdp sa-cache [**vrf**<*vrf-name*>] [<*ip-addr*>]

Clearing MSDP statistics

To clear MSDP statistics, enter the following command at the Privileged EXEC level of the CLI.

```
NetIron# clear ip msdp statistics
```

Syntax: clear ip msdp statistics <*ip-addr*>

The command in this example clears statistics for all the peers. To clear statistics for only a specific peer, enter the IP address of the peer.

Clearing MSDP VRF statistics

To clear the MSDP VRF statistics by entering the following command.

```
NetIron# clear ip msdp vrf blue statistics
```

Syntax: clear ip msdp statistics [**vrf**<*vrf-name*>] [<*ip-addr*>]

The command in this example clears statistics for all the peers. To clear statistics for only a specific peer, enter the IP address of the peer.

The command in this example clears all statistics for all the peers in the VRF “blue.”.

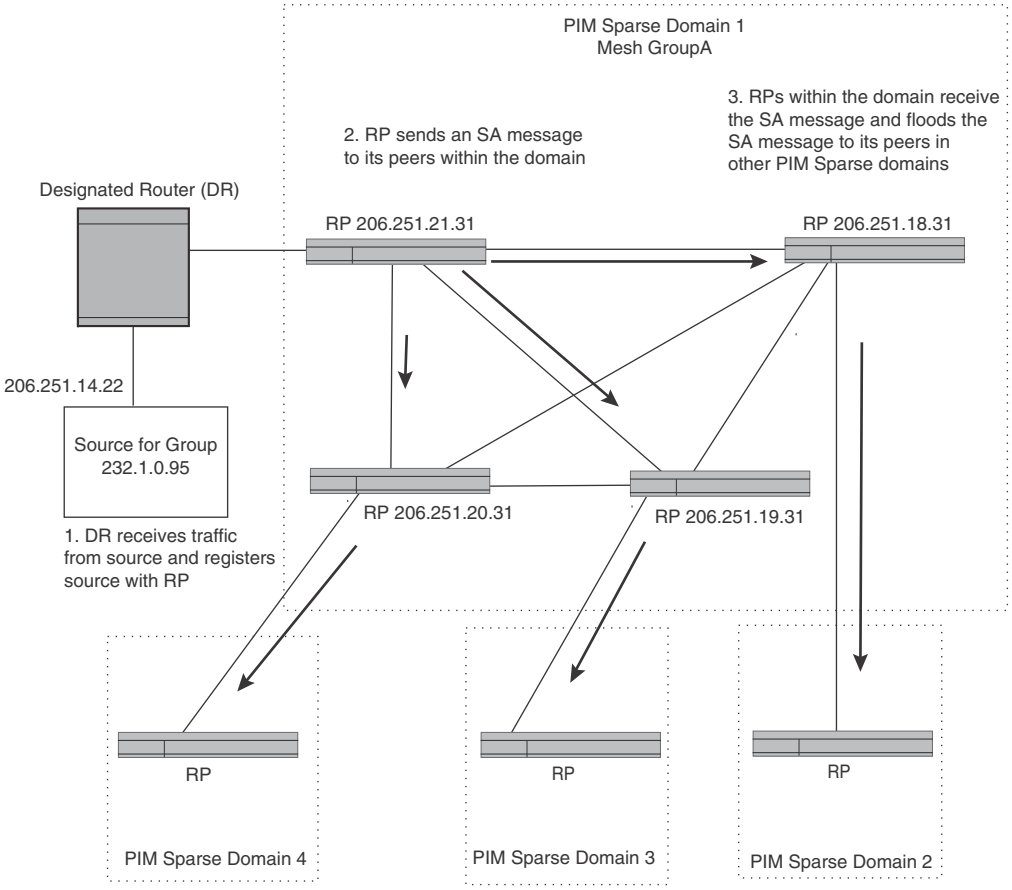
Configuring MSDP mesh groups

A PIM Sparse domain can have several RPs that are connected to each other to form an MSDP mesh group. To qualify as a mesh group, the RPs have to be fully meshed; that is, each RP must be connected to all peer RPs in a domain. (Refer to Figure 158.)

A mesh group reduces the forwarding of SA messages within a domain. Instead of having every RP in a domain forward SA messages to all the RPs within that domain, only one RP forwards the SA message. Since an MSDP mesh group is fully meshed, peers do not forward SA messages received in a domain from one member to any member of the group. The RP that originated the SA or the first RP in a domain that receives the SA message is the only one that forwards the message to the members of a mesh group. An RP can forward an SA message to any MSDP router as long as that peer is farther away from the originating RP than the current MSDP router.

Figure 158 shows an example of an MSDP mesh group. In a PIM-SM mesh group the RPs are configured to be peers of each other. They can also be peers of RPs in other domains.

FIGURE 158 Example of MSDP mesh group



PIM Sparse Domain 1 in Figure 158 contains a mesh group with four RPs. When the first RP, for example, RP 206.251.21.31 originates or receives an SA message from a peer in another domain, it sends the SA message to its peers within the mesh group. However, the peers do not send the message back to the originator RP or to each other. The RPs then send the SA message farther away to their peers in other domains.The process continues until all RPs within the network receive the SA message.

Configuring MSDP mesh group

To configure an MSDP mesh group, enter commands such as the following on each device that will be included in the mesh group.

```
NetIron(config)# router msdp
NetIron(config-msdp-router)# msdp-peer 206.251.18.31 connect-source loopback 2
NetIron(config-msdp-router)# msdp-peer 206.251.19.31 connect-source loopback 2
NetIron(config-msdp-router)# msdp-peer 206.251.20.31 connect-source loopback 2
NetIron(config-msdp-router)# mesh-group GroupA 206.251.18.31
NetIron(config-msdp-router)# mesh-group GroupA 206.251.19.31
NetIron(config-msdp-router)# mesh-group GroupA 206.251.20.31
NetIron(config-msdp-router)# exit
```

Syntax: [no] mesh-group <*group-name*> <*peer-address*>

The sample configuration above reflects the configuration in Figure 158. On RP 206.251.21.31 you specify its peers within the same domain (206.251.18.31, 206.251.19.31, and 206.251.20.31).

You first configure the MSDP peers using the **msdp-peer** command to assign their IP addresses and the loopback interfaces.

Next, place the MSDP peers within a domain into a mesh group. Use the **mesh-group** command. There are no default mesh groups.

The **group-name** parameter identifies the mesh group. Enter up to 31 characters for group-name. You can have up to 4 mesh groups within a multicast network. Each mesh group can include up to 15 peers.

The **peer-address** parameter specifies the IP address of the MSDP peer that is being placed in the mesh group.

NOTE
On each of the device that will be part of the mesh group, there must be a mesh group definition for all the peers in the mesh-group.

A maximum of 15 MSDP peers can be configured per mesh group.

MSDP Anycast RP

MSDP Anycast RP is a method of providing intra-domain redundancy and load-balancing between multiple Rendezvous Points (RP) in a Protocol Independent Multicast Sparse mode (PIM-SM) network. It is accomplished by configuring all RPs within a domain with the same anycast RP address which is typically a loopback IP address. Multicast Source Discovery Protocol (MSDP) is used between all of the RPs in a mesh configuration to keep all RPs in sync regarding the active sources.

PIM-SM routers are configured to register (statically or dynamically) with the RP using the same anycast RP address. Since multiple RPs have the same anycast address, an Interior Gateway Protocol (IGP) such as OSPF routes the PIM-SM router to the RP with the best route. If the PIM-SM routers are distributed evenly throughout the domain, the loads on RPs within the domain will be distributed. If the RP with the best route goes out of service, the PIM-SM router's IGP changes the route to the closest operating RP that has the same anycast address.

This configuration works because MSDP is configured between all of the RPs in the domain. Consequently, all of the RPs share information about active sources.

This feature uses functionality that is already available on the PowerConnect Router but re-purposes it to provide the benefits desired as described in RFC 3446.

Configuring MSDP Anycast RP

To configure MSDP Anycast RP, you must perform the following tasks:

- Configure a loopback interface with the anycast RP address on each of the RPs within the domain and enable PIM-SM on these interfaces.
- Ensure that the anycast RP address is leaked into the IGP domain. This is typically done by enabling the IGP on the loopback interface (in passive mode) or redistributing the connected loopback IP address into the IGP.

NOTE
The anycast RP address *must* not be the IGP router-id.

- Enable PIM-SM on all interfaces on which multicast routing is desired.
- Enable an IGP on each of the loopback interfaces and physical interfaces configured for PIM-SM.
- Configure loopback interfaces with unique IP addresses on each of the RPs for MSDP peering. This loopback interface is also used as the MSDP originator-id.
- The non-RP PIM-SM routers may be configured to use the anycast RP address statically or dynamically (by the PIMv2 bootstrap mechanism).

Example

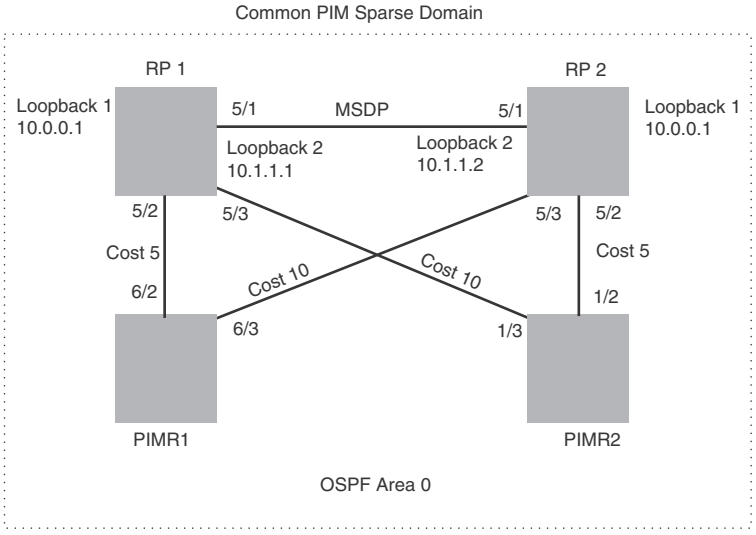
The example shown in Figure 159 is a simple MSDP Anycast-enabled network with two RPs and two PIM-SM routers. Loopback 1 in RP 1 and RP 2 have the same IP address. Loopback 2 in RP1 and Loopback 2 in RP2 have different IP addresses and are configured as MSDP peering IP addresses in a mesh configuration.

In the PIM configuration for PIM-SM routers PIMR1 and PIMR2 the RP address is configured to be the anycast RP address that was configured on the Loopback 1 interfaces on RP1 and RP2. OSPF is configured as the IGP for the network and all of the devices are in OSPF area 0.

Since PIMR1 has a lower cost path to RP1 and PIMR2 has a lower cost path to RP2 they will register with the respective RPs when both are up and running. This shares the load between the two RPs. If one of the RPs fails, the higher-cost path to the IP address of Loopback 1 on the RPs is used to route to the still-active RP.

The configuration examples demonstrate the commands required to enable this application.

FIGURE 159 Example of a MDSP Anycast RP network



RP 1 configuration

The following commands provide the configuration for the RP 1 router in Figure 159.

```
RP1(config)#router ospf
RP1(config-ospf-router)# area 0
RP1(config-ospf-router)# exit
RP1(config)# interface loopback 1
RP1(config-lbif-1)# ip ospf area 0
RP1(config-lbif-1)# ip ospf passive
RP1(config-lbif-1)# ip address 10.0.0.1/32
RP1(config-lbif-1)# ip pim-sparse
RP1(config-lbif-1)# exit
RP1(config)# interface loopback 2
RP1(config-lbif-2)# ip ospf area 0
RP1(config-lbif-2)# ip ospf passive
RP1(config-lbif-2)# ip address 10.1.1.1/32
RP1(config-lbif-2)# exit
RP1(config)# interface ethernet 5/1
RP1(config-if-e1000-5/1)# ip ospf area 0
RP1(config-if-e1000-5/1)# ip address 192.1.1.1/24
RP1(config-if-e1000-5/1)# ip pim-sparse
RP1(config)# interface ethernet 5/2
RP1(config-if-e1000-5/2)# ip ospf area 0
RP1(config-if-e1000-5/2)# ip ospf cost 5
RP1(config-if-e1000-5/2)# ip address 192.2.1.1/24
RP1(config-if-e1000-5/2)# ip pim-sparse
RP1(config)# interface ethernet 5/3
RP1(config-if-e1000-5/3)# ip ospf area 0
RP1(config-if-e1000-5/3)# ip ospf cost 10
RP1(config-if-e1000-5/3)# ip address 192.3.1.1/24
RP1(config-if-e1000-5/3)# ip pim-sparse
RP1(config-if-e1000-5/3)# exit
RP1(config)# router pim
RP1(config-pim-router)# rp-candidate loopback 1
RP1(config-pim-router)# exit
RP1(config)# router msdp
RP1(config-msdp-router)# msdp-peer 10.1.1.2 connect-source loopback 2
RP1(config-msdp-router)# originator-id loopback 2
```

RP 2 configuration

The following commands provide the configuration for the RP 2 router in Figure 159.

```
RP2(config)#router ospf
RP2(config-ospf-router)# area 0
RP2(config-ospf-router)# exit
RP2(config)# interface loopback 1
RP2(config-lbif-1)# ip ospf area 0
RP2(config-lbif-1)# ip ospf passive
RP2(config-lbif-1)# ip address 10.0.0.1/32
RP2(config-lbif-1)# ip pim-sparse
RP2(config-lbif-1)# exit
RP2(config)# interface loopback 2
RP2(config-lbif-2)# ip ospf area 0
RP2(config-lbif-2)# ip ospf passive
RP2(config-lbif-2)# ip address 10.1.1.2/32
RP2(config-lbif-2)# exit
RP2(config)# interface ethernet 5/1
RP2(config-if-e1000-5/1)# ip ospf area 0
RP2(config-if-e1000-5/1)# ip address 192.1.1.2/24
RP2(config-if-e1000-5/1)# ip pim-sparse
RP2(config)# interface ethernet 5/2
RP2(config-if-e1000-5/2)# ip ospf area 0
RP2(config-if-e1000-5/2)# ip ospf cost 5
RP2(config-if-e1000-5/2)# ip address 192.5.2.1/24
RP2(config-if-e1000-5/2)# ip pim-sparse
RP2(config)# interface ethernet 5/3
RP2(config-if-e1000-5/3)# ip ospf area 0
RP2(config-if-e1000-5/3)# ip ospf cost 10
RP2(config-if-e1000-5/3)# ip address 192.6.1.2/24
RP2(config-if-e1000-5/3)# ip pim-sparse
RP2(config-if-e1000-5/3)# exit
RP2(config)# router pim
RP2(config-pim-router)# rp-candidate loopback 1
RP2(config-pim-router)# exit
RP2(config)# router msdp
RP2(config-msdp-router)# msdp-peer 10.1.1.1 connect-source loopback 2
RP2(config-msdp-router)# originator-id loopback 2
```

PIMR1 configuration

The following commands provide the configuration for the PIMR1 router in Figure 159.

```
PIMR1(config)#router ospf
PIMR1(config-ospf-router)# area 0
PIMR1(config-ospf-router)# exit
PIMR1(config)# interface ethernet 6/2
PIMR1(config-if-e1000-6/2)# ip ospf area 0
PIMR1(config-if-e1000-6/2)# ip ospf cost 5
PIMR1(config-if-e1000-6/2)# ip address 192.2.1.2/24
PIMR1(config-if-e1000-6/2)# ip pim-sparse
PIMR1(config)# interface ethernet 6/3
PIMR1(config-if-e1000-6/3)# ip ospf area 0
PIMR1(config-if-e1000-6/3)# ip ospf cost 10
PIMR1(config-if-e1000-6/3)# ip address 192.6.1.1/24
PIMR1(config-if-e1000-6/3)# ip pim-sparse
PIMR1(config-if-e1000-6/3)# exit
```

```
PIMR1(config)# router pim
PIMR1(config-pim-router)# rp-address 10.0.0.1
PIMR1(config-pim-router)# exit
```

PIMR2 configuration

The following commands provide the configuration for the PIMR2 router in Figure 159.

```
PIMR2(config)#router ospf
PIMR2(config-ospf-router)# area 0
PIMR2(config-ospf-router)# exit
PIMR2(config)# interface ethernet 1/2
PIMR2(config-if-e1000-1/2)# ip ospf area 0
PIMR2(config-if-e1000-1/2)# ip ospf cost 5
PIMR2(config-if-e1000-1/2)# ip address 192.5.2.2/24
PIMR2(config-if-e1000-1/2)# ip pim-sparse
PIMR2(config)# interface ethernet 1/3
PIMR2(config-if-e1000-1/3)# ip ospf area 0
PIMR2(config-if-e1000-1/3)# ip ospf cost 10
PIMR2(config-if-e1000-1/3)# ip address 192.3.1.2/24
PIMR2(config-if-e1000-1/3)# ip pim-sparse
PIMR2(config-if-e1000-1/3)# exit
PIMR2(config)# router pim
PIMR2(config-pim-router)# rp-address 10.0.0.1
PIMR2(config-pim-router)# exit
```

PIM Anycast RP

PIM Anycast RP is a method of providing load balancing and fast convergence to PIM RPs in an IPv4 multicast domain. The RP address of the Anycast RP is a shared address used among multiple PIM routers, known as PIM RP. The PIM RP routers create an Anycast RP set. Each router in the Anycast RP set is configured using two IP addresses; a shared RP address in their loopback address and a separate, unique ip address. The loopback address must be reachable by all PIM routers in the multicast domain. The separate, unique ip address is configured to establish static peering with other PIM routers and communication with the peers.

When the source is activated in a PIM Anycast RP domain, the PIM First Hop (FH) will register the source to the closet PIM RP. The PIM RP follows the same MSDP Anycast RP operation by decapsulating the packet and creating the (s,g) state. If there are external peers in the Anycast RP set, the router will re-encapsulate the packet with the local peering address as the source address of the encapsulation. The router will unicast the packet to all Anycast RP peers. The re-encapsulation of the data register packet to Anycast RP peers ensures source state distribution to all RPs in a multicast domain.

Configuring PIM Anycast RP

A new PIM CLI is introduced for PIM Anycast RP under the router pim sub mode. The PIM CLI specifies mapping of the RP and the Anycast RP peers.

To configure PIM Anycast RP, enter the following command.

```
NetIron(config)#router pim
NetIron(config-pim-router)#rp-address 100.1.1.1
NetIron(config-pim-router)#anycast-rp 100.1.1.1 my-anycast-rp-set-acl
```

Syntax: [no] anycast-rp <*rp-address*> <*anycast-rp-set-acl*>

The <*rp address*> parameter specifies a shared RP address used among multiple PIM routers.

The <*anycast-rp-set-acl*> parameter specifies a host based simple acl used to specifies the address of the Anycast RP set, including a local address.

The following example is a configuration of PIM Anycast RP 100.1.1.1.The example avoids using loopback 1 interface when configuring PIM Anycast RP because the loopback 1 address could be used as a router-id. A PIM First Hop router will register the source with the closest RP. The first RP that receives the register will re-encapsulate the register to all other Anycast RP peers. Please refer to Figure 160 as described in the configuration of PIM Anycast RP 100.1.1.1.

```
NetIron(config)#interface loopback 2
NetIron(config-lbif-2)#ip address 100.1.1.1/24
NetIron(config-lbif-2)#ip pim-sparse
NetIron(config-lbif-2)#interface loopback 3
NetIron(config-lbif-3)#ip address 1.1.1.1/24
NetIron(config-lbif-3)#ip pim-sparse
NetIron(config-lbif-3)#router pim
NetIron(config-pim-router)#rp-address 100.1.1.1
NetIron(config-pim-router)#anycast-rp 100.1.1.1 my-anycast-rp-set
NetIron(config-pim-router)#ip access-list standard my-anycast-rp-set
NetIron(config-std-nacl)#permit host 1.1.1.1
NetIron(config-std-nacl)#permit host 2.2.2.2
NetIron(config-std-nacl)#permit host 3.3.3.3
```

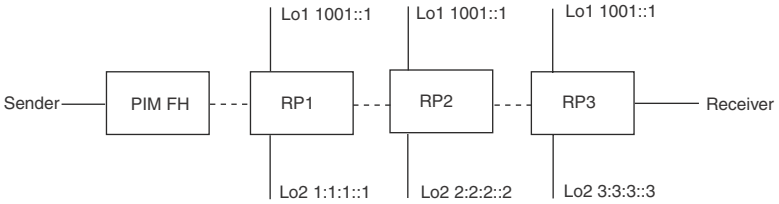
The RP shared address 100.1.1.1 is used in the PIM domain. IP addresses 1.1.1.1, 2.2.2.2, and 3.3.3.3 are listed in the ACL that forms the self inclusive Anycast RP set. Multiple anycast-rp instances can be configured on a system; each peer with the same or different Anycast RP set.

NOTE
The PIM Anycast CLI applies to only PIM routers running RP. All deny statements in the anycast_rp_set acl are ignored.

Example

The example shown in Figure 160 is a PIM Anycast-enabled network with 3 RPs, 1 PIM-FH router connecting to its active source and local receiver. Loopback 2 in RP1, RP2, and RP3 have the same IP addresses 100.1.1.1. Loopback 3 in RP1, RP2, and RP3 each have separate IP addresses configured to communicate with their peers in the Anycast RP set.

FIGURE 160 Example of a PIM Anycast RP network



Displaying information for a PIM Anycast RP interface

To display information for a PIM Anycast RP interface, enter the following command.

```
NetIron(config)#show ip pim anycast-rp
Number of Anycast RP: 1
Anycast RP: 100.1.1.1
  ACL ID: 200
  ACL Name: my-anycast-rp-set
  ACL Filter: SET
  Peer List:
    1.1.1.1
    2.2.2.2
    3.3.3.3
```

Syntax: show ip pim <*anycast-rp*>

The following table describes the parameters of the **show ip pim anycast-rp** command:

TABLE 194 Display of show ip pim-anycast-rp

This field...	Displays...
Number of Anycast RP:	The Number of Anycast RP specifies the number of Anycast RP sets in the multicast domain.
Anycast RP:	The Anycast RP address specifies a shared RP address used among multiple PIM routers.
ACL ID:	The ACL ID specifies the ACL ID assigned.
ACL Name	The ACL Name specifies the name of the Anycast RP set.
ACL Filter	The ACL Filter specifies the ACL filter state SET or UNSET.
Peer List	The Peer List specifies host addresses that are permitted in the Anycast RP set.

NOTE
MSDP and Anycast RP do not interoperate. If transitioning from MSDP to Anycast RP or vice versa, all RPs in the network must be configured for the same method of RP peering; either Anycast RP or MSDP.

DVMRP overview

The PowerConnect provides multicast routing with the Distance Vector Multicast Routing Protocol (DVMRP) routing protocol. DVMRP uses IGMP to manage the IP multicast groups.

DVMRP is a broadcast and pruning multicast protocol that delivers IP multicast datagrams to its intended receivers. The receiver registers the interested groups using IGMP. DVMRP builds a multicast delivery tree with the sender forming the root. Initially, multicast datagrams are delivered to all nodes on the tree. Those leaves that do not have any group members send ***prune messages*** to the upstream router, noting the absence of a group. The upstream router maintains a prune state for this group for the given sender. A prune state is aged out after a given configurable interval, allowing multicasts to resume.

DVMRP employs ***reverse path forwarding*** and ***pruning*** to keep source specific multicast delivery trees with the minimum number of branches required to reach all group members. DVMRP builds a multicast tree for each source and destination host group.

Initiating DVMRP multicasts on a network

Once DVMRP is enabled on each router, a network user can begin a video conference multicast from the server on R1. ***Multicast Delivery Trees*** are initially formed by source-originated multicast packets that are propagated to downstream interfaces as seen in Figure 161. When a multicast packet is received on a DVMRP-capable router interface, the interface checks its DVMRP routing table to determine whether the interface that received the message provides the shortest path back to the source. If the interface does provide the shortest path, the interface forwards the multicast packet to adjacent peer DVMRP routers, except for the router interface that originated the packet. Otherwise, the interface discards the multicast packet and sends a prune message back upstream. This process is known as ***reverse path forwarding***.

In Figure 161, the root node (R1) is forwarding multicast packets for group 229.225.0.2 that it receives from the server to its downstream nodes, R2, R3, and R4. Router R4 is an intermediate router with R5 and R6 as its downstream routers. Because R5 and R6 have no downstream interfaces, they are leaf nodes.

The receivers in this example are those workstations that are resident on routers R2, R3, and R6.

Pruning a multicast tree

After the multicast tree is constructed, ***pruning*** of the tree will occur after IP multicast packets begin to traverse the tree.

As multicast packets reach leaf networks (subnets with no downstream interfaces), the local IGMP database checks for the recently arrived IP multicast packet address. If the local database does not contain the address (the address has not been learned), the router prunes (removes) the address from the multicast tree and no longer receives multicasts until the prune age expires.

In Figure 162, Router 5 is a leaf node with no group members in its local database. Consequently, Router 5 sends a prune message to its upstream router. This router will not receive any further multicast traffic until the prune age interval expires.

FIGURE 161 Downstream broadcast of IP multicast packets from source host

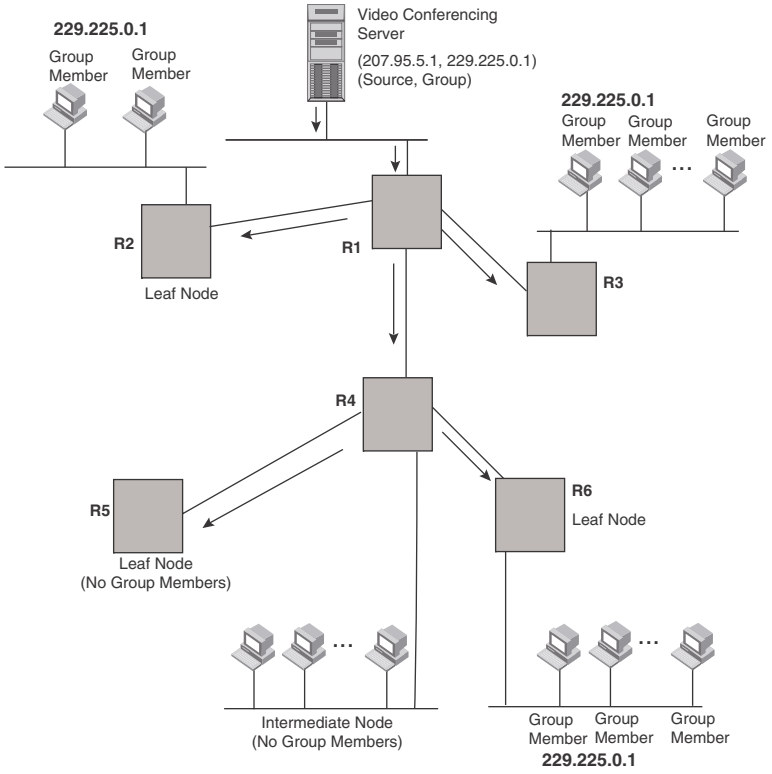


FIGURE 162 Pruning leaf nodes from a multicast tree

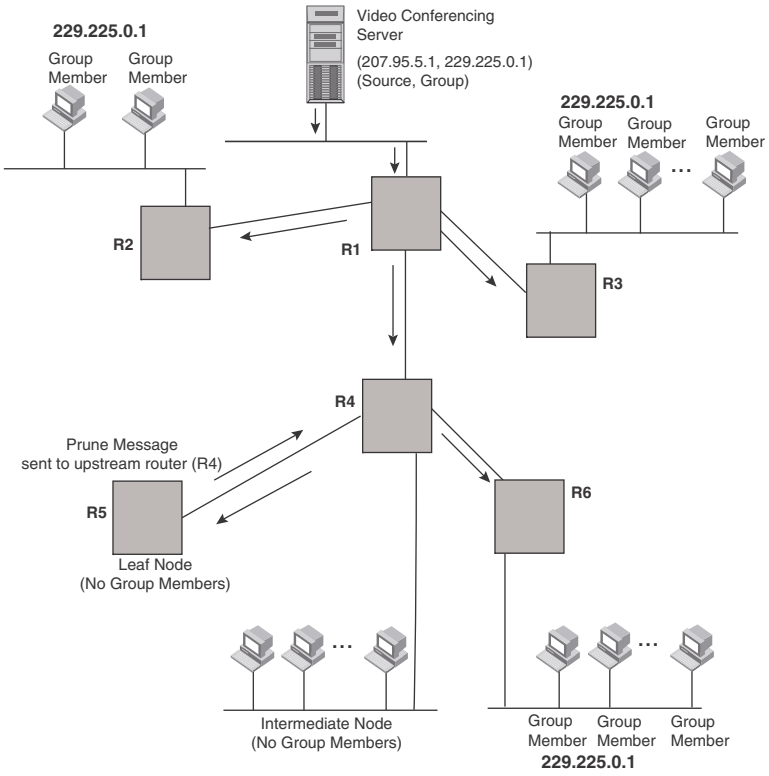


Grafts to a multicast tree

A DVMRP router restores pruned branches to a multicast tree by sending graft messages towards the upstream router. Graft messages start at the leaf node and travel up the tree, first sending the message to its neighbor upstream router.

In the example above, if a new 229.255.0.1 group member joins on router R6, which had been pruned previously, a graft will be sent upstream to R4. Since the forwarding state for this entry is in a prune state, R4 sends a graft to R1. Once R4 has joined the tree, it along with R6 will once again receive multicast packets.

You do not need to perform any configuration to maintain the multicast delivery tree. The prune and graft messages automatically maintain the tree.

Configuring DVMRP

Enabling DVMRP globally and on an interface

Suppose you want to initiate the use of desktop video for fellow users on a sprawling campus network. All destination workstations have the appropriate hardware and software but the device's that connect the various buildings need to be configured to support DVMRP multicasts from the designated video conference server as seen in Figure 161.

DVMRP is enabled on each of the PowerConnect devices, shown in Figure 161, on which multicasts are expected. You can enable DVMRP on each PowerConnect independently or remotely from one PowerConnect by a Telnet connection. Follow the same steps for each router.

Globally enabling and disabling DVMRP

To globally enable DVMRP, enter the following command.

```
NetIron(config)# router dvmrp
NetIron(config-dvmrp-router)#
```

Syntax: [no] router dvmrp

- Entering a **router dvmrp** command to enable DVMRP does not require a software reload.
- Entering a **no router dvmrp** command removes all DVMRP configurations on a PowerConnect (**router dvmrp** level) only.

Enabling DVMRP for a specified VRF

To enable DVMRP for the VRF named "blue", use the following commands.

```
NetIron(config)# router dvmrp vrf blue
```

Syntax: [no] router dvmrp [vrf <*vrf-name*>]

The **vrf** parameter allows you to configure DVMRP on the virtual routing instance (VRF) specified by the <*vrf-name*> variable. All DVMRP parameters available for the default router instance are configurable for a VRF-based DVMRP instance:

- Entering a **router dvmrp vrf** command to enable DVMRP does not require a software reload.

- Entering a **no router dvmrp vrf** command removes the DVMRP configuration from the specified VRF only.

Enabling DVMRP on an interface

After globally enabling DVMRP on a PowerConnect, enable it on each interface that will support the protocol.

To enable DVMRP on Router 1 and interface 3, enter the following.

```
NetIron(config)# int e 3/1
NetIron(config-if-e10000-3/1)# ip dvmrp
```

Modifying DVMRP global parameters

DVMRP global parameters come with preset values. The defaults work well in most networks, but you can modify the following global parameters if you need to:

- Neighbor timeout
- Route expire time
- Route discard time
- Prune age
- Graft retransmit time
- Probe interval
- Report interval
- Trigger interval
- Default route

Modifying neighbor timeout

The neighbor timeout specifies the period of time that a router will wait before it defines an attached DVMRP neighbor router as down. Possible values are 60 – 8000 seconds. The default value is 180 seconds.

To modify the neighbor timeout value to 100, enter the following.

```
NetIron(config-dvmrp-router)# nbr 100
```

Syntax: [no] nbr-timeout <*40-8000*>

The default is 180 seconds.

Modifying route expires time

The Route Expire Time defines how long a route is considered valid in the absence of the next route update. Possible values are from 20 – 4000 seconds. The default value is 200 seconds.

To modify the route expire setting to 50, enter the following.

```
NetIron(config-dvmrp-router)# route-expire-timeout 50
```

Syntax: [no] route-expire-timeout <*60-4000*>

Modifying route discard time

The Route Discard Time defines the period of time before a route is deleted. Possible values are from 40 – 8000 seconds. The default value is 340 seconds.

To modify the route discard setting to 150, enter the following.

```
NetIron(config-dvmrp-router)# route-discard-timeout 150
```

Syntax: [no] route-discard-timeout <*40-8000*>

Modifying prune age

The Prune Age defines how long a prune state will remain in effect for a source-routed multicast tree. After the prune age period expires, flooding will resume. Possible values are from 20 – 3600 seconds. The default value is 180 seconds.

To modify the prune age setting to 150, enter the following.

```
NetIron(config-dvmrp-router)# prune 25
```

Syntax: [no] prune-age <*20-3600*>

Modifying graft retransmit time

The Graft Retransmit Time defines the initial period of time that a router sending a graft message will wait for a graft acknowledgement from an upstream router before re-transmitting that message.

Subsequent retransmissions are sent at an interval twice that of the preceding interval. Possible values are from
5 – 3600 seconds. The default value is 10 seconds.

To modify the setting for graft retransmit time to 120, enter the following.

```
NetIron(config-dvmrp-router)# graft 120
```

Syntax: [no] graft-retransmit-time <*5-3600*>

Modifying probe interval

The Probe Interval defines how often neighbor probe messages are sent to the ALL-DVMRP-ROUTERS IP multicast group address. A router's probe message lists those neighbor DVMRP routers from which it has received probes. Possible values are from 5 – 30 seconds. The default value is 10 seconds.

To modify the probe interval setting to 10, enter the following.

```
NetIron(config-dvmrp-router)# probe 10
```

Syntax: [no] probe-interval <*5-30*>

Modifying report interval

The Report Interval defines how often routers propagate their complete routing tables to other neighbor DVMRP routers. Possible values are from 10 – 2000 seconds. The default value is 60 seconds.

To support propagation of DVMRP routing information to the network every 90 seconds, enter the following.

```
NetIron(config-dvmrp-router)# report 90
```

Syntax: [no] report-interval <*10-2000*>

Modifying trigger interval

The Trigger Interval defines how often trigger updates, which reflect changes in the network topology, are sent. Example changes in a network topology include router up or down or changes in the metric. Possible values are from 5 – 30 seconds. The default value is 5 seconds.

To support the sending of trigger updates every 20 seconds, enter the following.

```
NetIron(config-dvmrp-router)# trigger-interval 20
```

Syntax: [no] trigger-interval <*5-30*>

Modifying default route

This defines the default gateway for IP multicast routing.

To define the default gateway for DVMRP, enter the following.

```
NetIron(config-dvmrp-router)# default-gateway 192.35.4.1
```

Syntax: [no] default-gateway <*ip-addr*>

Modifying DVMRP interface parameters

DVMRP global parameters come with preset values. The defaults work well in most networks, but you can modify the following interface parameters if you need to:

- TTL Threshold
- Metric
- Advertising

Modifying the TTL threshold

The TTL defines the minimum value required in a packet in order for the packet to be forwarded out the interface. For example, if the TTL for an interface is set at 10 it means that only those packets with a TTL value of 10 or more are forwarded. Likewise, if an interface is configured with a TTL Threshold value of 1, all packets received on that interface are forwarded. Possible values are from 1 – 64. The default value is 1.

To set a TTL of 64, enter the following.

```
NetIron(config)# int e 1/4
NetIron(config-if-e10000-1/4)# ip dvmrp ttl-threshold 60
```

Syntax: [no] ip dvmrp ttl-threshold <*1-64*>

Modifying the metric

The router uses the metric when establishing reverse paths to some networks on directly attached interfaces. Possible values are from 1 – 31 hops. The default is 1.

To set a metric of 15 for a DVMRP interface, enter the following.

```
NetIron(config)# interface e 3/5
NetIron(config-if-e10000-3/5)# ip dvmrp metric 15
```

Syntax: [no] ip dvmrp metric <*1-31*>

Disabling advertising

You can disable the advertisement of a local route on the interface. By default, advertising is enabled.

To disable advertising on an interface, enter the following.

```
NetIron(config-if-e10000-1/4)# ip dvmrp advertise-local off
```

Syntax: [no] ip dvmrp advertise-local off

Use the **no** option with this command to re-enable advertising.

Displaying DVMRP information

You can display the following DVMRP information:

- DVMRP group information
- DVMRP interface information
- DVMRP multicast cache information
- DVMRP neighbor information
- DVMRP active prune information
- Available multicast resources
- IP multicast route information
- Active multicast traffic information

Displaying DVMRP group information

To display DVMRP group information, enter the following command.

```
NetIron# show ip dvmrp group
Total number of groups: 2
1    Group 225.1.1.1           Ports
     Group member at  e2/3: v30
2    Group 226.1.1.1           Ports
     Group member at  e2/4: v40
```

Syntax: show ip dvmrp [vrf <*vrf-name*>] group

The **vrf** option allows you to display DVMRP group information for the VRF instance identified by the <*vrf-name*> variable.

The display shows the following information.

Table 0.2:

This field...	Displays...
Total Number of Groups	The total number of DVMRP groups in the network.
Group	The DVMRP group address.
Ports	The PowerConnect ports connected to receivers of the groups.

Clearing the DVMRP group membership table

To clear the DVMRP group membership table, enter the following command.

```
NetIron# clear ip dvmrp cache
```

Syntax: clear ip dvmrp [vrf <*vrf-name*>] cache

This command clears the DVMRP membership for the default router instance or for a specified VRF.

Use the **vrf** option to clear the traffic information for a VRF instance specified by the <*vrf-name*> variable.

Displaying DVMRP interface information

To display DVMRP Interface information, enter the following command.

```
NetIron# show ip dvmrp interface
Interface e5/2
TTL Threshold: 1, Enabled, Querier
Local Address: 172.5.1.1
DR: itself
Neighbor:
  172.5.1.2
Interface e8/1
TTL Threshold: 1, Enabled, Querier
Local Address: 172.8.1.1
DR: itself
Interface v10
TTL Threshold: 1, Enabled, Querier
Local Address: 192.1.1.1 logical Vid=1
DR: itself
Interface v20
TTL Threshold: 1, Enabled, Querier
Local Address: 192.2.1.1 logical Vid=2
DR: itself
Interface v30
TTL Threshold: 1, Enabled, Querier
Local Address: 192.3.1.1 logical Vid=3
DR: itself
Interface v40
TTL Threshold: 1, Enabled, Querier
Local Address: 192.4.1.1 logical Vid=4
DR: itself
```

Syntax: show ip dvmrp [vrf <*vrf-name*>] interface

The **vrf** option allows you to display DVMRP interface information for the VRF instance identified by the <*vrf-name*> variable.

The display shows the following information

Table 0.3:

This field...	Displays...
Interface	The type of interface and the interface number. The interface can be one of the following: • Ethernet • VE The number is either a port and slot number or the virtual interface (VE) number.
TTL Threshold	Following the TTL threshold value, the interface state is listed. The interface state can be one of the following: • Disabled • Enabled
Local Address	Indicates the IP address configured on the port or virtual interface
DR	Designated router.

Displaying DVMRP multicast cache information

To display DVMRP Multicast Cache information, enter the following command.

```
NetIron# show ip mcache
Total 2 entries
1    (192.2.1.2, 226.1.1.1) in v20 (e2/2)
     L3 (HW) 1: e2/4(VL40)
     fast=1 slow=0 leaf=0 prun=0 frag=0 tag=0 tnnl=0 swL2=0 hwL2=0 swRepl=0
     age=0 fid: 8012,
2    (192.1.1.2, 225.1.1.1) in v10 (e2/1)
     L3 (HW) 1: e2/3(VL30)
     fast=1 slow=0 leaf=0 prun=0 frag=0 tag=0 tnnl=0 swL2=0 hwL2=0 swRepl=0
     age=0 fid: 8011,
Total number of mcache entries 2
```

Syntax: show ip dvmrp [vrf <*vrf-name*>] mcache

The **vrf** option allows you to display DVMRP Multicast cache information for the VRF instance identified by the <*vrf-name*> variable

The display shows the following information

Table 0.4:

This field...	Displays...
Total number of mcache entries	The total number of entries in the DVMRP multicast cache.

Displaying DVMRP neighbor information

To display DVMRP Neighbor information, enter the following command:

```
NetIron# show ip dvmrp nbr
Port   Phy_p  Neighbor        GenId    Age   UpTime
e5/2   e5/2   172.5.1.2       00000000 170   440
```

Syntax: show ip dvmrp [vrf <*vrf-name*>] nbr

The **vrf** option allows you to display DVMRP neighbor information for the VRF instance identified by the <*vrf-name*> variable.

The display shows the following information.

Table 0.5:

This field...	Displays...
Port	The port and slot number for the neighbors interface.
Phy_p	The physical port and slot number for the neighbors interface.
Neighbor	The IP address of the DVMRP neighbor.
GenId	The neighbor's generation ID.
Age	The minimum time remaining before this DVMRP neighbor is aged out.
UpTime	The time in seconds that the DVMRP neighbor has been up.

Displaying DVMRP active prune information

To display DVMRP Active Prune information, enter the following command.

```
NetIron# show ip dvmrp prune
Port SourceNet       Group           Nbr             Age
                                                     sec
e5/2  192.2.1.2       226.1.1.1      172.5.1.1       60
e5/2  192.1.1.2       225.1.1.1      172.5.1.1       60
```

Syntax: show ip dvmrp [vrf <*vrf-name*>] prune

The **vrf** option allows you to display DVMRP active prune information for the VRF instance identified by the <*vrf-name*> variable.

The display shows the following information.

Table 0.6:

This field...	Displays...
Port	The port and slot number for the DVMRP prune.
SourceNet	The address of the source or source network that has been pruned.
Group	The group address that has been pruned
Nbr	The IP address of the DVMRP neighbor.
Age Sec	The amount of time remaining before this prune expires at the upstream neighbor.

Displaying available multicast resources

To display Available Multicast Resources, enter the following command.

```
NetIron# show ip dvmrp resource
                     allocated    in-use available allo-fail  up-limita
DVMRP route               2048        13      2035         0      2048
route interface           2048        13      2035         0      8192
NBR list                   128         1       127         0      1874
prune list                  64         2        62         0       256
graft list                  64         0        64         0       256
mcache                     128         2       126         0      4096
mcache hash link           547         2       545         0  no-limit
graft if no mcache         197         0       197         0  no-limit
IGMP group                 256         2       254         0      2048
pim/dvm intf. group        256         2       254         0  no-limit
pim/dvm global group       256         2       254         0      4096
HW replic vlan            2000         4      1996         0  no-limit
HW replic port            1024         2      1022         0  no-limit
```

Syntax: show ip dvmrp [vrf <*vrf-name*>] resource

The **vrf** option allows you to display available multicast resources for the VRF instance identified by the <*vrf-name*> variable.

Displaying IP multicast route Information

To display IP multicast route information, enter the following command.

```
NetIron# show ip dvmrp route
P:Parent M:Metric
Total Routes=10
SourceNet        Mask             Gateway         P      M

100.1.1.0       255.255.255.0     172.5.1.2       e5/2   2
 Int e5/2   phy_p e5/2   nbr        172.5.1.2 age=0 NOT downstream
101.1.1.0       255.255.255.0     172.5.1.2       e5/2   2
 Int e5/2   phy_p e5/2   nbr        172.5.1.2 age=0 NOT downstream
102.1.1.0       255.255.255.0     172.5.1.2       e5/2   2
 Int e5/2   phy_p e5/2   nbr        172.5.1.2 age=0 NOT downstream
103.1.1.0       255.255.255.0     172.5.1.2       e5/2   2
 Int e5/2   phy_p e5/2   nbr        172.5.1.2 age=0 NOT downstream
```

Syntax: show ip dvmrp [vrf <*vrf-name*>] route

The **vrf** option allows you to display multicast route information for the VRF instance identified by the <*vrf-name*> variabl.

The display shows the following information.

Table 0.7:

This field...	Displays...
Total Routes	The number of entries in the DVMRP routing table.
SourceNet	The IP address of the source network for the route.
Mask	The subnet mask for the router.
Gateway	The IP address of the gateway for the route.
P	The parent port.
M	The metric which is the distance in hops to the source subnet.

Displaying active multicast traffic information

To display active multicast traffic information, enter the following command.

```
NetIron# show ip dvmrp traffic
Port          Probe                    Graft                    Prune
     [Rx      Tx      Dscrd] [Rx      Tx      Dscrd] [Rx      Tx      Dscrd]
e5/2   111     112     0       0       0       0       9       0       1
e8/1   0       220     0       0       0       0       0       0       0
v10    0       211     0       0       0       0       0       0       0
v20    0       210     0       0       0       0       0       0       0
Total 111     1718     0       0       0       0       9       0       1
IGMP Statistics:
  Total Discard/chksum  0/0
```

Syntax: show ip dvmrp [vrf <*vrf-name*>] traffic

The **vrf** option allows you to display multicast traffic information for the VRF instance identified by the <*vrf-name*> variable.

The display shows the following information.

Table 0.8:

This field...	Displays...
Port	The port or virtual interface on which the PIM interface is configured.
Probe	The number of received, transmitted, and discarded probe messages.
Graft	The number of received, transmitted, and discarded graft messages.
Prune	The number of received, transmitted, and discarded prune messages.
Total Discard or chksum	The total number of IGMP messages discarded, including a separate counter for those that failed the checksum comparison.

Clearing DVMRP traffic statistics

To clear statistics for DVMRP traffic, enter the following command.

```
NetIron# clear ip dvmrp traffic
```

Syntax: clear ip dvmrp [vrf <*vrf-name*>] traffic

This command clears all the dvmrp multicast traffic information on all interfaces on the device or for the interfaces of a specified VRF.

Use the **vrf** option to clear the traffic information for a VRF instance specified by the <*vrf-name*> variable.

Displaying DVMRP Settings

To display global DVMRP settings or DVMRP settings for a specified VRF. To display global IGMP settings, enter the following command.

```
NetIron# show ip dvmrp settings
Global DVMRP Settings
  Version: 3.5
  Probe interval: 10, Neighbor timeout: 180
  Graft Retransmit interval: 10, Prune Lifetime/Age: 180
  Maximum Routes: 0, Active Route Count: 0 (0)
  Route Expire interval: 200, Route Discard interval: 340
  Route Report interval: 60, Trigger Update interval: 5
  Maximum Mcache: 0,  Current Count: 0
```

Syntax: show ip dvmrp [vrf <*vrf-name*>] settings

The **vrf** parameter specifies that you want to display DVMRP settings information for the VRF specified by the <*vrf-name*> variable.

The report shows the following information:

Table 0.9:

This field	Displays
Version	The DVMRP version operating on the router.
Probe Interval	The frequency in seconds at which neighbor probe messages are sent to the ALL-DVMRP-ROUTERS IP multicast group address. Possible values are 5 to 30 seconds. The default value is 10 seconds. This parameter is configured in "Modifying probe interval".
Neighbor timeout	The period of time in seconds that a router will wait before it defines an attached DVMRP neighbor router as down. Possible values are 60 to 8000 seconds and the default value is 180 seconds. This parameter is configured in "Modifying neighbor timeout"
Graft Retransmit Interval	The initial period of time in seconds that a router sending a graft message will wait for a graft acknowledgement from an upstream router before re-transmitting that message. Subsequent retransmissions are sent at an interval twice that of the preceding interval. Possible values are 5 to 3600 seconds and the default value is 120 seconds. This parameter is configured in "Modifying graft retransmit time"
Prune Lifetime or Age	The period of time in seconds that a prune state will remain in effect for a source-routed multicast tree. After the prune age period expires, flooding will resume. Possible values are from 20 to 3600 seconds. The default value is 180 seconds. This parameter is configured in "Modifying prune age"
Maximum Routes	The maximum number of DVMRP routes allowed on the router.
Active Route Count	The number of active DVMRP routes.
Route Expire Interval	The time period in seconds during which a route is considered valid in the absence of the next route update. Possible values are from 20 to 4000 seconds and the default value is 200 seconds.. This parameter is configured in "Modifying route expires time".
Route Discard Interval	The time period in seconds before a route is deleted. Possible values are from 40 to 8000 seconds and the default value is 340 seconds.. This parameter is configured in "Modifying route discard time".

Table 0.9:

This field	Displays
Route Report Interval	The time interval in seconds between which the router propagates its complete routing table to other neighbor DVMRP routers. Possible values are from 10 to 2000 seconds and the default value is 60 seconds.. This parameter is configured in "Modifying report interval".
Trigger Update Interval	The time interval in seconds between which the router sends trigger updates which reflect changes in the network topology. Possible values are from 5 to 30 seconds and the default value is 5 seconds.. This parameter is configured in "Modifying trigger interval"
Maximum Mcache	The maximum number multicast cache entries for DVMRP allowed on the router.
Current Count	The number of multicast cache entries currently used.

Configuring a static multicast route

Static multicast routes allow you to control the network path used by multicast traffic. Static multicast routes are especially useful when the unicast and multicast topologies of a network are different. You can avoid the need to make the topologies similar by instead configuring static multicast routes.

NOTE
This feature is not supported for DVMRP.

You can configure more than one static multicast route. The NetIron always uses the most specific route that matches a multicast source address. Thus, if you want to configure a multicast static route for a specific multicast source and also configure another multicast static route for all other sources, you can configure two static routes as shown in the examples below.

To add static routes to multicast router A (refer to Figure 163), enter commands such as the following.

```
PIMRouterA(config)# ip mroute 207.95.10.0 255.255.255.0 ethernet 1/2 distance 1
PIMRouterA(config)# ip mroute 0.0.0.0 0.0.0.0 ethernet 2/3 distance 1
PIMRouterA(config)# write memory
```

Syntax: [no] ip mroute <*ip-addr*> interface ethernet <*slot*>/<*portnum*> | pos <*slot*>/<*portnum*> |ve <*num*> [distance <*num*>]

Or

Syntax: [no] ip mroute <*ip-addr*> rpf_address <*rpf-num*>

The <*ip-addr*> command specifies the PIM source for the route.

NOTE
In IP multicasting, a route is handled in terms of its source, rather than its destination.

You can use the **ethernet** <*slot*>/<*portnum*> or **pos** <*slot*>/<*portnum*> parameters to specify a physical port or the **ve** <*num*> parameter to specify a virtual interface.

NOTE
The **ethernet** <*slot*>/<*portnum*> and **pos** <*slot*>/<*portnum*>parameters do not apply to PIM SM.

The **distance** <*num*> parameter sets the administrative distance for the route. When comparing multiple paths for a route, the NetIron prefers the path with the lower administrative distance.

NOTE
Regardless of the administrative distances, the NetIron always prefers directly connected routes over other routes.

The **rpf_address** <*rpf-num*> parameter specifies an RPF number.

The example above configures two static multicast routes. The first route is for a specific source network, 207.95.10.0/24. If the NetIron receives multicast traffic for network 207.95.10.0/24, the traffic must arrive on port 1/2. The second route is for all other multicast traffic. Traffic from multicast sources other than 207.95.10.0/24 must arrive on port 2/3.

Figure 163 shows an example of an IP Multicast network. The two static routes configured in the example above apply to this network. The commands in the example above configure PIM router A to accept PIM packets from 207.95.10.0/24 when they use the path that arrives at port 1/2, and accept all other PIM packets only when they use the path that arrives at port 2/3.

The distance parameter sets the administrative distance. This parameter is used by the software to determine the best path for the route. Thus, to ensure that the NetIron uses the default static route, assign a low administrative distance value. When comparing multiple paths for a route, the NetIron prefers the path with the lower administrative distance.

Configuring a static multicast route within a VRF

The Multi-Service IronWare software allows you to configure a static multicast route within a virtual routing instance (VRF). The static multicast route is defined within the VRF configuration as shown in the following.

```
NetIron(config)# ip vrf vpn1
NetIron(config-vrf-vpn1)# ip mroute 105.105.105.0/24 14.14.14.105
```

Syntax: [no] ip vrf <*vrf-name*>

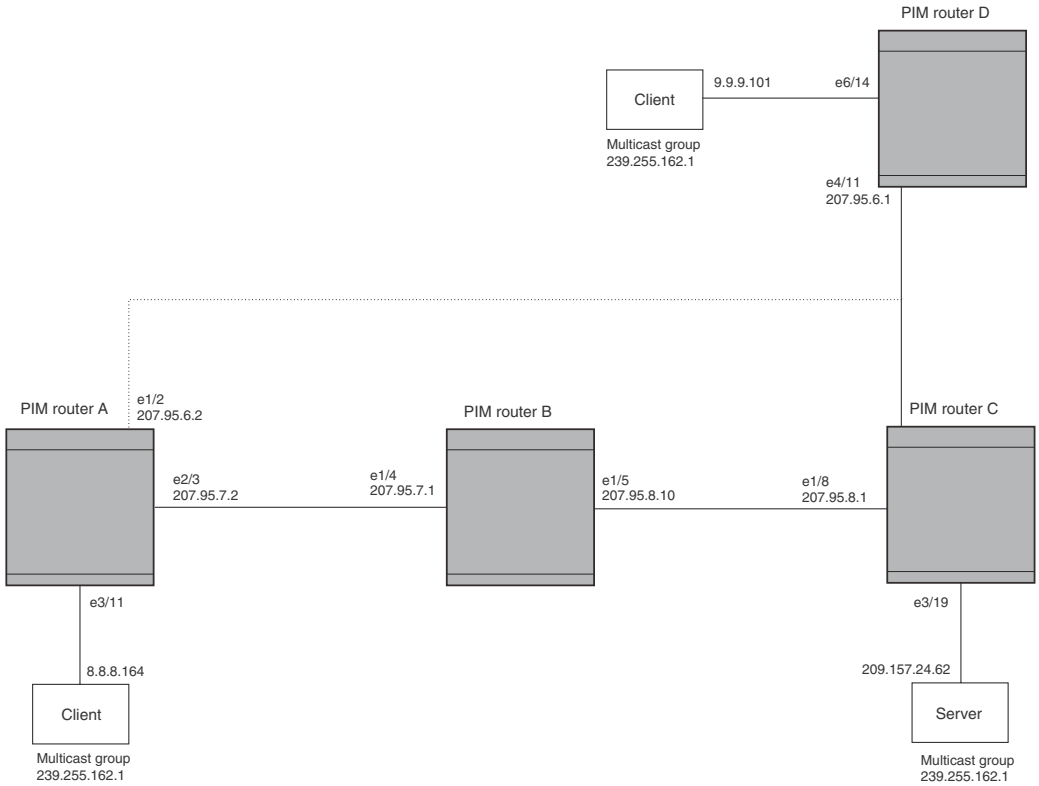
Syntax: [no] ip mroute <*ip-addr*>

The **ip vrf** parameter specifies the virtual routing instance (VRF) specified by the variable <*vrf-name*>.

The <*ip-addr*> parameter specifies the destination IP address .

NOTE
Configuring a static multicast route for the default VRF is still accomplished using the command described in "Configuring a static multicast route" on page 1219.

FIGURE 163 Example multicast static routes



To add a static route to a virtual interface, enter commands such as the following.

```
NetIron(config)# mroute 3 0.0.0.0 0.0.0.0 int ve 1 distance 1
NetIron(config)# write memory
```

IGMP V3

The Internet Group Management Protocol (IGMP) allows an IPV4 system to communicate IP Multicast group membership information to its neighboring routers. The routers in turn limit the multicast of IP packets with multicast destination addresses to only those interfaces on the router that are identified as IP Multicast group members.

In IGMP V2, when a router sent a query to the interfaces, the clients on the interfaces respond with a membership report of multicast groups to the router. The router can then send traffic to these groups, regardless of the traffic source. When an interface no longer needs to receive traffic from a group, it sends a leave message to the router which in turn sends a group-specific query to that interface to see if any other clients on the same interface is still active.

In contrast, IGMP V3 provides selective filtering of traffic based on traffic source. A router running IGMP V3 sends queries to every multicast enabled interface at the specified interval. These general queries determine if any interface wants to receive traffic from the router. The following are the three variants of the Query message:

- A "General Query" is sent by a multicast router to learn the complete multicast reception state of the neighboring interfaces. In a General Query, both the Group Address field and the Number of Sources (N) field are zero.

- A "Group-Specific Query" is sent by a multicast router to learn the reception state, with respect to a *single* multicast address, of the neighboring interfaces. In a Group-Specific Query, the Group Address field contains the multicast address of interest, and the Number of Sources (N) field contains zero.
- A "Group-and-Source-Specific Query" is sent by a multicast router to learn if any neighboring interface desires reception of packets sent to a specified multicast address, from any of a specified list of sources. In a Group-and-Source-Specific Query, the Group Address field contains the multicast address of interest, and the Source Address [i] fields contain the source address(es) of interest.

The interfaces respond to these queries by sending a membership report that contains one or more of the following records that are associated with a specific group:

- Current-State Record that indicates from which sources the interface wants to receive and not receive traffic. The record contains source address of interfaces and whether or not traffic will be received or included (IS_IN) or not received or excluded (IS_EX) from that source.
- Filter-mode-change record. If the interface changes its current state from IS_IN to IS_EX, a TO_EX record is included in the membership report. Likewise, if an interface's current state changes from IS_EX to IS_IN, a TO_IN record appears in the membership report.

  IGMP V2 Leave report is equivalent to a TO_IN (empty) record in IGMP V3. This record means that no traffic from this group will be received regardless of the source.

  An IGMP V2 group report is equivalent to an IS_EX (empty) record in IGMP V3. This record means that all traffic from this group will be received regardless of source.
- Source-List-Change Record. If the interface wants to add or remove traffic sources from its membership report, the membership report can have an ALLOW record, which contains a list of new sources from which the interface wishes to receive traffic. It can also contains a BLOCK record, which lists current traffic sources from which the interfaces wants to stop receiving traffic.

In response to membership reports from the interfaces, the router sends a Group-Specific or a Group-and-Source Specific query to the multicast interfaces. For example, a router receives a membership report with a Source-List-Change record to block old sources from an interface. The router sends Group-and-Source Specific Queries to the source and group (S,G) identified in the record. If none of the interfaces is interested in the (S,G), it is removed from (S,G) list for that interface on the router.

Each IGMP V3-enabled router maintains a record of the state of each group and each physical port within a virtual routing interface. This record contains the group, group-timer, filter mode, and source records information for the group or interface. Source records contain information on the source address of the packet and source timer. If the source timer expires when the state of the group or interface is in Include mode, the record is removed.

Default IGMP version

IGMP V3 is available for PowerConnect Routers; however, these routers are shipped with IGMP V2-enabled. You must enable IGMP V3 globally or per interface.

Also, you can specify what version of IGMP you want to run on a device globally, on each interface (physical port or virtual routing interface), and on each physical port within a virtual routing interface. If you do not specify an IGMP version, IGMP V2 will be used.

Compatibility with IGMP V1 and V2

Different multicast groups, interfaces, and routers can run their own version of IGMP. Their version of IGMP is reflected in the membership reports that the interfaces send to the router. Routers and interfaces must be configured to recognized the version of IGMP you want them to process.

An interface or router sends the queries and reports that include its IGMP version specified on it. It may recognize a query or report that has a different version. For example, an interface running IGMP V2 can recognize IGMP V3 packets, but cannot process them. Also, a router running IGMP V3 can recognize and process IGMP V2 packet, but when that router sends queries to an IGMP V2 interface, the downgraded version is supported, no the upgraded version.

If an interface continuously receives queries from routers that are running versions of IGMP that are different from what is on the interface, the interface logs warning messages in the syslog every five minutes. Reports sent by interfaces to routers that contain different versions of IGMP do not trigger warning messages; however, you can see the versions of the packets using the **show ip igmp traffic** command.

The version of IGMP can be specified globally, per interface (physical port or virtual routing interface), and per physical port within a virtual routing interface. The IGMP version set on a physical port within a virtual routing interface supersedes the version set on a physical or virtual routing interface. Likewise, the version on a physical or virtual routing interface supersedes the version set globally on the device. The sections below present how to set the version of IGMP.

Globally enabling the IGMP version

To globally identify the IGMP version on a Dell device, enter the following command.

```
NetIron(config)# ip igmp version 3
```

Syntax: [no] ip igmp version <*version-number*>

Enter 1, 2, or 3 for <*version-number*>. Version 2 is the default version.

Enabling the IGMP version per interface setting

To specify the IGMP version for a physical port, enter a command such as the following.

```
NetIron(config)# interface eth 1/5
NetIron(config-if-1/5)# ip igmp version 3
```

To specify the IGMP version for a virtual routing interface on a physical port, enter a command such as the following.

```
NetIron(config)# interface ve 3
NetIron(config-vif-1) ip igmp version 3
```

Syntax: [no] ip igmp version <*version-number*>

Enter 1, 2, or 3 for <*version-number*>. Version 2 is the default version.

Enabling the IGMP version on a physical port within a virtual routing interface

To specify the IGMP version recognized by a physical port that is a member of a virtual routing interface, enter a command such as the following.

```
NetIron(config)# interface ve 3
NetIron(config-vif-3)# ip igmp version 2
NetIron(config-vif-3)# ip igmp port-version 3 e1/3 to e1/7 e2/9
```

In this example, the second line sets IGMP V2 on virtual routing interface 3. However, the third line set IGMP V3 on ports 1/3 through 1/7 and port e2/9. All other ports in this virtual routing interface are configured with IGMP V2.

Syntax: [no] ip igmp port-version <*version-number*> ethernet <*port-number*>

Enter 1, 2, or 3 for <*version-number*>. IGMP V2 is the default version.

The **ethernet** <*port-number*> parameter specifies which physical port within a virtual routing interface is being configured.

Enabling membership tracking and fast leave

NOTE
The IGMP V3 fast leave feature is supported in include mode, but does not work in the exclude mode.

IGMP V3 provides membership tracking and fast leave of clients. In IGMP V2, only one client on an interface needs to respond to a router's queries; therefore, some of the clients may be invisible to the router, making it impossible for the switch to track the membership of all clients in a group. Also, when a client leaves the group, the switch sends group specific queries to the interface to see if other clients on that interface need the data stream of the client who is leaving. If no client responds, the switch waits three seconds before it stops the traffic.

IGMP V3 contains the tracking and fast leave feature that you enable on virtual routing interfaces. Once enabled, all physical ports on that virtual routing interface will have the feature enabled. IGMP V3 requires all clients to respond to general and group specific queries so that all clients on an interface can be *tracked. Fast leave* allows clients to leave the group without the three second waiting period, if the following conditions are met:

- If the interface, to which the client belongs, has IGMP V3 clients only. Therefore, all physical ports on a virtual routing interface must have IGMP V3 enabled and no IGMP V1 or V2 clients can be on the interface. (Although IGMP V3 can handle V1 and V2 clients, these two clients cannot be on the interface in order for fast leave to take effect.)
- No other client on the interface is receiving traffic from the group to which the client belongs.

  Every group on the physical interface of a virtual routing interface keeps its own tracking record. It can track by (source, group).

For example, two clients (Client A and Client B) belong to group1 but each is receiving traffic streams from different sources. Client A receives a stream from (source_1, group1) and Client B receives it from (source_2, group1). Now, if Client B leaves, the traffic stream (source_2, group1) will be stopped immediately. The **show ip igmp group tracking** command displays that clients in a group that are being tracked.

If a client sends a leave message, the client is immediately removed from the group. If a client does not send a report during the specified group membership time (the default is 140 seconds), that client is removed from the tracking list.

To enable the tracking and fast leave feature, enter commands such as the following.

```
NetIron(config)# interface ve 13
NetIron(config-vif-13)# ip igmp tracking
```

Syntax: [no] ip igmp tracking

Creating a static IGMP group

To configure a physical port to be a permanent (static) member of an IGMP group, enter the following commands.

```
NetIron(config)# interface ethernet 1/5
NetIron(config-if-e1000-1/5)# ip igmp static-group 224.10.1.1
```

Syntax: [no] ip igmp static-group <*ip-address*>

Enter the IP address of the static IGMP group for <*ip-address*>.

To configure a virtual port to be a permanent (static) member of an IGMP group, enter the following commands.

```
NetIron(config)# interface ve 10
NetIron(config-vif-10)# ip igmp static-group 224.10.1.1 ethernet 1/5
```

Syntax: [no] ip igmp static-group <*ip-address*> ethernet <*slot-number*>/<*port-number*>

Enter the IP address of the static IGMP group for <*ip-address*>.

Enter the ID of the physical port of the VLAN that will be a member of the group for **ethernet** <*slot-number*>/<*port-number*>.

NOTE
IGMPv3 does not support static IGMP group members.

NOTE
Static IGMP groups are supported only in Layer 3 mode.

Setting the query interval

The IGMP query interval period defines how often a switch will query an interface for group membership. Possible values are 2-3600 seconds and the default value is 125 seconds, but the value you enter must be a little more than twice the group membership time.

To modify the default value for the IGMP query interval, enter the following.

```
NetIron(config)# ip igmp query-interval 120
```

Syntax: [no] ip igmp query-interval <*2-3600*>

The interval must be a little more than two times the group membership time.

Setting the group membership time

Group membership time defines how long a group will remain active on an interface in the absence of a group report. Possible values are from 5 – 26000 seconds and the default value is 260 seconds.

To define an IGMP membership time of 240 seconds, enter the following.

```
NetIron(config)# ip igmp group-membership-time 240
```

Syntax: [no] ip igmp group-membership-time <*5-26000*>

Setting the maximum response time

The maximum response time defines the maximum number of seconds that a client can wait before it replies to the query sent by the router. Possible values are 1 – 25. The default is 10.

To change the IGMP maximum response time, enter a command such as the following at the global CONFIG level of the CLI.

```
NetIron(config)# ip igmp max-response-time 8
```

Syntax: [no] ip igmp max-response-time <*num*>

The <*num*> parameter specifies the maximum number of seconds for the response time. Enter a value from 1 – 25. The default is 10.

Displaying IGMPv3 information

The sections below present the show commands available for IGMP V3.

Displaying IGMP group status

You can display the status of all IGMP multicast groups on a device by entering the following command.

```
NetIron# show ip igmp group
Total 2 entries
------------------------------------------------------
Idx Group Address    Port   Intf   Mode    Timer Srcs
---+----------------+------+------+-------+-----+----
  1 232.0.0.1        e6/2   v30    include     0   7
  2 226.0.0.1        e6/2   v30    exclude   240   2
                     e6/3   e6/3   include     0   3
Total number of groups 2
```

To display the status of one IGMP multicast group, enter a command such as the following.

```
NetIron# show ip igmp group 239.0.0.1 detail
Total 2 entries
------------------------------------------------------
Idx Group Address    Port   Intf   Mode    Timer Srcs
---+----------------+------+------+-------+-----+----
  1 226.0.0.1        e6/2   v30    exclude   218   2
     S: 40.40.40.12
     S: 40.40.40.11
     S: 40.40.40.10
     S: 40.40.40.2          (Age: 218)
     S: 40.40.40.3          (Age: 218)
    226.0.0.1        e6/3   e6/3   include     0   3
     S: 30.30.30.3          (Age: 165)
     S: 30.30.30.2          (Age: 165)
     S: 30.30.30.1          (Age: 165)
```

If the tracking and fast leave feature is enabled, you can display the list of clients that belong to a particular group by entering commands such as the following.

```
NetIron# show ip igmp group 224.1.10.1 tracking
Total 2 entries
------------------------------------------------------
Idx Group Address    Port   Intf   Mode    Timer Srcs
---+---------------+------+------+-------+-----+----
  1 226.0.0.1        e6/2   v30    exclude   253   3
     S: 40.40.40.12
     S: 40.40.40.11
     S: 40.40.40.10
     S: 40.40.40.2          (Age: 253)
                    C: 10.10.10.1       (Age: 253)
    S: 40.40.40.3          (Age: 253)
                    C: 10.10.10.1       (Age: 253)
    226.0.0.1       e6/3   e6/3   include     0   3
     S: 30.30.30.3          (Age: 196)
                    C: 10.2.0.1         (Age: 196)
     S: 30.30.30.2          (Age: 196)
                    C: 10.2.0.1         (Age: 196)
     S: 30.30.30.1          (Age: 196)
                    C: 10.2.0.1         (Age: 196)
```

Syntax: show ip igmp [vrf <*vrf-name*>] group [<*group-address*> [detail] [tracking]]

If you want a report for a specific multicast group, enter that group's address for <*group-address*>. Omit the <*group-address*> if you want a report for all multicast groups.

The **vrf** parameter specifies that you want to display IGMP group information for the VRF specified by the <*vrf-name*> variable.

Enter **detail** if you want to display the source list of the multicast group.

Enter **tracking** if you want information on interfaces that have tracking enabled.

IGMP V2 and V3 statistics displayed on the report for each interface.

Table 0.10:

This field	Displays
Group	The address of the multicast group
Port	The physical port on which the multicast group was received.
Intf	The virtual interface on which the multicast group was received.
Timer	Shows the number of seconds the interface can remain in exclude mode. An exclude mode changes to include mode if it does not receive an "IS_EX" or "TO_EX" message during a certain period of time. The default is 140 seconds.
Mode	Indicates current mode of the interface: include or exclude. If the interface is in Include mode, it admits traffic only from the source list. If an interface is in exclude mode, it denies traffic from the source list and accepts the rest.
Srcs	Identifies the source list that will be included or excluded on the interface. If IGMP V2 group is in exclude mode with a #_src of 0, the group excludes traffic from 0 (zero) source list, which means that all traffic sources are included.

Clearing the IGMP group membership table

To clear the IGMP group membership table, enter the following command.

```
NetIron# clear ip igmp cache
```

Syntax: clear ip igmp [vrf <*vrf-name*>] cache

This command clears the IGMP membership for the default router instance or for a specified VRF.

Use the **vrf** option to clear the traffic information for a VRF instance specified by the <*vrf-name*> variable.

Displaying static IGMP groups

The following command displays static IGMP groups for the “eng” VRF.

```
NetIron#show ip igmp vrf eng static
Group Address    Interface Port List
---------------+---------+---------
      229.1.0.12       4/1 ethe 4/1
      229.1.0.13       4/1 ethe 4/1
      229.1.0.14       4/1 ethe 4/1
      229.1.0.92       4/1 ethe 4/1
```

Syntax: show ip igmp [vrf <*vrf-name*>] static

The **vrf** parameter specifies that you want to display static IGMP group information for the VRF specified by the <*vrf-name*> variable.

Table 0.11:

This field	Displays
Group Address	The address of the multicast group.
Interface Port List	The physical ports on which the multicast groups are received.

Displaying the IGMP status of an interface

You can display the status of a multicast enabled port by entering a command such as the following.

```
NetIron# show ip igmp interface
---------+------+---------+---------------+---------+-----+-----+---------
Intf/Port|Groups| Version |Querier        |  Timer  |V1Rtr|V2Rtr|Tracking
         |      |Oper  Cfg|               |OQrr GenQ|     |     |
---------+------+----+----+---------------+----+----+-----+-----+---------
e6/3           1    3    3 Self              0   94 No    No     Disabled
e6/4           0    2    - Self              0   94 No    No     Disabled
v30            1    3    3                                       Disabled
     e6/2           3    - Self              0   20 No    No
v40            0    3    3                                       Disabled
     e6/2           3    - Self              0   20 No    No
v50            0    2    -                                       Disabled
    e12/1           2    - Self              0   29 No    No
     e6/8           2    - 50.1.1.10        46    0 No    Yes
     e6/1           2    - Self              0  115 No    Yes
```

Syntax: show ip igmp [vrf <*vrf-name*>] interface [ve <*number*> | ethernet <*slot/port*> | pos <*slot/port*> | tunnel <*num*>]

The **vrf** parameter specifies that you want to display IGMP interface information for the VRF specified by the <*vrf-name*> variable.

Enter **ve** and its <*number*>, **pos** and its <*slot/port*> or **ethernet** and its <*slot/port*> to display information for a specific virtual routing interface, pos interface or ethernet interface.

The **tunnel** <*num*> parameter specifies a GRE tunnel interface that is being configured. The GRE tunnel interface is enabled under the router PIM configuration.

Entering an address for <*group-address*> displays information for a specified group on the specified interface.

The report shows the following information:

Table 0.12:

This field	Displays
Intf	The virtual interface on which IGMP is enabled.
Port	The physical port on which IGMP is enabled.
Groups	The number of groups that this interface or port has membership.
Version	
Oper	The IGMP version that is operating on the interface.
Cfg	The IGMP version that is configured for this interface.
Querier	Where the Querier resides: The IP address of the router where the querier is located or Self – if the querier is on the same router as the intf or port.
Max response	
oQrr	Other Querier present timer.
GenQ	General Query timer
V1Rtr	Whether IGMPv1 is present on the intf or port.
V2Rtr	Whether IGMPv2 is present on the intf or port.
Tracking	Fast tracking status: Enabled or Disabled

Displaying IGMP traffic status

To display the traffic status on each virtual routing interface, enter the following command.

```
NetIron# show ip igmp traffic
Recv  QryV2 QryV3 G-Qry GSQry MbrV2 MbrV3 Leave  IsIN  IsEX ToIN ToEX ALLOW BLK
v5       29     0     0     0     0     0     0     0     0    0    0     0   0
v18      15     0     0     0     0    30     0    60     0    0    0     0   0
v110      0     0     0     0     0    97     0   142    37    2    2     3   2
Send  QryV1 QryV2 QryV3 G-Qry GSQry
v5       0     2     0     0     0
v18      0     0    30    30     0
v110     0     0    30    44    11
```

Syntax: show ip igmp [vrf <*vrf-name*>] traffic

The **vrf** parameter specifies that you want to display IGMP traffic information for the VRF specified by the <*vrf-name*> variable.

The report shows the following information:

Table 0.13:

This field	Displays
QryV2	Number of general IGMP V2 query received or sent by the virtual routing interface.
QryV3	Number of general IGMP V3 query received or sent by the virtual routing interface.
G-Qry	Number of group specific query received or sent by the virtual routing interface.
GSQry	Number of source specific query received or sent by the virtual routing interface.
MbrV2	The IGMP V2 membership report.
MbrV3	The IGMP V3 membership report.
Leave	Number of IGMP V2 “leave” messages on the interface. (See ToEx for IGMP V3.)
IsIN	Number of source addresses that were included in the traffic.
IsEX	Number of source addresses that were excluded in the traffic.
ToIN	Number of times the interface mode changed from exclude to include.
ToEX	Number of times the interface mode changed from include to exclude.
ALLOW	Number of times that additional source addresses were allowed or denied on the interface:
BLK	Number of times that sources were removed from an interface.

Clearing IGMP traffic statistics

To clear statistics for IGMP traffic, enter the following command.

```
NetIron# clear ip igmp traffic
```

Syntax: clear ip igmp [vrf <*vrf-name*>] traffic

This command clears all the multicast traffic information on all interfaces on the device.

Use the **vrf** option to clear the traffic information for a VRF instance specified by the <*vrf-name*> variable. T

Displaying IGMP settings

To display global IGMP settings or IGMP settings for a specified VRF. To display global IGMP settings, enter the following command.

```
NetIron# show ip igmp  settings
IGMP Global Configuration
  Query Interval            : 125s
  Configured Query Interval : 125s
  Max Response Time         : 10s
  Group Membership Time     : 260s
  Configured Version        : 2
  Operating Version         : 2
```

Syntax: show ip igmp [vrf <*vrf-name*>] settings

The **vrf** parameter specifies that you want to display IGMP settings information for the VRF specified by the <*vrf-name*> variable.

The report shows the following information:

Table 0.14:

This field	Displays
Query Interval	How often the router will query an interface for group membership.
Configured Query Interval	The query interval that has been configured for the router.
Max Response Time	The length of time in seconds that the router will wait for an IGMP (V1 or V2) response from an interface before concluding that the group member on that interface is down and removing it from the group.
Group Membership Time	The length of time in seconds that a group will remain active on an interface in the absence of a group report.
Configured Version	The IGMP version configured on the router.
Operating Version	The IGMP version operating on the router.

Source-specific multicast

Using the Any-Source Multicast (ASM) service model, sources and receivers register with a multicast address. The protocol uses regular messages to maintain a correctly configured broadcast network where all sources can send data to all receivers and all receivers get broadcasts from all sources.

With Source-specific multicast (SSM), the “channel” concept is introduced where a “channel” consists of a single source and multiple receivers who specifically register to get broadcasts from that source. Consequently, receivers are not burdened with receiving data they have no interest in, and network bandwidth requirements are reduced because the broadcast need only go to a sub-set of users. The address range 232/8 has been assigned by the Internet Assigned Numbers Authority (IANA) for use with SSM.

IGMP V3 and source specific multicast protocols

When IGMP V3 and PIM Sparse (PIM-SM) is enabled, the source specific multicast service (SSM) can be configured. SSM simplifies PIM-SM by eliminating the RP and all protocols related to the RP. IGMPv3 and PIM-SM must be enabled on any ports that you want SSM to operate.

Configuring PIM SSM group range

PIM Source Specific Multicast (SSM) is a subset of the PIM SM protocol. In PIM SSM mode, the shortest path tree (STP) is created at the source. The STP is created between the receiver and source, but the STP is built without the help of the RP. The router closest to the interested receiver host is notified of the unicast IP address of the source for the multicast traffic. PIM SSM goes directly to the source-based distribution tree without the need of the RP connection. PIM SSM is different from PIM SM because it forms its own STP tree, without forming a shared tree. The multicast address group range is 232.0.0.0/8.

To configure a single SSM group address, enter the following command under the router pim configuration:

```
NetIron(config)#router pim
NetIron(config-pim-router)#ssm-enable range 232.1.1.1/8
```

Syntax: [no] ssm-enable range <*group-address*><*address-mask*>

The <*group-address*> parameter specifies the multicast address for the SSM address range .If this is not configured, the range will default to 232/8 as assigned by the Internet Assigned Numbers Authority (IANA) for use with SSM.

The< *address-mask*> parameter specifies the mask for the SSM address range.

To disable SSM, use the [no] form of this command.

Displaying source-specific multicast configuration information

To display PIM Sparse configuration information, use the **show ip pim sparse** command as described in"Displaying basic PIM Sparse configuration information" on page 1174.

Configuring multiple SSM group ranges

The **ssm-enable range** <*acl-id/acl-name*> command allows you to configure multiple SSM group ranges using an ACL.

Configuration Considerations

- The existing **ssm-enable range** <*group-address*><*address-mask*> command will continue to exist.
- The ACL must be configured with the SSM group address in the permit clause of the **ssm-enable range** <*acl-id or acl-name*> command. If the **ssm-enable range** <*group-address*><*address-mask*> command permits a clause, then that group will also operate in the PIM-SM mode.
- If the **ssm-enable range** <*acl-id or acl-name*> command is configured with a non-existent or empty ACL, then the SSM group will operate in PIM-SM mode (non PIM-SSM mode). However when an ACL is added or updated, then the group will exist in a PIM-SSM mode. By default, an empty ACL will deny all.
- By default, the group address mentioned in the IGMPv2 ssm-mapping ACL will decide if the group address is a PIM-SSM group or non PIM-SSM group. Therefore, if a user wants to prevent a group from operating in PIM-SSM mode, then the user's configuration must consistently deny the group in all configuration options for PIM-SSM range.

- ACL of any type (named or unnamed, standard or extended) can be used to specify the SSM group range. If an extended ACL is used, then the destination ip address should be used to specify the group address. Any configuration in the source address of an extended ACL is ignored. Only permit statements are considered in the ACL configuration. Any deny statements in the ACL clause are also ignored.

To configure multiple SSM group address using an ACL, enter the following command under the router pim configuration:

```
NetIron(config)#router pim
NetIron(config-pim-router)#ssm-enable range xyz
```

The example displayed above configures PIM so that it uses the group addresses allowed by ACL, xyz as its PIM SSM range.

Syntax: [no] ssm-enable range <*acl-id or acl-name*>

The <*acl-id/acl-name*> parameter specifies the ACL id or name used to configure multiple SSM group ranges.

To disable the SSM mapping range ACL, use the [no] form of this command.

NOTE
The **ssm-enable range** <*acl-id or acl-name*> command also supports IPv6 traffic. The **ssm-enable range** <*acl-id or acl-name*> command must be configured under the IPv6 router pim configuration to support IPv6.

Displaying information for PIM SSM range ACL

To display information for PIM SSM range ACL configuration enter the following command at any CLI level:

```
NetIron#show ip pim sparse

Global PIM Sparse Mode Settings
 Maximum Mcache         : 0          Current Count              : 0
  Hello interval        : 30          Neighbor timeout          : 105
  Join/Prune interval   : 60          Inactivity interval       : 180
  Register Suppress Time : 60         Register Probe Time       : 10
  SPT Threshold         : 1           Hardware Drop Enabled     : Yes
  Bootstrap Msg interval : 60         Candidate-RP Msg interval  : 60
  Register Stop Delay   : 60          Register Suppress interval : 60
  SSM Enabled           : Yes
  SSM Group Range       : 224.1.1.1/24
  SSM Group Range ACL   : xyz
  Route Precedence      : mc-non-default mc-default uc-non-default uc-default
```

NOTE
The **show ipv6 pim sparse** command also displays PIM SSM range ACL configuration.

IGMPv2 SSM mapping

The PIM-SSM feature requires all IGMP hosts to send IGMPv3 reports. Where you have an IGMPv2 host, this can create a compatibility problem. In particular, the reports from an IGMPv2 host contain a Group Multicast Address but do not contain source addresses. The IGMPv3 reports contain both the Group Multicast Address and one or more source addresses. This feature converts IGMPv2 reports into IGMPv3 reports through use of the **ip igmp ssm-map** commands and a properly configured ACL.

The ACL used with this feature filters for the Group Multicast Address. The ACL is then associated with one or more source addresses using the **ip igmp ssm-map static** command. When the **ip igmp ssm-map enable** command is configured, IGMPv3 reports are sent for IGMPv2 hosts.

The following sections describe how to configure the ACL and the **ip igmp ssm-map** commands to use the IGMPv2 SSM mapping feature:

- Configuring an ACL for IGMPv2 SSM mapping
- Configuring the IGMPv2 SSM Mapping Commands

NOTE
IGMPv2 SSM Mapping is not supported for IGMP static groups.

Configuring an ACL for IGMPv2 SSM mapping

You can use either a standard or extended ACL to identify the group multicast address you want to add source addresses to when creating a IGMPv3 report.

For standard ACLs, you must create an ACL with a permit clause and the **ip-source-address** variable must contain the group multicast address. This can be configured directly with a subnet mask or with the **host** keyword in which case a subnet mask of all zeros (0.0.0.0) is implied.

In the following example, **access-list 20** is configured for the group multicast address: 224.1.1.0 with a subnet mask of 0.0.0.255.

```
NetIron(config)# access-list 20 permit 224.1.1.0 0.0.0.225
```

In the following example, **access-list 20** is configured for the group multicast address: 239.1.1.1 by including the **host** keyword.

```
NetIron(config)# access-list 20 host 239.1.1.1
```

For extended ACLs, the **source address** variable must contain either **000** or the **any** keyword. Additionally, the extended ACL must be configured with a **permit** clause and the host keyword. This can be configured directly with a subnet mask or with the **host** keyword in which case a subnet mask of all zeros (0.0.0.0) is implied.

The **ip-destination-address** variable must contain the group multicast address.

In the following example, **access-list 100** is configured for the group multicast address: 232.1.1.1 with a subnet mask of 0.0.0.255.

```
NetIron(config)# access-list 20 permit 224.1.1.0 0.0.0.225
```

In the following example, **access-list 100** is configured for the group multicast address: 232.1.1.1.

```
NetIron(config)# access-list 100 permit any host 232.1.1.1
```

Configuring the IGMPv2 SSM mapping commands

The **ip ssm-map** commands are used to enable the IGMPv2 mapping feature and to define the maps between IGMPv2 Group addresses and multicast source addresses as described in the following sections.

Enabling IGMPv2 SSM mapping

To enable the IGMPv2 mapping feature enter the command as shown in the following.

```
NetIron(config)# ip igmp ssm-map enable
```

Syntax: [no] ip igmp ssm-map enable

The **no** option is used to turn off the IGMPv2 mapping feature that has previously been enabled.

Configuring the map between a IGMPv2 group address and a multicast source

To configure a map between an IGMPv2 Group address and a multicast source address use the **ip igmp ssm-map static** command, as shown in the following.

```
NetIron(config)# ip igmp ssm-map static 20 1.1.1.1
```

Syntax: [no] ip igmp ssm-map static <*acl-number*> <*source-address*>

The <*acl-number*> variable specifies the ACL that contains the group multicast address.

The <*source-address*> variable specifies the source address that you want to map to the group multicast address specified in the ACL.

The **no** option is used to delete a previously configured SSM map.

Example configuration

In the following example configuration, one extended ACL and two standard ACLs are defined with group multicast addresses. The **ip igmp ssm-map** commands are configured to map the ACLs to source addresses and to enable the feature on the router.

```
NetIron(config)# access-list 20 host 239.1.1.1
NetIron(config)# access-list 20 permit 224.1.1.0 0.0.0.225
NetIron(config)# access-list 100 permit any host 232.1.1.1
NetIron(config)# ip igmp ssm-map static 20 1.1.1.1
NetIron(config)# ip igmp ssm-map static 20 2.2.2.2
NetIron(config)# ip igmp ssm-map static 100 1.1.1.1
NetIron(config)# ip igmp ssm-map enable
```

Displaying an IGMP SSM mapping information

The **show ip igmp ssm-map** command displays the association between a configured ACL and source address mapped to it, as shown in the following.

```
NetIron# show ip igmp ssm-map
+---------+-----------------+
| Acl id  | Source Address  |
+---------+-----------------+
        20          1.1.1.1
       100          1.1.1.1
        20          2.2.2.2
        20          2.2.2.3
```

```
        20          2.2.2.4
        20          2.2.2.5
        20          2.2.2.6
```

Syntax: show ip igmp ssm-map

The **show ip igmp ssm-map** < *group-address*> displays the ACL ID that has the specified multicast group address in its permit list and lists the source addresses mapped to the specified multicast group address , as shown in the following.

```
NetIron# show ip igmp ssm-map 232.1.1.1
+---------+-----------------+
| Acl id  | Source Address  |
+---------+-----------------+
        20          1.1.1.1
       100          1.1.1.1
        20          2.2.2.2
        20          2.2.2.3
        20          2.2.2.4
        20          2.2.2.5
        20          2.2.2.6
```

Syntax: show ip igmp ssm-map <*group-address*>

IP multicast traffic reduction

In Layer 2 mode, by default, the PowerConnect forwards all IP multicast traffic out all ports except the port on which the traffic was received. Forwarding decisions are based on the Layer 2 information in the packets. To reduce multicast traffic through the device, you can enable IP Multicast Traffic Reduction. When this feature is enabled, forwarding decisions are made in hardware, based on multicast group. The device will forward multicast traffic only on the ports attached to multicast group members, instead of forwarding all multicast traffic to all ports.

By default, the device broadcasts traffic addressed to an IP multicast group that does not have any entries in the IGMP table. When you enable IP Multicast Traffic Reduction, the device determines the ports that are attached to multicast group members based on entries in the IGMP table. The IGMP table entries are created when the VLAN receives a group membership report for a group. Each entry in the table consists of an IP multicast group address and the ports from which the device has received Group Membership reports.

When the device receives traffic for an IP multicast group, the device looks in the IGMP table for an entry corresponding to that group. If the device finds an entry, it forwards the group traffic out the ports listed in the corresponding entries, as long as the ports are members of the same VLAN. If the table does not contain an entry corresponding to the group, or if the port is a member of the default VLAN, the device broadcasts the traffic.

Configuration requirements

Consider the following configuration requirements and application notes:

- The IP Multicast Traffic Reduction feature is applicable to Layer 2 mode only.
- If the **route-only** feature is enabled on the PowerConnect, then IP Multicast Traffic Reduction will not be supported.

- This feature is not supported on the default VLAN of the PowerConnect.
- When one or more PowerConnect devices are running Layer 2 IP Multicast Traffic reduction, configure one of the devices for active IGMP and leave the other devices configured for passive IGMP. However, if the IP multicast domain contains a multicast-capable router, configure all the PowerConnect devices for passive IGMP and allow the router to actively send the IGMP queries.
- IP multicast traffic reduction and PIM SM Traffic Snooping are supported on the PowerConnect.

Configuring IP multicast traffic reduction

When you enable IP Multicast Traffic Reduction, you also can configure the following features:

- **IGMP mode** – When you enable IP Multicast Traffic Reduction, the device passively listens for IGMP Group Membership reports by default. If the multicast domain does not have a router to send IGMP queries to elicit these Group Membership reports, you can enable the device to actively send the IGMP queries. The IGMP passive mode is also known as IGMP snooping and facilitates IP Multicast Traffic Reduction.
- **Query interval** – The query interval specifies how often the device sends Group Membership queries. This query interval applies only to the active IGMP mode. The default is 60 seconds. You can change the interval to a value from 10 – 600 seconds.
- **Age interval** – The age interval specifies how long an IGMP group can remain in the IGMP group table without the device receiving a Group Membership report for the group. If the age interval expires before the device receives another Group Membership report for the group, the device removes the entry from the table. The default is 140 seconds. You can change the interval to a value from 10 – 1220 seconds.

Furthermore, when you enable IP Multicast Traffic Reduction, the device forwards all IP multicast traffic by default, but you can enable the device to do the following:

- Forward IP multicast traffic only for groups for which the device has received a Group Membership report.
- Drop traffic for all other groups.

The following sections describe how to configure IP multicast traffic reduction and PIM SM Traffic Snooping parameters on a PowerConnect.

Enabling IP multicast traffic reduction

To enable IP Multicast Traffic Reduction, enter the following command.

```
NetIron(config)# ip multicast
```

Syntax: [no] ip multicast active | passive

When you enable IP multicast on a PowerConnect, all ports on the device are configured for IGMP.

The **active** mode enables all ports to send IGMP queries and receive IGMP reports. I

The **passive** mode enables all ports to receive IGMP queries.

IP Multicast Traffic Reduction cannot be disabled on individual ports of a PowerConnect. IP Multicast Traffic Reduction must be disabled globally by entering the **no ip multicast** command.

To verify that IP Multicast Traffic Reduction is enabled, enter the following command at any level of the CLI.

```
NetIron(config)# show ip multicast
IP multicast is enabled - Active
```

Syntax: show ip multicast

Changing the IGMP mode

When you enable IP Multicast Traffic Reduction on the device, IGMP also is enabled. The device uses IGMP to maintain a table of the Group Membership reports received by the device. You can use active or passive IGMP mode. There is no default mode.

The active and passive IGMP modes are described as follows:

- **Active** – When active IGMP mode is enabled, a Dell device actively sends out IGMP queries to identify IP multicast groups on the network and makes entries in the IGMP table based on the Group Membership reports received from the network.

  NOTE
  Routers in the network generally handle this operation. Use the active IGMP mode only when the device is in a stand-alone Layer 2 Switched network with no external IP multicast router attachments. In this case, enable the active IGMP mode on only one of the devices and leave the other devices configured for passive IGMP mode.

- **Passive** – When passive IGMP mode is enabled, the device listens for IGMP Group Membership reports but does not send IGMP queries. The passive mode is sometimes called "IGMP snooping". Use this mode when another device in the network is actively sending queries.

To enable active IGMP, enter the following command.

```
NetIron(config)# ip multicast active
```

Syntax: [no] ip multicast active | passive

To enable passive IGMP, enter the following command.

```
NetIron(config)# ip multicast passive
```

Modifying the query interval

If IP Multicast Traffic Reduction is set to active mode, you can modify the query interval, which specifies how often a PowerConnect enabled for active IP Multicast Traffic Reduction sends group membership queries.

NOTE
The query interval applies only to the active mode of IP Multicast Traffic reduction.

To modify the query interval, enter a command such as the following.

```
NetIron(config)# ip multicast query-interval 120
```

Syntax: [no] ip multicast query-interval <*interval*>

The <*interval*> parameter specifies the interval between queries. You can specify a value from 10 – 600 seconds. The default is 125 seconds.

Modifying the age interval

When the device receives a Group Membership report, the device makes an entry in the IGMP group table for the group in the report. The age interval specifies how long the entry can remain in the table without the device receiving another Group Membership report.

To modify the age interval, enter a command such as the following.

```
NetIron(config)# ip multicast age-interval 280
```

Syntax: [no] ip multicast age-interval <*interval*>

The <*interval*> parameter specifies the interval between queries. You can specify a value from 10 – 1220 seconds. The default is 260 seconds.

Filtering multicast groups

By default, the PowerConnect forwards multicast traffic for all valid multicast groups. You can configure a PowerConnect to filter out all multicast traffic for groups other than the ones for which the device has received Group Membership reports.

When the device starts up, it forwards all multicast groups even though multicast traffic filters are configured. This process continues until the device receives a group membership report. Once the group membership report is received, the device drops all multicast packets for groups other than the ones for which the device has received the group membership report.

To enable IP multicast filtering, enter the following command.

```
NetIron(config)# ip multicast filter
```

Syntax: [no] ip multicast filter

NOTE
When IGMP snooping is enabled on the multicast instance, the traffic will be forwarded to router ports although multicast filter is configured. Also, the ip multicast filter command is used only to avoid flooding. In case of PIM snooping, traffic is dropped since there are no router ports.

PIM SM traffic snooping

By default, when a PowerConnect receives an IP multicast packet, the device does not examine the multicast information in the packet. Instead, the device simply forwards the packet out all ports except the port that received the packet. In some networks, this method can cause unnecessary traffic overhead in the network. For example, if the PowerConnect is attached to only one group source and two group receivers, but has devices attached to every port, the device forwards group traffic out all ports in the same broadcast domain except the port attached to the source, even though there are only two receivers for the group.

PIM SM traffic snooping eliminates the superfluous traffic by configuring the device to forward IP multicast group traffic only on the ports that are attached to receivers for the group.

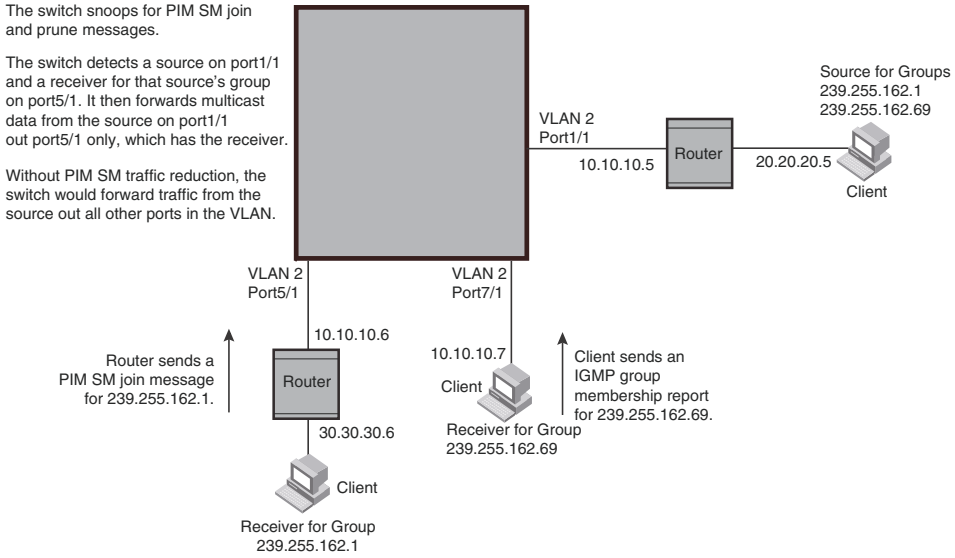
PIM SM traffic snooping requires IP multicast traffic reduction to be enabled on the device. IP multicast traffic reduction configures the device to listen for IGMP messages. PIM SM traffic snooping provides a finer level of multicast traffic control by configuring the device to listen specifically for PIM SM join and prune messages sent from one PIM SM router to another through the device.

NOTE
This feature applies only to PIM SM version 2 (PIM V2).

Application examples

Figure 164 shows an example application of the PIM SM traffic snooping feature. In this example, a device is connected through an IP router to a PIM SM group source that is sending traffic for two PIM SM groups. The device also is connected to a receiver for each of the groups.

FIGURE 164 PIM SM traffic reduction in enterprise network



When PIM SM traffic snooping is enabled, the device starts listening for PIM SM join and prune messages and IGMP group membership reports. Until the device receives a PIM SM join message or an IGMP group membership report, the device forwards IP multicast traffic out all ports. Once the device receives a join message or group membership report for a group, the device forwards subsequent traffic for that group only on the ports from which the join messages or IGMP reports were received.

In this example, the router connected to the receiver for group 239.255.162.1 sends a join message toward the group's source. Since PIM SM traffic snooping is enabled on the device, the device examines the join message to learn the group ID, then makes a forwarding entry for the group ID and the port connected to the receiver's router. The next time the device receives traffic for 239.255.162.1 from the group's source, the device forwards the traffic only on port 5/1, since that is the only port connected to a receiver for the group.

Notice that the receiver for group 239.255.162.69 is directly connected to the device. As result, the device does not see a join message on behalf of the client. However, since IP multicast traffic reduction also is enabled, the device uses the IGMP group membership report from the client to select the port for forwarding traffic to group 239.255.162.69 receivers.

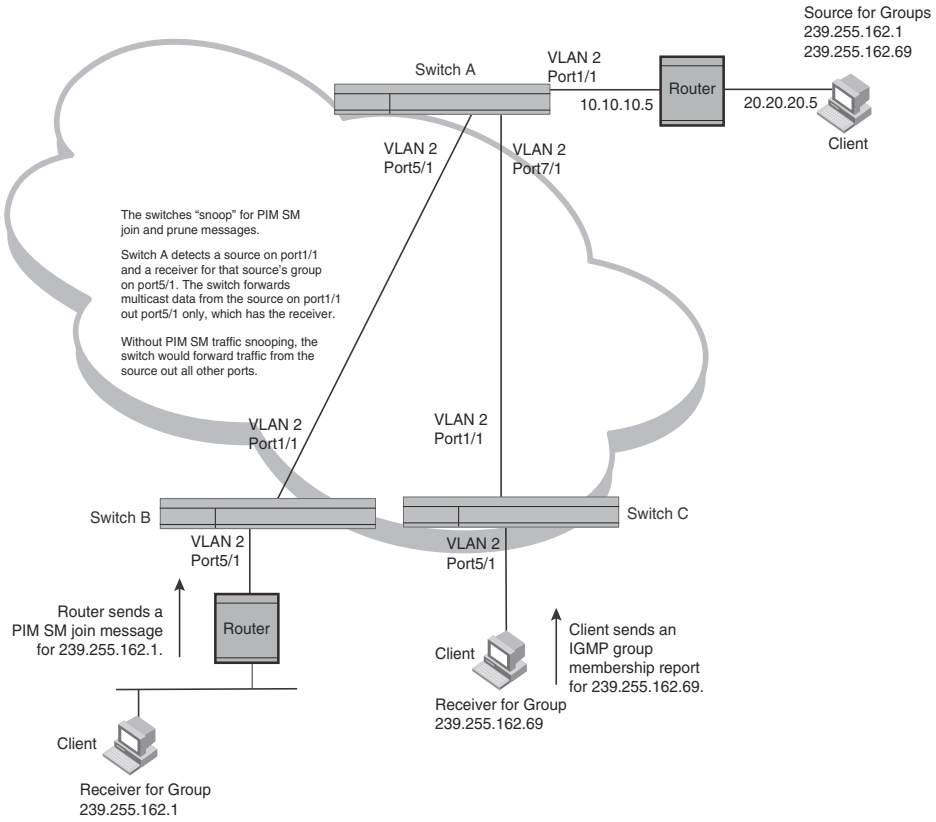
The IP multicast traffic reduction feature and the PIM SM traffic snooping feature together build a list of groups and forwarding ports for the VLAN. The list includes PIM SM groups learned through join messages as well as MAC addresses learned through IGMP group membership reports. In this case, even though the device never sees a join message for the receiver for group 239.255.162.69, the device nonetheless learns about the receiver and forwards group traffic to the receiver.

The device stops forwarding IP multicast traffic on a port for a group if the port receives a prune message for the group.

Notice that the ports connected to the source and the receivers are all in the same port-based VLAN on the device. This is required for the PIM SM snooping feature. The feature also requires the source and the downstream router to be on different IP subnets, as shown in Figure 164.

Figure 165 shows another example application for PIM SM traffic snooping. This example shows devices on the edge of a Global Ethernet cloud (a Layer 2 Packet over SONET cloud). Assume that each device is attached to numerous other devices such as other PowerConnect's.

FIGURE 165 PIM SM traffic reduction in Global Ethernet environment



The devices on the edge of the Global Ethernet cloud are configured for IP multicast traffic reduction and PIM SM traffic snooping. Although this application uses multiple devices, the feature has the same requirements and works the same way as it does on a single device.

Configuration requirements

Consider the following configuration requirements:

- IP multicast traffic reduction must be enabled on the device that will be running PIM SM snooping. The PIM SM traffic snooping feature requires IP multicast traffic reduction.

  NOTE
  Use the passive mode of IP multicast traffic reduction instead of the active mode. The passive mode assumes that a router is sending group membership queries as well as join and prune messages on behalf of receivers. The active mode configures the device to send group membership queries.

- All the device ports connected to the source and receivers or routers must be in the same port-based VLAN.
- The PIM SM snooping feature assumes that the group source and the device are in different subnets and communicate through a router. The source must be in a different IP subnet than the receivers. A PIM SM router sends PIM join and prune messages on behalf of a multicast group receiver only when the router and the source are in different subnets. When the receiver and source are in the same subnet, they do not need the router in order to find one another. They find one another directly within the subnet.

  The device forwards all IP multicast traffic by default. Once you enable IP multicast traffic reduction and PIM SM traffic snooping, the device initially blocks all PIM SM traffic instead of forwarding it. The device forwards PIM SM traffic to a receiver only when the device receives a join message from the receiver. Consequently, if the source and the downstream router are in the same subnet, and PIM SM traffic snooping is enabled, the device blocks the PIM SM traffic and never starts forwarding the traffic. This is because the device never receives a join message from the downstream router for the group. The downstream router and group find each other without a join message because they are in the same subnet.

NOTE
If the “route-only” feature is enabled on a PowerConnect, PIM SM traffic snooping will not be supported.

Enabling PIM SM traffic snooping

To enable PIM SM traffic snooping, enter the following commands at the global CONFIG level of the CLI.

```
NetIron(config)# ip multicast
NetIron(config)# ip pimsm-snooping
```

The first command enables IP multicast traffic reduction. This feature is similar to PIM SM traffic snooping but listens only for IGMP information, not PIM SM information. You must enable both IP multicast traffic reduction and PIM SM traffic snooping to enable the device to listen for PIM SM join and prune messages.

Syntax: [no] ip multicast [active | passive]

This command enables IP multicast traffic reduction. The **active | passive** parameter specifies the mode. The PIM SM traffic snooping feature assumes that the network has routers that are running PIM SM.

Syntax: [no] ip pimsm-snooping

This command enables PIM SM traffic snooping.

To disable the feature, enter the following command.

```
NetIron(config)# no ip pimsm-snooping
```

If you also want to disable IP multicast traffic reduction, enter the following command.

```
NetIron(config)# no ip multicast
```

Multicast traffic reduction per VLAN or VPLS instance

You can configure the following methods for reducing multicast traffic globally on a PowerConnect router:

- IGMP snooping – This is described in "Changing the IGMP mode" on page 1238.
- PIM snooping – This is described in "PIM SM traffic snooping" on page 1239.

When these are set globally on a router, they apply to all VLANs and all VPLS instances that are configured on the router. You can configure specified VLANs or VPLS instances for multicast traffic reduction by these methods as described in the following sections. Additionally, you are able to configure IGMP and PIM proxy which are only configurable per VLAN or VPLS instance.

Multicast traffic reduction per VPLS instance is supported for dual-mode, untagged, single-tagged, and dual-tagged VPLS endpoints.

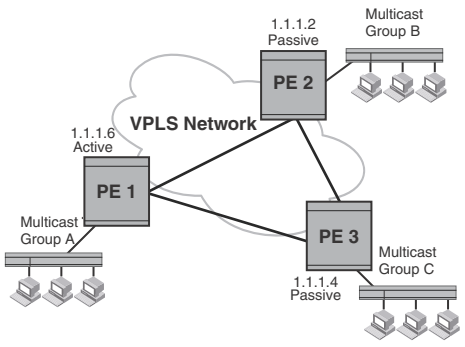
NOTE
IGMP snooping cannot be concurrently enabled on a router with VPLS CPU Protection on a VPLS instance.

NOTE
Traffic will continue to be forwarded only to those VPLS endpoints or peers from which a join for the (S, G) has been recieved irrespective of the status of the local switching option.

Application example

Figure 166 shows an example of multicast traffic reduction in a VPLS network.

FIGURE 166 IP multicast traffic reduction in a VPLS network



In the example shown in Figure 166, when IP multicast traffic reduction (IGMP snooping) is enabled on the VPLS network, PE 1 will be selected as the active port (querier) because it has the lowest router ID amongst the PEs in the VPLS instance. PE 1 will actively send out IGMP queries to solicit information from IP multicast groups within the VPLS instance. PE 2 and PE 3 will not send out queries as they are in passive mode, but will respond to the query from PE 1, with the respective report information received from their hosts.

In a snooping configuration within a VPLS instance, multicast traffic is always flooded to the device that is in active IGMP mode (the router port). If the IP multicast domain includes an IP multicast router, that router will be the querier. In this case, the querier is also known as the router port. If there is no IP multicast router in the domain, one of the devices in the network can be manually configured for active IGMP mode. Otherwise, the device with the lowest router ID will be elected as the querier. In the example in Figure 166, PE 1 is the elected querier.

In a VPLS scenario, reports are always forwarded to all VPLS peers whether or not the peer is the querier. In the above example, PE 1 is elected the querier, but if PE 2 is connected to a receiver, it forwards the reports received from the receiver to both VPLS peers PE 3 and PE 1. Therefore, any traffic for the host connected to PE 2 received from PE 3 are sent by PE 3 to both the router port PE 1 as well as the receiver PE 2.

PE 1 drops the traffic received from PE 3 because it is aware of the presence of a receiver attached to the router PE 2. Traffic sent from PE 3 will only be received by the host connected to PE 2.

If there is no receiver present in the setup, then traffic from PE 3 will only be flooded to its local endpoints and the router port PE 1. Router PE 1 sends the traffic out of its endpoints.

In case of PIM SM snooping, traffic received for unknown groups is always dropped. There is no router port concept in case of PIM SM snooping.

Configuring the IGMP mode per VLAN or VPLS instance

In the following example, multicast traffic reduction is applied using IGMP snooping to VLAN 2.

```
NetIron(config)# vlan 2
NetIron(config-vlan-2)# multicast passive
```

To remove multicast traffic reduction configurations in VLAN 2, and take the global multicast traffic reduction configuration, enter the following command.

```
NetIron(config)# vlan 2
NetIron(config-vlan-2)# no multicast
```

In the following example, multicast traffic reduction is applied using IGMP snooping to VPLS instance V1.

```
NetIron(config)# router mpls
NetIron(config-mpls)# vpls v1 10
NetIron(config--mpls-vpls-v1)# multicast passive
```

Syntax: [no] multicast active | passive

When you enable IP multicast for a specific VLAN or VPLS instance, IGMP snooping is enabled. The device uses IGMP to maintain a table of the Group Membership reports received by the device for the specified VLAN or VPLS instance. You can use active or passive IGMP mode. There is no default mode.

The description for the IGMP modes is as follows:

- **Active** – When active IGMP mode is enabled, the router actively sends out IGMP queries to identify IP multicast groups within the VLAN or VPLS instance and makes entries in the IGMP table based on the Group Membership reports received from the network.
- **Passive** – When passive IGMP mode is enabled, the router listens for IGMP Group Membership reports on the VLAN or VPLS instance specified but does not send IGMP queries. The passive mode is called "IGMP snooping". Use this mode when another device in the VLAN or VPLS instance is actively sending queries.

Configuring the PIM SM traffic snooping per VLAN or VPLS instance

In the following example, multicast traffic reduction is applied using PIM SM Traffic snooping to VLAN 2.

```
NetIron(config)# vlan 2
NetIron(config-vlan-2)# multicast pimsm-snooping
```

In the following example, multicast traffic reduction is applied using PIM SM traffic snooping to VPLS instance V1.

```
NetIron(config)# router mpls
NetIron(config-mpls)# vpls v1 10
NetIron(config--mpls-vpls-v1)# multicast pimsm-snooping
```

Syntax: [no] multicast pimsm-snooping

Configuring PIM proxy per VLAN or VPLS instance

Using the PIM proxy function, multicast traffic can be reduced by configuring an PowerConnect router to issue PIM join and prune messages on behalf of hosts that the configured router discovers through standard PIM interfaces. The router is then able to act as a proxy for the discovered hosts and perform PIM tasks upstream of the discovered hosts. Where there are multiple PIM downstream routers, this removes the need to send multiple messages.

To configure a PowerConnect router to function as a PIM proxy on VLAN 2, use the following commands.

```
NetIron(config)# vlan 2
NetIron(config-vlan-2)# multicast pim-proxy-enable
```

To configure an PowerConnect router to function as an PIM proxy on VPLS instance V1, use the following commands.

```
NetIron(config)# router mpls
NetIron(config-mpls)# vpls v1 10
NetIron(config--mpls-vpls-v1)# multicast pim-proxy-enable
```

Syntax: [no] multicast pim-proxy-enable

Configuring IGMP snooping tracking per VLAN or VPLS instance

When IGMP Snooping Tracking is enabled, the PowerConnect immediately removes any IGMP host port from the IP multicast group entry when it detects an IGMP-leave message on the specified host port without first sending out group-specific queries to the interface. By default, IGMP Snooping Tracking is disabled.

The **ip multicast tracking** command may be enabled globally as well as per VLAN basis. To enable IGMP Snooping Tracking globally, enter a command such as the following.

```
NetIron(config)# multicast tracking
```

Syntax: [no] ip multicast tracking

The **no** form of this command disables the tracking process globally.

To enable IGMP Snooping Tracking per VLAN, enter commands such as the following.

```
NetIron(config)# vlan 100
NetIron(config-vlan-100)# multicast tracking
```

Syntax: [no] multicast tracking

The **no** form of this command disables the tracking process per VLAN.

To enable IGMP Snooping Tracking per VPLS instance, enter commands such as the following.

```
NetIron(config)# router mpls
NetIron(config-mpls)# vpls v1 10
NetIron(config--mpls-vpls-v1)# multicast tracking
```

For IGMPv3, the above command also internally tracks all the IGMPv3 hosts behind a given port. The port is not removed from the IP multicast group entry in the forwarding table until all the hosts behind that port have left that multicast group. When the last IGMPv3 host sends a IGMPv3 leave message, the port is removed from the IP multicast group entry in the forwarding table immediately without first sending out group_source_specific query to the interface

Syntax: [no] multicast tracking

The **no** form of this command disables the tracking process per VPLS instance.

Multicast snooping over VPLS will not load-balance the multicast traffic among multiple tunnels,
Multicast snooping over VPLS will not load-balance the multicast traffic among multiple tunnels,

NOTE
Multicast snooping over VPLS will not load-balance the multicast traffic among multiple tunnels when IGMP Snooping is enabled,

Static IGMP membership

When configuring a static IGMP membership, you have two options:

The **multicast static-group uplink** command which sends the traffic to the router, and saves a port.

The **multicast static-group** <*group-address*> <*port-list*> command is for downstream traffic and uses a port.

Configuring a multicast static group uplink per VLAN

When the **multicast static-group uplink** command is enabled on a snooping VLAN, the snooping device behaves like an IGMP host on ports connected to the multicast router. The snooping device will respond to IGMP queries from the uplink multicast PIM router for the groups and sources configured. Upon the multicast router receiving the IGMP join message, it will initiate the PIM join on its upstream path towards the source to pull the source traffic down. The source traffic will stop at the IGMP snooping device. The traffic will then be forwarded to the multicast receiver and router ports or dropped in hardware if no other multicast receiver and routers are present in the VLAN.

The **multicast static-group uplink** command cannot be configured globally per VPLS basis. It can be configured under the VLAN configuration only.

The **multicast static-group uplink** command must be used with the **multicast static-group** command in order to connect a remote multicast source with the snooping vlan where the static-group is configured.

When using IGMP v3, you can use the **multicast static-group include** or **multicast static-group exclude** command to statically *include* or *exclude* multicast traffic, respectively for hosts that cannot signal group membership dynamically.

To configure the snooping device to statically join a multicast group on the uplink interface, enter commands such as the following.

```
NetIron(config)# vlan 100
NetIron(config-vlan-100)# multicast static-group 224.10.1.1 uplink
```

To configure the physical interface 10.43.3.12 to statically join a multicast group on port 2/4, enter commands such as the following.

```
NetIron(config)# vlan 100
NetIron((config-vlan-100)# multicast static-group 224.10.1.1  2/4
```

To configure the snooping device to statically join a multicast stream with the source address of 10.43.1.12 in the include mode, enter commands such as the following.

```
NetIron(config)# vlan 100
NetIron(config-vlan-100)# multicast static-group 224.10.1.1 include 10.43.1.12
uplink
```

To configure the snooping device to statically join all multicast streams on the uplink interface excluding the stream with source address 10.43.1.12, enter commands such as the following.

```
NetIron(config)# vlan 100
NetIron(config-vlan-100)# multicast static-group 224.10.1.1 exclude 10.43.1.12
uplink
```

Configuring multicast static group <port-list> per VLAN

When the **multicast static-group** <*group-address*> <*port-list*> command is enabled on a snooping VLAN, the snooping device will add the ports to the outgoing interface list of the multicast group entry in the forwarding table as if IGMP joins were received from these ports. These ports will not be aged out from the multicast group for not responding to the IGMP queries.

The **multicast static-group** <*group-address*> <*port-list*> command cannot be configured globally per VPLS basis.

It can be configured under the VLAN configuration level only.

To configure the physical interface ethernet 2/4 to statically join a multicast group, enter commands such as the following.

```
NetIron(config)# vlan 100
NetIron(config-vlan-100)# multicast static-group 224.10.1.1 ethernet 2/4
```

To configure the physical interface ethernet 3/4 to statically join a multicast stream with source address of 10.43.1.12 in the include mode , enter commands such as the following.

```
NetIron(config)# vlan 100
NetIron(config-vlan-100)# multicast static-group 224.10.1.1 include 10.43.1.12
ethernet 3/4
```

To configure the physical interface ethernet 3/4 to statically join all multicast streams on the uplink interface excluding the stream with source address of 10.43.1.12, enter commands such as the following.

```
NetIron(config)# vlan 100
NetIron(config-vlan-100)# multicast static-group 224.10.1.1 exclude 10.43.1.12
ethernet 3/4
```

Syntax: [no] multicast static-group <*group-address*> uplink

Syntax: [no] multicast static-group <*group-address*> <*port-list*>

IGMP v3 Commands

Syntax: [no] multicast static-group <*group-address*> [include I exclude <*source-address*>] uplink

Syntax: [no] multicast static-group <*group-address*> [include I exclude <*source-address*>] <*port-list*>

The **group-address** parameter specifies the group multicast address.

The **include** or **exclude** keyword indicates a filtering action. You can specify which source (for a group) to include or exclude. The **include** or **exclude** keyword is only supported on IGMPv3.

The **source-address** parameter specifies the IP address of the multicast source. Each address must be added or deleted one line per source.

The **uplink** parameter specifies the port as an uplink port that can receive multicast data for the configured multicast groups.. Upstream traffic will be sent to the router and will not use a port.

The **port-list** parameter specifies the range of ports to include in the configuration.

The **no** form of this command removes the static multicast definition. Each configuration must be deleted separately.

Displaying IP multicast information

The following sections show how to display and clear IP multicast reduction information.

Displaying multicast information

You can display IP multicast traffic introduction in a brief mode for all instances or in a detail mode for a specified VLAN or VPLS instance.

```
NetIron#show ip multicast
Global Multicast Traffic Reduction Configuration
   igmp Snooping State:     Active    Version             :          2

            SG join ports: 12/2 10/7
```

Syntax: show ip multicast pimsm-snooping

This display shows the following information.

Table 0.15:

This field...	Displays...
The PIM SM traffic snooping state	The first line of the display indicates whether the feature is enabled or disabled; and if it is enabled, if it is passive or active. The PIM SM traffic snooping feature requires the IP multicast traffic reduction feature.
VLAN ID	The port-based VLAN to which the neighbors and groups listed below the VLAN ID apply. Each port-based VLAN is a separate Layer 2 broadcast domain. **NOTE:** PIM SM traffic snooping requires the source and the receivers to be in the same port-based VLAN on the device. If the source and receivers are in different port-based VLANs, the device blocks the multicast traffic.
PIM SM Neighbor list	The PIM SM routers that are attached to the device's ports in the VLAN. The value following "expires" indicates how many seconds the device will wait for a hello message from the neighbor before determining that the neighbor is no longer present and removing the neighbor from the list.
Number of Multicast Group	The total number of groups for which the VLAN's ports have received PIM join or prune messages and IGMP group membership reports.
Multicast Group	The IP address of the multicast group. The "Num SG" entry indicates how many Source to Group flows are created for that Multicast Group as there can be more than one source for a given group. **NOTE:** The fid and camindex values are used by Dell Technical Support for troubleshooting.
Forwarding Port	The ports attached to the group's receivers. A port is listed here when it receives a join message for the group, an IGMP membership report for the group, or both.
PIMv2 Group Port	The ports on which the PowerConnect has received PIM SM join messages for the group.
Source, Port list	The IP address of each PIM SM source and the PowerConnect ports connected to the receivers of the source.
SG join ports:	Ports from which a join message was received. The PowerConnect forwards the traffic only on this port.
(S, G) age	The actual aging value. If this entry shows the value 0 seconds, software age value is still 0 and the flow is programmed in the CAM. If the entry shows a value other than 0 seconds, then the CAM entry has aged out and the software aging has begun. Once this age value reaches the Group Age value the entry will be deleted from the table. Group age value can be can be from 10 – 1220 seconds. The default is 260 seconds.

Displaying IP multicast statistics

To display IP multicast statistics on a device, enter the following commands at any level of the CLI.

```
NetIron# show ip multicast statistics
IP multicast is enabled - Passive

VLAN ID 1
Reports Received:               34
Leaves Received:                21
```

```
General Queries Received:        60
Group Specific Queries Received: 2
Others Received:                 0
General Queries Sent:            0
Group Specific Queries Sent:     0

VLAN ID 2
Reports Received:                0
Leaves Received:                 0
General Queries Received:        60
Group Specific Queries Received: 2
Others Received:                 0
General Queries Sent:            0
Group Specific Queries Sent:     0
```

The command in this example shows statistics for two port-based VLANs.

Syntax: show ip multicast statistics

Clearing IP multicast statistics

To clear IP multicast statistics on a device, enter the following command at the Privileged EXEC level of the CLI.

```
NetIron# clear ip multicast statistics
```

This command resets statistics counters for all the statistics displayed by the **show ip multicast statistics** command to zero.

Syntax: clear ip multicast statistics

Clearing IGMP group flows

To clear all the IGMP flows learned by the device, enter the following command at the Privileged EXEC level of the CLI.

```
NetIron# clear ip multicast all
```

The following example shows IGMP flows information listed by the **show ip multicast** command, followed by removal of the information by the **clear ip multicast all** command.

```
NetIron# show ip multicast
IP multicast is enabled - Active
VLAN ID 1
Active 192.168.2.30 Router Ports  4/13
Multicast Group: 239.255.162.5, Port: 4/4 4/13
Multicast Group: 239.255.162.4, Port: 4/10 4/13

NetIron# clear ip multicast all

NetIron# show ip multicast
IP multicast is enabled - Active
VLAN ID 1
Active 192.168.2.30 Router Ports  4/13
```

To clear the learned IGMP flows for a specific IP multicast group, enter a command such as the following.

```
NetIron# clear ip multicast group 239.255.162.5
```

The following example shows how to clear the IGMP flows for a specific group and retain reports for other groups.

```
NetIron# show ip multicast
IP multicast is enabled - Active
VLAN ID 1
Active 192.168.2.30 Router Ports  4/13
Multicast Group: 239.255.162.5, Port: 4/4 4/13
Multicast Group: 239.255.162.4, Port: 4/10 4/13

NetIron# clear ip multicast group 239.255.162.5

NetIron# show ip multicast
IP multicast is enabled - Active
VLAN ID 1
Active 192.168.2.30 Router Ports  4/13
Multicast Group: 239.255.162.4, Port: 4/10 4/13
```

Syntax: clear ip multicast all | group <*group-id*>

The **all** parameter clears the learned flows for all groups.

The **group** <*group-id*> parameter clears the flows for the specified group but does not clear the flows for other groups.

Configuring MBGP 28

Overview

The following displays the Multi-protocol Border Gateway Protocol (MBGP) features supported by PowerConnect B-MLXe.

- MBGP
- Advertising Routes from the Local AS to MBGP
- Network Prefix to Advertise
- Redistribution of Directly-Connected Multicast Routes into MBGP
- Static IP Multicast Routes
- Aggregating Routes Advertised to BGP4 Neighbors
- Displaying MBGP Information
- Clearing MBGP Information
- IPv6 Support
- VRF Support
- IPv4 Multicast
- IPv6 Multicast

This chapter provides details on how to configure ***Multi-protocol Border Gateway Protocol (MBGP)***. MBGP is an extension to BGP that allows a router to support separate unicast and multicast topologies. BGP4 cannot support a multicast network topology that differs from the network's unicast topology. MBGP allows you to support a multicast topology that is distinct from the network's unicast topology. For example, if you want to dedicate a link on your Internet router to multicast traffic, use MBGP to handle the routes on that link.

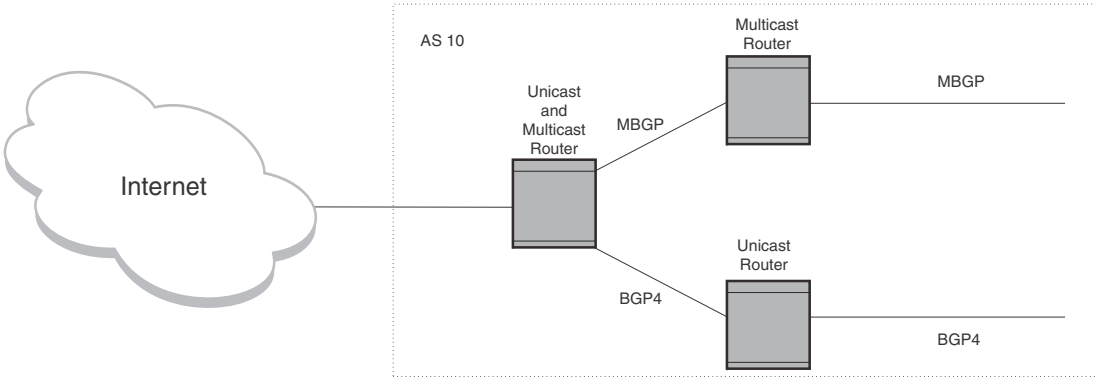
NOTE
The IPv6 multicast address family for MBGP is supported. However, only static mroutes and directly connected routes over IPv6 multicast enabled interfaces may be enabled for distribution.

MBGP provides the following benefits:

- You can support a network whose multicast topology is different from its unicast topology. Even if the unicast and multicast networks have the same topologies, you can support different sets of routing policies for unicast and multicast.
- You can use BGP4's powerful feature set with MBGP.

Figure 167 shows an example of a network that contains both a unicast topology and a multicast topology. The unicast and multicast router in this example receives unicast and multicast routes from the Internet. The router advertises the multicast routes to the multicast router and advertises the unicast routes to the unicast router. Likewise, the unicast and multicast router can advertise unicast routes received from the unicast router to the Internet, and can advertise multicast routes received from the multicast router to the Internet.

FIGURE 167 MBGP used when multicast topology is different from unicast topology



An MBGP router learns MBGP routes from its neighbors in other ASs. An MBGP router also can advertise MBGP routes to its neighbors. The implementation of MBGP enables you to advertise multicast routes from the following sources:

- Explicitly configured network prefixes
- Static IP multicast routes
- Directly-connected multicast routes redistributed into MBGP.

You can configure an aggregate address to aggregate network prefixes into a single, more general prefix for advertisement.

MBGP is described in detail in RFC 2858.

Configuration considerations

The configuration considerations are as follows:

- MBGP does not redistribute DVMRP routes. It redistributes static routes only.
- You cannot redistribute MBGP routes into BGP4.
- By default, the PowerConnect does not place a limit any limit on the number of multicast routes. You can configure the device to place a limit on the number of multicast routes by using the **ip max-mroute** command.

Configuring MBGP

1. Optional – Set the maximum number of multicast routes supported by the PowerConnect.
2. Enable MBGP by doing the following:

- Enable PIM Sparse Mode (PIM SM) or PIM Dense Mode (PIM DM) globally and on the individual Reverse Path Forwarding (RPF) interfaces. PIM must be running on the PowerConnect in order for the device to send multicast prefixes to other multicast devices.
- Enable BGP4. If this is the first time you have configured BGP4 on this device, you also need to specify the local AS number.

3. Identify the neighboring MBGP routers.
4. Optional – Configure an MBGP default route.
5. Optional – Configure an IP multicast static route.
6. Optional – Configure an MBGP aggregate address.
7. Optional – Configure a route map to apply routing policy to multicast routes.
8. Save the configuration changes to the startup-config file.

Setting the maximum number of multicast routes supported

NOTE
This procedure requires a software reload to place the change into effect.

Use the **system-max multicast-route** command to increase the maximum number of multicast routes for IPv6 address families.

Entering the following commands.

```
NetIron(config)# system-max multicast-route 12000
NetIron(config)# write memory
NetIron(config)# end
NetIron# reload
```

These commands increase the maximum number of multicast routes supported, save the configuration change to the startup-config file, and reload the software to place the change into effect.

Syntax: [no] system-max multicast-route <*num*>

The <*num*> parameter specifies the number of multicast routes. This value can range from 1024 to the maximum routes supported by the system, subject to a maximum of 153,600 routes.

You can use the following runtime command to define the maximum number of multicast routes supported. This parameter can be defined for the default VRF using the following command.

```
NetIron(config)# ip max-mroute
```

Syntax: [no] ip max-mroute <*num*>

The <*num*> parameter specifies the number of multicast routes and can be from 1024 – 153,600.

To define the maximum number of multicast routes for a specified VRF, use the following commands.

```
NetIron(config)# ip vrf blue
NetIron(config-vrf-blue)# ip max-mroute
```

Syntax: [no] ip vrf <*vrf-name*>

Syntax: [no] ip max-mroute <*num*>

The **ip vrf** parameter specifies the virtual routing instance (VRF) specified by the variable *<vrf-name>*

The *<num>* parameter specifies the number of multicast routes. This value can range from 1024 to the maximum routes supported by the system, subject to a maximum of 153,600 routes.

Enabling MBGP

To make use of MBGP4, you must enable PIM SM or DM and BGP4. Enter commands such as the following.

```
NetIron> enable
NetIron# configure terminal
NetIron(config)# router pim
NetIron(config)# interface ethernet 1/1
NetIron(config-if-1/1)# ip address 1.1.1.1/24
NetIron(config-if-1/1)# ip pim
NetIron(config-if-1/1)# exit
NetIron(config)# router bgp
BGP4: Please configure 'local-as' parameter in order to enable BGP4.
NetIron(config-bgp)# local-as 10
```

NOTE
For IPv6 address family, make sure you enter the IPv6 versions of the commands.

The commands in this example configure PIM DM globally and on port 1/1, then enable BGP4. Once you enable PIM DM or PIM SM both globally and on the individual RPF interfaces, and enable BGP4, support for MBGP is automatically enabled.

Once MBGP is enabled, MBGP parameters are configured under the IPv4 multicast address family. Enter the following command to enter the IPv4 multicast address family level.

```
NetIron(config-bgp)#address-family ipv4 multicast
NetIron(config-bgp-ipv4m)#
```

Syntax: [no] address-family ipv4 multicast

To enable MBGP for IPv6, enter the following command.

```
NetIron(config-bgp)#address-family ipv6 multicast
NetIron(config-bgp-ipv6m)#
```

Syntax: [no] address-family ipv6 multicast

Adding MBGP neighbors

To add an MBGP neighbor, enter a command such as the following.

```
NetIron(config-bgp-ipv4m)#neighbor 1.2.3.4 remote-as 44
```

This command adds a router with IP address 1.2.3.4 as an MBGP neighbor.

The **remote-as 44** parameter specifies that the neighbor is in remote BGP4 AS 44. The PowerConnect will exchange only multicast routes with the neighbor.

NOTE
If the PowerConnect has multiple neighbors with similar attributes, you can simplify configuration by configuring a peer group, then adding individual neighbors to it. The configuration steps are similar, except you specify a peer group name instead of a neighbor IP address when configuring the neighbor parameters, then add individual neighbors to the peer group.

The command is the same as the command for configuring a unicast BGP neighbor, except in MBGP, the command is entered in the IPv4 multicast address family level. Here is the full syntax for the neighbor command.

Syntax: **[no] neighbor** <*ip-addr*> **|** <*peer-group-name*>
[default-originate [route-map <*map-name*>**]]**
[description <*string*>**]**
[distribute-list in | out <*num,num,...*> **|** <*acl-num*> **in | out]**
[ebgp-multihop [<*num*>**]]**
[filter-list in | out <*num,num,...*> **|** <*acl-num*> **in | out | weight]**
[maximum-prefix <*num*> *[*<*threshold*>**] [teardown]]**
[next-hop-self]
[password [0 | 1] <*string*>**]**
[prefix-list <*string*> **in | out]**
[remote-as <*as-number*>**]**
[remove-private-as]
[route-map in | out <*map-name*>**]**
[route-reflector-client]
[send-community]
[soft-reconfiguration inbound]
[shutdown [generate-rib-out]]
[timers keep-alive <*num*> **hold-time** <*num*>**]**
[update-source loopback <*num*>**]**
[weight <*num*>**]**

The <*ip-addr*> | <*peer-group-name*> parameter indicates whether you are configuring an individual neighbor or a peer group. If you specify a neighbor's IP address, you are configuring that individual neighbor. If you specify a peer group name, you are configuring a peer group. Make sure you enter the IP address in the correct address family format.

The **remote-as** <*as-number*> parameter specifies the AS the MBGP neighbor is in. The <*as-number*> can be a number from 1 – 65535. There is no default.

NOTE
The PowerConnect attempts to establish a BGP4 session with a neighbor as soon as you enter a command specifying the neighbor's IP address. If you want to completely configure the neighbor parameters before the PowerConnect establishes a session with the neighbor, you can administratively shut down the neighbor.

Optional configuration tasks

The following sections describe how to perform some optional BGP4 configuration tasks.

NOTE
This section shows some of the more common optional tasks, including all the tasks that require you to specify that they are for MBGP. Most tasks are configured only for BGP4 but apply both to BGP4 and MBGP.

Advertising routes from the local AS to MBGP

You can configure the PowerConnect to advertise directly-connected and static multicast routes from the local AS to other ASs using the following methods:

- **For directly-connected routes:**
  - Enable redistribution of directly-connected multicast routes.
- **For indirectly-connected routes:**
  - Configure static IP multicast routes. The corresponding IP route must be present in the IP multicast table.
  - Explicitly configure network prefixes to advertise (**network** command).

NOTE
You can configure the device to advertise directly-connected networks into MBGP using the **network** command. You are not required to use redistribution or configure static multicast routes.

Configuring a network prefix to advertise

By default, the PowerConnect advertises MBGP routes only for the networks you identify using the network command or that are redistributed into MBGP from IP multicast route tables.

NOTE
The exact route must exist in the IP multicast route table so that the PowerConnect can create a local MBGP route.

To configure the PowerConnect to advertise network 207.95.22.0/24 as a multicast route, enter the following command.

```
NetIron(config-bgp-ipv4m)# network 207.95.22.0 255.255.255.0
```

Syntax: [no] network <*ip-addr*> <*ip-mask*> **[route-map** <*map-name*>**] [backdoor] [weight** <*num*>**]**

The <*ip-addr*> is the network number and the <*ip-mask*> specifies the network mask.

NOTE
For IPv6 address family, make sure you enter the IP address in IPv6 format.

The **route-map** <*map-name*> parameter specifies the name of the route map you want to use to set or change BGP4 attributes for the network you are advertising. The route map must already be configured.

The **backdoor** parameter changes the administrative distance of the route to this network from the EBGP administrative distance (20 by default) to the Local BGP weight (200 by default), thus tagging the route as a backdoor route.

The **weight** <*num*> parameter specifies a weight to be added to routes to this network.

Enabling redistribution of directly-connected multicast routes into MBGP

To redistribute a directly-connected multicast route into MBGP enable redistribution of directly-connected routes into MBGP, using a route map to specify the routes to be redistributed.

Example

```
NetIron(config)# access-list 10 permit 207.95.22.0 0.0.0.255
NetIron(config)# route-map mbgpmap permit 1
NetIron(config-routemap mbgpmap)# match ip address 10
NetIron(config-routemap mbgpmap)# exit
NetIron(config)# router bgp
NetIron(config-bgp-ipv4m)# redistribute connected route-map mbgpmap
```

The first command configures an IP ACL for use in the route map. The ACL matches on the destination network for the route to be redistributed. The next four commands configure a route map that matches on routes to the multicast network specified in IP ACL 10. The PowerConnect redistributes routes that match the route map into MBGP.

Syntax: [no] redistribute [connected | static] [metric <*num*>**] [route-map** <*map-name*>**]**

The **connected** parameter indicates that you are redistributing routes to directly attached devices into MBGP.

The **static** parameter indicates that you are redistributing static mroutes into MBGP.

The **metric** <*num*> parameter changes the metric. You can specify a value from 0 – 4294967295. The default
is 0.

The **route-map** <*map-name*> parameter specifies a route map to be consulted before redistributing the routes into MBGP.

NOTE
The route map you specify must already be configured.

NOTE
For IPv6 address family, make sure you enter the IPv6 versions of the commands.

Configuring static IP multicast routes

To configure static IP multicast routes, enter commands such as the following.

```
NetIron(config)# ip mroute 207.95.10.0 255.255.255.0 interface ethernet 1/2
NetIron(config)# ip mroute 0.0.0.0 0.0.0.0 interface ethernet 2/3
```

The commands in this example configure two static multicast routes. The first route is for a specific source network, 207.95.10.0/24. If the PowerConnect receives multicast traffic for network 207.95.10.0/24, the traffic must arrive on port 1/2. The second route is for all other multicast traffic. Traffic from multicast sources other than 207.95.10.0/24 must arrive on port 2/3.

If you configure more than one static multicast route, the PowerConnect always uses the most specific route that matches a multicast source address. Thus, if you want to configure a multicast static route for a specific multicast source and also configure another multicast static route for all other sources, you can configure two static routes as shown in this example.

Syntax: [no] **ip mroute** <*ip-addr*> <*ip-mask*> [<*next-hop-ip-addr*> | **ethernet** <*slot/port*> | **ve** <*num*> | **tunnel** <*num*> | **null0**] [<*cost*>] [**distance** < *num*>]

The **ip-addr** and **ip-mask** parameters specifies the PIM source for the route. Also, for IPv6 address family, make sure you enter the IP address in IPv6 format.

The **ethernet** <*slot/port*> parameter specifies a physical port.

The **ve** <*num*> parameter specifies a virtual interface.

The **tunnel** <*num*> parameter specifies a GRE tunnel interface that is being configured. The GRE tunnel interface is enabled under the router PIM configuration.

The **null0** parameter is the same as dropping the traffic.

The **distance** <*num*> parameter sets the administrative distance for the route.

The <*cost*> parameter specifies the cost metric of the route.
Possible values are: 1 - 6
Default value: 1

NOTE
Regardless of the administrative distances, the PowerConnect always prefers directly connected routes over other routes.

Aggregating routes advertised to BGP4 neighbors

By default, the PowerConnect advertises individual MBGP routes for all the multicast networks. The aggregation feature allows you to configure the PowerConnect to aggregate routes in a range of networks into a single CIDR number. For example, without aggregation, the PowerConnect will individually advertise routes for networks 207.95.10.0/24, 207.95.20.0/24, and 207.95.30.0/24. You can configure the PowerConnect to instead send a single, aggregate route for the networks. The aggregate route would be advertised as 207.95.0.0/16.

To aggregate MBGP routes for 207.95.10.0/24, 207.95.20.0/24, and 207.95.30.0/24, enter the following command.

```
NetIron(config-bgp-router)# aggregate-address 207.95.0.0 255.255.0.0
```

Syntax: [no] **aggregate-address** <*ip-addr*> <*ip-mask*> [**as-set**] [**summary-only**] [**suppress-map** <*map-name*>] [**advertise-map** <*map-name*>] [**attribute-map** <*map-name*>]

The <*ip-addr*> and <*ip-mask*> parameters specify the aggregate value for the networks. Also, for IPv6 address family, make sure you enter the IP address in IPv6 format.

The **as-set** parameter causes the router to aggregate AS-path information for all the routes in the aggregate address into a single AS-path.

The **summary-only** parameter prevents the router from advertising more specific routes contained within the aggregate route.

The **suppress-map** <*map-name*> parameter prevents the more specific routes contained in the specified route map from being advertised.

The **advertise-map** <*map-name*> parameter configures the PowerConnect to advertise the more specific routes in the specified route map.

The **attribute-map** <*map-name*> parameter configures the PowerConnect to set attributes for the aggregate routes based on the specified route map.

NOTE
For the **suppress-map**, **advertise-map**, and **attribute-map** parameters, the route map must already be defined.

Displaying MBGP information

All of the BGP show commands have MBGP equivalents. Use **mbgp** instead of **bgp** in the command syntax. For example, to display the MBGP route table, enter the **show ip mbgp routes** command instead of the **show ip bgp routes** command.

Table 195 lists the MBGP show commands and describes their output. For information about a command, refer to 26, "Configuring BGP4 (IPv4)".

TABLE 195 MBGP show commands for IPv4

Command	Description
show ip mbgp summary	Displays summary configuration information and statistics.
show ip mbgp config	Shows the configuration commands in the running-config.
show ip mbgp neighbors	Displays information about MBGP neighbors.
show ip mbgp peer-group	Displays information about MBGP peer groups.
show ip mbgp routes	Displays MBGP routes.
show ip mbgp <*ip-addr*>[/<*prefix*>]	Displays a specific MBGP route.
show ip mbgp attribute-entries	Displays MBGP route attributes.
show ip mbgp dampened-paths	Displays MBGP paths that have been dampened by route flap dampening.
show ip mbgp flap-statistics	Displays route flap dampening statistics.
show ip mbgp filtered-routes	Displays routes that have been filtered out.
show ip mbgp vpn4	Displays VPN-IPv4 address family information
show ip mbgp vrf	Displays IPv4 address family information for a VPN Routing/Forwarding instance

Table 196 lists the show commands available to display MBGP IPv6 information:

TABLE 196 MBGP show commands for IPv6

Command	Description
show ipv6 mbgp summary	Displays summary configuration information and statistics.
show ipv6 mbgp config	Shows the configuration commands in the running-config.
show ipv6 mbgp neighbors	Displays information about MBGP neighbors.
show ip mbgp peer-group	Displays information about MBGP peer groups.
show ipv6 mbgp routes	Displays MBGP routes.
show ipv6 mbgp <*ip-addr*>[/<*prefix*>]	Displays a specific MBGP route.
show ipv6 mbgp attribute-entries	Displays MBGP route attributes.
show ipv6 mbgp dampened-paths	Displays MBGP paths that have been dampened by route flap dampening.

TABLE 196 MBGP show commands for IPv6 (Continued)

Command	Description
show ipv6 mbgp flap-statistics	Displays route flap dampening statistics.
show ipv6 mbgp filtered-routes	Displays routes that have been filtered out.

The following sections show examples of some of the MBGP show commands. An example of the **show ip mroute** and the **show ipv6 mroute** commands are also included. Both of the commands display the multicast route table.

Displaying summary MBGP information

To display a summary of MBGP IPv4 information, enter the following command at any CLI prompt.

```
NetIron# show ip mbgp summary
   BGP4 Summary
  Router ID: 9.9.9.1   Local AS Number : 200
  Confederation Identifier : not configured
  Confederation Peers:
  Maximum Number of Paths Supported for Load Sharing : 1
  Number of Neighbors Configured : 1, UP: 1
  Number of Routes Installed : 5677
  Number of Routes Advertising to All Neighbors : 5673
  Number of Attribute Entries Installed : 3
  Neighbor Address  AS#   State   Time     Rt:Accepted Filtered Sent   ToSend
  166.1.1.2         200   ESTAB   0h24m54s    3        0        5673   0
```

Syntax: show ip mbgp summary

NOTE
This command's display looks similar to the display for the **show ip bgp config** command. However, the **show ip mbgp config** command lists only the MBGP neighbors, whereas the show ip bgp config command lists only the BGP neighbors.

To display a summary of MBGP IPv6 information, enter the following command at any CLI prompt.

```
NetIron# show ipv6 mbgp summary
  BGP4 Summary
  Router ID: 1.1.1.1   Local AS Number: 100
  Confederation Identifier: not configured
  Confederation Peers:
  Maximum Number of IP ECMP Paths Supported for Load Sharing: 1
  Number of Neighbors Configured: 1, UP: 1
  Number of Routes Installed: 4, Uses 344 bytes
  Number of Routes Advertising to All Neighbors: 7, Uses 308 bytes
  Number of Attribute Entries Installed: 2, Uses 184 bytes
  Neighbor Address  AS#   State   Time     Rt:Accepted Filtered Sent   ToSend
  2004::2           200   ESTAB   0h39m50s    4        0         3      0
```

Syntax: show ipv6 mbgp summary

Displaying the active MBGP configuration

To display the active MBGP IPv4 configuration information contained in the running-config without displaying the entire running-config, enter the following command at any level of the CLI.

```
NetIron# show ip mbgp config
Current BGP configuration:

router bgp
 local-as 200
 neighbor 166.1.1.2 remote-as 200

 address-family ipv4 unicast
 no neighbor 166.1.1.2 activate
 exit-address-family

 address-family ipv4 multicast
 redistribute connected
 redistribute static
 neighbor 166.1.1.2 activate
 exit-address-family

 address-family ipv6 unicast
 exit-address-family
end of BGP configuration
```

Syntax: show ip mbgp config

NOTE
This command displays exactly the same information as the **show ip bgp config** command. Each command displays both the BGP and MBGP configuration commands that are in the running-config.

To display the active MBGP IPv6 configuration information contained in the running-config without displaying the entire running-config, enter the following command at any level of the CLI.

```
NetIron# show ipv6 mbgp config
Current BGP configuration:

router bgp
 local-as 100
 neighbor 2004::2 remote-as 200

 address-family ipv4 unicast
 no neighbor 2004::2 activate
 exit-address-family

 address-family ipv4 multicast
 exit-address-family

 address-family ipv6 unicast
 exit-address-family

 address-family ipv6 multicast
 neighbor 2004::2 activate
 redistribute connected
 redistribute static
 exit-address-family

 address-family vpnv4 unicast
 exit-address-family
end of BGP configuration
```

Syntax: show ipv6 mbgp config

Displaying MBGP neighbors

To view MBGP IPv4 neighbor information including the values for all the configured parameters, enter the **show ip mbgp neighbor** command. This display is similar to the **show ip bgp neighbor** display but has additional fields that apply only to MBGP. These fields are shown in bold type in the example and are explained below.

NOTE
The display shows all the configured parameters for the neighbor. Only the parameters that have values different from their defaults are shown.

```
NetIron # show ip mbgp neighbor 7.7.7.2
    Total number of BGP Neighbors: 1
1   IP Address: 166.1.1.2, Remote AS: 200 (IBGP), RouterID: 8.8.8.1
    State: ESTABLISHED, Time: 0h33m26s, KeepAliveTime: 60, HoldTime: 180
       KeepAliveTimer Expire in 9 seconds, HoldTimer Expire in 161 seconds
       PeerGroup: mbgp-mesh
       MD5 Password: $Gsig@U\
       NextHopSelf: yes
       RefreshCapability: Received
    Messages:    Open    Update  KeepAlive Notification Refresh-Req
       Sent    : 2       3264    17        0            0
       Received: 1       1       34        0            0
    Last Update Time: NLRI       Withdraw          NLRI       Withdraw
                  Tx: ---        ---           Rx: ---        ---
    Last Connection Reset Reason:Unknown
    Notification Sent:     Unspecified
    Notification Received: Unspecified
    Neighbor NLRI Negotiation:
      Peer Negotiated IPV4  multicast  capability
      Peer configured for  IPV4 multicast  Routes
    TCP Connection state: ESTABLISHED, MD5-Password: ********
    TTL check: 0, value: 0, rcvd: 64
       Byte Sent:   284418, Received: 767
       Local host:  166.1.1.1, Local  Port: 179
       Remote host: 166.1.1.2, Remote Port: 8137
       ISentSeq:    2763573  SendNext:    3047992  TotUnAck:          0
       TotSent:      284419  ReTrans:           0  UnAckSeq:    3047992
       IRcvSeq:     3433336  RcvNext:     3434104  SendWnd:       65000
        TotalRcv:        768  DupliRcv:          0  RcvWnd:        65000
       SendQue:           0  RcvQue:            0  CngstWnd:       1440
```

Syntax: show ip mbgp neighbors [<*ip-addr*>]

The <*ip-addr*> parameter specifies the neighbor's IP address.

To view MBGP IPv6 neighbor information including the values for all the configured parameters, enter the following command.

NOTE
The display shows all the configured parameters for the neighbor. Only the parameters that have values different from their defaults are shown.

```
NetIron # show ipv6 mbgp neighbor 2004::2
1   IP Address: 2004::2, AS: 200 (EBGP), RouterID: 2.2.2.2, VRF: default-vrf
    State: ESTABLISHED, Time: 0h47m45s, KeepAliveTime: 60, HoldTime: 180
       KeepAliveTimer Expire in 19 seconds, HoldTimer Expire in 163 seconds
    Minimal Route Advertisement Interval: 0 seconds
       RefreshCapability: Received
    Messages:    Open    Update  KeepAlive Notification Refresh-Req
       Sent    : 7       4       201       6            0
       Received: 7       3       207       0            0
    Last Update Time: NLRI       Withdraw          NLRI       Withdraw
                  Tx:  0h49m43s    ---           Rx: 0h47m45s   ---
    Last Connection Reset Reason:Unknown
    Notification Sent:     Unspecified
    Notification Received: Unspecified
    Neighbor NLRI Negotiation:
      Peer Negotiated IPV6  multicast  capability
      Peer configured for IPV6  multicast  Routes
    TCP Connection state: ESTABLISHED, flags:00000044 (0,0)
    TTL check: 0, value: 0, rcvd: 0
       Byte Sent:   1071, Received: 1291
       Local host:  2004::1, Local  Port: 179
       Remote host: 2004::2, Remote Port: 8202
       ISentSeq:  679044370  SendNext:  679045442  TotUnAck:          0
       TotSent:        1072  ReTrans:           0  UnAckSeq:  679045442
       IRcvSeq:   678124443  RcvNext:   678125735  SendWnd:       65000
       TotalRcv:       1292  DupliRcv:          0  RcvWnd:        65000
       SendQue:           0  RcvQue:            0  CngstWnd:       1440
```

Syntax: show ipv6 mbgp neighbors [<*ipv6-addr*>]

The <*ipv6-addr*> parameter specifies the neighbor's IPv6 address.

Both examples show how to display information for a specific neighbor, by specifying the neighbor's IP address with the command. The number in the far left column, for example 1, on the first line following the issued command, is similar to an index that indicates the neighbor for which the information is displayed. When you list information for multiple neighbors, this number makes the display easier to read.

The Neighbor NLRI Negotiation section (shown in bold type) lists the types of routes that this PowerConnect can exchange with the MBGP neighbor.

The TCP statistics at the end of the display show status for the TCP session with the neighbor. Most of the fields show information stored in the PowerConnect's Transmission Control Block (TCB) for the TCP session between the PowerConnect and its neighbor. These fields are described in detail in section 3.2 of RFC 793, "Transmission Control Protocol Functional Specification".

Displaying MBGP routes

To display the MBGP IPv4 route table, enter the following command.

```
NetIron#show ip mbgp route
Total number of BGP Routes: 2
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED s:STALE
       Prefix           Next Hop        Metric     LocPrf     Weight  Status
1      8.8.8.0/24       166.1.1.2       0          100        0       BI
       AS_PATH:
2     31.1.1.0/24       166.1.1.2       0          100        0       BI
       AS_PATH:
```

Syntax: show ip mbgp routes

To display the MBGP IPv6 route table, enter the following command.

```
NetIron#show ipv6 mbgp route
Total number of BGP Routes: 4
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH m: NOT-INSTALLED-MULTIPATH
       S:SUPPRESSED F:FILTERED s:STALE
       Prefix             Next Hop        Metric     LocPrf     Weight Status

10      101.1.8.0/24       DIRECT          ve 8        0/0        D
11      8.8.8.0/24         166.1.1.2       eth 4/1     200/0      B
12      31.1.1.0/24        166.1.1.2       eth 4/1     200/0      B
```

Syntax: show ip mroute [<*ip-addr*> <*ip-mask*> **| bgp | static**]

The <*ip-addr*> <*ip-mask*> options display IPv4 multicast route information for a specific destination address only.

The **bgp** parameter displays IPv4 multicast route information for BGP routes only.

The **static** parameter displays IPv4 multicast route information for static routes only.

To display the IPv6 multicast route table, enter the following command.

```
NetIron#show ipv6 mroute
 IPv6 Routing Table - 6 entries:
Type Codes -  B:BGP C: Connected I:ISIS L:Local O:OSPF R:RIP S:Static
OSPF  Type:  i - Inter, 1 - External Type1, 2 - External Type2, e - External
Type IPv6 Prefix               Next Hop Router           Interface  Dis/Metric
B  2003::/64                   2004::2                   eth 4/4     20/1
C  2004::/64                   ::                        eth 4/4     0/0
B  2005::/64                   2004::2                   eth 4/4     20/1
C  2007::/64                   ::                        eth 4/2     0/0
C  2010::1/128                 ::                        loopback 1  0/0
B  2017::1/128                 2004::2                   eth 4/4     20/2
```

Syntax: show ipv6 mroute [<*ip-addr*> <*ip-mask*> **| bgp | static**]

The <*ip-addr*> <*ip-mask*> options display IPv6 multicast route information for a specific destination address only.

The **bgp** parameter displays IPv6 multicast route information for BGP routes only.

The **static** parameter displays IPv6 multicast route information for static routes only.

Displaying MBGP Attribute Entries

To display MBGP Attributes for IPv4.

```
NetIron#show ip mbgp attribute-entries
        Total number of BGP Attribute Entries: 4

Syntax: show ipv6 mbgp peer-group

Clearing MBGP information

Use the commands in this section to clear MBGP information.

Clearing route flap dampening information

To clear MBGP IPv4 route flap dampening information, enter the following command.

```
NetIron#clear ip mbgp dampening
```

Syntax: clear ip mbgp dampening

To clear MBGP IPv6 route flap dampening information, enter the following command.

```
NetIron#clear ipv6 mbgp dampening
```

Syntax: clear ipv6 mbgp dampening

Clearing route flap statistics

To clear MBGP IPv4 route flap statistics, enter the following command.

```
NetIron#clear ip mbgp flap-statistics
```

Syntax: clear ip mbgp flap-statistics

To clear MBGP IPv6 route flap statistics, enter the following command.

```
NetIron#clear ipv6 mbgp flap-statistics
```

Syntax: clear ipv6 mbgp flap-statistics

Clearing local information

To clear MBGP IPv4 local information, enter the following command.

```
NetIron#clear ip mbgp local
```

Syntax: clear ip mbgp local

To clear MBGP IPv6 local information, enter the following command.

```
NetIron#clear ipv6 mbgp local
```

Syntax: clear ipv6 mbgp local

Clearing BGP neighbor information

To clear MBGP IPv4 BGP neighbor, enter the following command.

```
NetIron#clear ip mbgp  neighbor
```

Syntax: clear ip mbgp neighbor

To clear MBGP IPv6 BGP neighbor, enter the following command.

```
NetIron#clear ipv6 mbgp neighbor
```

Syntax: clear ipv6 mbgp neighbor

Clearing BGP routes

To clear MBGP IPv4 BGP routes, enter the following command.

```
NetIron#clear ip mbgp  routes
```

Syntax: clear ip mbgp routes

To clear MBGP IPv6 BGP routes, enter the following command.

```
NetIron#clear ipv6 mbgp  routes
```

Syntax: clear ipv6 mbgp routes

Clearing traffic counters

To clear MBGP IPv4 BGP traffic counters, enter the following command.

```
NetIron#clear ip mbgp  traffic
```

Syntax: clear ip mbgp traffic

To clear MBGP IPv6 BGP traffic counters, enter the following command.

```
NetIron#clear ipv6 mbgp  traffic
```

Syntax: clear ipv6 mbgp traffic

Clearing VPN4 address family

To clear MBGP IPv4 VPNV4 address family information, enter the following command.

```
NetIron#clear ip mbgp vpnv4
```

Syntax: clear ip mbgp vpnv4

Clearing VPN Routing/Forwarding information

To clear MBPG IPv4 VPN Routing/Forwarding (VRF) instance information, enter the following command.

```
NetIron#clear ip mbgp vrf
```

Syntax: clear ip mbgp vrf

Configuring Multi-VRF 29

Overview of Multi-VRF

The following list displays the Multi-VRF features supported by PowerConnect B-MLXe.

NOTE
Packet over Sonet (POS) modules do not support Multi-VRF.

- Multi-VRF
- Multi-VRF for IPv4 Unicast - Static routing
- Multi-VRF for IPv4 Unicast - RIP
- Multi-VRF for IPv4 Unicast - OSPF
- Multi-VRF for IPv4 Unicast - BGP
- Multi-VRF for IBGP

Note: All VRFs share the same AS number.

Virtual Private Networks (VPNs) have been a key application in networking for a long time. Many possible solutions have been proposed over the last several years. Among the many requirements driving this need have been the need for secure transport of sensitive information and controlling information access to those who need it. In large enterprises, particularly those distributed across disparate locations, sensitivity to information pertinent to a department drives the requirement for an IT manager to logically demarcate information flows to be within that department. The need for privacy is another driver behind deployment of VPN solutions.

VPN technologies can be broadly classified into 2 types:

- secure VPNs
- trusted VPNs.

Secure VPNs require traffic to be encrypted and authenticated and are most important when communication occurs across an infrastructure that is not trusted (e.g. over the public Internet). The most commonly deployed types of secure VPNs are IPSec VPNs and SSL (Secure Sockets Layer) VPNs. Both offer encryption of data streams. While IPSec VPNs operate at the network layer and require special client software, SSL VPNs are more application centric and can generally work with any SSL-enabled browser.

Trusted VPNs ensure integrity and privacy of the data transfers but do not provide any encryption capabilities. Trusted VPNs are most useful when the goal is to leverage a shared infrastructure to allow virtual networks to be built. Examples of such "trusted VPN" technologies include IP or MPLS based Layer 2 VPNs (VPLS, VLL), BGP or MPLS VPNs, ATM or Frame Relay circuits, Layer 2 Tunneling Protocol (L2TP), etc. In short, all these technologies allow a shared infrastructure to be used without compromising the privacy needs of different users or user groups.

Central to Multi-VRF is the ability to maintain multiple "Virtual Routing and Forwarding" (VRF) tables on the same Provider Edge (PE) Router. Multi-VRF uses multiple instances of a routing protocol such as BGP or OSPF to exchange route information for a VPN among peer PE routers. The Multi-VRF capable PE router maps an input customer interface to a unique VPN instance. The router maintains a different VRF table for each VPN instance on that PE router. Multiple input interfaces may also be associated with the same VRF on the router, if they connect to sites belonging to the same VPN. This input interface can be a physical interface or a virtual Ethernet interface on a port.

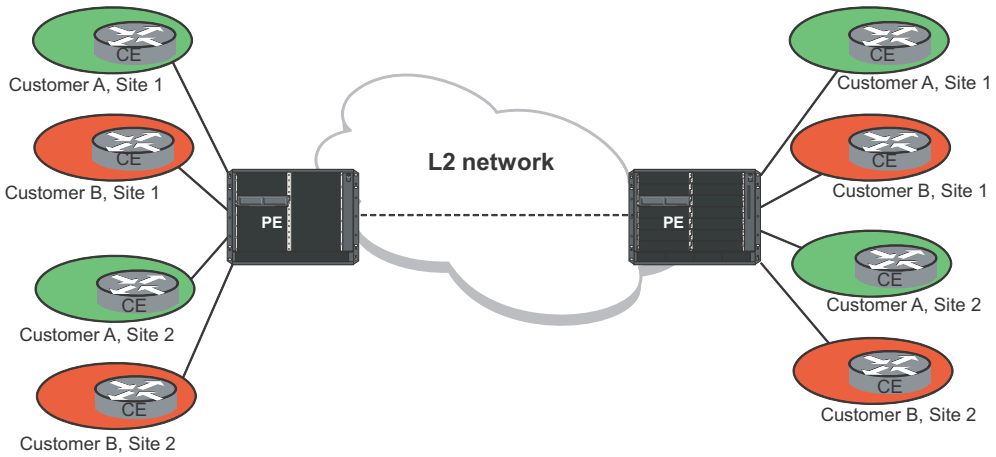
Multi-VRF routers communicate with one another by exchanging route information in the VRF table with the neighboring PE router. This exchange of information among the PE routers is done using BGP or OSPF. The PE routers that communicate with one another should be directly connected at Layer 3. Customers connect to PE routers in the network using Customer Edge (CE) routers as shown in Figure 168.

Different routing protocols may be used for exchanging information between the PE-PE routers and between the adjacent PE-CE routers. Further, different PE-CE routing protocols may be used in a VPN to exchange customer routes with the various customer sites in that VPN. The routes learned from the PE-CE protocol are added to the corresponding VRF instance and redistributed through the PE-PE protocol to the peer router in the backbone network.

Figure 168 depicts a network using Multi-VRF to provide connectivity among sites that belong to multiple VPNs. To share the VPN route table information with remote PEs, each PE creates separate virtual interfaces and run different instances of the PE-PE routing protocol for each VRF.

NOTE
Some vendors also use the terminology of "Multi-VRF CE" or "VRF-Lite" for this technology.

FIGURE 168 A Network deploying Multi-VRF



Multi-VRF and BGP or MPLS VPNs share some common aspects. For instance, in both cases the edge router maintains a VRF for all directly connected sites that are part of the same VPN. Also in both cases, the PE and CE routers share customer route information using a variety of PE-CE routing protocols, such as OSPF, RIP, E-BGP or static routes. Overlapping address spaces among different VPNs are allowed for both.

There are however, several differences between the two VPN technologies. The fundamental difference between the two technologies is that Multi-VRF requires that peering PE routers be directly connected at Layer 3. A Layer 2 network however, can be present between these directly-connected PE routers. BGP or MPLS VPNs do not have this restriction. In BGP or MPLS VPNs, the MPLS network determines the path to the peer router. In order to distinguish between devices with overlapping IP addresses, route targets are used in BGP or MPLS VPNs. Multi-VRF uses the input interface to uniquely identify the associated VPN, which is why the two PE routers should be directly connected at Layer 3. Table compares Multi-VRF and BGP or MPLS VPNs in more detail

TABLE 197 Comparison between Multi-VRF and BGP or MPLS VPNs

	Multi-VRF	**BGP or MPLS VPN**
PE-PE Routing Protocol	BGP, OSPF, RIP or Static routing	BGP
PE-CE Routing Protocol	BGP, OSPF, RIP or Static routing	BGP, OSPF, RIP or Static routing
PE-PE Routing Connectivity	PE Routers should be directly connected at Layer 3	PE Routers are interconnected through an IP or MPLS Network
Determination of VRF Instance	Based on input interface only	Based on route target (network interface) or input interface (CE)
Number of Routing Protocol Instances (PE to PE)	Unique routing protocol instance for each VRF instance	Single routing protocol instance
Controlling Advertisement of Routes	No need for route targets to be used. Advertisement on one VRF is indendant of advertisement in other VRFs.	Route targets used to identify the customer VPN in advertised routes. The destination PE filters the routes advertised from a peer PE by comparing the route target with the VPNs maintained locally on that PE.
Number of VRF Instances	Unique VRF instance for each VPN	Unique VRF instance for each VPN
Overlapping Private Addresses allowed over VPNs?	Yes	Yes
Scalability	Reasonably Scalable	Highly Scalable
MPLS Required	No	Yes

Benefits and applications of Multi-VRF

Multi-VRF provides a reliable mechanism for a network administrator to maintain multiple virtual routers on the same device. The goal of providing isolation among different VPN instances is accomplished without the overhead of heavyweight protocols used in secure VPN technologies or the administrative complexity of MPLS VPNs. It is particularly effective when operational staff has expertise in managing IP networks but may not have the same familiarity in managing MPLS networks. Overlapping address spaces can be maintained among the different VPN instances.

As the two examples in the following sections demonstrate, the simplicity of Multi-VRF allows for several interesting applications.

Example of Multi-VRF usage in an enterprise data center

Figure 169 displays an example of Multi-VRF in an enterprise data center. Each server farm is used for a dedicated application or set of applications. For security reasons, only specific servers in this farm may be allowed to communicate with other servers. Access in some cases may be completely prohibited whereas in other cases access may be allowed through the firewall. Each server is placed on a different subnet. To ensure optimal performance of the data center, trusted servers should be allowed to communicate directly whereas un-trusted servers should not be allowed to directly communicate at all. While Figure 169 shows a limited number of servers; in practice, the number of servers used for this application can run from the tens to the hundreds.

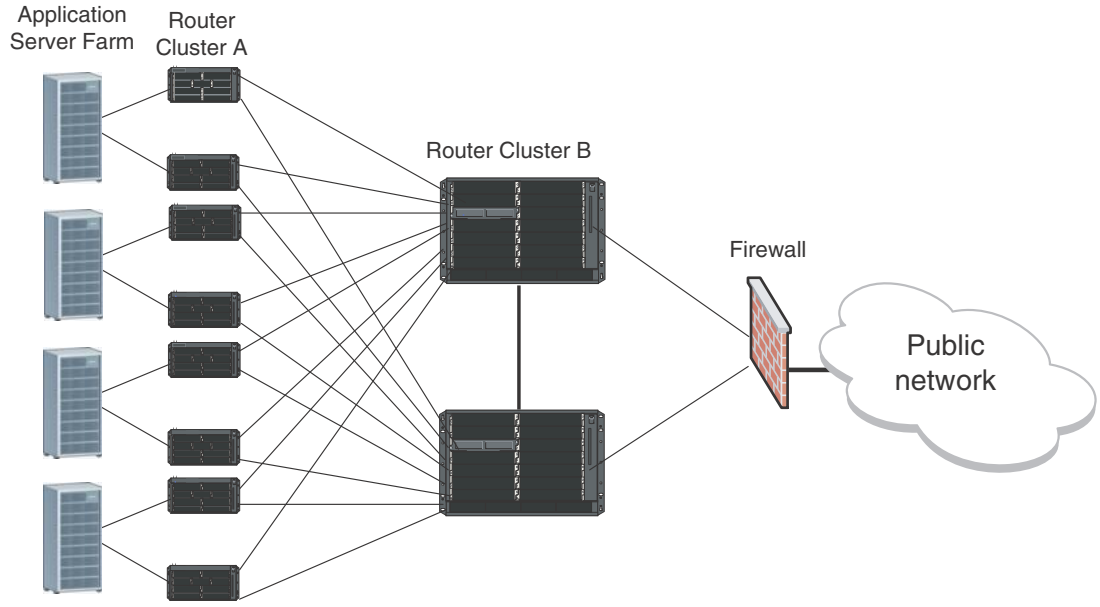
A common way to configure this example is by using Policy Based Routing (PBR). However, because PBR can become very difficult to administer and manage as the network begins to grow, it may require frequent configuration changes which is prone to introducing operator errors.

MPLS VPNs can also be used to configure this example. However, it may be too heavy-weight for what needs to be accomplished in this scenario. In addition, operational staff in enterprise data centers may not always be conversant with administering MPLS.

Secure VPN technologies like IP-Sec are not required here because the infrastructure is already secure. Therefore, the overhead of encryption is not needed.

Multi-VRF is an ideal solution for an application like this example. The servers that are allowed to communicate can be placed in the same Multi-VRF instance. If server access is to be controlled at a more granular level (e.g. at the application layer), then traffic from specific applications on that server can be sent on a specific tagged interface to the router in Cluster A. As shown in Figure 169, a highly redundant cluster is achieved by ensuring that no single node becomes a point of failure within this network.

FIGURE 169 Example of Multi-VRF usage in an enterprise data center application



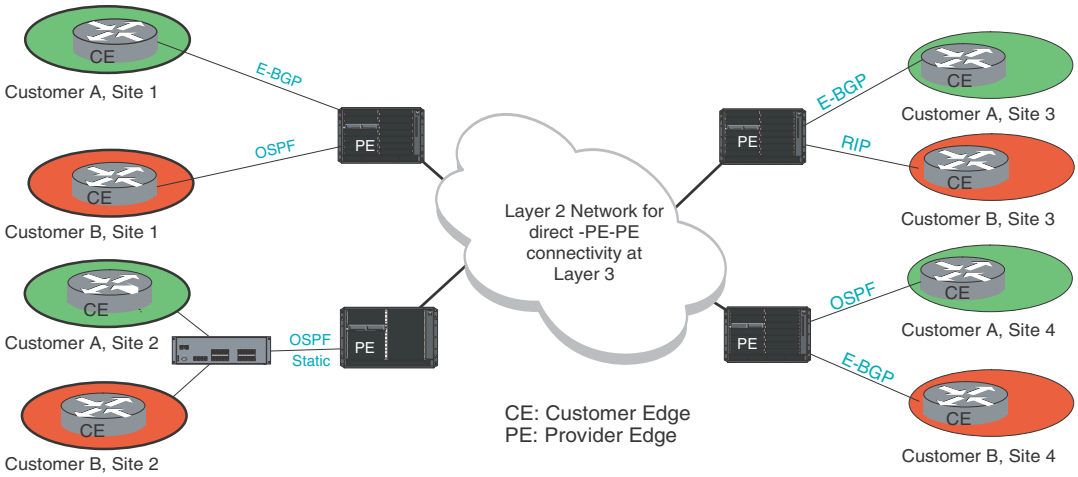
Example of Multi-VRF usage in a service provider network

Figure 170 depicts the use of Multi-VRF in a typical service provider application. This service provider owns a Layer 2 network connecting the PEs and offers managed VPN services to end users. As shown in Figure 169, a host of PE-CE routing protocols can be used-E-BGP, OSPF, RIP or Static Routing.

It is also possible that a site (such as site 2) may have several customers in close geographical proximity as in a business park. This may warrant a dedicated MTU to be placed on-site, which is owned by the service provider. In such a scenario, the different customers may share the same MTU and still use overlapping private address spaces. The MTU is a switch that adds a unique VLAN tag for each connected customer. The PE router (labeled PE2) maps a Layer 3 tagged interface to a unique VRF. Thus, it could be sharing routes using OSPF with one CE and just using Static Routing with another CE (both of these may occur over different virtual interfaces on the same physical interface).

Layer 3 BGP or MPLS VPNs could also be used in a network such as the above. However, if one of the PE routers does not support MPLS or if the operational staff is not conversant with MPLS operations, Multi-VRF provides an alternative mechanism to achieve the same objective.

FIGURE 170 Multi-VRF in a service provider application



Summary

Multi-VRF provides a reliable mechanism for trusted virtual private networks to be built over a shared infrastructure. The ability to maintain multiple virtual routing or forwarding tables allows overlapping private IP addresses to be maintained across VPNs and accomplish goals very similar to that those of more complex VPN technologies such as BGP or MPLS VPNs.

Configuring Multi-VRF

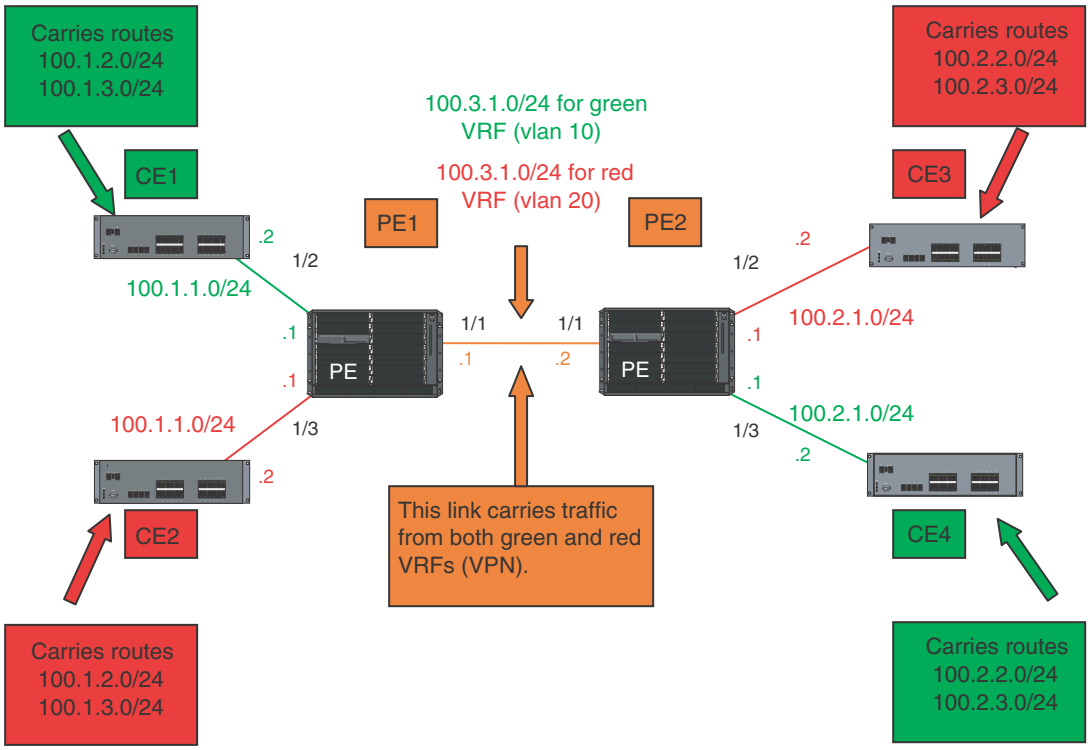
Configuration of the Multi-VRF feature uses the following commands that are defined in "Configuring BGP VPNs on a PE" on page 1603:

- "Defining a VRF routing instance" – This procedure describes how to define a VRF using the **ip vrf** command.
- "Assigning a Route Distinguisher to a VRF" – This procedure describes how to define a Route Distinguisher (RD). The RD sets a unique identity to an instance of a VRF. As such, it allows the same IP address to be used in different VPNs without creating any conflict.
- "Assigning a VRF routing instance to an interface" – This procedure describes how to assign a VRF to one or more virtual or physical interfaces.
- "Assigning a VRF routing instance to a LAG interface"– This procedure describes how to assign a VRF to a LAG interface.

The main difference between configurations described in "Configuring BGP VPNs on a PE"and Multi-VRF is that there is no MPLS configuration required for Multi-VRF. This section provides a common Multi-VRF configuration with two possible methods to achieve that configuration.

The diagram in Figure 171 shows a typical network utilizing the multi-VRF feature to implement layer 3 VPNs across 2 directly connected (at layer3) PE routers.

FIGURE 171 Example network topology with both RED and GREEN VPNs



In the diagram in Figure 171, CE1 and CE4 are customer edge (CE) routers for the “green” VPN, while CE2 and CE3 belong to “red” VPN. These CE routers can be any routers or layer 3 switches that are capable of running one or many dynamic routing protocols such as BGP, OSPF or RIP or even simple static routing.

The 2 PEs routers have to be routers that are capable of supporting VRF routing (either with or without MPLS support). They connect all four CE routers together with a single link between the two of them. Note that this single link between the 2 PEs could also be replaced by a layer-2 switched network if direct physical connection between the PEs is not possible. The only requirement for the connections is that the 2 PEs have to be “directly connected” at layer 3.

Both the customer RED and customer GREEN networks (or VPN) consist of internal routes with overlapping IP address ranges. Thus, traffic communication within each customers’ VPN across the 2 PE routers, i.e. between CE1 and CE4, and between CE2 and CE3, must be separated using VRFs.

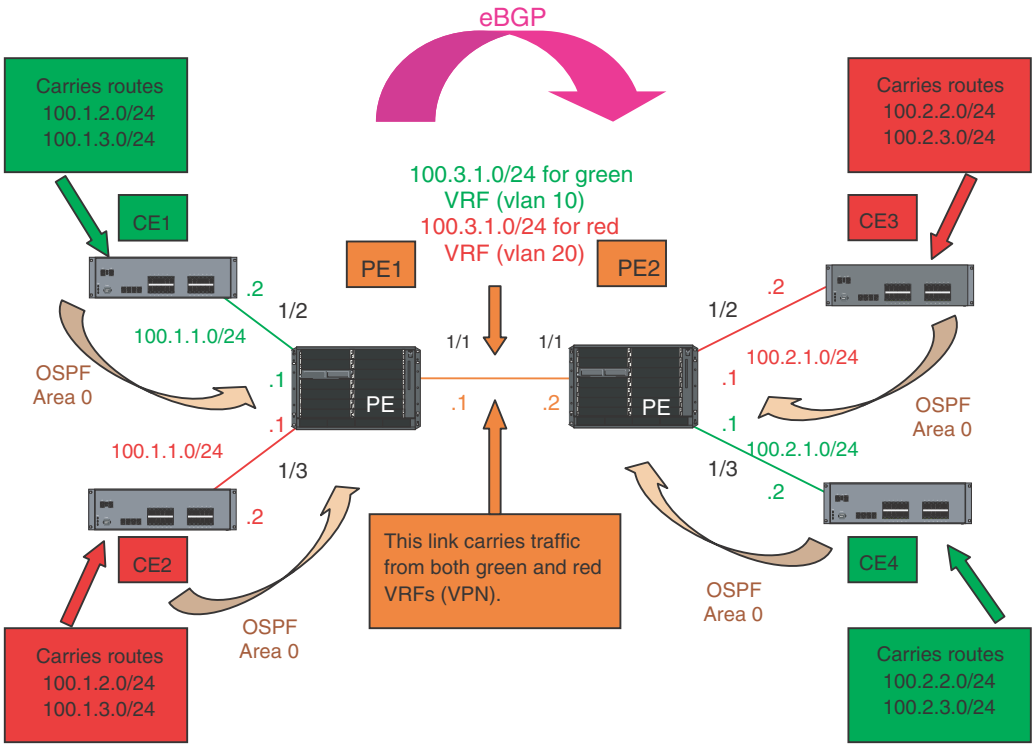
The following sections provide two examples of how to set-up the network shown in Figure 171 using different routing protocol configurations:

- **Configuration 1** – eBGP Configured between PE1 and PE2 with OSPF (Area 0) Configured between PEs and CEs
- **Configuration 2** – OSPF (Area 0) Configured between PE1 and PE2 with OSPF (Area 1 and Area 2) Configured between PEs and CEs

Configuration 1

As shown in Figure 172, eBGP is configured between PE1 and PE2 and OSPF (Area 0) is configured between PEs and CEs.

FIGURE 172 eBGP configured between PE1 and PE2 with OSPF (Area 0) configured between PEs and CEs



The following configuration examples for PE1, PE2, CE1, CE2, CE3, and CE4 describe how to create the example shown in Figure 172.

PE1 configuration

In this configuration, VLANs 10 and 20 are created as a link on a tagged port (e 1/10) between PE1 and PE2. Two VRFs (“RED” and “GREEN”) are then defined with each having a unique Route Distinguisher (RD). VRF “Green” is assigned an RD value of 10:10, and VRF “Red” is assigned an RD value of 20:20.

In the BGP configuration, PE1 is defined in Local AS1. VRFs “Green” and “Red” are configured and both “Green” and “Red” have the same IP network address assigned (100.3.1.2/24). This is possible because each of the BGP VRF instances have their own seperate BGP tables. This is also the same IP network address that will be assigned to VRFs “Green” and “Red” on PE2 within Local AS 2. Redistribution of OSPF routes from PE1’s CE peers is enabled to all for their advertisement to PE2.

Both VRFs are configured in Area “0” and directed to redistribute their routes to BGP. The physical interfaces (e 1/2 and e 1/3) to the CEs are assigned to the correct VRF and are configured with the same IP address (100.1.1.1/24) and OSPF Area “0”.

The virtual Interfaces (ve10 and ve20) are configured with the same IP address (100.3.1.1/24) and for IP VRF forwarding in the appropriate VRF (Green or Red).

```

NetIron(config-vif-10)# ip address 100.3.1.1/24
```

CE 1 and CE 2 configurations

The CE1 and CE2 router configurations are exactly the same. Both are configured in OSPF Area 0 with route redistribution enabled. The IP addresses: 100.1.2.1/32 and 100.1.3.1/32 are configured for the Loopback1 interface allowing them to carry routes from these networks.

```
NetIron(config)# router ospf
NetIron(config-ospf-router)# area 0
NetIron(config-ospf-router)# redistribution connected
NetIron(config-ospf-router)# exit
NetIron(config)# interface loopback 1
NetIron(config-lbif-1)# ip address 100.1.2.1/32
NetIron(config-lbif-1)# ip address 100.1.3.1/32
NetIron(config-lbif-1)# interface ethernet 1/1
NetIron(config-if-e1000-1/1)# ip ospf area 0
NetIron(config-if-e1000-1/1)# ip address 100.1.1.2/24
```

CE 3 and CE 4 configurations

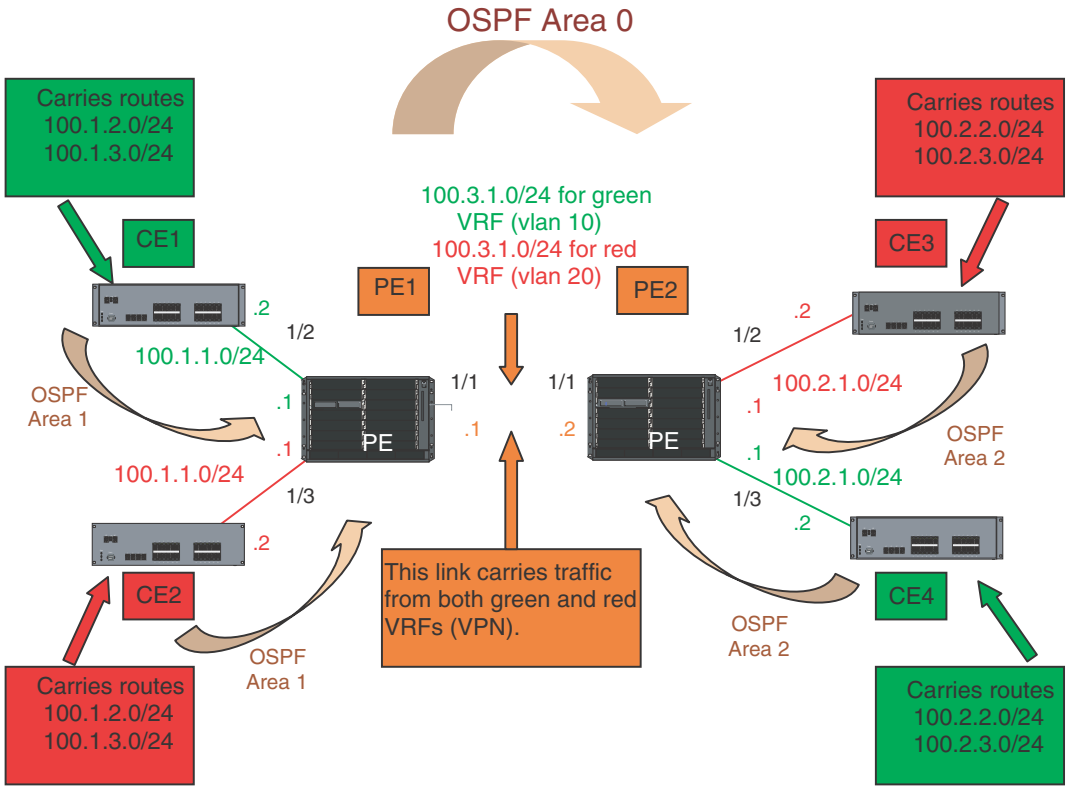
The CE3 and CE4 router configurations are exactly the same. Both are configured in OSPF Area 0 with route redistribution enabled. The IP addresses: 100.2.2.1/32 and 100.2.3.1/32 are configured for the Loopback1 interface allowing them to carry routes from these networks.

```
NetIron(config)# router ospf
NetIron(config-ospf-router)# area 0
NetIron(config-ospf-router)# redistribution connected
NetIron(config-ospf-router)# exit
NetIron(config)# interface loopback 1
NetIron(config-lbif-1)# ip address 100.2.2.1/32
NetIron(config-lbif-1)# ip address 100.2.3.1/32
NetIron(config-lbif-1)# interface ethernet 1/1
NetIron(config-if-e1000-1/1)# ip ospf area 0
NetIron(config-if-e1000-1/1)# ip address 100.2.1.2/24
```

Configuration 2

As shown in Figure 172, OSPF (Area 0) is configured between PE1 and PE2 and OSPF (Area 1 and Area 2) is configured between PEs and CEs. The biggest difference between this configuration and Configuration 1 is that OSPF is used between the 2 PEs instead of eBGP. Otherwise most of the configuration is the same as Configuration 1.

FIGURE 173 OSPF (Area 0) configured between PE1 and PE2 with OSPF (Area 1 and Area 2) configured between PEs and CEs



The following configuration examples for PE1, PE2, CE1, CE2, CE3, and CE4 describe how to create the example shown in Figure 173.

PE1 configuration:

In this configuration, VLANs 10 and 20 are created as a link on a tagged port (e 1/10) between PE1 and PE2. Two VRFs (“RED” and “GREEN”) are then defined with each having a unique Route Distinguisher (RD). VRF “Green” is assigned an RD value of 10:10, and VRF “Red” is assigned an RD value of 20:20.

Because OSPF is the only routing protocol used in this set-up, multiple OSPF areas are used. Area 0 is configured between the two PEs. Area 1 is configured PE1 and CE’s 1 and 2. Area 0 is configured between the two PEs. Area 2 is configured PE2 and CE’s 3 and 4.

The virtual Interfaces (ve10 and ve20) are configured with the same IP address (100.3.1.1/24) and for IP VRF forwarding in the appropriate VRF (Green or Red). Both are also configured in OSPF Area 0.

```

Configuring MPLS Traffic Engineering 30

Overview

The following list displays the MPLS Traffic Engineering features supported by PowerConnect B-MLXe:

- Multiprotocol Label Switching (MPLS)
- MPLS Traffic Engineering
- OSPF-TE Link State Advertisements for MPLS Interfaces
- MPLS Traffic Engineering - OSPF-TE
- MPLS Traffic Engineering - ISIS-TE
- ISIS Link State Protocol data units with TE Extensions for MPLS Interfaces
- RSVP Message Authentication
- MPLS over Virtual Ethernet Interfaces
- MPLS Signalling: LDP and RSVP-TE support
- New encryption code for passwords, authentication keys, and community strings
- Traffic Engineering Database
- MPLS Fast Reroute Using One-to-One Backup
- Resetting LSPs
- Adaptive LSPs: timer-triggered LSP optimization
- Hot-standby LSPs
- RSVP Message Authentication
- Signalled LSPs
- LSP Accounting
- MPLS BFD
- Traps and Syslogs for LSPs
- Show Command to Display TE path
- Enhancements to MPLS path and route display
- Display changes for MPLS show commands for long LSP and Path names

This chapter explains how to configure ***Multiprotocol Label Switching (MPLS)*** on the PowerConnect for traffic engineering purposes. MPLS can be used to direct packets through a network over a predetermined path of routers. Forwarding decisions in MPLS are based on the contents of a label applied to the packet.

Traffic engineering is the ability to direct packets through a network efficiently, using information gathered about network resources. When used as an application of MPLS, traffic engineering involves creating paths that make the best use of available network resources, avoiding points of congestion and making efficient use of high bandwidth interfaces. Packets travelling over these paths are forwarded using MPLS.

IETF RFC and Internet draft support

The implementation of MPLS supports the following IETF RFCs and Internet Drafts.

MPLS

RFC 3031 – Multiprotocol Label Switching Architecture

RFC 3032 – MPLS Label Stack Encoding

RFC 3036 – LDP Specification

RFC 2205 – Resource ReSerVation Protocol (RSVP) -- Version 1 Functional Specification

RFC 2209 – Resource ReSerVation Protocol (RSVP) -- Version 1 Message Processing Rule

RFC 3209 – RSVP-TE

RFC 3270 – MPLS Support of Differentiated Services

RFC 4090 – Facility backup and Fast Reroute

OSPF

RFC 3630 TE Extensions to OSPF v2

ISIS

RFC 3784 Intermediate System to Intermediate System (IS-IS) Extensions for Traffic Engineering (TE)

How MPLS works

MPLS uses a ***label switching*** forwarding method to direct packets through a network. In label switching, a packet is assigned a label and passes along a predetermined path of routers. Forwarding decisions are based on the contents of the label, rather than information in the packet's IP header.

The following sections describe these basic MPLS concepts:

- How packets are forwarded through an MPLS domain
- The kinds of Label Switched Paths (LSPs) that can be configured on a device
- The components of an MPLS label header

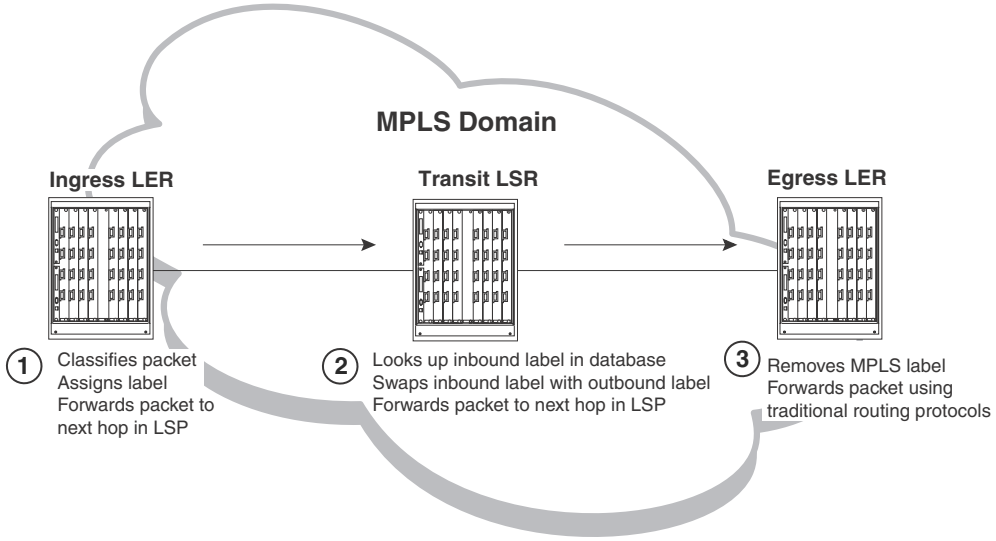
How packets are forwarded through an MPLS domain

An ***MPLS domain*** consists of a group of MPLS-enabled routers, called ***LSRs*** (Label Switching Routers). In an MPLS domain, packets are forwarded from one MPLS-enabled router to another along a predetermined path, called an ***LSP*** (Label Switched Path). LSPs are one-way paths between MPLS-enabled routers on a network. To provide two-way traffic, you configure LSPs in each direction.

The LSRs at the headend and tailend of an LSP are known as ***LERs*** (Label Edge Routers). The LER at the headend, where packets enter the LSP, is known as the ***ingress LER***. The LER at the tailend, where packets exit the LSP, is known as the ***egress LER***. Each LSP has one ingress LER and one egress LER. Packets in an LSP flow in one direction: from the ingress LER towards the egress LER. In between the ingress and egress LERs there may be zero or more ***transit LSRs***. A device enabled for MPLS can perform the role of ingress LER, transit LSR, or egress LER in an LSP. Further, a device can serve simultaneously as an ingress LER for one LSP, transit LSR for another LSP, and egress LER for some other LSP.

Figure 174 depicts an MPLS domain with a single LSP consisting of three LSRs: an ingress LER, a transit LSR, and an egress LER.

FIGURE 174 Label switching in an MPLS domain



Label switching in an MPLS domain works as described below.

1. The Ingress LER receives a packet and pushes a label onto it.

   When a packet arrives on an MPLS-enabled interface, the device determines to which LSP (if any) the packet should be assigned. Specifically, the device determines to which Forwarding Equivalence Class (FEC) the packet belongs. An FEC is simply a group of packets that should all be forwarded in the same way. For example, a FEC could be defined as all packets from a given Virtual Leased Line. FECs are mapped to LSPs. If a packet belongs to a FEC, and an LSP is mapped to that FEC, the packet is assigned to the LSP.

When a packet is assigned to an LSP, the device, acting as an ingress LER, applies (pushes) a tunnel ***label*** onto the packet. A label is a 32-bit, fixed-length identifier that is significant only to MPLS. Refer to "MPLS label header encoding" on page 1296 for specific information about the contents of a label. From this point until the packet reaches the egress LER at the end of the path, the packet is forwarded using information in its label, not information in its IP header. The packet's IP header is not examined again as long as the packet traverses the LSP. The ingress LER may also apply a VC label onto the packet based on the VPN application.

On the ingress LER, the label is associated with an outbound interface. After receiving a label, the packet is forwarded over the outbound interface to the next router in the LSP.

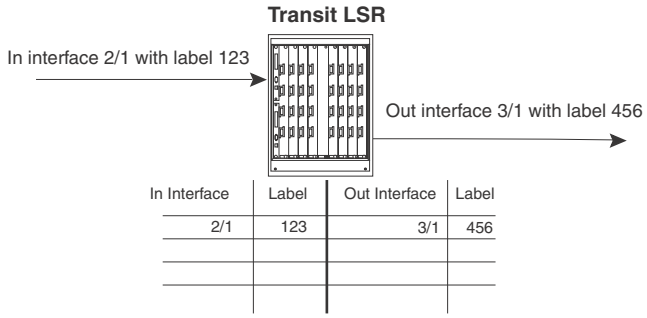
2. A transit LSR receives the labelled packet, swaps the label, and forwards the packet to the next LSR.

   In an LSP, zero or more transit LSRs can exist between the ingress and egress LERs. A transit LSR swaps labels on an MPLS packet and forwards the packet to the next router in the LSP.

   When a transit LSR receives an MPLS packet, it looks up the label in its ***MPLS forwarding table***. This table maps the label and inbound interface to a new label and outbound interface. The transit LSR replaces the old label with the new label and sends the packet out the outbound interface specified in the table. This process repeats at each transit LSR until the packet reaches the next-to-last LSR in the LSP (for signalled LSPs).

   Figure 175 shows an example of the label swapping process on a transit LSR.

FIGURE 175 Label swapping on a transit LSR



In this example, a packet comes into interface 2/1 with label 123. The transit LSR then looks up this interface-label pair in its MPLS forwarding table. The inbound interface-label pair maps to an outbound-interface-label pair – in this example, interface 3/1 with label 456. The LSR swaps label 123 with label 456 and forwards the packet out interface 3/1.

3. The egress LER receives labelled packet, pops label, and forwards IP packet.

   When the packet reaches the egress LER, the MPLS label is removed (called ***popping*** the label), and the packet can then be forwarded to its destination using standard hop-by-hop routing protocols. On signalled LSPs, the label is popped at the penultimate (next to last) LSR, rather than the egress LER. Refer to "Penultimate hop popping" on page 1295 for more information.

Types of LSPs

An LSP in an MPLS domain can be either ***static*** or ***signalled***.

Signalled LSPs

Signalled LSPs are configured at the ingress LER only. When the LSP is enabled, RSVP signalling messages travel to each LSR in the LSP, reserving resources and causing labels to be dynamically associated with interfaces. When a packet is assigned to a signalled LSP, it follows a pre-established path from the LSP's ingress LER to its egress LER. This path can be one of the following:

- A path that traverses an explicitly specified set of MPLS routers
- The IGP shortest path across the MPLS domain, determined from local routing tables
- A traffic-engineered path calculated by the device using constraints such as bandwidth reservations, administrative groups, and network topology information

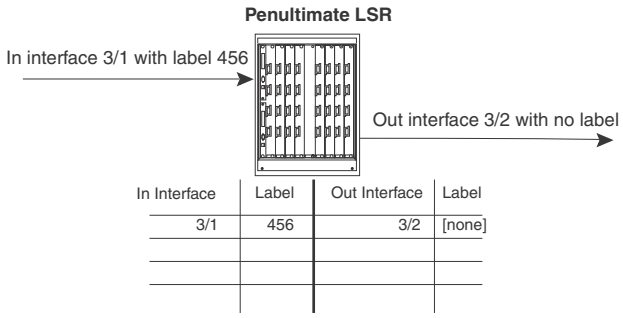
For more information, refer to "How CSPF calculates a traffic-engineered path" on page 1301, "How RSVP establishes a signalled LSP" on page 1302, and "Setting up signalled LSPs" on page 1333.

Penultimate hop popping

On signalled LSPs, the MPLS label is popped at the next-to-last LSR in the LSP, instead of at the egress LER. This action is called ***penultimate hop popping***. Penultimate hop popping improves forwarding efficiency by allowing the egress LER to avoid performing both a MPLS forwarding table lookup and an IP forwarding table lookup for each packet exiting the LSP. Instead, the MPLS label is popped at the penultimate (next-to-last) LSR, and the packet is forwarded to the egress LER with no MPLS encoding. The egress LER, in fact, does not recognize the packet as emerging from an LSP.

Figure 176 illustrates the operation that takes place at the penultimate LSR in an LSP.

FIGURE 176 Penultimate hop popping



When an LSR receives an MPLS packet, it looks up the label in its MPLS forwarding table. Normally, this table maps the label and inbound interface to a new label and outbound interface. However, when this is the penultimate LSR in an LSP, the label and inbound interface map only to an outbound interface. The penultimate LSR pops the label and forwards the packet – now a regular IP packet – out the outbound interface. When the packet reaches the egress LER, there is no indication that it had been forwarded over an LSP. The packet is forwarded using standard hop-by-hop routing protocols.

NOTE
Penultimate hop popping is always performed on signalled LSPs.

MPLS label header encoding

The following diagram illustrates the structure of the 32-bit MPLS label header. When a packet enters an LSP, the ingress LER pushes a label onto the packet.

FIGURE 177 Structure of an MPLS Label Header

An MPLS label header is composed of the following parts:

Label value (20 bits)

The label value is an integer in the range 16 – 1048575. (Labels 0 – 15 are reserved by the IETF for special usage.) For signalled LSPs, the device dynamically assigns labels in the range 1024 – 499999.

EXP field (3 bits)

The EXP field is designated for experimental usage. By default, a device uses the EXP field to define a Class of Service (CoS) value for prioritizing packets travelling through an LSP. Please refer to 9, "Configuring Quality of Service for the NetIron MLX", for more information. Please note that software forwarded VPLS packets do not use the EXP encode table.

S (Bottom of Stack) field (1 bit)

An MPLS packet can be assigned multiple labels. If an MPLS packet has multiple labels, they are logically organized in a last-in, first-out ***label stack***. An LSR performs a pop or swap operation on the topmost label; that is, the most recently applied label in the stack. The Bottom of Stack field indicates whether this label is the last (oldest) label in the stack. If the label is the last one in the stack, the Bottom of Stack field is set to 1. If not, the Bottom of Stack field is set to 0.

A device acting as an LSR can perform one push, swap, or pop operation on an incoming MPLS packet. The device can accept MPLS packets that contain multiple labels, but only the topmost label is acted upon.

TTL field (8 bits)

The TTL field indicates the Time To Live (TTL) value for the MPLS packet. At the ingress LER, an IP packet's TTL value is copied to its MPLS TTL field. At each transit LSR hop, the MPLS TTL value is decremented by 1. If the MPLS TTL value reaches 0, the packet is discarded. Optionally, you can configure the LSRs not to decrement the MPLS TTL value at each hop.

Using MPLS in traffic engineering

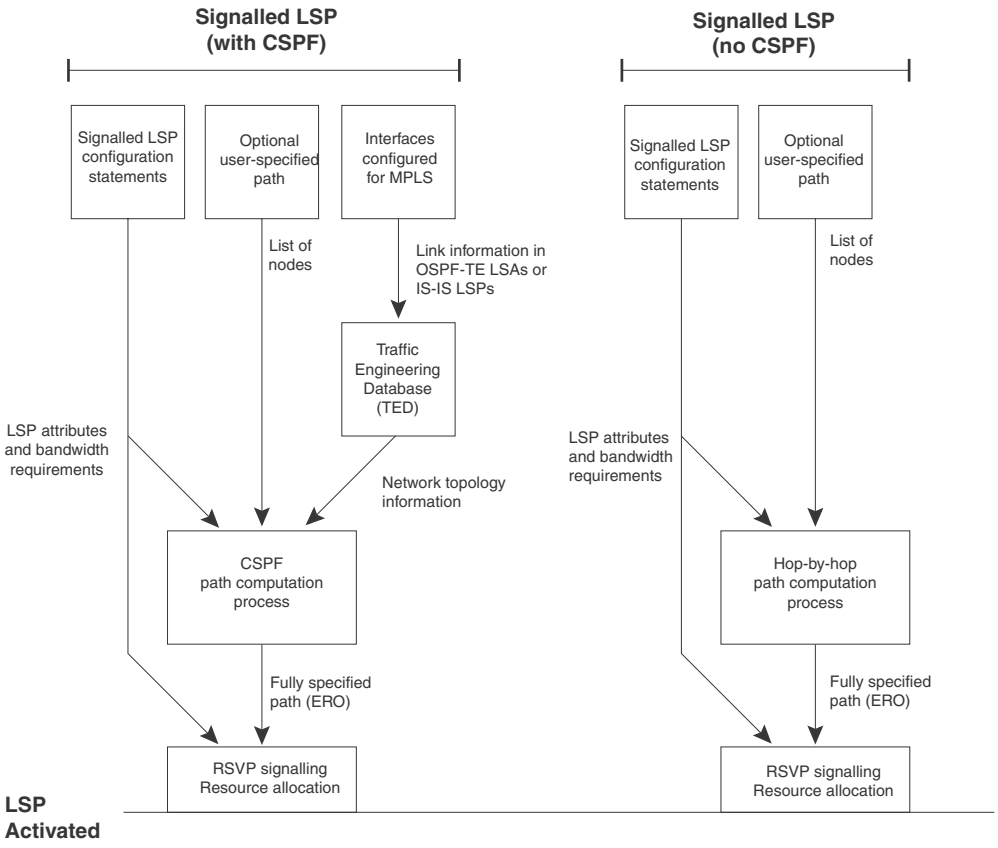
Traffic engineering is the task of routing network traffic to avoid points of congestion and make efficient use of high bandwidth interfaces. When used as an application of MPLS, traffic engineering involves creating LSPs that make the best use of available network resources; that is, ***traffic-engineered LSPs***. This section explains the process of creating traffic-engineered LSPs.

Creating traffic-engineered LSPs involves the following tasks:

- Gathering information about the network
- Using the gathered information to select optimal paths through the network
- Setting up and maintaining the paths

For traffic-engineered signalled LSPs, devices can perform these tasks dynamically. Figure 178 illustrates the process that takes place to configure, establish, and activate traffic-engineered signalled LSPs.

FIGURE 178 How traffic-engineered LSPs are configured, established, and activated



Traffic-engineered, signalled LSPs are configured, established, and activated by the following processes (but with some differences between OSPF and IS-IS):

CSPF calculates a traffic-engineered path

When you configure a signalled Label Switched Path, you specify the address of the egress LER, as well as optional attributes, such as the LSP's priority and bandwidth requirements. You can optionally specify a path of LSRs that the LSP must pass through on the way to the egress LER. When you enable the signalled LSP, the ***Constrained Shortest Path First (CSPF)*** process on the ingress LER uses this information to calculate a ***traffic-engineered path*** between the ingress and egress LERs.

CSPF is an advanced form of the Shortest Path First (SPF) process used by IGP routing protocols. The CSPF process on the ingress LER uses the configured attributes of the LSP, user-specified path (if there is one), and the information in the ***Traffic Engineering Database*** (TED) to calculate the traffic-engineered path, which consists of a sequential list of the physical interfaces that packets

assigned to this LSP will pass through to travel from the ingress LER to the egress LER. The traffic-engineered path takes into account the network topology, available resources, and user-specified constraints. The traffic-engineered path calculated by CSPF may or may not be the same as the shortest path that would normally be calculated by standard IGP routing protocols.

CSPF is enabled by default for signalled LSPs, but can be disabled. When signalled LSPs are configured without CSPF, the shortest path from the ingress LER to the egress LER is calculated using standard hop-by-hop routing methods. If the LSP also is configured to use a user-specified path, the device calculates the shortest path between each LSR in the path. As with CSPF, the output of this process is a fully specified path of physical interfaces on LSRs.

The advantage of configuring signalled LSPs without CSPF is that it can span multiple OSPF areas or IS-IS levels. Since OSPF-TE LSAs and IS-IS LSPs with TE extensions have area/level flooding scope, the information in an LSR's TED is relevant only to their area or level. Consequently, signalled LSPs that use CSPF can span only an OSPF area or IS-IS level. Signalled LSPs that do not use CSPF, because they do not rely on information in the TED, do not have this restriction.

Once the path for the LSP has been calculated, RSVP signalling then causes resources to be reserved and labels to be allocated on each LSR specified in the path. This may cause already existing, lower priority LSPs to be preempted. Once resources are reserved on all the LSRs in the path, the signalled LSP is considered to be ***activated***; that is, packets can be forwarded over it.

The following sections provide additional information about the individual components of the process for activating traffic-engineered signalled LSPs, illustrated in Figure 178 on page 1297.

OSPF-TE Link State Advertisements for MPLS interfaces

MPLS-enabled devices running OSPF can be configured to send out LSAs that have special extensions for traffic engineering. These LSAs, called ***OSPF-TE LSAs***, contain information about interfaces configured for MPLS. The OSPF-TE LSAs are flooded throughout the OSPF area. LSRs that receive the OSPF-TE LSAs place the traffic engineering information into a TED, which maintains topology data about the nodes and links in the MPLS domain.

Traffic engineering information is carried in OSPF traffic engineering (OSPF-TE) LSAs. OSPF-TE LSAs are Type 10 Opaque LSAs, as defined in RFC 2370. Type 10 Opaque LSAs have area flooding scope.

OSPF-TE LSAs have special extensions that contain information related to traffic engineering; these extensions are described in RFC 3630. The extensions consist of Type/Length/Value triplets (TLVs) containing the following information:

- Type of link (either point-to-point or multiaccess network)
- ID of the link (for point-to-point links, this is the Router ID of the LSR at the other end of the link; for multiaccess links, this is the address of the network's designated router)
- IP address of the local interface for the link
- IP address of the remote interface for the link (this could be zero for multicast links)
- Traffic engineering metric for the link (by default, this is equal to the OSPF link cost)
- Maximum bandwidth on the interface
- Maximum reservable bandwidth on the interface
- Unreserved bandwidth on the interface
- Administrative groups to which the interface belongs

When configured to do so, the device sends out OSPF-TE LSAs for each of its MPLS-enabled interfaces. You can optionally specify the maximum amount of bandwidth that can be reserved on an interface, as well as assign interfaces to administrative groups. refer to "Setting traffic engineering parameters for MPLS interfaces" on page 1323 for more information.

The following events trigger the device to send out OSPF-TE LSAs:

- Change in the interface's administrative group membership
- Change in the interface's maximum available bandwidth or maximum reservable bandwidth
- Significant change in unreserved bandwidth per priority level:
  - If for any priority level, the difference between the previously advertised unreserved bandwidth and the current unreserved bandwidth exceeds 5 percent of the maximum reservable bandwidth
  - Any changes while the total reserved bandwidth exceeds 95 percent of the maximum reservable bandwidth

In addition, OSPF-TE LSAs can be triggered by OSPF; for example, when an interface's link state is changed. When an interface is no longer enabled for MPLS, the device stops sending out OSPF-TE LSAs for the interface.

IS-IS Link State Protocol data units with TE extensions for MPLS interfaces

An MPLS-enabled device running IS-IS can be configured to send out ***Link State Protocol (LSP)*** data units that contain special extensions to support Traffic Engineering (TE). (In this section—and nowhere else in this chapter—LSP is the acronym for Link State Protocol. In other sections, LSP means Label Switched Path.) These LSPs are composed of a fixed header and a number of tuples known as Type/Length/Value triplets (TLVs). LSPs that are used for traffic engineering contain a new object called a sub-TLV. Sub-TLVs are similar to regular TLVs except that, where regular TLVs exist inside IS-IS packets, sub-TLVs reside within regular TLVs. Each sub-TLV consists of three fields: a one-octet Type field, a one-octet Length field, and zero or more octets of Value.

These LSPs are flooded throughout the IS-IS domain. LSRs that receive the IS-IS LSPs with TE extensions place the traffic engineering information into a ***Traffic Engineering Database (TED)***, which maintains topology data about the nodes and links in the MPLS domain.

IS-IS LSPs have special extensions that contain information related to traffic engineering and are described in RFC 3784. The extensions consist of Type/Length/Value triplets (sub-TLVs) containing the following information:

- IP address of the local interface for the link
- IP address of the remote interface for the link (for point-to-point adjacencies)
- Traffic engineering metric for the link (by default, this is equal to the ISIS link cost)
- Maximum bandwidth on the interface
- Maximum reservable bandwidth on the interface
- Unreserved bandwidth on the interface
- Administrative groups to which the interface belongs

When configured to do so, the device sends out IS-IS LSPs with TE extensions for each of its MPLS-enabled interfaces. You can optionally specify the maximum amount of bandwidth that can be reserved on an interface, as well as assign interfaces to administrative groups. Refer to "Setting traffic engineering parameters for MPLS interfaces" on page 1323 for more information.

Any of the following events trigger the device to send out IS-IS LSPs with a TE extension:

- Change in the interface's administrative group membership.
- Change in the interface's maximum available bandwidth or maximum reservable bandwidth.
- Significant change in unreserved bandwidth per priority level, which can be either of the following:
  - For any priority level, the difference between the previously advertised, unreserved bandwidth and the current, unreserved bandwidth exceeds 5 percent of the maximum reservable bandwidth.
  - Any change if the total reserved bandwidth exceeds 95 percent of the maximum reservable bandwidth.

In addition, IS-IS LSPs with TE extensions can be triggered by IS-IS (for example, when an interface's link state changes). Furthermore, when an interface is no longer enabled for MPLS, the device stops sending out IS-IS LSPs with TE extensions for that interface.

Traffic engineering database

An LSR TED stores topology information about the MPLS domain. This topology information comes from OSPF-TE LSAs and IS-IS LSPs with TE extensions that are flooded throughout the OSPF area or IS-IS domain. When an LSR receives OSPF-TE LSAs or IS-IS LSPs with TE extensions from neighboring LSRs, it places the traffic engineering information into its TED. In this way, each LSR in the OSPF area builds an identical topology database that reflects the traffic engineering constraints, bandwidth reservations, and administrative group memberships of the area's MPLS-enabled interfaces and the links that connect them.

The topology information in the TED is used by the CSPF process when it calculates traffic-engineered paths for signalled LSPs, as the section "How CSPF calculates a traffic-engineered path"describes. You can display the contents of an LSR's TED (refer to "Displaying MPLS and RSVP information" on page 1354).

LSP attributes and requirements used for traffic engineering

In addition to the topology information in the TED, the device considers attributes and requirements specified in configuration statements for the LSP. The following user-specified parameters are considered when the device calculates a traffic-engineered path for a signalled LSP:

- Destination address of the egress LER
- Explicit path to be used by the LSP
- Bandwidth required by the LSP
- Setup priority for the LSP
- Metric for the LSP
- Whether the LSP includes or excludes links belonging to specified administrative groups

Refer to "Configuring signalled LSP parameters" on page 1334 for more information on how to set these parameters.

How CSPF calculates a traffic-engineered path

Using information in the TED in addition to the attributes and requirements of the LSP, CSPF calculates a traffic-engineered path for the LSP by performing the tasks listed below.

1. If more than one LSP needs to be enabled, CSPF selects the LSP for path calculation based on the LSP's setup priority and bandwidth requirement.

   When multiple LSPs are enabled simultaneously, such as when the device is booted, CSPF calculates the paths one at a time. CSPF starts with the LSP that has the highest configured setup priority. If more than one LSP has the same setup priority, CSPF calculates the path first for the LSP with the highest configured bandwidth requirement.

2. Eliminate unsuitable links from consideration.

   The device examines the topology information in its TED and uses this information to eliminate links from consideration for the traffic-engineered path. A link is eliminated if any of the following are true:

   - The link is half duplex.
   - The link does not have enough reservable bandwidth to fulfill the LSP's configured requirements.
   - The LSP has an **include** statement, and the link does not belong to an administrative group in the statement.
   - The LSP has an **exclude** statement, and either the link belongs to an administrative group specified in the exclude statement or the link does not belong to any administrative group at all.

3. Using the remaining links, calculate the shortest path through the MPLS domain.

   Using the links that were not eliminated in the previous step, the device calculates the shortest path between the ingress and egress LERs. If the LSP is configured to use an explicit path, the device individually calculates the shortest path between each node in the path. Refer to "Setting up paths" on page 1333 for more information on explicit paths.

   By default, the path calculated by CSPF can consist of no more than 255 hops, including the ingress and egress LERs. You can optionally change this maximum to a lower number. Refer to "Limiting the number of hops the LSP can traverse" on page 1343.

4. If multiple paths have the same cost, select one of them.

   The shortest path calculation performed in the previous step may result in multiple, equal-cost paths to the egress LER. In this case, the device chooses the path whose final node is the physical address of the destination interface.

   If more than one path fits this description, by default, the device chooses the path with the fewest hops. If multiple paths have this number of hops, the device chooses one of these paths at random. You can optionally configure the device to choose the path that has either the highest available bandwidth or the lowest available bandwidth. Refer to "Specifying a tie-breaker for selecting CSPF equal-cost paths" on page 1344.

The output of the CSPF process is a traffic-engineered path, a sequential list of the physical interfaces that packets assigned to this LSP pass through to reach the egress LER. Once the traffic-engineered path has been determined, RSVP signalling attempts to establish the LSP on each LSR in the path. Refer to the next section, "How RSVP establishes a signalled LSP", for a description of how this works.

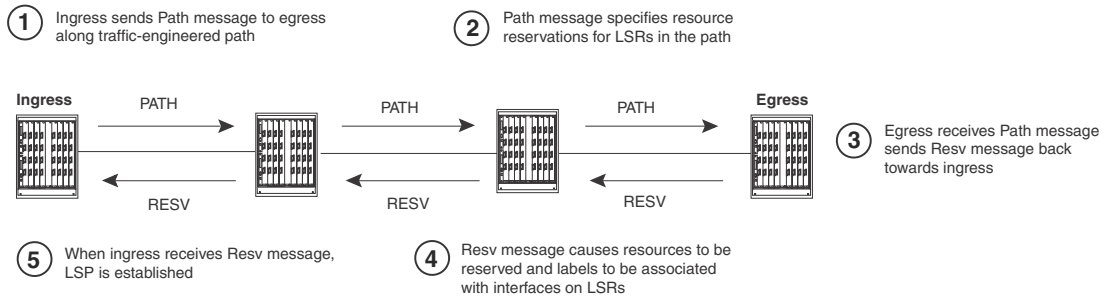
How RSVP establishes a signalled LSP

The traffic-engineered path calculated by CSPF consists of a sequential list of physical interface addresses, corresponding to a path from the ingress LER to the egress LER. Using this traffic-engineered path, RSVP establishes the forwarding state and resource reservations on each LSR in the path.

As with OSPF, special extensions for traffic engineering are defined for RSVP. These extensions include the EXPLICIT_ROUTE, LABEL_REQUEST, LABEL, and RECORD_ROUTE objects in addition to the Fixed Filter (FF) reservation style. These extensions are described in RFC 3209.

The following diagram illustrates how RSVP establishes a signalled LSP.

FIGURE 179 How RSVP establishes a signalled LSP



RSVP signalling for LSPs works as described below.

1. The ingress LER sends an RSVP Path message towards the egress LER.

   The Path message contains the traffic engineered path calculated by the CSPF process, specified as an EXPLICIT_ROUTE object (ERO). The Path message travels to the egress LER along the route specified in the ERO.

   The Path message also describes the traffic for which resources are being requested and specifies the bandwidth that needs to be reserved to accommodate this traffic. In addition, the Path message includes a LABEL_REQUEST object, which requests that labels be allocated on LSRs and tells the egress LER to place a LABEL object in the Resv message that it sends back to the ingress LER.

   Before sending the Path message, the ingress LSR performs ***admission control*** on the outbound interface, ensuring that enough bandwidth can be reserved on the interface to meet the LSP's requirements. Admission control examines the LSP's configured ***setup priority*** and ***mean-rate*** settings. For the LSP to pass admission control, the outbound interface must have reservable bandwidth at the LSP's setup priority level that is greater than the amount of bandwidth specified by the LSP's mean-rate setting. Refer to "Admission control, bandwidth allocation, and LSP preemption", for more information and examples of this process.

2. The Path message requests resource reservations on the LSRs along the path specified in the ERO.

   If the LSP passes admission control, the ingress LER sends a Path message to the address at the top of the ERO list. This is the address of a physical interface on the next LSR in the path. As the ingress LER did, this LSR performs admission control to make sure the outbound interface has enough reservable bandwidth to accommodate the LSP.

   If the LSP passes admission control, the LSR then removes its address from the top of the ERO list and sends the Path message to the address now at the top of the ERO list. This process repeats until the Path message reaches the last node in the ERO list, which is the egress LER.

3. The egress LER receives the Path message and sends a Resv message towards the ingress LER.

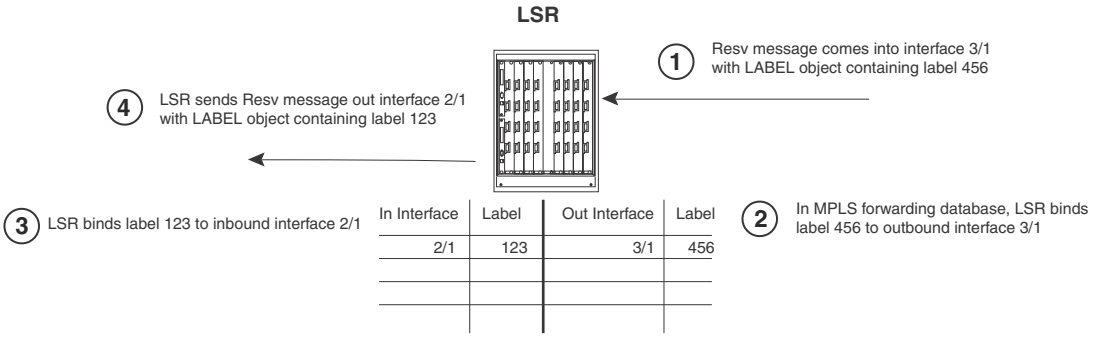
   Resv messages flow upstream from the receiver of the Path message to the sender (that is, from the egress LER to the ingress LER), taking the exact reverse of the path specified in the ERO. In response to the LABEL_REQUEST object in the Path message, the Resv message from the egress LER includes a LABEL object. The LABEL object is used to associate labels with interfaces on the LSRs that make up the LSP.

4. As the Resv messages travel upstream, resources are reserved on each LSR.

   When an LSR receives a Resv message, it again performs admission control on the interface where the Resv message was received (that is, the interface that will be the outbound interface for packets travelling through the LSP). If the LSP still passes admission control, bandwidth is allocated to the LSP. The LSR allocates the amount of bandwidth specified by the LSP's mean-rate setting, using bandwidth available to its ***hold priority*** level. This may cause lower priority LSPs active on the device to be preempted.

   Once bandwidth has been allocated to the LSP, the LABEL object in the Resv message is used to associate labels with interfaces in the LSR's MPLS forwarding table. Figure 180 shows an example of how this works.

FIGURE 180 How the RSVP LABEL object associates a label with an interface in the MPLS forwarding table



In the example above, the LSR receives a Resv message on interface 3/1 from the downstream LSR in the ERO. The Resv message has a LABEL object containing label 456. After performing admission control and bandwidth allocation, the LSR adds an entry to its MPLS forwarding table for this LSP, associating label 456 with outbound interface 3/1.

The LSR then takes a label from its range of available labels (for example, 123) and places it in the LABEL object in the Resv message that it sends to the upstream LSR. In this example, the LSR sends the Resv message out interface 2/1 to the upstream LSR in the ERO. In its MPLS forwarding table for this LSP, the LSR associates label 123 with inbound interface 2/1.

This process repeats at each LSR until the Resv message reaches the ingress LER.

NOTE
To enable penultimate hop popping for the LSP, the LABEL object sent by the egress LER to the penultimate LSR contains a value of 3 (Implicit Null Label). This is an IETF-reserved label value that indicates to the penultimate LSR that it must pop the label of MPLS-encoded packets that belong to this LSP.

5. Once the Resv message reaches the ingress LER, and the process described in Step 4 takes place, the LSP is activated. At this point each LSR in the LSP has reserved resources, allocated labels, and associated labels with interfaces. The LSP is activated, and the ingress LER can assign packets to the LSP.

Refresh messages

Once a signalled LSP is enabled at the ingress LER, the router persistently attempts to establish the LSP through periodic retries until the LSP is successfully established. To maintain the forwarding states and resource reservations on the routers in an LSP, Path and Resv messages are exchanged between neighboring LSRs at regular intervals. If these refresh messages are not received on the routers in the LSP, the RSVP forwarding states and resource reservations are removed. You can control how often the Path and Resv messages are sent, as well as how long the device waits before removing forwarding states and resource reservations. Refer to "Setting RSVP parameters" on page 1327 for more information.

Admission control, bandwidth allocation, and LSP preemption

When a Resv message is received on an LSR, admission control determines whether the LSP can be established, based on its configured priority. If an LSP passes admission control, bandwidth is allocated to the new LSP, possibly preempting existing LSPs that have lower priority.

An LSP's priority consists of a ***setup*** priority and a ***hold*** priority. The setup priority is the priority for taking resources; the hold priority is the priority for holding resources. An LSP's setup priority is considered during admission control, and its hold priority is considered when bandwidth is allocated to the LSP. The setup and hold priorities are expressed as numbers between 0 (highest priority level) and 7 (lowest priority level). An LSP's setup priority must be lower than or equal to its hold priority. You can configure either of these values for an LSP; by default, an LSP's setup priority is 7 and its hold priority is 0.

On an MPLS-enabled interface, a certain amount of bandwidth is allocated for usage by LSPs; this amount can be either the maximum available bandwidth on the interface (the default) or a user-specified portion. The amount of bandwidth an individual LSP can reserve from this pool of allocated bandwidth depends on two user-configured attributes of the LSP: the LSP's priority and the LSP's ***mean-rate*** (the average rate of packets that can go through the LSP). The following conditions also apply:

- For an LSP to pass admission control, the bandwidth available to its setup priority level must be greater than the value specified by its mean-rate.
- If an LSP passes admission control, the bandwidth specified by its mean-rate is allocated to the LSP, using bandwidth available to its hold priority level.
- For the allocation of bandwidth to the new LSP, the system might preempt existing, lower-priority LSPs.

When setting up an LSP, the device actually performs admission control twice: when the Path message is received and when the Resv message is received. If the LSP passes admission control after the Resv message is received, bandwidth allocation and LSP preemption take place.

The sections that follow include examples of how admission control, bandwidth allocation, and preemption work.

Admission control

Admission control examines the LSPs setup priority and mean-rate settings to determine whether the LSP can be activated. To pass admission control, the reservable bandwidth available at the LSP's setup priority level must be greater than the value specified by its mean-rate.

For example, if the maximum reservable bandwidth on an interface is 10,000 Kbps and no LSPs are currently active, the amount of reservable bandwidth on the interface for each priority level would be as follows:

Priority	Unreserved Bandwidth
0	10,000
1	10,000
2	10,000
3	10,000
4	10,000
5	10,000
6	10,000
7	10,000
Active LSPs: None	

The LSR receives a Resv message for an LSP that has a configured setup priority of 6 and a hold priority of 3. The mean-rate specified for this LSP is 1,000 Kbps. For priority level 6, up to 10,000 Kbps can be reserved. Because the configured mean-rate for this LSP is only 1,000 Kbps, the new LSP passes admission control.

Bandwidth allocation

Once the LSP passes admission control, bandwidth is allocated to it. The bandwidth allocation procedure examines the LSP's hold priority and mean-rate settings. The amount of bandwidth specified by the mean-rate is allocated to the LSP, using reservable bandwidth available at the LSP's hold priority level.

In this example, the LSP's hold priority is 3 and mean-rate is 1,000 Kbps. On this interface, for priority level 3, up to 10,000 Kbps can be reserved. The amount of bandwidth specified by the mean-rate (1,000 Kbps) is allocated to the LSP.

After bandwidth is allocated to this LSP, the amount of unreserved bandwidth on the interface is reduced accordingly. In the example, the reservable bandwidth array for the interface now looks like this:

Priority	Unreserved Bandwidth
0	10,000
1	10,000
2	10,000
3	9,000
Active: LSP with setup 6, hold 3, mean-rate 1,000	

Priority	Unreserved Bandwidth
4	9,000
5	9,000
6	9,000
7	9,000
Active: LSP with setup 6, hold 3, mean-rate 1,000	

Given the bandwidth allocation above, if an LSP were established with a setup priority of 3 and a mean-rate of 9,500 Kbps, it would not pass admission control because only 9,000 Kbps is available at priority 3.

LSP preemption

If there is not enough unallocated bandwidth on an interface to fulfill the requirements of a new LSP that has passed admission control, existing LSPs that have a lower priority may be preempted. When preemption occurs, bandwidth allocated to lower-priority LSPs is reallocated to the higher-priority LSP. LSP preemption depends on the bandwidth requirements and priority of the new LSP, compared to the bandwidth allocation and priority of already existing LSPs.

When LSP preemption is necessary, the device uses the following rules:

- Preempt existing LSPs that have lower priority than the new LSP.
- If several existing LSPs have lower priority than the new LSP, preempt the LSP that has the lowest priority.
- If two LSPs have equal priority and one must be preempted, preempt the LSP with the higher bandwidth requirement.
- Preempt the fewest number of LSPs necessary.

In the example above, bandwidth has been allocated to an LSP that has a hold priority of 3 and a mean-rate of 1,000 Kbps. When a new LSP with a setup priority of 2, hold priority of 1, and mean-rate of 10,000 Kbps is established, admission control, bandwidth allocation, and LSP preemption work as described below.

1. **Admission control:** On the interface, there is 10,000 Kbps available to priority 2. The mean-rate for the new LSP is 10,000, so the LSP passes admission control; bandwidth can be allocated to it.
2. **Bandwidth allocation:** The hold priority for the new LSP is 1. On the interface, 10,000 Kbps is available to priority 1. This entire amount is allocated to the LSP.
3. **LSP preemption:** The first LSP had been using 1,000 Kbps of this amount, but its hold priority is only 3. Consequently, the first LSP is preempted, and its bandwidth allocation removed in order to make room for the new LSP.

Once this happens, the reservable bandwidth array for the interface looks like this:

Priority	Unreserved Bandwidth
0	10,000
1	0
2	0
3	0
4	0
5	0
6	0
7	0
Active: LSP with setup 2, hold 1, mean-rate 10,000 **Preempted:** LSP with setup 6, hold 3, mean-rate 1,000	

On this interface, the only LSP that could preempt the active LSP would be have a setup and hold priority of 0.

When multiple LSPs are candidates for preemption, the device normally preempts the LSP with the lowest priority. However, if preempting a higher priority LSP with a high bandwidth requirement would allow lower priority LSPs with lower bandwidth requirements to avoid preemption, the higher-priority LSP is preempted.

For example, consider an interface with 10,000 Kbps of reservable bandwidth, allocated to two active LSPs: one with a setup priority of 3, hold priority of 2, and mean-rate of 5,000 Kbps; and another with a setup priority of 4, hold priority of 3, and mean-rate of 2,500 Kbps. When an LSP with a setup priority of 1, hold priority of 0, and mean-rate of 7,500 Kbps is established, the following take place.

1. **Admission control:** On the interface, there is 10,000 Kbps available to priority 1. The mean-rate for the new LSP is 7,500 Kbps, so the LSP passes admission control; bandwidth can be allocated to it.
2. **Bandwidth allocation:** The hold priority for the new LSP is 0. On the interface, 10,000 Kbps is available to priority 0. Of this amount, 7,500 Kbps is allocated to the new LSP.
3. **LSP preemption:** To reserve enough bandwidth for the new LSP, one of the active LSPs must be preempted. The LSP with hold priority 2 uses 5,000 Kbps, and the LSP with hold priority 3 uses 2,500 Kbps. Instead of preempting both LSPs, the device preempts the higher priority LSP and its allocation of 5,000 Kbps. This clears enough bandwidth to allow both the new LSP and the lower priority LSP to be active.

After preemption, the reservable bandwidth array for the interface looks like this:

Priority	Unreserved Bandwidth
0	2,500
1	2,500
2	2,500
3	0
4	0
5	0
6	0
7	0
Active: LSP with setup 1, hold 0, mean-rate 7,500 LSP with setup 4, hold 3, mean-rate 2,500 **Preempted:** LSP with setup 3, hold 2, mean-rate 5,000	

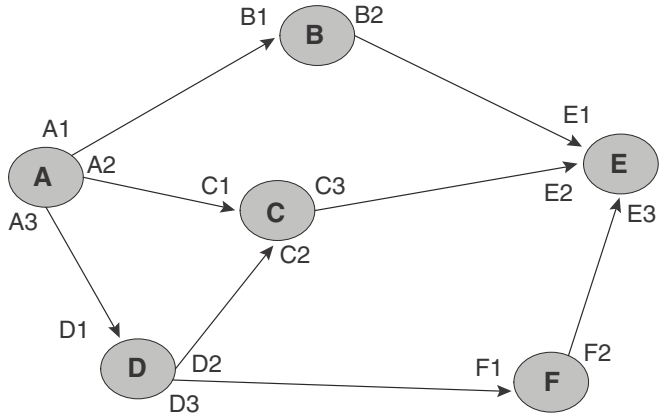
Calculating a path based on an interface address

Under normal conditions, router IDs are used to configure hops within an MPLS path. In situations where you want to exercise more control over the path, you can specify actual interface addresses in the MPLS path to make sure that the path will traverse the interface specified. In previous versions, the CSPF calculation would always resolve a specified interface address to the router ID. Consequently, although a particular interface on a router is specified, the CSPF calculation can end up connecting the path through a different interface on the router where the interface has been specified.

In the network described in Figure 181, the source node is “A” and the destination node is “E”. In this configuration, incoming and outgoing interfaces are defined in the figure by their relationship to where the arrowhead on the connecting line points. The arrowheads point to the incoming interface from the outgoing interface. For instance “A1”, “A2” and “A3” are the outgoing interfaces of node A and “C1” and “C2” are the incoming interfaces of node C. The following example describes how the router might calculate a path between “A” and “B” under the default operating condition.

In this example, an MPLS path has been configured with a source “A” and a destination “E1”. Under default operation, the interface “E1” destination is resolved to the routerID for “E”. This means that the path can be calculated to arrive at the “E” node on any of the following interfaces: “E1, “E2” or “E3”. While a path that travels from node “A” to node “B” to node “E” is the only path that actually satisfies the intent of the configuration, any of the following paths could be created by CSPF under the default operation condition: “A” to “C” to “E”, “A” to “D” to “C” to “E” or “A” to “D” to “F” to “E”.

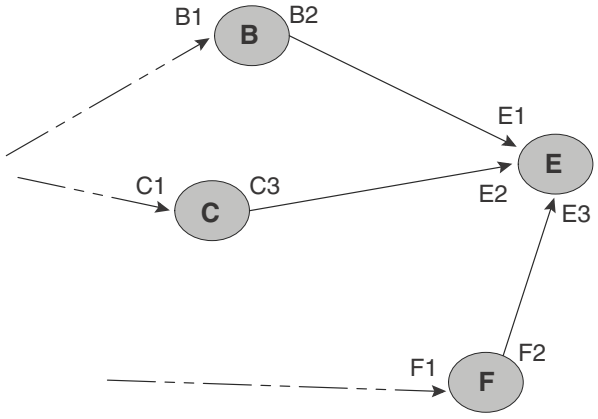
FIGURE 181 Calculating a path based on an interface



The global **cspf-interface-constraint** command directs the router to include the interface address as a constraint when it determines the shortest path. When invoked, this command ensures that a specified interface must be included in an LSP. This constraint can be turned on and off dynamically and does not affect established primary or secondary LSPs. CSPF interface constraint is significant for the ingress node only, where CSPF calculation takes place for an LSP.

When configuring CSPF interface constraint, you should be aware that the imposition of this additional constraint can increase the possibility of no path being found where otherwise there could be a path. One case where this can occur is where the path required to conform to the interface constraint fails the configured bandwidth constraint. Additionally, no path may be found where a configured path contains an inherently contradictory condition. For example if a path is configured "B1 (strict) to E2 (loose) as shown in Figure 182, no path will be found. This is because CSPF will always append B1 into the final CSPF path. This has the effect of making "B" the source node of the next hop and will therefore exclude "E1 as a traversed interface in subsequent paths to the destination node "E". Consequently, in this example the LSP will be down. However, if the **cspf-interface-constraint** command is not active, a CSPF path will be found and the LSP will go up.

FIGURE 182 Example of where no path is found



The **cspf-interface-constraint** command is described in "Configuring CSPF interface constraint" on page 1322.

MPLS fast reroute using one-to-one backup

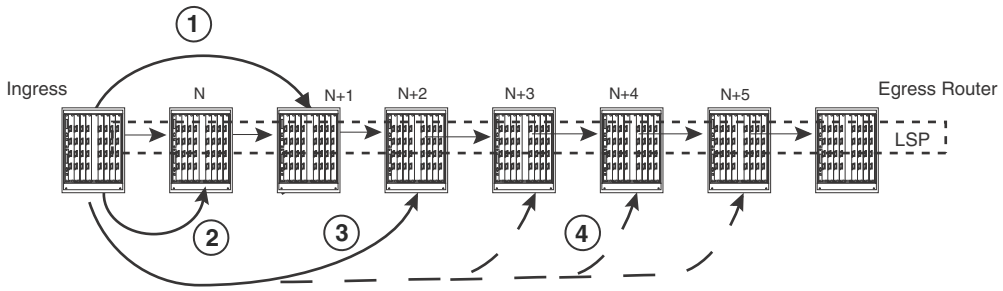
The Multi-Service IronWare software supports MPLS Fast Reroute to provide the ability for an LSP to route traffic around a failed node by using a detour route as described in RFC 4090. By using the one-to-one backup method, each LSR except the egress router is identified as a Point of Local Repair (PLR). Each PLR tries to initiate a *detour LSP* to provide a backup route for the protected path. This detour LSP is used to reroute traffic locally on the detour path in the event of a failure on the protected path.

Finding a detour at a PLR

Figure 183 illustrates how the algorithm works to determine the detour at each PLR.

NOTE
Although the example illustrates this method from only the Ingress router point-of-view, the same functionality operates on each PLR in the protected path.

FIGURE 183 Fast reroute using one-to-one backup



As shown In Figure 183, MPLS Fast Reroute operates according to the steps in the following list in a situation where the path from the ingress router to router N becomes inoperable.

1. The router first tries to find a detour path from the ingress router to the N + 1 node that excludes the failed link that the protected path traverses out of the ingress route and Node N.
2. If unable to find a detour path to node N + 1, in step 1, the router attempts to find a detour path from the ingress router to node N that excludes the link that the protected path traverses out of the ingress router.
3. If it is unable to find a detour path in steps 1 and 2, it attempts to find a detour path to any downstream node (until it reaches the egress LSR) immediately following the node N+1 in strict order. The exclusion criteria includes the downstream links (in the direction of the protected LSP) used in the protected path at each PLR.

Failover sequence

The following steps describe what happens when the ingress LER learns that a downstream break along an LSP has caused the LSP to take a detour.

1. At the PLR, the LSP's traffic has switched over to a detour within 50 msecs. Signaling has informed the router at the ingress LER of the tunnel that this event has occurred.
2. If the secondary path configured is a standby and it is in an operationally UP state, the ingress LER waits up to two minutes before switching the traffic to the LSP's secondary path. If the secondary path configured is a non-standby, the ingress LER attempts to bring the secondary path UP. Once the non-standby secondary path comes up, the ingress LER switches the traffic to the secondary path immediately.
3. The ingress LER tears down the LSP's primary path and builds a new primary path.

After the new primary path is up for the duration of the user-configured LSP revert timer, the LSP switches over to the primary LSP path.

MPLS Fast Reroute using facility backup over a bypass LSP

A bypass LSP is an MPLS LSP that serves as a tunnel to support facility backup of multiple, Fast Reroute LSPs, as specified in RFC 4090. Although the underlying mechanism of this feature is facility backup, the execution of facility backup is implemented through a user-defined bypass LSP, so this section focuses on bypass LSP.

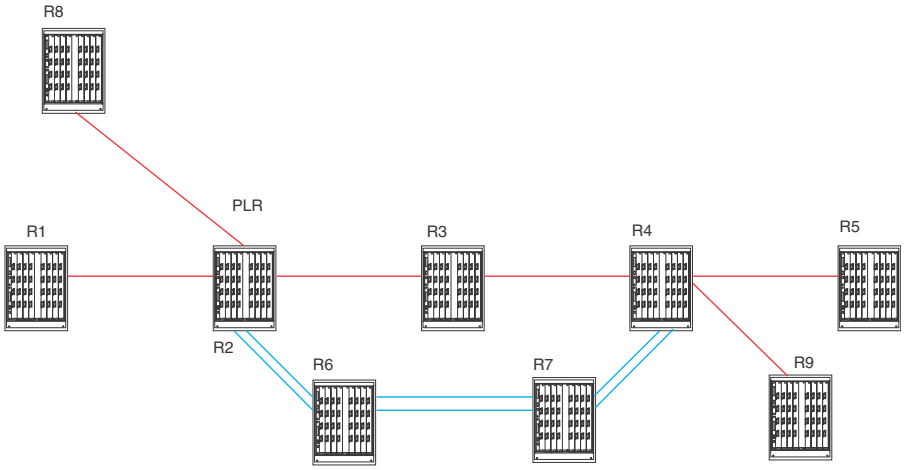
The advantage to using bypass LSP is an improvement in the scalability of protection. It provides a nearly hitless backup and, as a result, improves network resiliency. A bypass LSP consists of a predefined tunnel with a list of LSPs for which it is always ready to reroute traffic and is, therefore, a many-to-one backup. (With a detour backup, as described in "MPLS fast reroute using one-to-one backup" on page 1310, the network calculates an end-to-end detour for each disrupted LSP.)

The following definitions are important for understanding and configuring bypass LSPs:

- **Protected LSP:** An LSP whose traffic is carried over the bypass LSP if a link or router fails along the path of the protected LSP. When an MPLS LSP is configured to have Fast Reroute backup, that LSP can also be configured to request either facility backup or one-to-one backup.
- **Facility backup:** The standards-based mechanism for many-to-one backup.
- **Bypass LSP:** A tunnel that carries traffic if any number of its protected LSPs fail.
- **Point of local repair (PLR):** A router where the protected LSP and the bypass LSP first intersect and the LSP's bypass protection begins. Put another way, the PLR is the ingress of the bypass LSP. The PLR can be the ingress of the protected LSP or a transit node of the protected LSP. (refer to PLR/R2 in Figure 184 and the description in "Configuring a bypass LSP" on page 1312.)
- **Merge point (MP):** The egress router of the bypass LSP, where it merges the traffic back into the protected LSPs. (R4 in Figure 184 is the MP.) At the MP, the protected LSPs continue to carry traffic towards their own egress routers. Just as the PLR is common to all the LSPs protected by a specific bypass LSP, the MP must also be common to the protected LSPs.
- **Exclude interface:** An MPLS interface that is either a physical interface or a LAG and has the following traits:
  - It is an interface on the path of the protected LSP. (The notion that an excluded interface is protected by a bypass LSP is described in "Configuring a bypass LSP" on page 1312.)

- It is an interface that cannot be part of the bypass LSP itself.
- Exclude interfaces can consist of individual interfaces, ranges of interfaces, groups, or a LAG.

FIGURE 184 Facility backup applied to multiple routers over a bypass LSP



Configuring a protected LSP

To acquire the protection of one or more bypass LSPs along its route, an LSP that is requesting facility backup checks the interfaces that it traverses for the availability of a bypass LSPs that meet its requirements. (A Fast Reroute LSP that needs facility backup must request it. Refer to "Protecting MPLS LSPs through a bypass LSP" on page 1352 for the configuration steps.) The requesting LSP checks all of the bypass LSPs on the outbound interface of each router and selects a candidate bypass LSP that best meets its criteria so that, if the protected LSP fails, its traffic immediately switches to the bypass LSP that is upstream from the point of failure.

When an LSP is enabled for Fast Reroute, the CLI enters the configuration level for Fast Reroute, which has the option for requesting facility backup. Entering the keyword **facility-backup** in the Fast Reroute level configures the LSP to request facility backup as provided by a bypass LSP. Subsequently, for the LSP to acquire the protection of a bypass LSP, that bypass LSP must have the bandwidth, the constraints, the route (for the merge point), and other criteria that the LSP requires. Furthermore, the configuration of the bypass LSP itself must list the interface on the router where the candidate LSP and the bypass LSP first intersect. The description of linking a Fast Reroute LSP to a bypass LSP is in "Configuring a bypass LSP" on page 1312.

Configuring a bypass LSP

The crucial topics to understand for configuring a bypass LSP are the PLR, the merge point, and the excluded interfaces. This section provides a detailed definition of these items and describes how they relate to each other. Refer to Figure 184 and Figure 185 for the description of these topics.

The PLR is the ingress of a bypass LSP. If a protected link breaks downstream from the PLR, the bypass LSP carries the traffic of the LSPs it protects around the break. As shown in Figure 184, the LSPs from R1 and R8 enter R2 (the PLR). The double line that originates at R2 and then traverses R6 and R7 to terminate at R4 is the bypass LSP.

In Figure 184, the egress router for the protected LSPs is R5. Upstream from R5 is the point (R4) where the bypass LSP terminates and merges the traffic back into the protected LSPs. This router is the merge point.

In facility backup, the interfaces that go into this arrangement can belong to either:

- The bypass LSP
- The protected LSP

The specification of a bypass LSP includes manual entry of a list of interfaces at the PLR that cannot make up the bypass LSP's own route. These *excluded* interfaces are the interfaces that the protected LSPs traverse. Therefore, from the standpoint of the bypass LSP, the protected interfaces on the PLR are called *excluded* interfaces. (If the protected interfaces were included in the backup path rather than excluded from the backup path, then the interfaces would be protecting themselves—a logical contradiction.)

In facility backup, the linkage of the protected LSP to the bypass LSP is established by the following events:

- The request from an MPLS LSP for facility backup: At the ingress node (R1 in Figure 184, for example), LSP 1 is configured to request facility backup.
- The intersection of an MPLS LSP and a bypass LSP: If an LSP requesting facility backup traverses an interface on a router (R2 Figure 184) with a bypass LSP that has LSP 1's outbound interface in its user-specified list of excluded interfaces, then LSP 1 can become protected at that point, and R2 is a PLR.

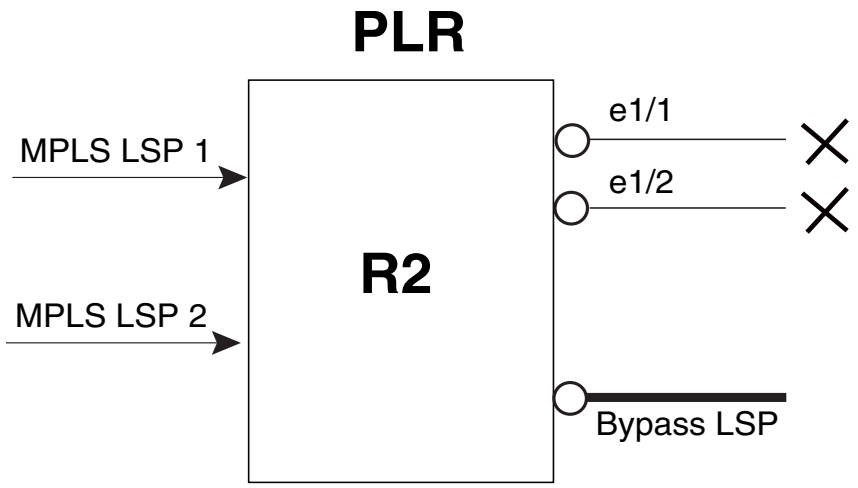
  The bypass LSP identifies the interfaces to protect in the command that creates the bypass LSP. In Figure 185, LSP 1 and LSP 2 enter R2. The outbound interfaces for these LSPs are e 1/1 and e1/2. To provide protection to LSP 1 and LSP 2, the interfaces e 1/1 and e 1/2 are listed as exclude interfaces in the configuration of the bypass LSP.

  In complex topologies, an interface can have multiple bypass LSPs protecting it. For example, the LSPs that traverse an interface might have destinations that make a single merge point impossible, so multiple bypass LSPs would be needed in this case to support different LSPs. Therefore, more than one bypass LSP can have the same interface in its list of exclude interfaces.

NOTE
The bypass LSP must have the bandwidth capacity to carry the traffic of all of its assigned LSPs. Before a candidate LSP chooses a bypass LSP on a given interface, software determines whether the bypass LSP can reserve sufficient bandwidth for the candidate LSP.

NOTE
In the current release, BFD for facility backup FRR LSP is not supported. The system returns an error if you try either to enable BFD for facility backup for an LSP or to set facility-backup mode for an LSP with BFD enabled. Further, the BFD option is not available in the bypass LSP configuration context.

FIGURE 185 Excluded interfaces on a PLR



Bypass LSP, like one-to-one backup, fits within the scope of MPLS Traffic Engineering, so the configuration of bypass LSP includes elements of traffic engineering. For example, setting up a bypass LSP relies on RSVP and CSPF. In fact, CSPF is automatically enabled on a bypass LSP and, therefore, does not appear as a configurable option at the bypass LSP configuration level.

CLI differences between a protected LSP and a bypass LSP

In the Fast Reroute context of MPLS LSP configuration, the option to request facility backup is available. For example, to request facility backup for LSP mlxe2-199, the CLI would be.

```
config-mpls-mlxe2-199-frr>#facility-backup
```

For the configuration of a bypass LSP, certain parameters are either unsupported or unnecessary. These are:

- CSPF (because it is always enabled)
- BFD (not supported in this release)
- Commit
- Secondary path
- FRR
- Selected path
- Adaptive (not supported)
- IPMTU
- Metric
- Reoptimize_timer
- Revert-timer
- Select-path
- Shortcuts

In contrast, the parameter that is unique to bypass LSP is the specification of excluded interfaces, which can be embodied as individual interfaces, ranges of interfaces, groups, or LAGs. With bypass LSP 123.

Example

```
config-mpls->#bypass-lsp 123
config-mpls-bypasslsp-123># exclude-interface <linkid>, <linkid>,
<linkid-begin-linkid-end>
```

MPLS over virtual Ethernet interfaces

Dell routers supports MPLS over virtual ethernet (VE) interfaces. MPLS over VE interfaces enables MPLS to be configured over tagged links. With this feature, MPLS can run over a single tag on the port. Other tags on the port can be used for other applications, such as Layer 2 VLANs, VPLS endpoints, VLL endpoints, etc.

An MPLS enabled VE interface supports the following services.

- IP over MPLS
- L3VPN
- Transit LSR
- PBR over MPLS
- LSP Accounting
- MPLS VLL
- MPLS VPLS
- Multicast Snooping over VPLS
- 802.1ag
- MPLS OAM
- BFD

NOTE
MPLS encapsulated packets are not supported for sFlow processing.

NOTE
Multi-port static ARP configuration in not supported for MPLS uplinks.

Configuration considerations before enabling MPLS on a VE interface

Before enabling MPLS on a VE interface, consider the configuration notes in this section.

- You must create a VE <*vid*> virtual interface id. The virtual interface id is a decimal number that represents an already configured VE interface. For more information on enabling MPLS on a VE interface, refer to "Configuring MPLS on a VE interface" on page 1328
- At least one IP address must be configured over a VE interface.
- You can enable MPLS on two or more tags on the same port.
- In the output of the **show vlan** command, MPLS packets that are received on an MPLS enabled VE interface are displayed in the Bytes received field. For more information on displaying VLAN byte counters on an MPLS enabled VE interface, refer to "Displaying VLAN information" on page 275.

In order to support configuration of MPLS uplinks and layer 2 VPN endpoints on the same physical port, consider the following:

- When an untagged or tagged Layer 2 VPN endpoint is configured and the port belongs to a MPLS VE enabled default VLAN, the configuration will be rejected. The following error message is displayed.

```
NetIron(config-mpls-vll-test)#untagged ethernet 4/3
Error - Cannot configure VLL endpoint on port 4/3 since it belongs to the
MPLS VE enabled default VLAN
```

- When an untagged or tagged Layer 2 VPN endpoint is deleted and the port is returned to the default VLAN, if an MPLS VE exists on the default VLAN, the port will automatically be converted to an MPLS uplink.

MPLS enabled interface

When enabling MPLS on a VE interface, consider the following.

- You cannot delete a VE interface while MPLS is enabled on it. You must first remove MPLS from the interface configuration. The following error message is displayed.

```
NetIron(config)#no interface ve 20
Error - VE 20 has MPLS enabled
```

- You cannot delete a VLAN associated with a VE if MPLS is enabled on that VE. You must first disable MPLS from the VE interface. The following error message is displayed:

```
NetIron(config)#no vlan 20
Error - vlan can't be deleted as MPLS is enabled on associated VE interface
```

- When MPLS is enabled on an interface, the last IP address of a VE cannot be removed. The command is rejected. The following error message is displayed:

```
NetIron(config-vif-54)#no ip address 40.40.40.5/24
IP/Port: Errno(31) Can not remove IP address as MPLS is configured on the
port
```

VPLS CPU protection

When enabling MPLS on a VE interface with VPLS CPU protection turned on, consider the following.

- VPLS CPU protection must be disabled globally, or disabled on all instances of VPLS that has VE member port as the VPLS endpoint. If VPLS CPU protection is not disabled, then MPLS cannot be enabled on a VE interface. The following error message is displayed.

```
NetIron(config-mpls)#mpls-interface ve 1
Error - Port 4/3 belongs to a VPLS instance that has CPU-protection ON
```

- You cannot configure a VPLS endpoint on a member of a MPLS VE enabled interface when VPLS CPU protection is configured globally, or for a specified instance. The configuration is rejected, and the following error message is displayed.

```
NetIron(config-mpls-vpls-test-vlan-11)#tagged ethernet 4/3
Error - VPLS instance test has CPU protection ON and port 4/3 belongs to a
MPLS VE
```

- If a VPLS endpoint belonging to a VPLS instance (with CPU protection turned on) is on a port that does not belong to the VE, then you cannot add a port in an untagged or tagged mode to a VLAN which has a MPLS VE on it.

```
NetIron(config-vlan-100)#tagged ethernet 4/7
Error - Port 4/7 belongs to a VPLS instance that has CPU protection ON
```

- On an MPLS VE enabled interface, if a VPLS endpoint is a member of the VE interface, but VPLS CPU protection is not configured for the VPLS instance, then configuring VPLS CPU protection globally will not enable CPU protection for that instance. If VPLS CPU protection is enabled locally on that instance, the configuration will also be rejected. The following error message is displayed.

```
NetIron(config-mpls)#vpls-cpu-protection
Error - Cannot configure CPU protection for VPLS 111 as end-points share
the same physical port as MPLS VE interfaces.
CPU protection feature is not turned on for VPLS 111
```

Reverse path forwarding

When enabling MPLS on a VE interface with reverse path forwarding, consider the following.

- You cannot configure MPLS on a VE interface that has at least one member port enabled with RPF strict mode. The command is rejected, and the following error message is displayed.

```
NetIron(config-if-e1000-4/3)#mpls-interface ve 1
Error - Cannot configure MPLS on VE with RPF strict mode port e 4/3
```

- You cannot configure RPF strict mode on a port that is a member of a MPLS VE interface. The command is rejected, and the following error message is displayed.

```
NetIron(config-if-e1000-4/3)#rpf-mode strict
Error: RPF: Cannot configure RPF strict mode on an MPLS VE enabled
interface
```

- You cannot add a port to a MPLS VE enabled VLAN if the RPF strict mode is already enabled on the port. The command is rejected, and the following error message is displayed.

```
NetIron(config-vlan-100)#tagged ethernet 4/3
Error - Cannot add RPF strict mode port 4/3 to MPLS VE enabled VLAN 100
```

Port mirroring

When enabling MPLS on a VE interface with port mirroring configured, consider the following.

- You cannot configure MPLS on a VE interface that has at least one member port enabled with port mirroring. The command is rejected, and the following error message is displayed

```
NetIron(config-mpls)#mpls-interface ve 54
Error - Can not configure MPLS tunnel on ve 54 with mirror port e4/3
```

- You cannot configure a MPLS VE member port as a mirror port. The command is rejected, and the following error message is displayed.

```
NetIron(config)#mirror-port e 4/3
Error: Cannot mirror a port that has MPLS VE configured
```

- You cannot add a mirror port to a MPLS VE enabled VLAN. The command is rejected, and the following error message is displayed.

```
NetIron(config-vlan-100)#tagged ethernet 4/3
Error - Cannot add mirror port 4/3 to MPLS VE enabled VLAN 100
```

Protocol-based VLANs

When enabling MPLS on a VE interface associated with a protocol-based VLAN, consider the following.

NOTE
MPLS is supported only on VE interfaces that are configured on port-based VLANs.

- You cannot configure MPLS on a VE interface associated with a protocol based VLAN. The command is rejected, and the following error message is displayed:

```
NetIron(config-mpls)#mpls-interface ve 1
Error: Cannot configure MPLS on VE built on protocol-based VLAN
```

VRF

When enabling MPLS on a VE interface for a VRF instance, consider the following.

NOTE
When configuring MPLS on a VE interface on a VLAN port, you can also configure a VRF instance on other VLANs of the same port.

- You cannot configure a VRF instance on a MPLS VE enabled interface. The following error message is displayed:

```
NetIron(config-vif-20)#vrf forwarding test
Error - cannot configure VRF on an MPLS VE enabled interface
```

Class of Service (CoS)

By default, the internal priority of a packet received on a tagged MPLS uplink is mapped from PCP and EXP bits. When determining the internal priority, the first step is to merge the PCP and EXP bits. In this step, when configuring the **qos exp force** command on an interface, the internal priority is mapped only from EXP bits and PCP bits are ignored.The **qos exp force** command does not override the port priority command. In the second step, the port priority will be merged with the internal priority and hence, the **qos exp force** command has no effect on this step.

By default, the internal priority of a packet sent out on a tagged MPLS uplink is mapped into EXP and PCP bits. When configuring the **qos pcp-encode policy off** command on an outgoing interface, the PCP bits is 0.

Configuring MPLS

This section explains how to set up MPLS on devices. It contains the following topics:

- "Configuring MPLS Fast Reroute using one-to-one backup" on page 1350
- "Protecting MPLS LSPs through a bypass LSP" on page 1352

Enabling MPLS

MPLS is disabled by default. To enable MPLS on a device, you must perform the steps listed below.

1. Enable MPLS on the device
2. Enable MPLS on individual interfaces
3. Set global MPLS policy parameters (optional)
4. Set traffic engineering parameters for MPLS-enabled interfaces (optional)
5. Set RSVP parameters (optional)

Enabling MPLS on the device

To enable MPLS on the device, enter the following commands.

```
NetIron> enable
NetIron# configure terminal
NetIron(config)# router mpls
```

Syntax: [no] router mpls

To disable MPLS on the device, use the **no** form of the command.

Enabling MPLS on individual interfaces

After you enable MPLS globally on the device, you can enable it on one or more interfaces. For example, to enable MPLS on interface e 3/1.

```
NetIron(config-mpls)# mpls-interface e 3/1
```

Syntax: [no] mpls-interface all-ethernet | ethernet <*slot/port*> **| pos** <*slot/port*> **|ve** <*vid*>

The **all-ethernet** option specifies all Layer-3 Ethernet interfaces

The **ethernet** option specifies the individual Ethernet interface described by the <*slot/port*> variable.

The **pos** option specifies the individual POS interface described by the <*slot/port*> variable.

The **ve** option specifies the individual virtual ethernet (VE) interface described by the <*vid*> variable.

Configuration Considerations for enabling MPLS on a LAG interface

When MPLS is globally enabled on the device, a port that is configured in a LAG can be enabled as an MPLS interface port to create an MPLS LAG. You can do this through either of the following approaches:

- Include a primary LAG port that has already been MPLS -enabled in a new LAG.
- MPLS-enable a primary LAG port of a previously configured LAG.

You must consider the following points when configuring MPLS on a LAG

- MPLS configuration on dynamic lag interfaces are supported.
- Switch and LACP LAGs are not supported.
- MPLS is enabled on the primary port of the LAG and this enables MPLS on the entire LAG. Secondary ports of the LAG cannot be individually configured for MPLS.

Setting global MPLS policy parameters

You can optionally set the following global MPLS policy parameters (they apply to all MPLS-enabled interfaces on the device):

- Retry time
- Retry limit
- Administrative group names
- Whether the device sends out OSPF-TE LSAs for its MPLS-enabled interfaces
- Whether the device sends out IS-IS LSPs with TE extensions for its MPLS-enabled interfaces
- Configuring IP-over-MPLS TTL Propagation Control
- LSP Accounting

Setting the retry time

When a signalled LSP is enabled, the ingress LER attempts to connect to the egress LER over the primary path specified in the LSP's configuration. If the connection is not successful, by default the ingress LER waits 30 seconds before attempting the connection again. You can configure the amount of time the ingress LER waits between connection attempts.

For example, to specify a retry time of 45 seconds.

```
NetIron(config-mpls)# policy
NetIron(config-mpls-policy)# retry-time 45
```

Syntax: [no] retry-time <*seconds*>

Setting the retry limit

If the ingress LER fails to connect to the egress LER in a signalled LSP, the ingress LER tries indefinitely to make the connection unless you set a limit for these connection attempts. After this limit is exceeded, the ingress LER stops trying to connect to the egress LER over the primary path.

If a secondary path is configured for the LSP, it is immediately activated after the primary path fails. After the secondary path is activated, the ingress LER continues to try to connect to the egress LER over the primary path either up to the configured retry limit or indefinitely if no retry limit is set. If a connection over the primary path can be established, the secondary path is deactivated, and traffic for the LSP is again sent over the primary path.

To set the number of connection attempts to 20.

```
NetIron(config-mpls)# policy
NetIron(config-mpls-policy)# retry-limit 20
```

Syntax: [no] retry-limit <*number*>

Once the connection is established, the retry counter is reset to zero. In the example above, if an LSP needs to be established again, the ingress LER will make 20 attempts to establish a connection to the egress LER.

Establishing administrative group names

Administrative groups, also known as resource classes or link colors, allow you to assign MPLS-enabled interfaces to various classes. When a device calculates the path for an LSP, it can take into account the administrative group to which a interface belongs; you can specify which administrative groups the device can include or exclude when making its calculation.

Up to 32 administrative groups can be configured on the device. You can see an administrative group either by its name or its number. Before you can see an administrative group by its name, you must specify a name for the group at the MPLS policy level and associate the name with that administrative group's number.

For example, the following commands establish three administrative group names.

```
NetIron(config-mpls)# policy
NetIron(config-mpls-policy)# admin-group gold 30
NetIron(config-mpls-policy)# admin-group silver 20
NetIron(config-mpls-policy)# admin-group bronze 10
```

Syntax: [no] admin-group <*name*> <*number*>

The <*number*> has a range of 0 – 31.

After you associate an administrative group name with a number, you can see it by name when assigning interfaces to the group or including or excluding the group from LSP calculations. Refer to "Adding interfaces to administrative groups" on page 1324 and "Including or excluding administrative groups from LSP calculations" on page 1343.

Enabling OSPF-TE LSAs for MPLS interfaces

Information related to traffic engineering is carried in OSPF traffic engineering (OSPF-TE) LSAs. OSPF-TE LSAs have special extensions that contain information about an interface's traffic engineering metric, bandwidth reservations, and administrative group memberships.

When an MPLS-enabled device receives an OSPF-TE LSA, it stores the traffic engineering information in its Traffic Engineering database (TED). The device uses information in the TED when performing calculations to determine a path for an LSP.

You can configure the device to send out OSPF-TE LSAs for all of its MPLS-enabled interfaces. To do this, enter the following commands.

```
NetIron(config)# router mpls
NetIron(config-mpls)# policy
NetIron(config-mpls-policy)# traffic-engineering ospf
```

Syntax: [no] traffic-engineering ospf [area <*area-id*> **]**

You can use the **area** option to limit the CSPF calculations to the OSPF Area specified by the <*area-id*> variable. The <area-id> variable can accept area-id in both Decimal and IP address formats.

By default, the device does not send out OSPF-TE LSAs for its MPLS-enabled interfaces. Because information in the TED is used to make path selections using CSPF and information in the TED comes from OSPF-TE LSAs or IS-IS TE LSP, you must enable the device to send out OSPF-TE LSAs or IS-IS LSPs with TE extensions if you want CSPF to perform constraint-based path selection.

The **no** option removes an existing OSPF TE database. If you use the **no** option with the **area** option, the OSPF TE database is removed for only the specified OSPF area.

Refer to "Setting traffic engineering parameters for MPLS interfaces" on page 1323, for information on the traffic engineering information carried in OSPF-TE LSAs.

Enabling IS-IS LSPs with TE extensions for MPLS interfaces

Information related to traffic engineering is carried in IS-IS traffic engineering LSPs. IS-IS TE LSPs have special extensions that contain information about an interface's administrative group memberships, IPv4 interface address, IPv4 neighbor address, maximum link bandwidth, reservable link bandwidth, unreserved bandwidth, and default traffic engineering metrics.

When an MPLS-enabled device receives an IS-IS TE LSP, it stores the traffic engineering information in its Traffic Engineering database (TED). The device uses information in the TED when performing calculations to determine a path for an LSP.

You can configure the device to send out IS-IS TE LSPs for all of its MPLS-enabled interfaces. To do this, enter the following commands.

```
NetIron(config)# router mpls
NetIron(config-mpls)# policy
NetIron(config-mpls-policy)# traffic-engineering isis level-1
```

Syntax: [no] traffic-engineering isis level-1 | level-2

The level-1 option enables LSPs with TE extensions for the IS-IS level-1 domain.

The level-2 option enables LSPs with TE extensions for the IS-IS level-2 domain.

By default, the device does not send out IS-IS LSPs with TE extensions for its MPLS-enabled interfaces. Since information in the TED is used to make path selections using CSPF, and information in the TED comes from OSPF-TE LSAs or IS-IS LSPs with TE extensions, you must enable the device to send out OSPF-TE LSAs or IS-IS LSPs with TE extensions if you want CSPF to perform constraint-based path selection.

Refer to "Setting traffic engineering parameters for MPLS interfaces" on page 1323, for information on the traffic engineering information carried in IS-IS LSPs with TE extensions.

Configuring CSPF interface constraint

As described in detail in "Calculating a path based on an interface address" on page 1308, under the default condition, hops configured as interface addresses in an LSP path are resolved to the router ID. Consequently, an LSP can be configured that does not traverse a specified interface. The **cspf-interface-constraint** command was introduced that forces the CSPF calculation to include any specified interface when creating an LSP. The operation and constraints of using this command are described in the section mentioned.

You can configure a PowerConnect router to always include a specified interface when forming an LSP by configuring the **cspf-interface-constraint** command as shown in the following.

```
NetIron(config-mpls)# policy
NetIron(config-mpls-policy)# cspf-interface-constraint
```

Syntax: [no] cspf-interface-constraint

The default condition is for the CSPF interface Constraint feature to be disabled. If the feature has been enabled, you can use the **no** option to disable it.

The CSPF interface Constraint feature may be dynamically turned on or off. Turning the feature off or on has no effect on LSPs that have already been established (primary and secondary). For LSPs that are currently retried, changing the constraint setting will change the behavior on the next retry such as when an LSP whose path is configured to use that interface fails to come up due to an interface down condition.

Also note that the CSPF interface Constraint feature has significance for the ingress node only, where the CSPF calculation takes place for an LSP or a detour segment.

Setting traffic engineering parameters for MPLS interfaces

When using constraints to determine a path for an LSP, the device takes into account information included in OSPF-TE LSAs or IS-IS LSPs with TE extensions. This information can be used to set up a path for a new LSP or to preempt an existing LSP so that an LSP with a higher priority can be established.

OSPF-TE LSAs and IS-IS LSPs with TE extensions include Type/Length/Value triplets (TLVs) containing the following information:

- Link type (either point-to-point or multiaccess network) (OSPF-TE LSAs only)
- Link ID (for point-to-point links, this is the Router ID of the LSR at the other end of the link; for multiaccess links, this is the address of the network's designated router) (OSPF-TE LSAs only)
- IP address of the local interface
- IP address of the remote interface (must exist with point-to-point links)
- Traffic engineering metric for the link
- Maximum bandwidth on the interface
- Maximum reservable bandwidth on the interface
- Unreserved bandwidth on the interface
- Administrative groups to which the interface belongs

When configured to do so with the **traffic-engineering ospf** command, the device sends out OSPF-TE LSAs containing this information for each of its MPLS-enabled interfaces. When configured to do so with the **traffic-engineering isis** command, the device sends out IS-IS LSPs containing this TE information for each of its MPLS-enabled interfaces. Optionally, you can specify the maximum amount of bandwidth that can be reserved on an interface. In addition, you can assign interfaces to administrative groups.

Reserving bandwidth on an interface

OSPF-TE LSAs and IS-IS LSPs with TE extensions contain three TLVs related to bandwidth reservation:

- The Maximum Bandwidth TLV indicates the maximum outbound bandwidth that can be used on the interface. Maximum Bandwidth is the operating speed of the port. When calculated for a LAG, the Maximum Bandwidth is the operating speed of the primary port multiplied by the number of active ports in the LAG. Hence, this reflects the actual physical bandwidth of the interface. This TLV is not configurable by the user.
- The Maximum Reservable Bandwidth TLV indicates the maximum bandwidth that can be reserved on the interface. By default, the Maximum Reservable Bandwidth is the same as the Maximum Bandwidth for the interface. You can optionally change the reservable bandwidth to an amount greater or less than the maximum available bandwidth of the interface. When a Maximum Reservable Bandwidth is configured on the primary port within a LAG, the value configured applies to the entire LAG regardless of any change to the number of active ports within the LAG. By default, the Maximum Reservable Bandwidth for the LAG is the same as its Maximum Bandwidth.
- The Unreserved Bandwidth TLV indicates the amount of bandwidth not yet reserved on the interface. This TLV consists of eight octets, indicating the amount of unreserved bandwidth (in kbits second) at each of eight priority levels. The octets correspond to the bandwidth that can be reserved with a hold priority of 0 through 7, arranged in increasing order, with priority 0

occurring at the start of the TLV, and priority 7 at the end of the TLV. The value in each of the octets is less than or equal to the maximum reservable bandwidth. The Unreserved Bandwidth TLV itself is not user-configurable, although it is affected by modifications to the reservable bandwidth on an interface, as well as changes to LSPs.

You can optionally change the amount of reservable bandwidth on an MPLS-enabled interface (that is, modify the value in the Maximum Reservable Bandwidth TLV in OSPF-TE LSAs or IS-IS TE LSPs sent out for the interface). To do this, enter commands such as the following.

```
NetIron(config-mpls)# mpls-interface e 3/1
NetIron(config-mpls-interface)# reservable-bw 10000
```

Syntax: [no] reservable-bw <*number*>

The reservable bandwidth is expressed in Kbits/sec. By default, the reservable bandwidth is the same as the maximum available bandwidth on the interface. If the amount of reservable bandwidth is greater than the maximum available bandwidth, then the link can be oversubscribed. If the reservable bandwidth is less than the maximum available bandwidth, then LSPs cannot reserve all physical bandwidth on the interface. If the **reservable-bw** command is applied to the primary port within a LAG, the bandwidth configured for that port will apply to the entire LAG regardless of any change to the number of active ports within the LAG.

Changing the amount of reservable bandwidth on an interface causes the amount of unreserved bandwidth to be recalculated. In addition, it may cause an OSPF-TE LSA or IS-IS TE LSP to be issued, as well as possibly pre-empt existing LSPs if bandwidth reservations can no longer accommodate them.

Adding interfaces to administrative groups

You can place individual interfaces into administrative groups. Administrative groups, also known as resource classes or link colors, allow you to assign MPLS-enabled interfaces to various classes. For example, you can define a group called “gold” and assign high-bandwidth interfaces to it. When a device calculates the path for an LSP, it can take into account the administrative group to which a interface belongs. You can configure up to 32 administrative groups. By default, an interface does not belong to any administrative groups.

Administrative groups are in the range 0 – 31. You can see an administrative group either by name or number. To see an administrative group by name, first create a name for the group and associate the name with an administrative group number. Refer to “Establishing administrative group names” on page 1321 for details.

To assign MPLS-enabled interface e 3/1 to an administrative group called “gold”, enter the following.

```
NetIron(config-mpls)# mpls-interface e 3/1
NetIron(config-mpls-interface)# admin-group gold
```

Syntax: [no] admin-group <*number*> | <*name*> **...**

The <*number*> can be from 0 – 31. The administrative group name <*name*> must have been previously configured.

An MPLS-enabled interface can belong to any number of administrative groups. For example, to assign an interface to group “gold” and group 31, enter commands such as the following.

```
NetIron(config-mpls)# mpls-interface e 3/1
NetIron(config-mpls-interface)# admin-group gold 31
```

After you add interfaces to administrative groups, you can specify which groups can be included or excluded from LSP calculations. Refer to "Including or excluding administrative groups from LSP calculations" on page 1343.

IP-over-MPLS TTL propagation control

In the MPLS label header, the TTL field indicates the Time To Live (TTL) value for an MPLS packet. For IP-over-MPLS applications, at the ingress LER an IP packet's TTL value is decremented by one and the IP checksum is recalculated. The IP packet's TTL value is then copied to its MPLS TTL field. At each transit LSR hop, the MPLS TTL value is decremented by 1. If the MPLS TTL value reaches 1 or 0, the packet is discarded.

At the MPLS router that pops the label (either the penultimate LSR or the egress LER), the incoming packet's MPLS TTL value is copied to the packet's IP TTL field, the IP TTL field is decremented by 1, and the checksum is recalculated. The result is that each LSR in the MPLS domain is counted as one hop. This is the default behavior.

Optionally, you can configure TTL propagation so that the entire MPLS domain appears as a two hops. In this case, the ingress LER decrements the IP packet's TTL value by one and then places a value of 255 in the packet's MPLS TTL field. The MPLS TTL value is decremented by 1 as the MPLS packet passes through each LSR in the MPLS domain. When the label is popped, the value in the MPLS TTL field is discarded, not copied to the packet's IP TTL field. The unlabeled IP packet's TTL is then decremented by one as it passes through the egress LER. This means that the packet's IP TTL is decremented twice from the time it enters the ingress LER to the time it exits the egress LER, making the MPLS domain appear as two hops.

To configure TTL propagation so that the entire MPLS domain appears as two hops, enter the following commands on both the ingress LER and the MPLS router that pops the label (either the penultimate LSR or the egress LER).

```
NetIron(config-mpls)# policy
NetIron(config-mpls-policy)# no propagate-ttl
```

Syntax: [no] propagate-ttl

When **no propagate-ttl** is configured, the ingress LER places a value of 255 into the packet's MPLS TTL field, regardless of the TTL value in the packet's IP header. The packet's IP TTL value is decremented twice: once at the ingress LER and once at the egress LER. With this option, the entire MPLS domain (regardless of the number of transit LSR hops) counts as two hops for the IP TTL value.

NOTE

If you choose to configure TTL propagation in this way, it is important that you enter the **no propagate-ttl** command at ***both*** the ingress LER and the MPLS router that pops the label. If you omit the **no propagate-ttl** command at the MPLS router that pops the label, the value in the packet's MPLS TTL field would be copied into the packet's IP TTL field. This value could be as high as 255.

Enabling LSP accounting

The LSP accounting feature provides the ability to count the number of traffic bytes and packets forwarded through a specified LSP. The LSP accounting feature is supported for the following:

- RSVP-signalled LSPs
- LDP signalled LSPs

When the command **vlan-counter exclude-overhead** is configured or removed, the LSP counters in software and hardware are flushed, and accounting starts fresh. In summary:

- **Ingress-tunnel accounting without exclude-ethernet-overhead:**
  - With **vlan-counter exclude-overhead** not configured: the size includes 20-byte Ethernet overhead (IFG+ Preamble) and 4-byte CRC.
  - With **vlan-counter exclude-overhead** configured: excludes 20-byte per-packet Ethernet overhead from byte counting.
- **Ingress-tunnel accounting with exclude-ethernet-overhead:**
  - The **exclude-ethernet-overhead** option, lets you exclude the Ethernet header (14 bytes) and Ethernet overhead (20 bytes) and CRC overhead (4 bytes) when collecting the byte statistics. In other words, it counts only the size of MPLS packet. The **exclude-ethernet-overhead** option does not work with untagged ports carrying q-in-q packets for IP over MPLS, nor does it count multiple tags in a packet.

NOTE
This feature is applicable only on LSPs for which the devices are an ingress LER.

NOTE
LSP tunnel statistics are not supported when an ingress LER is a two node LSP (PHP), or when traffic is forwarded to a directly connected Provider Edge Router (PE).

LSP accounting is disabled by default. To enable LSP accounting for an LSP, enter the following commands.

```
NetIron(config-mpls)# policy
NetIron(config-mpls-policy)# ingress-tunnel-accounting
```

Syntax: [no] ingress-tunnel-accounting [exclude-ethernet-overhead]

NOTE
The command **no ingress-tunnel-accounting exclude-ethernet-overhead** disables only the **exclude-ethernet-overhead** option. To disable **ingress-tunnel-accounting** itself, enter the command **no ingress-tunnel-accounting**.

To use this feature, you must specify an LSP accounting CAM sub-partition value by using the following sequence.

```
NetIron(config)# system-max lsp-out-acl-cam 1000
```

Syntax: [no] system-max lsp-out-acl-cam <*number*>

The <*number*> variable is the number of CAM entries available for LSP accounting. The default value is 0.

The load-interval command can be set to a time during which the average byte and packet rates are calculated as shown in the following.

```
NetIron(config-mpls)# policy
NetIron(config-mpls-policy)# load-interval 30
```

Syntax: [no] load-interval <*seconds*>

The <*seconds*> variable can be configured in multiples of 30 seconds within the range of 30 to 300 seconds. The default value of load-interval is 300 seconds.

SNMP agent support for ACL accounting

The SNMP agent supports the LSP tunnel byte count in MIB ifHCOutOctets, and LSP tunnel packet count in MIB ifHCOutUcastPkts within the ifXTable.

Setting RSVP parameters

RSVP is automatically enabled when MPLS is enabled on the device. You can optionally configure the following RSVP parameters:

- Refresh interval
- Refresh multiple

Setting the refresh interval

To maintain path states and resource reservations on the routers in an LSP, RSVP Path and Resv messages are sent at regular intervals. Path messages flow downstream in an LSP, from the ingress LER towards the egress LER. Resv messages flow upstream, in the reverse direction of Path messages.

You can control how often the Path and Resv messages are sent by setting the refresh interval. By default, the refresh interval is 30 seconds. You can set the refresh interval to between 0 – 2147483 seconds.

To set the refresh interval to 20 seconds.

```
NetIron(config-mpls)# rsvp
NetIron(config-mpls-rsvp)# refresh-interval 20
```

Syntax: [no] refresh-interval <*seconds*>

Setting the refresh multiple

If refresh messages are not received, RSVP path states and resource reservations are removed from the routers in an LSP. By default, the device waits the length of 3 refresh intervals; if no refresh message is received by the end of that time, the path state or resource reservation is removed.

The refresh multiple is the number of refresh intervals that must elapse without a refresh message before a path state or resource reservation times out. By default, the refresh multiple is 3 intervals. You can set the refresh multiple to between 0 – 65535 intervals.

To set the refresh multiple to 5 intervals.

```
NetIron(config-mpls)# rsvp
NetIron(config-mpls-rsvp)# refresh-multiple 5
```

Syntax: [no] refresh-multiple <*intervals*>

RSVP message authentication

Support was added for RSVP message authentication using MD5 as described in RFC 2747. It is implemented on the PowerConnect routers to prevent spoofing of RSVP messages. This RFC defines the use of a message digest carried in the RSVP INTEGRITY object. This object carries the following information:

- Key ID: a 8-bit number unique to a given sender
- Sequence Number: a 64-bit monotonically increasing sequence number
- Keyed Message Digest: As implemented here using MD5 it is a 16-bit message digest

In order to support RFC 2747, this implementation supports the following:

- An authentication type using the MD5 cryptographic algorithm

- An authentication key for use with the authentication algorithm
- An authentication window of 1 which specifies that the maximum number of authenticated messages that can be received out of order is 1.

Configuring RSVP message authentication

RSVP Message Authentication is disabled by default. This authentication method uses MD5 and is configured within the MPLS configuration mode.

```
NetIron(config)# router mpls
NetIron(config-mpls)# mpls-interface ethernet 1/1
NetIron(config-mpls-if-e100-1/1)# rsvp-authentication key administrator
```

Syntax: [no] rsvp-authentication key <*string*>

The <*string*> variable specifies a text string of up to 64 characters that is encrypted and used for RSVP message authentication.

By default, the authentication key is encrypted. If you want the authentication key to be in clear text, insert a **0** between **key** and <*string*>.

Example

```
NetIron(config-mpls-if-e100-1/1)# rsvp-authentication key 0 administrator
```

The software adds a prefix to the authentication key in the configuration. For example, the following portion of the code has the encrypted code “2”.

```
rsvp-authentication 2 key $IUA2PWc9LW9VIW9zVQ=="
```

The prefix can be one of the following:

- 0 = the key string is not encrypted and is in clear text
- 1 = the key string uses proprietary simple crytographic 2-way algorithm
- 2 = the key string uses proprietary base64 crytographic 2-way algorithm

Configuring MPLS on a VE interface

To enable MPLS on a VE interface, first create a VE interface and configure an IP address for the VE as shown in the example below.

```
NetIron(config)#vlan 100
NetIron(config-vlan-100)#tagged ethernet 2/1
NetIron(config-vlan-100)#router-interface ve 100
NetIron(config-vlan-100)#exit
NetIron(config)#interface ve 100
NetIron(config-vif-100)#ip address 10.10.10.1/24
NetIron(config-vif-100)#exit
```

Then enable MPLS on the VE interface as shown in the example below.

```
NetIron(config)#router mpls
NetIron(config-mpls)#mpls-interface ve 100
NetIron(config-mpls-if-ve-100)#
```

Syntax: [no] mpls-interface [ve <*ve-id*>**]**

The **mpls-interface ve** parameter allows you to enable MPLS on a VE interface. The <*ve-id*> variable allows you to specify a VE interface ID. The **no mpls-interface ve** command removes all configuration for MPLS on a VE enabled interface.

The following MPLS commands are available on a VE interface under the mpls interface configuration mode.

- admin-group - "Adding an MPLS VE interface to an administrative group" on page 1329
- ldp-enable - "Configuring LDP on an MPLS VE interface" on page 1329
- ldp-params - "Setting the LDP hello interval on an MPLS VE interface (link Only)" on page 1330
- hello-interval - "Setting the LDP hello interval on an MPLS VE interface (link Only)" on page 1330
- hello-timeout - "Setting the LDP hello holdtime on an MPLS VE interface (link only)" on page 1330
- reservable-bandwidth - "Bandwidth computation for an MPLS VE interface" on page 1331
- rsvp-authentication - "Configuring RSVP message authentication on an MPLS VE interface" on page 1332
- exclude-interface - "Specifying a bypass LSP for an MPLS VE interface" on page 1332

Adding an MPLS VE interface to an administrative group

You can place individual interfaces into administrative groups. Administrative groups, also known as resource classes or link colors, allow you to assign MPLS enabled VE interface to various classes. For more information on assigning an MPLS-enabled interface to an administrative group, refer to **"Adding interfaces to administrative groups"** on page 1324.

To assign MPLS interface ve 100 to an administrative group called "gold", enter the following.

```
NetIron(config-mpls)#mpls-interface ve 100
NetIron(config-mpls-if-ve-100)# admin-group gold
```

Syntax: [no] admin-group <*number*> | <*name*> [<*number*> | <*name*>]

The <*number*> variable can be from 0 – 31. The administrative group <*name*> variable must have been previously configured. By default, no admin group is configured for any MPLS interfaces, including MPLS VE interface.

An MPLS enabled VE interface can belong to any number of administrative groups. For example, to assign an MPLS interface ve 100 to group "gold" and group 31, enter commands such as the following.

```
NetIron(config-mpls)#mpls-interface ve 100
NetIron(config-mpls-if-ve-100)# admin-group gold 31
```

Configuring LDP on an MPLS VE interface

NOTE
For more information on configuring LDP on physical interfaces, refer to "Configuring LDP on an interface" on page 1412.

To configure LDP on MPLS interface ve 100, enter commands such as the following.

```
NetIron(config)# router mpls
NetIron(config-mpls)# mpls-interface ve 100
NetIron(config-mpls)# ldp-enable
```

Syntax: [no] ldp-enable

The **no** option removes LDP on an MPLS interface, including LDP on an MPLS VE interface.

Setting the LDP hello interval on an MPLS VE interface (link Only)

NOTE
For more information on setting the LDP hello interval on physical interfaces, refer to "Setting the LDP Hello Interval per-Interface (link Only)" on page 1418.

You can set the LDP Hello Interval on an MPLS enabled VE interface. This option is only available for Link LDP sessions. The following example configures LDP hello-interval to 30 seconds for MPLS interface ve 100.

```
NetIron(config)# router mpls
NetIron(config-mpls)# mpls-interface ve 100
NetIron(config-mpls-if-ve-100)# ldp-params
NetIron(config-mpls-if-ve-100-ldp-params)# hello-interval 30
```

Syntax: [no] hello-interval <*seconds*>

The <*seconds*> variable specifies the value in seconds of the Hello Interval that you are configuring on an MPLS VE interface for LDP Link Hello messages. The LDP hello interval can be from 1 - 32767 seconds. The default value for LDP hello interval is 5 seconds.

The **no** option removes a previously configured LDP Hello Interval.

Setting the LDP hello holdtime on an MPLS VE interface (link only)

NOTE
For more information on setting the LDP hello holdtime on physical interfaces, refer to "Setting the LDP Hello Holdtime per-interface (link only)" on page 1420.

You can set the LDP Hello Holdtime on an MPLS enabled VE interface. This holdtime value is sent in Hello messages from the interface. This option is available for Link LDP sessions only. The following example configures LDP hello-timeout to 18 seconds for MPLS interface ve 100.

```
NetIron(config)# router mpls
NetIron(config-mpls)# mpls-interface ve 100
NetIron(config-mpls-if-ve-100)# ldp-params
NetIron(config-mpls-if-ve-100-ldp-params)# hello-timeout 18
```

Syntax: [no] hello-timeout <*seconds*>

The value configured in the <*seconds*> variable is the LDP Hello Timeout value that will be sent in LDP Hello messages from this interface. The range for this value is 1 – 65535 seconds. The default value is 15 seconds.

The **no** option removes a previously configured LDP Hello Timeout value and sets the value as described in "Determining the LDP Hold Time on an MPLS interface" on page 1419.

Bandwidth computation for an MPLS VE interface

The maximum reservable bandwidth for a VE interface is computed based on minimum speed of all active members on a physical port. If one of the member ports is a trunk port, MPLS computes the trunk bandwidth before computing the VE bandwidth. The bandwidth of a trunk port is the sum of all active physical member ports of the trunk. For example, there are two ports (One port is 10 gig and other port is 1 gig), and one trunk port configured on a VE interface. The trunk is carrying two ports, and each port is 1 gig. To calculate the bandwidth of the trunk, you take the sum of all active ports on a physical port. In this example, the bandwidth of the trunk is equal to 2 gig. To calculate the bandwidth of the VE interface, take the minimum of all active port members. In this example, the bandwidth of the VE interface is 1 gig.

Configuration Considerations

A VE interface bandwidth must be recomputed when any one of the following occurs:

- A new member port is added to a VLAN associated with a VE interface.
- A new member port is removed from a VLAN associated with a VE interface.
- When a member port of a VLAN associated with a VE interface is up.
- When an active member port of a VLAN associated with a VE interface that is down.

A physical port can be part of more than one VE interface. Each VE interface assumes that it has a full amount of reservable bandwidth for a physical port. However, the amount of reservable bandwidth on one VE will not be reflected on another VE interface even though both VE interfaces share the same physical port. For example, if there are two VE interfaces; VE1 and VE2. Each VE interface supports the same amount of reservable bandwidth of 1Gbps. The amount of reservable bandwidth used to set up LSPs on VE1 is not reflected in the amount reservable bandwidth that is available on VE2. This will result in an excess amount of reservable bandwidth that can be supported on a physical port. This will cause data traffic to be dropped.

The default bandwidth for a VE interface is computed automatically, and is based on the underlying physical links. You can now override the default bandwidth for a VE interface by executing the **reservable-bandwidth** command. The following example demonstrates how to override the default behavior by configuring reservable bandwidth to 400mbps on MPLS interface ve 100.

```
NetIron(config)# router mpls
NetIron(config-mpls)# mpls-interface ve 100
NetIron(config-mpls-if-ve-100)# reservable-bandwidth 400000
```

Syntax: [no] reservable-bandwidth <*number*>

The <*number*> variable refers to the amount of reservable bandwidth that is supported on an MPLS interface, including an MPLS enabled VE interface. The range for this value is 0 - 80000000 kbps. The **no** option removes all configuration for reservable bandwidth on an MPLS enabled VE interface.

RSVP message authentication on an MPLS VE interface

Support was added for RSVP message authentication using MD5 as described in RFC 2747. It is implemented on the PowerConnect routers to prevent spoofing of RSVP messages. All inbound RSVP messages on an interface must contain RSVP Integrity object for getting authenticated and accepted by RSVP. Inbound RSVP messages with no Integrity object, or an **incorrect** integrity object will be dropped by RSVP. All outbound RSVP messages on an interface contain an RSVP Integrity object. For more information on RSVP message authentication, refer to "RSVP message authentication" on page 1327.

Configuring RSVP message authentication on an MPLS VE interface

NOTE
For more information on configuring RSVP message authentication on physical interfaces, refer to **"Configuring RSVP message authentication"** on page 1328.

RSVP Message Authentication is disabled by default. This authentication method uses MD5 for an MPLS VE interface. The following example configures RSVP message authentication for MPLS interface ve 100.

```
NetIron(config)# router mpls
NetIron(config-mpls)# mpls-interface ve 100
NetIron(config-mpls-if-ve-100)# rsvp-authentication key private
```

Syntax: [no] **rsvp-authentication key** <*string*>

The <*string*> variable specifies a text string of up to 64 characters that is encrypted and used for RSVP message authentication.

Specifying a bypass LSP for an MPLS VE interface

You can create a bypass LSP by using the **bypass-lsp** command. This is used for facility backup FRR. In the context of bypass LSP, you can configure an MPLS interface as an exclude (protected) interface against resource failures using a bypass LSP. You can specify a VE interface as exclude-interface. If a protected LSP egress interface is a VE interface, then any fault on a VE interface could trigger FastReroute. The following example configures protection for MPLS interface ve 100 using facility backup FRR.

```
NetIron(config)# router mpls
NetIron(config-mpls)# bypass-lsp to4
NetIron(config-mpls-bypasslsp-to4)# exclude-interface ve 10
```

Syntax: [**no**] **exclude-interface ethernet** <*slot/port*> [**ethernet** <*slot/port*> | **to** <*slot/port*>] | **pos** <*slot/port*> [**pos** <*slot/port*> | **to** <*slot/port*>] | **ve** <*vid*>]

By default, a VE interface is not protected. The **ve** parameter allows you to configure a ve interface as exclude-interface specified by <*vid*>.

Setting up signalled LSPs

An LSP consists of an actual path of MPLS routers through a network, as well as the characteristics of the path, including bandwidth allocations and routing metrics. There are two kinds of LSPs: signalled and static. Signalled LSPs are configured at the ingress LER. When you enable a signalled LSP, RSVP causes resources to be allocated on the other routers in the LSP.

Configuring a signalled LSP consists of the following tasks:

- Specifying a path for the LSP to follow (optional)
- Setting parameters for the signalled LSP
- Specifying which packets are to be forwarded along the LSP (optional)

Setting up paths

A ***path*** is a list of router hops that specifies a route across an MPLS domain. Once you create a path, you can create signalled LSPs that see the path. Paths are configured separately from LSPs so that a path may be specified once and then used by several LSPs that see the path by name. An LSP may specify a primary and one or more redundant paths.

A path is always configured at the ingress LER and assumes that the ingress LER is the beginning of the path. A path can contain any number of ***nodes***, which correspond to MPLS-enabled routers in the network. Each node has one attribute: whether it is ***strict*** or ***loose***. A strict node means that the router must be directly connected to the preceding node. A loose node means that there can be other routers in between.

Creating a path is not absolutely necessary when configuring an LSP. If you configure a signalled LSP without naming a path, CSPF uses only information in the Traffic Engineering Database (TED), as well as the user-configured attributes and requirements of the LSP to calculate the path. Refer to "How CSPF calculates a traffic-engineered path" on page 1301 for more information. If the LSP has been configured not to use CSPF, the path between the ingress and egress LERs is determined using standard hop-by-hop routing methods, as if the path consisted of a single loose node.

The following commands set up a path called sf_to_sj that has four nodes.

```
NetIron(config-mpls)# path sf_to_sj
NetIron(config-mpls-path)# strict 216.150.1.1
NetIron(config-mpls-path)# strict 216.150.1.2
NetIron(config-mpls-path)# loose 64.1.1.1
NetIron(config-mpls-path)# strict 64.100.1.1
NetIron(config-mpls-path)# exit
```

Syntax: [no] path <*path name*>

Syntax: [no] strict | loose <*ip address*>

The path is assumed to start from the local node. You specify the nodes in order from ingress to egress. Specifying the local node itself as the first node in the path is optional. Further, the final node does not necessarily have to be the egress LER in the LSP. (The egress LER is specified at the LSP configuration level with the **to** command.) If the final node in the path differs from the egress LER, the hop between the final node in the path and the egress LER is treated as a hop to a loose node; that is, standard IP routing is used to determine the path between the final node and the egress LER.

The IP address defines an LSR and can be any interface address or a loopback interface address on the LSR.

The **strict** and **loose** parameters are relative to the preceding node. In the sf_to_sj path defined above, LSR 216.150.1.2 is a strict node; it must be directly connected to LSR 216.150.1.1. LSR 64.1.1.1 is a loose node; this means there can be other routers between LSR 216.150.1.2 and 64.1.1.1. When specifying a strict node, you should make sure that the LSR is actually directly connected to the preceding node.

Modifying a path

Once you have created a path, you can insert or delete nodes from it. For example, to delete a node from the sf_to_sj path defined above.

```
NetIron(config-mpls)# path sf_to_sj
NetIron(config-mpls-path)# delete loose 64.1.1.1
NetIron(config-mpls-path)# exit
```

Syntax: [no] delete strict | loose <*ip address*>

To insert a node into a path.

```
NetIron(config-mpls)# path sf_to_sj
NetIron(config-mpls-path)# insert strict 216.150.1.1 before 216.150.1.2
NetIron(config-mpls-path)# exit
```

Syntax: [no] insert strict | loose <*ip address*> **before** <*ip address*>

The **insert** command allows a new node to be inserted in front of an existing node within the path. In this example, the **insert strict 216.150.1.1 before 216.150.1.2** command assumes that 216.150.1.2 is already in the path and inserts 216.150.1.1 before it.

NOTE
When you modify a path, the changes are not carried over to active LSPs that see the path until the LSPs are deactivated and reactivated. For example, path sj_to_sf may be used by an LSP called lsp1. After lsp1 has been activated, any changes to path sj_to_sf do not cause the route followed by lsp1 to be modified. To get the LSP to use the modified path, you must deactivate and then reactivate lsp1.

Deleting a path

To delete an entire path from the LSR's configuration, enter a command such as the following.

```
NetIron(config-mpls)# no path sf_to_sj
```

Syntax: [no] path <*path name*>

Configuring signalled LSP parameters

Once you have configured a path, you can configure signalled LSPs that see it. An LSP's configuration can specify not only the path that label-switched packets follow in a network, but also the characteristics of the path, the resources allocated along the path, and actions applied to the packets by the ingress or egress LERs.

You can perform the following tasks when configuring a signalled LSP:

- Performing a Commit for an LSP
- Creating the LSP
- Specifying an egress LER for the LSP

- Specifying a primary path for the LSP (optional)
- Configuring secondary or hot-standby paths for the LSP (optional)
- Setting aliases for the egress LER (optional)
- Setting a Class of Service (CoS) value for the LSP (optional)
- Allocating bandwidth to the LSP (optional)
- Configuring the setup and hold priority for the LSP (optional)
- Setting a metric for the LSP (optional)
- Including or excluding administrative groups from LSP calculations (optional)
- Limiting the number of hops the LSP can traverse (optional)
- Specifying a tie-breaker for selecting CSPF equal-cost paths (optional)
- Disabling the Record-Route function (optional)
- Disabling CSPF path calculations (optional)
- Configure Maximum Packet Size without Fragmentation
- Enabling the LSP
- Disabling the LSP
- Generating Traps and Syslogs for LSPs

Performing a commit for an LSP configuration command

For LSP configuration commands to take effect, either an explicit or implicit commit must be performed. These are performed as shown in the following:

Performing and explicit commit

You can perform an explicit commit within the configuration of a specified LSP using the **commit** command. The following example demonstrates the creation of an LSP named “samplelsp” and its primary and secondary paths. After the configuration is entered, the commit command is executed to activate the configuration.

```
NetIron(config)# router mpls
NetIron(config-mpls)# lsp samplelsp
NetIron(config-mpls-lsp-samplelsp)# primary-path pathprimary
NetIron(config-mpls-lsp-samplelsp)# secondary-path pathsecondarya
NetIron(config-mpls-lsp-samplelsp)# secondary-path pathsecondaryb
NetIron(config-mpls-lsp-samplelsp)# select manual pathsecondaryb
NetIron(config-mpls-lsp-samplelsp)# commit
```

Syntax: [no] commit

Performing and implicit commit

The **reoptimize** and **reoptimize_timer** commands allow you to perform an implicit commit.

Using the **reoptimize** command, you can activate all pending LSP configuration changes for specified LSP or use the **all** option to activate all pending LSP configuration changes for all of the LSPs configured on the router. Configuration of this command is described in “Reoptimizing LSPs” on page 1349.

The **reoptimize_timer** command allows you to set a periodic timer to perform the reoptimize function for all LSPs at an interval specified in seconds. Configuration of this command is described in “Time-triggered reoptimizing” on page 1349.

Creating an LSP

To create a signalled LSP and enter the LSP configuration level, enter commands such as the following.

```
NetIron(config-mpls)# lsp tunnel1
NetIron(config-mpls-lsp)#
```

Syntax: [no] lsp <*name*>

Specifying the egress LER

Each LSP requires one and only one egress LER. The egress LER is the router from which packets exit the MPLS domain in this LSP. After the LSP is successfully established, the address of the egress LER is installed as an internal host route on the ingress LER, allowing the ingress LER to direct BGP next-hop traffic into the LSP. The destination address does not necessarily have to be the final node in the primary path specified for the LSP. If the final node in the path differs from the destination address, the hop between the final node in the path and the egress LER is treated as a loose hop.

To specify 64.100.1.1 as the address of the egress LER for LSP tunnel1.

```
NetIron(config-mpls)# lsp tunnel1
NetIron(config-mpls-lsp)# to 64.100.1.1
```

Syntax: to <*ip address*>

The egress LER is the only required parameter in an LSP. All other parameters are optional.

NOTE
If OSPF is used as the IGP, the egress LER should advertise the tunnel destination in type 1 (router) LSA in order for the LSP to be properly mapped by CSPF. To ensure that this happens, connect to the egress LER and enable OSPF on the interface which has the IP address of the tunnel destination. (See "Assigning interfaces to an area" on page 874 for details.) If none of the interfaces on the egress LER has the IP address of the tunnel destination (e.g., if the tunnel destination address is the egress LER's router ID rather than an interface address -- to manually set the router ID, see "Changing the router ID" on page 684), then the tunnel destination address must be included in the router address TLV in the type 10 LSA originated by the egress LER. This is accomplished by setting the egress LER's traffic engineering policy to OSPF with the **traffic-engineering ospf** command (see "Enabling OSPF-TE LSAs for MPLS interfaces" on page 1321).

NOTE
If IS-IS is used as the IGP, the egress LER should advertise the tunnel destination in Extended IP Reachability TLV 135 in order for the LSP to be properly mapped by CSPF. To ensure that this happens, connect to the egress LER and enable ISIS on the interface which has the IP address of the tunnel destination. (See "Disabling and enabling IS-IS on an interface" on page 968 for details.) If none of the interfaces on the egress LER has the IP address of the tunnel destination (e.g., if the tunnel destination address is the egress LER's router ID rather than an interface address -- to manually set the router ID, see "Changing the router ID" on page 684), then the tunnel destination address must be included in Traffic Engineering router ID TLV 134 in the LSP originated by the egress LER. This is accomplished by setting the egress LER's traffic engineering policy to IS-IS with the **traffic-engineering isis level** command (see "Enabling IS-IS LSPs with TE extensions for MPLS interfaces" on page 1322).

Specifying a source address for an LSP

You can optionally specify a source IP address for a signalled LSP. RSVP path messages carry this address.

To specify a source IP address of 1.2.3.4 for LSP tunnel1.

```
NetIron(config-mpls)# lsp tunnel1
NetIron(config-mpls-lsp)# from 1.2.3.4
```

Syntax: **from** <*ip address*>

The **from** command specifies the source IP address to be carried in RSVP Path messages for the LSP. This command is optional. If the **from** command is specified, then the address is always carried in RSVP Path messages as the source IP address for the LSP. If the **from** command is not specified, then when the LSP is enabled, the device dynamically determines the source address of the LSP (using the device's router ID or the address of the first loopback as the source address).

Note that the IP address specified in the **from** command affects only the address carried in the RSVP Path messages for the LSP. It does not affect the outgoing interface (and thus the actual path) that the Path messages are sent out.

Specifying the primary path for an LSP

The primary path is the route that packets generally travel when going through an LSP. You can specify a user-defined path or no path at all. Refer to "Setting up paths" on page 1333 for information on defining a path. Once the LSP is enabled, the ingress LER attempts to signal the other LSRs in the path so that resources can be allocated to the LSP. If you do not specify a primary path, the path used in the LSP is the shortest path to the egress LER, as determined from standard IP routing methods, or CSPF if it is enabled.

To specify the sf_to_sj path as the primary path for LSP tunnel1.

```
NetIron(config-mpls)# lsp tunnel1
NetIron(config-mpls-lsp)# primary-path sf_to_sj
```

Syntax: **[no] primary-path** <*path name*>

Configuring redundant paths for an LSP

NOTE
This section describes the behavior of redundant paths. However, you can exercise further control over the path selection process by specifying the path selection mode and preferred path using the **select-path** command. This process is described in detail in "Configuring path selection" on page 1339.

A signalled LSP has a primary path, which is either user-defined or computed by the ingress LER. Optionally, you can configure one or more redundant paths to serve as a backup. If the primary path fails, traffic for the LSP can be forwarded over the redundant path. When no redundant path is configured for the LSP, if the primary path fails, the ingress LER automatically attempts to compute a new path to the egress LER, establish the new path, and then redirect traffic from the failed path to the new path.

Configuring a redundant path allows you to exercise greater control over the rerouting process than if the ingress LER simply calculated a new path to the egress LER. When a redundant path is configured, if the primary path fails, the ingress LER attempts to establish the redundant path. As with the primary path, a redundant path follows an explicit route of loose or strict hops.

By default, the redundant path is established only when the primary path fails. You can optionally configure a redundant path to operate in ***hot-standby*** mode. A hot-standby path is established at the same time the primary path in the LSP is established. Resources are allocated to the hot-standby path, although no packets for the LSP are sent over the hot-standby path until the primary path fails. When the primary path fails, the already-established hot-standby path immediately takes over from the primary path. Since the hot-standby path is already active, service outages that can arise from the process of signaling and establishing a new path are eliminated.

After the redundant path has been activated, the ingress LER continues to try to connect to the egress LER over the primary path, either indefinitely or up to the configured retry limit. If a connection over the primary path can be established, the redundant path is deactivated, and traffic for the LSP is again sent over the primary path. Once the primary LSP becomes available again, the redundant path is torn down; if the path is a hot-standby path, it reverts to its backup status.

You can configure multiple redundant paths. When the primary path fails, the ingress LER attempts to establish a connection to the egress LER using the first redundant path configured for the LSP. If a connection cannot be established using the first redundant path, the second redundant path is tried, and so on. If a connection cannot be established after trying each redundant path in the configuration, the first redundant path is tried again, and the process repeats. (This behavior can be further modified using the **select-path** command; see "Configuring path selection" on page 1339.)

To configure a secondary path, first create a path, as described in "Setting up paths" on page 1333. After you create the path, you can specify that it is to be used as a redundant path. For example, the following commands cause a path called alt_sf_to_sj to be used if the primary path in LSP tunnel1 fails.

```
NetIron(config-mpls)# lsp tunnel1
NetIron(config-mpls-lsp)# secondary-path alt_sf_to_sj
NetIron(config-mpls-lsp-sec-path)#
```

Syntax: [no] secondary-path *<path name>*

Issuing the **secondary-path** command enters the secondary path configuration level. From this level, you can specify that this path is to operate in hot standby mode.

Example

```
NetIron(config-mpls-lsp-sec-path)# standby
```

Syntax: [no] standby

Once the LSP is enabled, both the primary and hot-standby paths are activated, although packets are directed over only the primary path.

NOTE
At the secondary path level, you can configure separate values for the following parameters: Class of Service (CoS), setup and hold priority, bandwidth allocations, and inclusion or exclusion of interfaces in administrative groups. If you do not configure these parameters at the secondary path level, the secondary path will use the default values for these parameters.

Configuring path selection

You can exercise further control over the paths used by an LSP by setting the select mode and by specifying a preferred path using the **select-path** command as described below.

By default, an LSP with primary and secondary paths configured immediately uses the primary path. If the primary path fails, a secondary (redundant) path is used. If the primary path comes back up, traffic reverts to the primary path and the secondary (redundant) path returns to a back-up state. However, path selection can be configured to operate in any of the following three modes:

- **auto select mode** – This is the default mode of the router and no special configuration is required. When this mode is operating, the router will always try to use the primary path to carry traffic when the primary path has stayed operating in the working state for at least the amount of time specified in **revert-timer** configuration command. If no **revert-timer** is configured for the LSP, a value of zero second is used which causes immediate switching of the path.
- **manual select mode** – In this mode, traffic is switched to a user-specified path after the selected path has stayed operating in the working state for at least the amount of time specified in **revert-timer** configuration. In **manual select** mode, traffic stays on the selected path as long as the path remains in working condition and only switches to an alternative path, such as the primary path, when the selected path experiences a failure. Once the selected path comes back into working condition for the amount of time specified by the revert-timer configuration, traffic is switched back to it.

  When an LSP is configured in manual select path mode with at least one other hot standby secondary path, the operation is as follows: if the selected path goes down, the system will try to bring up one hot standby secondary path to protect the primary path, but if selected path is up, system will bring down the hot standby secondary path since the selected path is already serving as a hot standby for the primary path.
- **unconditional select mode –** In this mode, traffic is switched to and stays on the selected path regardless of the path's condition even if it is in a failure state. The main difference between manual and unconditional select mode is the test of the working condition of the user selected path. When configured in unconditional mode, the router starts the signaling for the selected path if has not already done so and brings down all other paths; this includes the primary path and the path carrying traffic if it is not the selected path. Because the speed at which the selected path comes up cannot be guaranteed, traffic forwarding might be disrupted.

NOTE
The **auto-select** and **manual-select** mode configurations use the **revert-timer** configuration that is described in "Configuring a Path Selection Revert Timer" on page 1340.

The following example configured the LSP named "samplelsp" with a primary path named "pathprimary" and two secondary paths named "pathsecondarya" and pathsecondaryb". The path named "pathsecondaryb" is configured as a selected path in the "manual select" mode.

```
NetIron(config)# router mpls
NetIron(config-mpls)# lsp samplelsp
NetIron(config-mpls-lsp-samplelsp)# primary-path pathprimary
NetIron(config-mpls-lsp-samplelsp)# secondary-path pathsecondarya
NetIron(config-mpls-lsp-samplelsp)# secondary-path pathsecondaryb
NetIron(config-mpls-lsp-samplelsp)# select-path manual pathsecondaryb
NetIron(config-mpls-lsp-samplelsp)# commit
```

After configuring this example, traffic for “samplelsp” travels over the “pathsecondaryb” path whenever this path is in working condition because no revert-timer has been configured. If a revert-timer is configured, the router waits for the “pathsecondaryb” path to be up for at least the amount of time specified in the configuration of the **revert-timer** command. If the select mode is changed to **unconditional**, as shown in the following, traffic will be switched to the “pathsecondaryb” path regardless of its working condition.

```
NetIron(config-mpls-lsp-samplelsp)# select-path unconditional pathsecondaryb
```

Syntax: [**no**] **select-path** { **manual** | **unconditional** } { <*path-name*> | **primary** }

The **no** option returns an LSP to the default auto select mode if it has been previously configured to the manual select mode or unconditional select mode.

The <*path-name*> variable is the name of the path that you want to assign manual select mode or unconditional select mode to. You can optionally specify the primary path by using the **primary** keyword.

The **manual** option configures the specified path to operate in the manual select mode. If you select **primary** as the specified path with the **manual** option, the primary path is selected as the preferred path, which is the same as the default operation.

The **unconditional** option configures the specified path to operate in the unconditional select mode. If you select **primary** as the specified path with the **unconditional** option, the primary path is selected as the preferred path regardless of the condition of the primary path.

Configuration changes made to the select mode do not take effect for an already enabled LSP until the change is activated implicitly using the **commit** command or explicitly using a **reoptimize** command as described in “Performing a commit for an LSP configuration command” on page 1335 or a system reboot is performed.

NOTE
When you configure a primary path to be the selected path, a message is generated that states that it is already the default system behavior because the primary path is the default preferred path. In this instance, no configuration information is saved in the configuration file.

Configuring a Path Selection Revert Timer

The Path Selection Revert Timer feature provides an option to stabilize a path before traffic is switched to it. Without a configured Path Selection Revert Timer, the router switches between a primary and secondary path immediately after the current working path goes down. A problem with this mode of operation is that it can cause flapping if the current path goes up and down frequently. Also, the LSP to which the route is switching traffic might be unstable, which causes the router to fail back to the current LSP almost immediately.

The Path Revert Timer insures the stability of the LSP to which the traffic is switched by specifying the number of seconds that the LSP must be running before it actually carries traffic.

To configure a Path Selection Revert Timer for an LSP, use the **revert-timer** command in the LSP configuration context, as shown in the following.

```
NetIron(config-mpls)# lsp samplelsp
NetIron(config-mpls-lsp-samplelsp)# revert-timer 10
```

Syntax: [**no**] **revert-time** <*timer-value*>

The <*timer-value*> value is the number of seconds that the router waits after the primary or selected path comes up before traffic reverts to that path. The range is 1–65,535 seconds.

Usage considerations:

- The **revert-time** command has no effect on the unconditional select mode. Traffic is unconditionally switched to the user-selected path and stays on it.
- The path stability test used with the Revert Timer feature is based on the uptime of the latest instance of the path. This value can be different when the selected path has gone through a "make-before-break" procedure.
- For an LSP going through re-optimization, the new LSP does not carry traffic until the revert timer expires.
- When a user changes the revert timer, the basis of counting is the uptime of the path and is independent of the sequence or combination of configurations. Take, for example, a path that is configured in the manual select mode to be a secondary path with a revert-timer of 10 seconds. After the secondary path comes up, a 10-second timer starts, but after 5 seconds, the user changes the revert-timer value to 4. Now the path has already been stable beyond the new configured revert-timer, so the original timer is canceled and traffic immediately switches over. However, if the user were to change the revert-timer value to 8 seconds after running for 5 seconds, the existing count would terminate and start a new count of 3 seconds from the moment the first count terminated.

To configure a Path Selection Revert Timer, for an LSP, use the **revert-timer** command within the LSP configuration as shown in the following.

```
NetIron(config-mpls)# lsp samplelsp
NetIron(config-mpls-lsp-samplelsp)# revert-timer 10
```

Syntax: [**no**] **revert-time** <*timer-value*>

The <*timer-value*> value specifies an amount of time in seconds that the router will wait after the primary or selected path comes back up before reverting to it.

Setting a Class of Service value for the LSP

The 3-bit EXP field in the MPLS header can be used to define a Class of Service (CoS) value for packets travelling through the LSP. You can manually set a CoS value for the LSP. The CoS value that you set is applied to the CoS (EXP) field in the MPLS header of all packets entering this LSP. This lets all packets travelling through an LSP to be treated with the same priority as they travel the MPLS domain. You can assign the LSP a CoS in the range 0–7.

To assign a CoS value of 7 (highest priority) to all packets traveling through LSP tunnel 1.

```
NetIron(config-mpls)# lsp tunnel1
NetIron(config-mpls-lsp)# cos 7
```

Syntax: [**no**] **cos** <*number*>

The MPLS CoS value is used for determining priority within an MPLS domain only, so when the label is popped, the CoS value in the MPLS header is discarded; it is not copied back to the IP ToS field.

Allocating bandwidth to an LSP

You can specify the allocation of bandwidth for an LSP, including the maximum and average rates for packets that travel over it. Allocating bandwidth to an LSP lets the LSRs determine how much bandwidth the LSP can consume and how much of the available bandwidth resources can be advertised by using OSPF-TE LSAs.

You can specify an average <*mean-rate*> kbps for the data on the LSP. When necessary, data can travel at <*max-rate*> kbps, as long as the burst sent at the maximum rate contains no more than <*max-burst*> bytes.

To set the maximum rate of packets that can go through an LSP (in Kbits/sec).

```
NetIron(config-mpls)# lsp tunnel1
NetIron(config-mpls-lsp)# traffic-eng max-rate 20
```

Syntax: [**no**] **traffic-eng max-rate** <*rate*>

To set the average rate of packets that can go through an LSP (in Kbits/sec).

```
NetIron(config-mpls)# lsp tunnel1
NetIron(config-mpls-lsp)# traffic-eng mean-rate 10
```

Syntax: [**no**] **traffic-eng mean-rate** <*rate*>

To set the maximum size (in bytes) of the largest burst the LSP can send at the maximum rate.

```
NetIron(config-mpls)# lsp tunnel1
NetIron(config-mpls-lsp)# traffic-eng max-burst 10
```

Syntax: [**no**] **traffic-eng max-burst** <*bytes*>

Configuring a peiority for a signalled LSP

You can specify a priority for each signalled LSP for which this is the ingress LER. The priority determines the relative importance of the LSP during setup or preemption. The priority for an LSP has two components the setup priority and the hold priority.

When multiple LSPs are enabled at the same time, such as when the device is booted, LSPs that have a higher setup priority are enabled before LSPs that have a lower setup priority.

If an LSP is assigned a high setup priority, it may preempt an LSP that is already established, causing resources assigned to the lower priority LSP to be diverted to the higher priority LSP. The hold priority specifies how likely an established LSP is to give up its resources to another LSP. To be preempted, an LSP must have a lower hold priority than the preempting LSP's setup priority. In addition, an established LSP can be preempted by a higher priority LSP only if it would allow the higher priority LSP to be established successfully.

To configure LSP tunnel1 with a setup priority of 6 and hold priority of 1.

```
NetIron(config-mpls)# lsp tunnel1
NetIron(config-mpls-lsp)# priority 6 1
```

Syntax: **[no] priority** <*setup-priority*> <*hold-priority*>

Possible values are 0 (highest priority) through 7 (lowest priority). An LSP setup priority must be lower than or equal to the hold priority. The default LSP setup priority is 7, and the hold priority is 0.

Assigning a metric to the LSP

You can assign a metric to the LSP, which can be used by routing protocols to determine the relative preference among several LSPs towards a given destination.

To assign a metric of 5 to LSP tunnel1

```
NetIron(config-mpls)# lsp tunnel1
NetIron(config-mpls-lsp)# metric 5
```

Syntax: **[no] metric** <*number*>

The metric has a range of 1–65535. By default, all LSPs have a metric of 1. A lower metric is preferred over a higher one. If multiple LSPs have the same destination LSR, and they have the same metric, the traffic load is shared among them.

Including or excluding administrative groups from LSP calculations

Administrative groups, also known as resource classes or link colors, let you assign MPLS-enabled interfaces to various classes. When a device uses CSPF to calculate the path for an LSP, it takes into account the administrative group to which an interface belongs; you can specify which administrative groups the device can include or exclude for this calculation.

For example, to include interfaces in either of the administrative groups “gold” and “silver” in the path calculations for LSP tunnel1, do the following.

```
NetIron(config-mpls)# lsp tunnel1
NetIron(config-mpls-lsp)# include-any gold silver
```

Syntax: [no] include-any <*groups*>

The value specified for <*groups*> can be one or more valid administrative group names or numbers. In this example, the device includes any of the interfaces that are members of groups “gold” or “silver” when calculating the path for this LSP. Only those interfaces in the “gold” or “silver” groups are considered for the LSP. Interfaces that are not part of these groups, as well as interfaces that are not part of any group, are eliminated from consideration.

To exclude interfaces in either administrative group “gold” or “silver” when the path for LSP tunnel1 is calculated.

```
NetIron(config-mpls)# lsp tunnel1
NetIron(config-mpls-lsp)# exclude-any gold silver
```

Syntax: [no] exclude-any <*groups*>

In this example, the device excludes any interface that is a member of group “gold” or “silver” when it calculates the path for this LSP. Only interfaces that are not part of either group are considered for the LSP.

To specify that an interface must be a member of both the “gold” or “silver” administrative groups in order to be included in the path calculations for LSP tunnel1.

```
NetIron(config-mpls)# lsp tunnel1
NetIron(config-mpls-lsp)# include-all gold silver
```

Syntax: [no] include-all <*groups*>

In this example, an interface must be a member of all the groups specified in the **include-all** command in order to be considered for the LSP. Any interface that is not a member of all the groups is eliminated from consideration.

Limiting the number of hops the LSP can traverse

By default, the path calculated by CSPF can consist of no more than 255 hops, including the ingress and egress LERs. You can optionally change this maximum to a lower number.

For example, to limit CSPF to choosing a path consisting of no more than 20 hops for LSP tunnel1.

```
NetIron(config-mpls)# lsp tunnel1
NetIron(config-mpls-lsp)# hop-limit 20
```

Syntax: [no] hop-limit <*number*>

The range for the number of hops is 0–255.

Specifying a tie-breaker for selecting CSPF equal-cost paths

CSPF may calculate multiple, equal-cost paths to the egress LER. When this happens, the device chooses the path whose final node is the physical address of the destination interface. If more than one path fits this description, by default, the device chooses the path with the fewest hops. If multiple paths have this number of hops, the device chooses one of these paths at random. You can optionally configure the device to choose the path that has either the highest available bandwidth or the lowest available bandwidth.

For example, the following commands cause CSPF to select the path with the highest available bandwidth when choosing among equal-cost paths calculated for LSP tunnel1.

```
NetIron(config-mpls)# lsp tunnel1
NetIron(config-mpls-lsp)# tie-breaking least-fill
```

Syntax: [no] tie-breaking least-fill | most-fill | random

The **least-fill** parameter causes CSPF to choose the path with the highest available bandwidth (that is, the path with the least utilized links).

The **most-fill** parameter causes CSPF to choose the path with the lowest available bandwidth (that is, the path with the most utilized links).

The **random** parameter causes CSPF to choose the path randomly from the equal-cost paths. This is the default.

Disabling the record route function

The RSVP RECORD_ROUTE object (RRO) allows an LSP's path to be recorded. An RRO consists of a series of subobjects that can contain the addresses of the LSRs in the path. This information can be viewed with the **show mpls lsp detail** command. The path information is recorded in the RRO by default, but you can disable path recording.

To disable path recording in the RRO.

```
NetIron(config-mpls)# lsp tunnel1
NetIron(config-mpls-lsp)# no record
```

Syntax: [no] record

Disabling CSPF path calculations

By default, CSPF is enabled for signalled LSP calculations. That is, if the device receives OSPF-TE LSAs, it places the traffic engineering information from them in its Traffic Engineering Database (TED). When the device is the ingress LER for the LSP, it uses the information in the TED to help determine a path for the LSP. If all nodes in your network are not capable of sending out OSPF-TE LSAs, you may want to disable CSPF for the LSP.

To disable constraint-based path selection for LSP tunnel1.

```
NetIron(config-mpls)# lsp tunnel1
NetIron(config-mpls-lsp)# no cspf
```

Syntax: [no] cspf

Configuring the maximum packet size

This feature allows you to set a maximum IP packet size for packets that traverse an LSP without being fragmented. It can be configured for both primary and secondary paths.

To configure a maximum IP packet size for an LSP, enter commands such as the following.

```
NetIron(config-mpls)# lsp tunnel1
NetIron(config-mpls-lsp)# ipmtu 1500
```

Syntax: [no] ipmtu <*packet-size*>

The <*packet-size*> variable specifies the maximum packet size in bytes for IP packets transiting the LSP without being fragmented.

Enabling a signalled LSP

After you set the parameters for the signalled LSP, you can enable it. Enabling the LSP causes the path to be set up and resources reserved on the LSRs in the LSP's primary path. Enabling the LSP is the final step in configuring it.

To enable LSP tunnel1.

```
NetIron(config-mpls)# lsp tunnel1
NetIron(config-mpls-lsp)# enable
```

Syntax: [no] enable

Disabling an LSP

Disabling an LSP de-activates it, but does not remove the LSP from the device's configuration. (To remove the LSP from the device's configuration, use the **no lsp** <*name*> command.) To make changes to an active LSP, first disable the LSP, modify parameters on the LSP, and then enable the LSP.

To disable LSP tunnel1.

```
NetIron(config-mpls)# lsp tunnel1
NetIron(config-mpls-lsp)# disable
```

Syntax: [no] disable

Resetting LSPs

The **clear mpls lsp** command allows you to reset an RSVP LSP session. Changes in the routing table after an LSP path is established do not take effect unless the LSP is brought down and then brought up again. After you reset the LSP, it will realign to the new routing topology. The **clear mpls lsp** command can be used on the ingress LSR of the LSP.

Resetting normal LSPs

The **clear mpls lsp** command allows you to reset normal LSPs. You have the option of supplying the **primary**/**secondary** parameter for a normal LSP to reset only the primary/secondary path of the LSP.

To reset/clear a bypass RSVP LSP session.

```
NetIron(config-mpls)# clear mpls bypass-lsp <bypass-lsp-name>
```

When you reset an LSP with the `clear mpls lsp` command, the following information message is displayed.

`"Disconnecting signaled LSP <name>"`

"Connecting signaled LSP <*name*>"

Syntax: clear mpls lsp <*lsp-name*> **[primary | secondary]**

If a **primary** or **secondary** optional keyword is not specified when you reset a normal LSP, then both the **primary** and **secondary** LSP paths associated with the <*lsp-name*> will be reset and restarted

Resetting Bypass LSPs

This command allows you to reset bypass LSPs.

NOTE
The **primary** or **secondary** optional keywords are not applicable for bypass LSPs.

Reset LSP considerations

The **clear mpls lsp** and **clear mpls bypass-lsp** commands reset and restart an MPLS RSVP LSP.

NOTE
These commands are disruptive. Data traffic forwarding is impacted as the LSP is not in active state for sub-seconds after teardown. Resetting an LSP could trigger a series of actions depending upon the current state of the LSP.

The following describes the actions and state changes when an LSP is reset.

Resetting an LSP will also reset the associated backup/detour LSPs:

- Resetting the primary path of an LSP will cause the secondary LSP path to become active, if a hot-standby secondary path for the LSP is available. However, if the primary path comes up after the reset operation, the active path will switchover from the secondary to the primary again. If the "revert-timer" is configured, the LSP path switchover may be dampened and will obey the usual revert-timer rule. There is no change in the revert-timer behavior due to the reset LSP feature.

NOTE
The above state changes are described here for informational purposes only. There could be several other intermediate state changes that are not listed here.

- Resetting the primary path of an adaptive LSP will also reset the "other" new instances of the LSP's primary path, if available at the time of reset.
- Resetting the secondary path for an LSP will reset the current secondary path of the LSP. It will also reset the selected secondary path, if available at the time of reset.
- Resetting the secondary path for an LSP whose primary path is down may trigger the secondary path selection process to choose a new secondary path. If a new secondary path is found, it will be signaled and may become the active path. If no secondary paths are found, then the current secondary may become the active path again after successful RSVP signaling.
- The primary path is UP but not active, and the secondary path is UP and active. The secondary to primary switchover occured because the revert-timer has been configured (using a large value). Resetting the secondary LSP path will still force the path switchover from secondary to primary path in spite of the revert-timer configuration.

- For an adaptive LSP, if reset is performed before the **commit** command, then the LSP will be reset and will come-up with a new set of configuration parameters. However, this will be disruptive for data traffic unlike the **commit** command, because the current instance of the LSP will be reset while there is no new instance of the LSP available (because the **commit** command has not been executed yet)

Generating traps and syslogs for LSPs

Multi-Service IronWare software supports the ability to enable and disable SNMP traps and syslogs for LSPs. LSP traps and syslogs are enabled by default.

To enable LSP traps after they have been disabled, enter the following command.

```
NetIron(config)# snmp-server enable traps mpls lsp
```

Syntax: [no] snmp-server enable traps mpls lsp

Use the **no** form of the command to disable LSP traps.

To enable LSP syslogs after they have been disabled, enter the following command.

```
NetIron(config)# log enable mpls lsp
```

Syntax: [no] log enable mpls lsp

Use the **no** form of the command to disable the syslog for LSPs.

Configuring an adaptive LSP

The Multi-Service IronWare software supports Adaptive LSPs. Using this feature, you can change the following parameters of an LSP while it is in the enabled state:

- cspf
- exclude-any
- hop-limit
- include-all
- include-any
- primary-path
- priority
- tie-breaking
- traffic-eng

When one of these parameters is changed on a Adaptive LSP, a new instance of the same LSP is signaled using the newly defined parameters. Once the new LSP comes up, traffic is moved to the new LSP instance and the old LSP instance is torn down.

To configure an LSP named to20 as an Adaptive LSP, use the following commands.

```
NetIron(config)# router mpls
NetIron(config-mpls)# lsp to20
NetIron(config-mpls-lsp-to20)# adaptive
```

Syntax: [no] adaptive

Once an LSP is configured to be adaptive, it can have the parameters described above changed. In the following example, the Setup and hold priorities for adaptive LSP to20 are changed to 7 and 1.

```
NetIron(config-mpls)# lsp to20
NetIron(config-mpls-lsp-to20)# priority 7 1
```

The new parameters are not changed for the adaptive LSP until the **commit** command is issued for the LSP.

NOTE
Once the **commit** command has been issued, there may be a 30 ms traffic disruption.

In the following example of the **show mpls lsp** command for lsp to20, the priorities are not changed in the output.

```
NetIron(config-mpls-lsp-to212)#show mpls lsp to212
LSP to212, to 10.5.1.1
 From: 10.4.1.1, admin: UP, status: UP, tunnel interface: tnl1
  Times primary LSP goes up since enabled: 1
  Metric: 0, number of installed aliases: 0  Adaptive
  Maximum retries: 0, no. of retries: 0
  Setup priority: 7, hold priority: 0
  Max rate: 0 kbps, mean rate: 0 kbps, max burst: 0 bytes
  Constraint-based routing enabled: yes
  Tie breaking: random, hop limit: 0
  OTHER INSTANCE PRIMARY: NEW_INSTANCE admin: DOWN, status: DOWN
  Maximum retries: 0, no. of retries: 0
  Setup priority: 7, hold priority: 1
  Max rate: 0 kbps, mean rate: 0 kbps, max burst: 0 bytes
  Constraint-based routing enabled: yes
  Tie breaking: random, hop limit: 0
  Active Path attributes:
   Tunnel interface: tnl1, outbound interface: e1/2
   Tunnel index: 4, Tunnel instance: 1 outbound label: 3
   Path calculated using constraint-based routing: yes
   Explicit path hop count: 1
    10.2.1.2 (S)
   Recorded routes:
    Protection codes: P: Local  N: Node  B: Bandwidth  I: InUse
    10.2.1.2
```

The following **commit** command makes the new parameter settings active in Adaptive LSP to20's configuration

```
NetIron(config-mpls)# lsp to20
NetIron(config-mpls-lsp-to20)# commit
```

Syntax: [no] commit

After the commit command runs, you can see that the priorities have changed by using the **show mpls lsp** command for lsp to20.

```
NetIron(config-mpls-lsp-to212)#show mpls lsp to212
LSP to212, to 10.5.1.1
  From: 10.4.1.1, admin: UP, status: UP, tunnel interface: tnl1

```

Reoptimizing LSPs

Under ordinary conditions, an LSP path will not change unless the path becomes inoperable. Consequently, the router needs to be directed to consider configuration changes made to an LSP and to optimize the LSP path based on those changes. This is accomplished using the **mpls reoptimize** command as shown in the following.

```
NetIron# mpls reoptimize lsp to20
```

Syntax: [no] mpls reoptimize all | lsp <*lsp-name*>

The **all** option directs the router to reoptimize the paths for all LSPs configured.

The **lsp** option directs the router to reoptimize the path for the LSP specified by the <*lsp-name*>.

NOTE
On reoptimization of an adaptive LSP, LSP accounting statistics might miss the accounting of some of the packets.

Time-triggered reoptimizing

You can set a timer to optimize a specific LSP path on a periodic basis. Upon expiration of this timer, the LSP is optimized for a new path if the new path has a lower cost than the existing path. This timer can be configured when the LSP is in a disabled state, and the timer value can be adaptively changed when the LSP is in an enabled state.

To set the LSP reoptimization timer, use the **reoptimize_timer** command during LSP configuration, as the following shows.

```
NetIron(config)# router mpls
NetIron(config-mpls)# lsp to20
NetIron(config-mpls-lsp-to20)# reoptimize_timer 1000
```

Syntax: [no] reoptimize_timer <*seconds*>

The <*seconds*> variable specifies the number of seconds from the beginning of one reoptimization attempt to the beginning of the next attempt. The range of values for <*seconds*> is 300–65535.

The **no** option can be used to disable a timer that has been configured. By default, a timer is not configured.

Configuring a reoptimization timer does not interfere with running the manual **reoptimize** command as described in "Reoptimizing LSPs" on page 1349.

NOTE
When upgrading software, configured adaptive LSPs are initialized with no reoptimization timer.

NOTE
This feature does not apply to LSPs within a FRR network.

Configuring MPLS Fast Reroute using one-to-one backup

To configure MPLS Fast Reroute by using the one-to-one backup method for a defined LSP named "frr_tunnel," use the **ffr** command as in the following example.

```
NetIron(config)# router mpls
NetIron(config-mpls)# lsp frr_tunnel
NetIron(config-mpls-lsp-frr_tunnel)# to 30.1.1.1
NetIron(config-mpls-lsp-frr_tunnel)# primary-path direct_path
NetIron(config-mpls-lsp-frr_tunnel)# secondary-path alt_path
NetIron(config-mpls-lsp-frr_tunnel)# frr
NetIron(config-mpls-lsp-frr_tunnel-frr)# bandwidth 100
NetIron(config-mpls-lsp-frr_tunnel-frr)# hop-limit 20
NetIron(config-mpls-lsp-frr_tunnel-frr)#
```

Syntax: [no] frr

This command enables MPLS Fast Reroute using the one-to-one backup on the LSP under whose configuration it is enabled. Options for this command are described in the sections that follow.

MPLS Fast Reroute using one-to-one backup configuration options

The following options can be set for a MPLS Fast Reroute using one-to-one backup configuration:

- Bandwidth
- Exclude any
- Hop limit
- Include all
- Include any
- Priority

Configuring bandwidth for a MPLS Fast Reroute

To define a bandwidth constraint for the Fast Reroute path, use the following command.

```
NetIron(config-mpls-lsp-frr_tunnel)# frr
NetIron(config-mpls-lsp-frr_tunnel-frr)# bandwidth 100
```

Syntax: [no] bandwidth <*rate*>

The <*rate*> variable specifies the bandwidth in Kilobits/sec for the bypass route.

Acceptable value can be between 0 and 2 Gigabits/sec.

A value of 0 means that the detour route uses a best-effort value for bandwidth.

The default value is 0.

Configuring a hop limit for a MPLS Fast Reroute

By default, a detour route can consist of no more than 255 hops. You can optionally change this maximum to a lower number.

For example, to limit any detour route in the LSP named "frr_tunnel" to no more than 20 hops.

```
NetIron(config-mpls-lsp-frr_tunnel)# frr
NetIron(config-mpls-lsp-frr_tunnel-frr)# hop-limit 20
```

Syntax: [no] hop-limit <*number*>

The number of hops can be from 0 – 255.

Configuring priority for a MPLS Fast Reroute

You can specify setup and hold priorities for the detour routes within a specified LSP. These priorities are available to any LSP and function exactly the same on standard LSPs as they do on detour LSPs. The priority determines the relative importance of the detour routes during setup or preemption. The priority has two components the setup priority and the hold priority.

If a detour LSP is assigned a higher setup priority, it can preempt any LSP (detour or otherwise) that is already established and has a lower holding priority, causing resources assigned to the lower priority LSP to be diverted to the higher priority LSP. The hold priority specifies how likely an established LSP is to give up its resources to another LSP. To be preempted, an LSP must have a lower hold priority than the preempting LSP 's setup priority. In addition, an established LSP can be preempted by a higher priority LSP only if it would allow the higher priority LSP to be established successfully.

To configure the detour routes of LSP frr_tunnel with a setup priority of 6 and hold priority of 1.

```
NetIron(config-mpls-lsp-frr_tunnel)# frr
NetIron(config-mpls-lsp-frr_tunnel-frr)# priority 6 1
```

Syntax: [no] priority <*setup-priority*> <*hold-priority*>

Possible values are 0 (highest priority) through 7 (lowest priority). A setup priority must be lower than or equal to the configured hold priority on an LSP. By default, the setup priority is 7 and the hold priority is 0.

Including or excluding administrative groups from LSP calculations

Administrative groups, also known as resource classes or link colors, allow you to assign MPLS-enabled interfaces to various classes. When a device calculates the path for a detour LSP, it takes into account the administrative group to which a interface belongs; you can specify which administrative groups the device can include or exclude when making its calculation.

For example, to include interfaces in either administrative group “gold” or “silver” in the path calculations for detour routes of the LSP frr_tunnel.

```
NetIron(config-mpls-lsp-frr_tunnel)# frr
NetIron(config-mpls-lsp-frr_tunnel-frr)# include-any gold silver
```

Syntax: [no] include-any <*groups*>

The value specified for <*groups*> can be one or more valid administrative group names or numbers. In this example, the device includes any of the interfaces that are members of groups “gold” or “silver” when calculating detour routes for this LSP. Only those interfaces in the “gold” or “silver” groups are considered for the detour routes. Interfaces that are not part of these groups, as well as interfaces that are not part of any group, are eliminated from consideration.

To exclude interfaces in either administrative group “gold” or “silver” when detour routes for LSP frr_tunnel are calculated.

```
NetIron(config-mpls-lsp-frr_tunnel)# frr
NetIron(config-mpls-lsp-frr_tunnel-frr)# exclude-any gold silver
```

Syntax: [no] exclude-any <*groups*>

In this example, the device excludes any of the interfaces that are members of groups “gold” or “silver” when calculating detour routes for this LSP. Only interfaces that are not part of either group can be considered for the detour routes.

To specify that an interface must be a member of both the “gold” or “silver” administrative groups in order to be included in the detour routes for LSP frr_tunnel.

```
NetIron(config-mpls-lsp-frr_tunnel)# frr
NetIron(config-mpls-lsp-frr_tunnel-frr)# include-all gold silver
```

Syntax: [no] include-all *<groups>*

In this example, an interface must be a member of all the groups specified in the **include-all** command to be considered in a detour route for the LSP. Any interface that is not a member of all the groups is eliminated from consideration.

Protecting MPLS LSPs through a bypass LSP

Implementing a bypass LSP to back up one or more MPLS LSPs requires the following tasks:

- The LSPs that you intend to have the protection of a bypass LSP must be enabled for Fast Reroute and then must be specified as needing facility backup. (You do not need to create the LSP before the bypass LSP is created because the bypass LSP identifies the LSPs to protect by interface IDs, not by LSP names.)
- An LSP is configured to be a bypass LSP with enough bandwidth for all the LSPs that it protects.
- The interfaces that get the protection of a bypass LSP are identified to that particular LSP. Protected LSPs can be identified by individual interfaces, ranges of interfaces, interface groups, or a LAG.

NOTE
The name of the bypass LSP must be unique among all bypass LSPs and all protected LSPs.

The sections that follow describe the items unique to the bypass LSP feature. The common LSP parameters are described elsewhere throughout this chapter.

Specifying an LSP to request facility backup

LSP mlxe3-199 is configured for Fast Reroute and then configured to request facility backup.

```
NetIron(config-mpls)# lsp mlxe3-199
NetIron(config-mpls-mlxe3-199)# frr
NetIron(config-mpls-mlxe3-199-frr)# facility-backup
```

Syntax: [no] facility-backup *<name>*

A subsequent iteration of the **show** command in the bypass LSP context shows that this LSP is a candidate for protection by a bypass LSP. The display for protected LSP mlxe3-199 shows that, under frr, the facility-backup line shows this protection is requested.

```
NetIron(config-mpls-bypasslsp-123)#show mpls config lsp mlxe3-199
lsp mlxe3-199
to 33.33.33.33
primary mlxe3-100
priority 4 3
secondary mlxe3-101
   standby
frr
   facility-backup
revert-timer 10
enable
```

Syntax: show mpls configuration lsp <*name*>

Specifying a bypass LSP

You can create a bypass LSP by using the bypass-lsp command. Thereafter, in the bypass LSP context, you must specify at least one interface as an exclude (protected) interface. This interface can be on a LAG. In this example, xm4 is specified to be a bypass LSP; the protected LSP interfaces are specified; and then the options for a bypass LSP are displayed.

```
NetIron(config)#router mpls
NetIron(config-mpls)#bypass-lsp xm4-by
NetIron(config-mpls-bypasslsp-xm4-by)#
NetIron(config-mpls-bypasslsp-xm4-by>)# exclude-interface e 1/2, e 1/2, e 2/5-e 2/
NetIron(config-mpls-bypasslsp-xm4-by>)#?
clear                          Clear table/statistics/keys
cos                            Class of service
disable                        Tear down the LSP
enable                         Establish the LSP
end                            End Configuration level and go to Privileged level
exclude-any                    Exclude any of the administrative groups
exclude-interface              choose the interface to avoid as well as protect
exit                           Exit current level
from                           Set ingress router of the LSP
hop-limit                      Limit of hops the LSP can traverse
include-all                    Include all of the administrative groups
include-any                    Include any of the administrative groups
metric                         Set the LSP metric
no                             Undo/disable commands
primary-path                   Set primary explicit path
priority                       Setup/hold priorities
quit                           Exit to User level
record                         Enable or disable recording path routes
show                           Display system information
tie-breaking                   Choose the tie breaking mode for cspf
to                             Set egress router of the LSP
traffic-eng                    Set traffic engineering parameters
write                          Write running configuration to flash or terminal
```

Syntax: [no] bypass-lsp <*name*>

The <*name*> must be unique among all regular LSPs and bypass LSPs.

Syntax: [no] exclude-interface <*linkid*>, <*linkid*>, <*linkid-begin-linkid-end*>

Syntax: [no] exclude-any <*group*>

Displaying MPLS and RSVP information

You can display the following information about the MPLS configuration on the device:

- Information about MPLS-enabled interfaces on the device
- Statistics about the MPLS-enabled interfaces, including bypass LSPs
- MPLS summary information
- Contents of the Traffic Engineering Database (TED)
- Status information about signalled LSPs configured on the device
- Information about paths configured on the device
- The label applied at each hop in an LSP
- Contents of the MPLS routing table
- RSVP information, including the status of RSVP-enabled interfaces, session information, and statistics
- Information about OSPF-TE LSAs
- MPLS Fast Reroute Information
- MPLS Bypass LSP

Displaying information about MPLS-enabled interfaces

To display information about the interfaces on the device that have been enabled for MPLS.

```
NetIron#show mpls interface ethernet 4/15
e4/15
  Admin: Up  Oper: Up
  Maximum BW: 1000000 kbps, maximum reservable BW: 1000000 kbps
  Admin group: 0x00000000
  Reservable BW [priority] kbps:
    [0] 780000    [1] 780000    [2] 780000    [3] 760000
    [4] 760000    [5] 760000    [6] 760000    [7] 760000
  Last sent reservable BW [priority] kbps:
    [0] 780000    [1] 780000    [2] 780000    [3] 760000
    [4] 760000    [5] 760000    [6] 760000    [7] 760000
  Configured Protecting bypass lsps:
mlxe4-by(UP)
```

Syntax: show mpls interface [ethernet <*slot/port*> **| pos** <*slot/port*> **| ve** <*vid*> **]**

For each MPLS-enabled interface on the device, the following information is displayed.

TABLE 198 Output from the show mpls interface command

This Field...	Displays...
Interface	The interface type refers to any one of the following: • **ethernet** <*slot/port*> to limit the display to a single ethernet port. • **pos** <*slot/port*> to limt the display to a single pos port. • **ve** <*vid*> to limit the display to a VE interface ID specified by the <*vid*> variable.
Maximum BW	The maximum outbound bandwidth that can be used on the interface. This TLV reflects the actual physical bandwidth of the interface.
maximum reservable BW	The maximum bandwidth that can be reserved on the interface. By default, the Maximum Reservable Bandwidth is the same as the Maximum Bandwidth for the interface. You can optionally change the reservable bandwidth to an amount greater than or equal to the maximum available bandwidth of the interface with the **traffic-eng reservable-bw** command.
Admin group	The administrative groups to which this interface belongs, set with the **admin-group** command.
Reservable BW [priority] kbps	The amount of bandwidth not yet reserved on the interface. Eight octets are displayed, indicating the amount of unreserved bandwidth (in kbits per second) that can be reserved with a hold priority of 0 through 7. The value in each of the octets is less than or equal to the maximum reservable bandwidth.
Last sent reservable BW [priority] kbps	The values in the Unreserved Bandwidth TLV sent in the most recent OSPF-TE LSA. If the device is not sending out OSPF-TE LSAs for the interface, the unreserved bandwidth value for each of the priorities is 0.
Configured Protecting bypass LSPs	The name and operational state of any bypass LSPs that are protecting this interface.

Displaying MPLS statistics

The following sections describe the commands used to gather MPLS statistics.

Displaying MPLS label statistics

To display all of the MPLS traffic statistics by their MPLS label, enter the following command.

```
NetIron# show mpls statistics label
In-label   In-Port(s)   In-Packet Count
    1024         e3/1            315431
                 e3/2            349193
                 e3/3                 0
                 e3/4                 0
    1025         e3/1            419750
                 e3/2                 0
                 e3/3                 0
                 e3/4                 0
    1024 e5/1 - e5/10            364690
         e5/11 - e5/20                0
         e5/21 - e5/30                0
    1025 e5/1 - e5/10                 0
         e5/11 - e5/20                0
         e5/21 - e5/30                0
```

When applicable, the **show mpls statistics label** command also displays statistics for LDP over RSVP traffic as displayed in the following example.

```
NetIron#show mpls statistics label
In-label In-Port(s)    In-Packet Count
1024    e2/1 - e2/2    45454
        e2/3 - e2/4     0
1025    e2/1 - e2/2     0
        e2/3 - e2/4   454528
1024    e4/1 - e4/20    0
1025    e4/1 - e4/20    0
```

To display all of the MPLS traffic statistics by their MPLS label for the PowerConnect B-MLXe, enter the following command.

```
PowerConnect# show mpls statistics label
In-label In-Port(s) In-Bytes Count
1024 e1/1-e1/24      315431
       e1/25-e1/48     0
```

To display all MPLS traffic statistics by their MPLS label that are gathered by the corresponding network processor that contains a specific port, enter a command such as the following.

```
NetIron# show mpls statistics label 3/1
In-label      In-Port(s)    In-Packet Count
    1024    e3/1 - e3/20                30
    1026    e3/1 - e3/20                21
    1030    e3/1 - e3/20               100
    1032    e3/1 - e3/20                 0
    1033    e3/1 - e3/20                 0
    1034    e3/1 - e3/20                12
    1036    e3/1 - e3/20                 0
```

To display all MPLS traffic statistics by their MPLS label for a specific port for the PowerConnect B-MLXe, enter a command such as the following.

```
PowerConnect# show mpls statistics label 1/1
In-label In-Port(s) In-Bytes Count
1024 e1/1-e1/24      315431
```

Table 199 lists the output displayed for the **show mpls statistics label** command.

TABLE 199 MPLS statistics label parameters

This field...	Displays...
In-label	The MPLS label ID.
In-Port (s)	The port where the traffic arrives.
In-Packet Count	The number of packets meeting the In-label and In-port criteria.
In-Bytes Count	The number of bytes meeting the In-label and In-port criteria.

Syntax: show mpls statistics label <*interface*>

The <*interface*> variable allows you to limit label statistics displayed to a specified interface.

Displaying MPLS tunnel statistics

To display all of the MPLS traffic statistics by their MPLS tunnel, enter the following command.

```
NetIron# show mpls statistics tunnel
Tunnel       In-Port(s)       L3VPN/IPoMPLS Out-Pkt
0            e1/1 - e1/20     0
             e2/1 - e2/2      0
             e3/1 - e3/2      0
             e3/3 - e3/4      0
             e4/1 - e4/20     0
1            e1/1 - e1/20     0
             e2/1 - e2/2      0
             e3/1 - e3/2      0
             e3/3 - e3/4      0
             e4/1 - e4/20     0
```

To display all of the MPLS traffic statistics for a specific tunnel, enter a command such as the following.

```
NetIron# show mpls statistics tunnel 1
Tunnel       In-Port(s)       L3VPN/IPoMPLS Out-Pkt
1            e1/1 - e1/20     0
             e2/1 - e2/2      0
             e3/1 - e3/2      0
             e3/3 - e3/4      0
             e4/1 - e4/20     0
```

Table 200 lists the output displayed for the **show mpls statistics tunnel** command.

TABLE 200 MPLS statistics tunnel parameters

This field...	Displays...
Tunnel	The index number of the MPLS tunnel.
In-Port(s)	The port where the traffic is received.
L3VPN/IPoMPLS Out-Pkt	The number of Layer 3 VPN and IPoMPLS packets that have been sent outbound meeting the In-label and Tunnel criteria.

Syntax: show mpls statistics tunnel <*tunnel-index*>

The <*tunnel-index*> variable allows you to limit MPLS statistics displayed to a specified tunnel.

NOTE
When the traffic is being forwarding using PBR over MPLS tunnel, the MPLS tunnel statistics will not be incremented and only the PBR accounting will indicate these packets in the statistics.

Displaying MPLS VRF statistics

To display out-packet statistics for VRFs, enter the following command.

```
NetIron# show mpls statistics vrf
VRF Name        In-Port(s)     Endpt Out-Pkt     Tnl Out-Pkt
red             e3/1           0                 0
                e3/2           0                 0
                e3/3           0                 0
                e3/4           0                 0
                e5/1 - e5/10   0                 0
                e5/11 - e5/20  0                 0
                e5/21 - e5/30  0                 0
                e5/31 - e5/40  0                 0
green           e3/1           3707480           0
                e3/2           2692915           0
                e3/3           0                 0
                e3/4           0                 0
                e5/1 - e5/10   0                 0
                e5/11 - e5/20  0                 5834179
                e5/21 - e5/30  0                 0
                e5/31 - e5/40  0                 0
pink            e3/1           0                 0
                e3/2           0                 0
                e3/3           0                 0
                e3/4           0                 0
                e5/1 - e5/10   0                 0
                e5/11 - e5/20  0                 0
                e5/21 - e5/30  0                 0
                e5/31 - e5/40  0                 0
```

To display out-packet statistics for a specific VRF, enter the following command.

```
NetIron# show mpls statistics vrf black
VRF Name        In-Port(s)     Endpt Out-Pkt     Tnl Out-Pkt
black           e3/1           0                 0
                e3/2           29607351          0
                e3/3           27522998          25828420
                e3/4           0                 0
                e5/1 - e5/10   0                 0
                e5/11 - e5/20  0                 0

                e5/21 - e5/30  0                 0
                e5/31 - e5/40  0                 0

            e5/31 - e5/40  0
```

Table 201 lists the output for the **show mpls statistics vrf** command.

TABLE 201 MPLS statistics VRF parameters

This field...	Displays...
VRF Name	The name of the VRF from which packets originated or are destined.
In-Port(s)	The port that is either the VRF or MPLS interface.
Endpt Out-Pkt	The number of packets forwarded to the specified VRF interface.
Tnl Out-Pkt	The number of VRF data packets sent to the remote peer over an MPLS tunnel.

Syntax: show mpls statistics vrf <*vrf-name*>

The <*vrf-name*> variable allows you to limit the display of VRF statistics to a specific VRF.

Displaying LSP accounting statistics

If the **ingress-tunnel-accounting** command has been configured, you can display accounting statistics for RSVP-signaled LSPs using the commands described in this section.

If an LSP has the protection of a bypass LSP (as described in "MPLS Fast Reroute using facility backup over a bypass LSP" on page 1311), statistics for the protected LSP will always be shown under the protected LSP even if the protected LSP switches over to the backup LSP riding on a bypass LSP. Bypass LSP is not listed in the output of the **show mpls statistics lsp** command. Also, if you request statistics and name a bypass LSP, the system generates an error message.

For example, assume that LSP1 and LSP2 are protected LSPs and that BYPASS is the bypass LSP that protects both LSP1 and LSP2.

```
NetIron# show mpls statistic lsp BYPASS
Error - cannot find lsp BYPASS
```

If the bypass LSP is implicit NULL, then statistics are collected for a protected LSP only if the protected LSP is not implicit NULL.

Displaying LSP accounting statistics

To display RSVP-signaled LSP accounting statistics, enter the following command.

```
NetIron# show mpls statistics lsp
LSP tope4
  Tunnel index      0  0 pkt  0 Byte  0 Avg. pps  0 Avg. Bps
LSP 400
  Tunnel index      2  0 pkt  0 Byte  0 Avg. pps  0 Avg. Bps
LSP 4000
  Tunnel index      3  0 pkt  0 Byte  0 Avg. pps  0 Avg. Bps
LSP tope41
  Tunnel index      4  99205408 pkt  11314220016 Byte  84459 pps  9628340 Bps
```

When the **ingress-tunnel-accounting** command is enabled on the RSVP tunnel, the **show mpls statistics lsp** command displays statistics for LDP over RSVP traffic.

```
NetIron#show mpls statistics lsp
LSP test1
Tunnel interface tnl2 4241 pkt 1187480 Byte  10 pps  2800 Bps
LSP test2
Tunnel interface tnl3  0 pkt  0 Byte 0    Avg. pps   0 Avg. Bps
```

Syntax: show mpls statistics lsp [<*name*> **]**

The <*name*> variable specifies the LSP for which LSP accounting statistics are displayed. If you do not specify an LSP name, statistics are displayed for all RSVP-signalled LSPs.

Displaying LDP accounting statistics

To display LDP-signalled LSP accounting statistics, enter the following command.

```
NetIron# show mpls statistics ldp tunnel
LDP tunnel index  0  4241 pkt  1187480 Byte 10 Avg. pps  2800 Avg. Bps
```

Syntax: show mpls statistics ldp tunnel [<*tunnel-index*> **]**

The <*tunnel-index*> variable specifies the index number of the MPLS tunnel for which you want to display LDP-signalled, LSP accounting statistics. If you do not specify an index number, LSP accounting statistics are displayed for all LDP-signalled LSPs.

Table 202 shows the output of the **show mpls statistics lsp** and **show mpls statistics ldp tunnel** commands.

TABLE 202 MPLS LSP statistics parameters

This field...	Displays...
LSP	The name of the LSP that statistics are being displayed for. (Displayed for RSVP-signaled LSPs only.)
Tunnel	The index number of the MPLS tunnel.
pkt	The total number of packets forwarded through the specified LSP.
Byte	The total number of bytes forwarded through the specified LSP.
Avg. pps	The number of packets-per-second forwarded through the specified LSP.
Avg. Bps	The number of bytes-per-second forwarded through the specified LSP.

NOTE
The LSP accounting feature will display the primary tunnel interface even when the traffic is sent through the secondary path.

Clearing LSP and LDP accounting statistics

Byte and packet counters can be cleared for RSVP-signaled LSPs using the following command.

Syntax: clear mpls statistics lsp [<*name*>]

The <*name*> variable specifies LSP that you want to clear byte and packet counters for. If you do not specify an LSP name, byte and packet counters will be cleared for all RSVP-signalled LSPs.

Byte and packet counters can be cleared for LDP-signaled LSPs using the following commands.

Syntax: clear mpls statistics ldp tunnel [<*tunnel-index*>]

The <*tunnel-index*> variable specifies the index number of the MPLS tunnel for which you want to clear byte and packet counters. If you do not specify an index number, byte and packet counters are cleared for all LDP-signalled LSPs.

Displaying MPLS summary information

You can display a summary of MPLS information, including the number of configured paths and signalled LSPs for which this device is the ingress LER.

Example

```
NetIron# show mpls summary

Path:
        Paths configured    =     0

Signaled LSPs:
        LSPs configured     =     1
        LSPs enabled        =     1
        LSPs operational    =     0
```

Syntax: show mpls summary

Displaying the Traffic Engineering database

An LSR's Traffic Engineering Database (TED) contains topology information about nodes in an MPLS domain and the links that connect them. This topology information is obtained from either the OSPF traffic engineering (OSPF-TE) LSAs or IS-IS LSPs with traffic engineering extensions. OSPF-TE LSAs and IS-IS LSPs with TE extensions have special extensions that contain information about an MPLS-enabled interface's traffic engineering metric, bandwidth reservations, and administrative group memberships.

An LSR, when configured to do so, floods OSPF-TE LSAs or IS-IS LSPs with TE extensions for its MPLS-enabled interfaces to its neighboring routers in the OSPF or IS-IS area. Other LSRs store the information from the OSPF-TE LSAs or IS-IS LSPs with TE extensions in their own Traffic Engineering Databases, allowing each LSR in the area to maintain an identical TED describing the MPLS topology. The topology information in the TED is used by the CSPF process when it calculates traffic-engineered paths for signalled LSPs.

You can display the contents of an LSR's TED. The following example is for a router where OSPF-TE LSAs are enabled for MPLS interfaces.

```
NetIron# show mpls ted database
AreaId: 0
  NodeID: 2.2.2.2, Type: Router
    Type: M/A, To: 10.1.1.3, Local: 10.1.1.2, Remote: 0.0.0.0
  NodeID: 3.3.3.3, Type: Router
    Type: P2P, To: 6.6.6.6, Local: 40.1.1.1, Remote: 40.1.1.2
    Type: M/A, To: 10.1.1.3, Local: 10.1.1.3, Remote: 0.0.0.0
    Type: M/A, To: 20.1.1.2, Local: 20.1.1.1, Remote: 0.0.0.0
  NodeID: 10.1.1.3, Type: Network
    Type: M/A, To: 1.1.1.1, Local: 0.0.0.0, Remote: 0.0.0.0
    Type: M/A, To: 2.2.2.2, Local: 0.0.0.0, Remote: 0.0.0.0
    Type: M/A, To: 3.3.3.3, Local: 0.0.0.0, Remote: 0.0.0.0
  NodeID: 30.1.1.2, Type: Network
    Type: M/A, To: 1.1.1.1, Local: 0.0.0.0, Remote: 0.0.0.0
    Type: M/A, To: 6.6.6.6, Local: 0.0.0.0, Remote: 0.0.0.0
```

The following example is for a router where IS-IS TE LSPs are enabled for MPLS interfaces.

```
NetIron# show mpls ted database
This Router is MLXe3
Global Link Gen 106
ISIS(2)
  NodeID: MLXe4.00(12.12.12.12) , Type: Router
    Type: M/A, To: MLXe3.02 Local: 122.0.0.1, Remote: 0.0.0.0, Gen 54
    Type: M/A, To: MLXe3.03 Local: 129.0.0.2, Remote: 0.0.0.0, Gen 51
    Type: M/A, To: PE2-JNPR.04 Local: 147.0.0.1, Remote: 0.0.0.0, Gen 57
    Type: M/A, To: GSR.02 Local: 125.0.0.1, Remote: 0.0.0.0, Gen 78
  NodeID: MLXe3.00(15.15.15.15) , Type: Router
    Type: M/A, To: MLXe3.02 Local: 122.0.0.2, Remote: 0.0.0.0, Gen 49
    Type: M/A, To: MLXe3.03 Local: 129.0.0.1, Remote: 0.0.0.0, Gen 50
  NodeID: PE2-JNPR.00(5.5.5.5) , Type: Router
    Type: M/A, To: PE2-JNPR.04 Local: 147.0.0.2, Remote: 0.0.0.0, Gen 62
    Type: M/A, To: PE2-JNPR.02 Local: 126.0.0.1, Remote: 0.0.0.0, Gen 60
    Type: M/A, To: PE4.03 Local: 148.0.0.2, Remote: 0.0.0.0, Gen 104
  NodeID: GSR.00(9.9.9.9) , Type: Router
    Type: P2P, To: PE4.00(14.14.14.14) Local: 128.0.0.2, Remote: 128.0.0.1, Gen 1
    Type: M/A, To: GSR.02 Local: 125.0.0.2, Remote: 0.0.0.0, Gen 65
    Type: M/A, To: PE2-JNPR.02 Local: 126.0.0.2, Remote: 0.0.0.0, Gen 77
```

Syntax: show mpls ted database

The following table describes the output of the **show mpls ted database** command.

TABLE 203 Output from the show mpls ted data command

This field...	Displays...
Global Link Gen	The number of times the TED database has changed.
AreaId	The ID of this OSPF area.
NodeID	The ID of the node. For Router nodes, can be any interface address or a loopback interface address on the LSR. For Network nodes, this is the router ID of the network's designated router.
[node] Type	The type of node. The node type can be either Router or Network RouterIndicates the node is an actual LSR. NetworkIndicates the node represents a multi-access network.
[link] Type	The type of link. The link type can be either P2P or M/A P2P Indicates this is a point-to-point link. M/A Indicates the link is a broadcast, multi-access network.
To	The ID of the node at the end of this link.
Local	The address of the interface used to reach the remote node.
Remote	The address of the interface on the remote node that is connected to the local node. For M/A link types, this is always 0.0.0.0.
Gen	The number of times this link information has changed.

To display more detailed information about each node in the TED.

```
NetIron# show mpls ted database detail
AreaId: 0
  NodeID: 2.2.2.2, Type: Router
    Type: M/A, To: 10.1.1.3, Local: 10.1.1.2, Remote: 0.0.0.0
      Color: 0x00000007
      Metric: 1
      Max BW: 155000 kbps
      Reservable BW: 155000 kbps
      Available BW [priority] kbps:

        [4] 155000       [5] 155000       [6] 155000       [7] 155000
```

Syntax: show mpls ted database detail

In addition to the information described in Table 203, the **show mpls ted database detail** command gives the following

TABLE 204 Output from the show mpls ted database detail command

This field...	Displays...
Color	The administrative groups to which this interface belongs.
Metric	The traffic engineering metric for the interface (by default, this is equal to the OSPF link cost).
Max BW	The maximum outbound bandwidth that can be used on the interface. This is the actual physical bandwidth of the interface (155M for OC-3, 622M for OC-12, or 2488M for OC-48).
Reservable BW	The maximum bandwidth that can be reserved on the interface. By default, the Maximum Reservable Bandwidth is the same as the Maximum Bandwidth for the interface.
Available BW [priority] kbps	The amount of bandwidth not yet reserved on the interface. Eight octets are displayed, indicating the amount of unreserved bandwidth (in kbits per second) that can be reserved with a hold priority of 0 through 7. The value in each of the octets is less than or equal to the maximum reservable bandwidth.

Displaying a traffic engineering path to a destination

You can display a traffic engineering path to a IPv4 destination address using a specified set of resource parameters. This enhancement allows you to gain insight into a traffic engineering path in a network, before setting it up using RSVP. This will help you to avoid RSVP path setup failure due to unavailable requested resources along the path to the destination host.

To display the traffic engineering path to a IPv4 destination address, enter the following command.

```
NetIron# show mpls ted path 4.4.4.4
```

Syntax: **show mpls ted path** <*destIPAddress*> **[bandwidth** <*bw_in_kbps*>**]** **[hop-limit** <*max_hops*>**]** **[priority** <*setup_priority*>**]** **[exclude-any** <*STRING_List_of_Admin_Resource_groups_name_or_and_num*>**]** **[include-any** <*STRING_List_of_Admin_Resource_groups_name_or_and_num*>**]** **[include-all** <*STRING_List_of_Admin_Resource_groups_name_or_and_num*>**]** **[tie-breaking {random | least-fill | most-fill}]**

NOTE
When configuring the CLI command, any combination of resource constraint parameters can be used.

The following table describes the parameters of the **show mpls ted path** command

TABLE 205 Parameters from the show mpls ted path command

CLI parameter	Description
<*destIPAddress*>	The IPv4 address of the destination host.
bandwidth <*bw_in_kbps*>	The minimum bandwidth of the path to its destination. The bandwidth value is entered in decimal in kilo bits per second unit. The valid range is between 0- 2147483647. If the value entered is larger than 2147483647, then the value will be truncated to the max limit of 2147483647 and accepted as the bandwidth input.
hop-limit <*max_hops*>	The maximum hops for the path to reach to its destination. The valid range is between 0 - 255. If an invalid range is entered, then an error message will display. If a path to the destination is available, but the hop count for the path is greater than <*max_hops*> value, then MPLS will indicate that path is not available.
priority <*setup_priority*>	The setup priority of the path. The valid range is between 0 - 7. The default is 7, the lowest setup priority value. If an invalid range is entered, then an error message will display. The priority parameter should be entered along with the bandwidth parameter because while setting up an LSP, the setup priority value decides the ability to reserve a bandwidth amount.
exclude-any <*STRING*>	The <*STRING*> variable specifies the admin group name or number. The string must be enclosed in double quotes.The <*STRING*> variable is a list of any combination of admin group name and number. The valid range for the admin group number is between 0 and 31. The admin group name must start with an alphabet character. If an invalid range is entered for admin group number and admin group name, then the CLI will prompt a warning message. The CLI will be accepted, but the out of range value will be ignored.
include-any <*STRING*>	The <*STRING*> variable specifies the admin group name or number. The string must be enclosed in double quotes.The <*STRING*> variable is a list of any combination of admin group name and number. The valid range for the admin group number is between 0 and 31. The admin group name must start with an alphabet character. If an invalid range is entered for admin group number and admin group name, then the CLI will prompt a warning message. The CLI will be accepted, but the out of range value will be ignored.

TABLE 205 Parameters from the show mpls ted path command (Continued)

CLI parameter	Description
include-all <*STRING*>	The <*STRING*> variable specifies the admin group name or number. The string must be enclosed in double quotes.The <*STRING*> variable is a list of any combination of admin group name and number. The valid range for the admin group number is between 0 and 31. The admin group name must start with an alphabet character. If an invalid range is entered for admin group number and admin group name, then the CLI will prompt a warning message. The CLI will be accepted, but the out of range value will be ignored.
tie-breaking {random | least-fill | most-fill}	The tie-breaking method is used when multiple equal cost paths to the destination exist. The tie-breaking rule will select only one path to be displayed from among multiple equal cost paths. The default is random.

The following example displays an output from the **show mpls ted path** command.

```
NetIron# show mpls ted path 12.12.12.12 hop-limit 2
Path to 12.12.12.12 found! Time taken to compute: 0 msec
Hop-count: 2 Cost: 2000 ISIS Level-1
        Hop 1: 40.1.0.1, Rtr 13.13.13.13
        Hop 2: 50.1.0.2, Rtr 12.12.12.12
```

The following is an example for a router where the exclude-any parameter is used.

```
NetIron#show mpls ted path 11.11.11.11 exclude-any 0
Path to 11.11.11.11 found! Time taken to compute: 0 msec
Hop-count: 1 Cost: 10 ISIS Level-2
        Hop 1: 129.0.0.13, Rtr 11.11.11.11
```

The following is an example of an output with an error message using the hop-limit parameter, when an out of range parameter value is entered.

```
NetIron(config-mpls)# show mpls ted path 2.2.2.2 hop-limit 300
Error - Hop count value is out of range [0 - 255]
```

If an out of range parameter value is entered, the following error message is displayed for the priority parameter.

Priority

Error - Setup priority value is out of range [0 - 7]

The following table describes the output of the **show mpls ted path** command

TABLE 206 Output from the **show mpls ted path** command

This field...	Displays...
Path to 4.4.4.4 found	The IPv4 address of the destination host is found.
Time taken to compute	The total time taken by CSPF (in milliseconds) to compute this path.
Hop-count	The hop count of this path.
Cost	The total cost of this path.
ISIS	The ISIS or OSPF or CSPF area ID through which this path will traverse.

TABLE 206 Output from the **show mpls ted path** command

This field...	Displays...
Hop	The ingress interface IPv4 address at each hop.
Rtr	The traffic engineering router ID (IPv4 address) at each hop.

Displaying signalled LSP status information

You can display status information about signalled LSPs for which the device is the ingress LER as shown in the example below.

```
NetIron# show mpls lsp
*: The LSP is taking a Secondary Path
                                Admin Oper  Tunnel   Up/Dn Retry Active
Name            To              State State Intf     Times No.   Path
t1              3.3.3.3         UP    UP*   tnl1     1     5     v2
```

Syntax: show mpls lsp [brief]

NOTE
The **show mpls lsp brief** command displays the same information as the **show mpls lsp** command.

Table 207 describes the output of the **show mpls lsp** command.

TABLE 207 Output from the **show mpls lsp** command

This field...	Displays...
Name	The name of the LSP. LSPs are displayed in alphabetical order.
To	The egress LER for the LSP.
Admin State	The administrative state of the LSP. Once you activate the LSP with the **enable** command, the administrative state changes from DOWN to UP.
Oper State	The operational state of the LSP. This field indicates whether the LSP has been established through signalling and is capable of having packets forwarded through it. There may be a short period of time after you enable the LSP that the administrative state of the LSP is UP, but the operational state is DOWN. Once the LSP has been established through signalling, both the administrative state and the operational state will be UP.
Tunnel Intf	The MPLS tunnel interface port ID.
Up or Dn Times	The number of times the operational state of the LSP's primary path has transitioned from DOWN to UP.
Retry No.	The number of attempts the ingress LER has made to connect to the egress LER.
Active Path	The path currently in use for this LSP. Dashes (--) indicate that there is no named path for the LSP or that the LSP has not yet been established over the named path.

The **show mpls lsp detail** command displays detailed information about a specific LSP. To display detailed information about the status of the LSPs for which the device is the ingress LER, enter the **show mpls lsp detail** command as shown in the following example.

```
NetIron# show mpls lsp detail
LSP t1, to 3.3.3.3
  Path selected: pathsecondaryb, mode: manual revert-timer:
  Path selected is up for 3 seconds for the latest instance, traffic will be switchec
  it in 7 seconds.
  From: 1.2.3.4, admin: UP, status: UP, tunnel interface: tnl1
  Times primary LSP goes up since enabled: 1
  Metric: 1, number of installed aliases: 0
  Maximum retries: 0, no. of retries: 3
  Pri. path: dir, active: no
   Setup priority: 7, hold priority: 0, ipmtu 1400
   Max rate: 0 kbps, mean rate: 0 kbps, max burst: 0 bytes
   Constraint-based routing enabled: yes
   Tie breaking: random, hop limit: 0
  Sec. path: v2, active: active
   Hot-standby: no, status: up
   Setup priority: 7, hold priority: 0
   Max rate: 0 kbps, mean rate: 0 kbps, max burst: 0 bytes
   Constraint-based routing enabled: yes
   hop limit: 0
  Active Path attributes:
   Tunnel interface: tnl1, outbound interface: e1/1

```

Syntax: show mpls lsp [detail | <*lsp_name*>]

The <*lsp_name*> variable specifies the name of the LSP you want to display.

Table 208 describes the output from the **show mpls lsp detail** command.

TABLE 208 Output from the **show mpls lsp detail** command

This field...	Displays...
Name	The name of the LSP. LSPs are displayed in alphabetical order.
To	The egress LER for the LSP.
From	The LSP's source address, configured with the **from** command. If a source IP address has not been specified for the LSP with the **from** command, and the LSP has not been enabled, then "(n/a)" is displayed in the From field.
admin	The administrative state of the LSP. Once you activate the LSP with the **enable** command, the administrative state changes from DOWN to UP.
status	The operational state of the LSP. This field indicates whether the LSP has been established through signalling and is capable of having packets forwarded through it. If the status of the LSP is DOWN, the reason why the LSP is down is shown in parentheses. There may be a short period of time after you enable the LSP that the administrative state of the LSP is UP, but the status is DOWN. Once the LSP has been established through signalling, both the administrative state and the status will be UP.

TABLE 208 Output from the **show mpls lsp detail** command (Continued)

This field...	Displays...
Path selected	The path currently selected for this LSP.
mode	The path selection mode currently configured for the LSP. It can be one of the following: • auto • manual • unconditional
revert-timer	The time in seconds for which the revert-timer has been configured.
Path selected is ...	The current status of the selected path. During a transition period, this message describes the number of seconds that the path has been up in the latest instance and the number of seconds before traffic will be switched to it.
Times primary LSP goes up	The number of times the status of the LSP's primary path has transitioned from DOWN to UP.
Metric	The metric for the LSP, configured with the **metric** command.
no. of installed aliases	The number of aliases that have been installed for the egress LER.
Max retries	The maximum number of attempts the ingress LER will attempt to connect to the egress LER, set with the **retry-limit** command.
no. of retries	The number of attempts the ingress LER has made to connect to the egress LER.
Pri. path	The name of the primary path for this LSP and whether the path is currently active.
Sec. path	The name of the secondary path for this LSP and whether the path is currently active.
Hot-standby	Whether the secondary path is a hot-standby path.
status	The operational state of the secondary path.
Setup priority	The configured setup priority for the LSP.
hold priority	The configured hold priority for the LSP.
ipmtu	The maximum packet size in bytes for IP packets transiting the LSP without being fragmented.
Max rate	The maximum rate of packets that can go through the LSP (in kbps), set with the **traffic-eng max-rate** command.
mean rate	The average rate of packets that can go through the LSP (in kbps), set with the **traffic-eng mean-rate** command.
max burst	The maximum size (in bytes) of the largest burst the LSP can send at the maximum rate, set with the **traffic-eng max-burst** command.
Constraint-based routing enabled	Whether CSPF is in effect for the LSP.
Tie breaking	The tie-breaking method CSPF uses to select a path from a group of equal-cost paths to the egress LER, set with the **tie-breaking** command.
hop limit	The maximum number of hops a path calculated by CSPF can have, set with the **hop-limit** command.
outbound interface	The outbound interface taken by the active path of the LSP. If the egress interface is a VE-enabled interface, the VE interface ID specified by the <*vid*> variable is displayed here in the Outbound interface field (for example, ve 20).
Tunnel index	The tunnel index for the active path of the LSP.
outbound label	The outbound label used by the active path of the LSP.

TABLE 208 Output from the **show mpls lsp detail** command (Continued)

This field...	Displays...
Path calculated using constraint-based routing	Whether the explicit path used by the active path was calculated using the constraint-based routing.
Explicit path hop counts	The number of explicit hops configured for the LSP, the addresses of the hops, and whether the hops are strict (S) or loose (L).
Recorded routes	The addresses recorded by the RECORD_ROUTE object during RSVP signalling.
If the BFD admin state is enabled for the LSP, the following BFD information will be displayed.	
BFD session status	Describes the status of the BFD session on this LSP as either UP or DOWN. If a BFD session for the LSP is enabled and the BFD session is DOWN, one of the following reasons for failure will be displayed: • BFD disabled globally • LSP down • Max session exceeded • Max LP session exceeded • Peer session down • Wait for peer
Config Param	Describes how the BFD configuration values were derived: • global – Displayed if the configuration values were derived from the router's global LSP BFD configuration. • local – Displayed if the configuration values were derived from a BFD configuration specific to this LSP.
min-tx	The min-tx value in milliseconds that is configured for this LSP.
min-rx	The min-rx value in milliseconds that is configured for this LSP.
multiplier	The multiplier value that is configured for this LSP.
tx-interval	The tx-interval value in milliseconds that has been negotiated between this router and its peer for this LSP.
rx-interval	The rx-interval value in milliseconds that has been negotiated between this router and its peer for this LSP.
multiplier	The multiplier value in milliseconds that has been negotiated between this router and its peer for this LSP.
Local discriminator	Value of the "local discriminator" field in the BFD Control Message as used by the local router in the last message sent.
remote discriminator	Value of the "local discriminator" field in the BFD Control Message as received in the last message sent by the remote peer.

The **show mpls lsp wide** command allows the user to display the full LSP name in a single line. Previously, a long LSP name (greater than 12 characters) was text-wrapped in multiple lines. Now, the full LSP name can be displayed in a single line as shown in the following example.

NOTE
The **show mpls lsp wide** command is supported on PowerConnect B-MLXe devices.

```
NetIron(config)#show mpls lsp wide
Note: LSPs marked with * are taking a Secondary Path
                                                        Admin Oper  Tunnel   Up/Dn Retry Active
Name                                                    To              State State Intf     Times No.   Path
tunnel1                                                 3.3.3.3         UP    UP    tnl0     1     0     --
tunnel2                                                 3.3.3.3         UP    UP    tnl4     1     0     ppath1
tunnelfromsanfranciscotonewyork                         3.3.3.3         UP    UP    tnl3     1     0
pathfromsanfranciscotonewyork
```

Syntax: show mpls lsp wide

The **include** option can be used with the **show mpls lsp wide** command to filter and display a specific LSP name.

```
NetIron#show mpls lsp wide | include tunnelfromsanfranciscotonewyork
                                                      Admin Oper  Tunnel   Up/Dn Retry Active
Name                                                   To              State State Intf     Times No.   Path
tunnelfromsanfranciscotonewyork                        3.3.3.3         UP    UP    tnl3     1     0
pathfromsanfranciscotonewyork
```

Syntax: show mpls lsp [**wide** [**| include** <*lsp_name*>]]

The <*lsp_name*> variable specifies the name of the LSP you want to display.

Displaying path information

A path is a list of router hops that specifies a route across an MPLS domain. You can create a path and then configure LSPs that see the path. When the LSP is enabled, the ingress LER attempts to signal the other LSRs in the path, so that resources can be allocated to the LSP.

You can display information about the paths configured on the device as shown in the following example.

```
NetIron#show mpls path
Path Name           Address             Strict/loose        Usage Count
to110_120           110.110.110.2       Strict              1
                    120.120.120.3       Strict
to2_pri             10.10.10.2          Strict              0
to2_sec             110.110.110.2       Strict              0
to3                 110.110.110.2       Loose               1
                    120.120.120.3       Loose
to3_pri             10.10.10.2          Strict              1
                    20.20.20.3          Strict
to3_sec             110.110.110.2       Strict              0
                    120.120.120.3       Strict
to4                 110.110.110.2       Loose               1
                    120.120.120.3       Loose
                    130.130.130.4       Loose
to_23               110.110.110.2       Strict              1
                    20.20.20.3          Strict
```

Syntax: show mpls path [<*path-name*>]

You can display information for all paths configured on the device, or for a specified <*path-name*>. Table 209 describes the output shown in the **show mpls path** command.

TABLE 209 Output of the **show mpls path** command

This column...	Displays...
Path Name	The configured name of the path.
Address	The IP address of each node in the path. A node corresponds to an MPLS-enabled router in the network.
Strict or loose	Whether the node is strict or loose. A strict node means that the router must be directly connected to the preceding node. A loose node means that other routers can reside between the source and destination nodes.
Usage Count	The number of LSPs that are either currently using or configured to use the path. For example, if an LSP named "to_sqa" has primary and secondary paths and both paths are configured to use the same MPLS path "path_to_sqa," then the usage count for "path_to_sqa" would be two (if no other LSP in the system is configured to use "path_to_sqa").

The **show mpls path wide** command allows the user to display the full path name in a single line. Previously, a long path name (greater than 12 characters) was text-wrapped in multiple lines. Now, the full path name can be displayed in a single line as shown in the following example.

NOTE
The **show mpls path wide** command is supported on PowerConnect B-MLXe devices.

```
NetIron(config)#show mpls path wide
Path Name                          Address       Strict/loose   Usage
Count
Pathfromsanfranciscotonewyork       10.10.10.2   Strict          1
ppath1                              10.10.10.2   Strict          1
spath1                              20.20.20.2   Strict          1
```

Syntax: show mpls path wide

The **include** option can be used with the **show mpls path wide** command to filter and display a specific path.

```
NetIron#show mpls path wide | include pathfromsanfranciscotonewyork
Path Name                          Address       Strict/loose   Usage
Pathfromsanfranciscotonewyork      10.10.10.2      Strict         1
```

Syntax: show mpls path [**wide** [**| include** <*path-name*>]]

The <*path-name*> variable specifies the name of the path you want to display.

Displaying the MPLS routing table

The MPLS routing table is used to store routes to egress LERs.

To display the contents of the MPLS routing table, enter the **show mpls route** command, as follows. The port field now displays whether an interface/port is either Ethernet or POS. For example, Ethernet port 3 on slot 2 is displayed as e2/3.

NOTE
The output display from the **show mpls route** command is applicable to PowerConnect B-MLXe devices.

```
NetIron#show mpls route
Total number of MPLS tunnel routes: 1
R:RSVP L:LDP S:Static O:Others
      Destination          Gateway           Tnnl    Port  Label  Sig Cost Use
1     140.140.140.4/32     140.140.140.4     tnl0    e1/2  3      R   0    0
```

Syntax: show mpls route [*<ip_prefix_addr>*/*<mask_len>* **[longer]** | *<ip_prefix_addr>* *<ip_mask>* **[longer]]**

where:

- *<ip_prefix_addr>* means display the route to the specified IP address.
- *<mask_len>* is the number of bits in the mask.
- **longer** means that if an IP address has been specified, display only the routes that match that IP address.
- *<ip_mask>* is the bytes of a network mask or, for CIDR format, the number of bits in the network mask.

TABLE 210 Output from the show mpls route command

This field...	Displays...
Destination	The destination for the route. This can be either the address of the egress LER in an LSP, or a configured alias.
NetMask	The network mask for the route. If the destination address is the egress LER, the mask is 32 bits.
Gateway	The address of the egress LER in the LSP. If the destination address is not a network alias, the gateway is the same as the destination address.
Port	The MPLS tunnel interface associated with the LSP. The port field displays whether an interface/port is an Ethernet port, POS port, or a VE interface. The VE interface ID is specified by the *<vid>* variable. When applicable, the egress interface of the routing entry displays the VE interface. The port display format for interface/port is as follows: • [e|p] <slot>/<port> "e" represents an Ethernet port "p" represents a POS port
Cost	The metric for the LSP, set with the **metric** command in the LSP's configuration.
Label	The MPLS label received from the downstream router.
sig	The signal protocol type associated with the label. Possible values are: • L – LDP • R – RSVP
Usage	The number of LSPs that are either currently using or configured to use the path. For example, if an LSP named "to_sqa" has primary and secondary paths and both paths are configured to use the same MPLS path "path_to_sqa," then the usage count for "path_to_sqa" would be two (if no other LSP in the system is configured to use "path_to_sqa")."

The **show mpls forwarding** command is introduced to display MPLS forwarding information. The out-intf field in the output of the **show mpls forwarding** command displays whether an interface/port is either an Ethernet port or a POS port. For example, Ethernet port 3 on slot 2 is displayed as e2/3.

To display MPLS forwarding information, enter the **show mpls forwarding** command as shown in the example below.

NOTE
The output display from the **show mpls forwarding** command is applicable to both PowerConnect B-MLXe devices.

```
NetIron#show mpls forwarding
Total number of MPLS forwarding entries: 2
      Dest-prefix        In-lbl In-intf Out-lbl Out-intf Sig Next-hop
1     140.140.140.4/32                 3       e1/2     R   20.20.20.2
2     140.140.140.4/32                 1024    e1/10    R   20.20.20.2        DET
```

Syntax: show mpls forwarding [<*ip_prefix_addr*>/<*mask_len*> **[longer]** | <*ip_prefix_addr*> <*ip_mask*> **[longer]**]

TABLE 211 Output from the show mpls forwarding command

This field...	Displays...
dest-prefix	The destination FEC of the LSP.
in-lbl	The incoming segment or upstream label for the LSP. A value of 0 indicates the absence of the segment.
in-intf	The interface through which the label identified in the “in-lbl” column has been received for the LSP. A value of 0 indicates the absence of the segment. When applicable, the in-intf field also displays a VE interface specified by the <*vid*> variable.
out-lbl	The outgoing segment or downstream label for the LSP .
out-intf	The interface through which the label identified in the “out-lbl” column has been distributed for the LSP. The out-intf field displays whether an interface/port is an Ethernet port, POS port, or a VE interface. The VE interface ID specified by the <*vid*> variable. The out-intf display format for interface/port is as follows: • [e|p] <slot>/<port> “e” represents an Ethernet port “p” represents a POS port
sig	The signal protocol type associated with the label. Possible values are: • L – LDP • R – RSVP
next-hop	The next hop of the LSP.
DET	DET specifies that this is a Detour path.

Displaying RSVP information

You can display RSVP version information, the status of RSVP interfaces, RSVP session information, and RSVP statistics.

Displaying the RSVP version

To display the RSVP version number, as well as the refresh interval and refresh multiple.

```
NetIron #show mpls rsvp
Resource ReSerVation Protocol, version 1. rfc2205
RSVP protocol        = Enabled
R (refresh interval) = 30 seconds
K (refresh multiple) = 3
```

Syntax: show mpls rsvp

Displaying the status of RSVP interfaces

To display the status of RSVP on devices where it is enabled.

```
NetIron# show mpls rsvp interface
Interface State MD5 Auth
     e2/1 Up    OFF
     e2/2 Dn    OFF
     e4/1 Dn    OFF
     e4/2 Dn    OFF
```

Syntax: show mpls rsvp interface [brief]

NOTE
The **show mpls rsvp interface brief** command displays the same information as the **show mpls rsvp interface** command.

In this example, interfaces e 2/1, 2/2, 4/1, and 4/2 have been enabled for RSVP. Of these interfaces, interface e 2/1 can actively send and receive RSVP messages.

To display detailed information about RSVP-enabled interfaces.

```
NetIron# show mpls rsvp interface detail
Interface State MD5 Auth
     e2/1 Up    OFF
                        Total                  Since last clear
 PacketType        Sent      Received        Sent      Received
  Path             0         5745            0         5745
  Resv             5852      0               5852      0
  PathErr          0         0               0         0
  ResvErr          0         0               0         0
  PathTear         0         6               0         6
  ResvTear         0         0               0         0

 Errors                Total                 Since last clear
  Rcv MD5 Auth Errors  0                     0
```

Syntax: show mpls rsvp interface detail

For each RSVP-enabled interface, the following information is displayed

TABLE 212 Output from the **show mpls rsvp interface detail** command

This field...	Displays...
Interface	The RSVP-enabled interface can be an Ethernet interface or a VE-enabled interface. The VE interface ID is specified by the <*vid*> variable.
Path	The number of Path messages sent and received on the interface. Path messages store information about the state of the path along the LSRs in the LSP.
PathErr	The number of PathErr messages sent and received on the interface.
PathTear	The number of PathTear messages sent and received on the interface. PathTear messages cause path states to be deleted.
Resv	The number of Resv messages sent and received on the interface. Resv messages include FF (Fixed Filter), WF (Wildcard Filter), and SE (Shared Explicit) messages.
ResvErr	The number of ResvErr messages sent and received on the interface.
ResvTear	The number of ResvTear messages sent and received on the interface. ResvTear messages cause reservation states to be deleted.
MD5 Auth Errors	The number of MD5 authentication errors on received packets on this interface.

To clear the RSVP statistics counters, use the following command.

```
NetIron# clear mpls rsvp statistics
```

Syntax: clear mpls rsvp statistics

This command resets the counters listed under "Since last clear" for the **show mpls rsvp interface detail** and **show mpls rsvp statistics** commands.

Displaying RSVP session information

To display RSVP session information, use the following command.

```
NetIron(config)#show mpls rsvp session
Codes: DI:Ingress Detour  DT:Transit Detour  DM:Merged Detour
       DE:Egress Detour  BI:Ingress Backup BM: Merged Backup BE:Egress Backup

```

Syntax: show mpls rsvp session [name <*session-name*> **] [ingress | transit | egress] [brief | detail | extensive | wide | include]**

The **ingress** option limits the display to Ingress RSVP sessions.

The **transit** option limits the display to Transit RSVP sessions.

The **egress** option limits the display to Egress RSVP sessions.

The **brief** option limits the display to only brief RSVP session information.

The **detail** option displays detailed RSVP session information.

The **extensive** option displays extensive RSVP session information.

The **wide option** displays display the full LSP name in a single line.

NOTE
The **show mpls rsvp session brief** command displays the same information as the **show mpls rsvp session** command.

Table 213 describes the output of the **show mpls rsvp session** command.

TABLE 213 Output from the **show mpls rsvp session** command

This field...	Displays...
Ingress RSVP	Information about ingress RSVP sessions.
Transit RSVP	Information about transit RSVP sessions.
Egress RSVP	Information about egress RSVP sessions.
To	Destination (egress LER) of the session.
From	Source (ingress LER) of the session; the source address for the LSP that was configured with the **from** command.
St	State can be UP or DOWN.
Style	The RSVP reservation style. Possible values are FF (Fixed Filter), WF (Wildcard Filter), or SE (Shared Explicit).
Lbl_In	The label for inbound packets on this LSP.
Lbl_Out	The label applied to outbound packets on this LSP.
Out_If	The outbound interface displays the egress interface for a session. When applicable, the outbound interface displays a VE interface specified by the <*vid*> variable.
LSPname	The name of the LSP.

The **show mpls rsvp session detail** command displays if the session is downstream only, as shown in the following example.

NOTE
The output display from the **show mpls rsvp session detail** command is applicable to PowerConnect B-MLXe devices.

```
NetIron#show mpls rsvp session detail
Codes: DI:Ingress Detour  DT:Transit Detour  DM:Merged Detour
       DE:Egress Detour  BI:Ingress Backup BM: Merged Backup BE:Egress Backup
       RP:Repaired Session BYI: Bypass Ingress

  RESV rcvfrom: 20.20.20.2      (e1/10          ) (MD5 OFF)
```

Syntax: show mpls rsvp session detail

The **show mpls rsvp session** command with the **detail** option displays the same information described in Table 213, as well additional fields described in Table 214.

TABLE 214 Output from the **show mpls rsvp session detail** command

This field...	Displays...
Time left in seconds	The amount of time left for the PATH or RESV refreshes.
Tspec	Traffic engineering specification for the LSP, including the max-rate (“peak”), mean rate (“rate”), number of burst bytes (“size”), maximum policed unit (“M”—or maximum packet size), and minimum policed unit (“m”—or minimum packet size).
Explicit path hop count	The number of explicit hops used in this RSVP session.
Received RRO count	The number of Record Route Objects received on this RSVP session.
PATH sentto	Address of the next LSR in the LSP, and the interface used to reach this LSR. When applicable, PATH sentto displays a VE interface specified by the <*vid*> variable.
PATH rcvfrom	Address of the previous LSR in the LSP, and the interface used to reach this LSR. If the session is downstream only, then it will be displayed. When applicable, PATH rcvfrom displays a VE interface specified by the <*vid*> variable.

The **extensive** option provides the contents of the history buffer for the last 20 RSVP events, as shown in the following example.

```
NetIron#show mpls rsvp session extensive
Codes: DI:Ingress Detour  DT:Transit Detour  DM:Merged Detour

```

The **show mpls rsvp session** command with the **extensive** option displays the same information described in Table 213, Table 214, Table 216 and Table 217, as well as a history of the last 20 RSVP events with each event containing the following information:

- Event index (used to provide the total number of events).
- Time stamp.
- File name and line number where the event is logged.
- Event description and extra information associated with each event. For repeated events, such as route query, the attempt count indicates the number of times the event has occurred.

The **show mpls rsvp session wide** command allows the user to display the full LSP name in a single line. Previously, a long LSP name (greater than 12 characters) was text-wrapped in multiple lines. Now, the full LSP name can be displayed in a single line as shown in the following example.

NOTE
The **show mpls rsvp session wide** command is supported on PowerConnect B-MLXe devices.

```
NetIron#show mpls rsvp session wide
Codes: DI:Ingress Detour  DT:Transit Detour  DM:Merged Detour
       DE:Egress Detour  BI:Ingress Backup BM: Merged Backup BE:Egress Backup
       RP:Repaired Session BYI: Bypass Ingress

Ingress RSVP:     4 session(s)
To              From                St Style Lbl_In  Lbl_Out Out_If LSPname
3.3.3.3         2.2.2.2             Up SE    -       3       e1/1   tunnel1

3.3.3.3         5.10.10.10(BI)      Dn -     -       -       e1/3   tunnelfromsanfranciscotonewyork
3.3.3.3         2.2.2.2(BYI)        Up SE    -       3       e1/3   bypasstunnelfromsfotonewyork

Transit RSVP:     0 session(s)
Egress RSVP:      0 session(s)
```

Syntax: show mpls rsvp session wide

The **include** option can be used with the **show mpls rsvp session wide** command to filter and display a specific RSVP session.

```
NetIron#show mpls rsvp session wide | include tunnelfromsanfranciscotonewyork
To              From                St Style Lbl_In  Lbl_Out Out_If LSPname
3.3.3.3         2.2.2.2             Up SE    -       3       e1/1   tunnelfromsanfranciscotonewyork
3.3.3.3         5.10.10.10(BI)      Dn -     -       -       e1/3   tunnelfromsanfranciscotonewyork
```

Syntax: show mpls rsvp session [**wide** [**| include** <*session-name*>]]

The <*session-name*> variable specifies the name of the RSVP session you want to display.

The **show mpls rsvp session wide** command can also be used with other RSVP session options, such as **backup**, **detour**, **ingress,** and so on to display the full LSP name in a single line. The following example displays the output from the **show mpls rsvp session backup wide** command.

NOTE
The **show mpls rsvp session wide backup** command and the **show mpls rsvp session backup wide** command can be used interchangeably. The output from both commands are the same.

```
NetIron#show mpls rsvp session backup wide
Codes: DI:Ingress Detour  DT:Transit Detour  DM:Merged Detour
       DE:Egress Detour  BI:Ingress Backup BM: Merged Backup BE:Egress Backup
       RP:Repaired Session BYI: Bypass Ingress

Ingress RSVP:     2 session(s)
To              From                St Style Lbl_In  Lbl_Out Out_If LSPname
3.3.3.3         2.2.2.2             Up SE    -       3       e1/1   tunnel1
3.3.3.3         5.10.10.10(BI)      Dn -     -       -       e1/3   tunnel1
3.3.3.3         2.2.2.2             Up SE    -       3       e1/1   tunnelfromsanfranciscotonewyork
3.3.3.3         5.10.10.10(BI)      Dn -     -       -       e1/3   tunnelfromsanfranciscotonewyork

Transit RSVP:     0 session(s)
Egress RSVP:      0 session(s)
```

Syntax: show mpls rsvp session wide [backup | bypass |detour | ingress | egress | transit | name | up | down]

The **backup** option limits the display to backup RSVP sessions.

The **bypass** option limits the display to bypass RSVP sessions.

The **detour** option limits the display to detour RSVP sessions.

The **ingress** option limits the display to ingress RSVP sessions.

The **egress** option limits the display to egress RSVP sessions.

The **transit** option limits the display to transit RSVP sessions.

The **name** option limits the display to the RSVP session name.

The **up** option limits the display to an active RSVP session.

The **down** option limits the display to an inactive RSVP session.

Displaying RSVP statistics

The device constantly gathers RSVP statistics. RSVP statistics are collected from the time RSVP is enabled, as well as from the last time the RSVP statistics counters were cleared.

To display RSVP statistics.

```
NetIron# show mpls rsvp statistics
                      Total                   Since last clear
 PacketType        Sent      Received        Sent      Received
  Path             4         4               4         4
  Resv             4         4               4         4
  PathErr          0         0               0         0
  ResvErr          0         0               0         0
  PathTear         0         0               0         0
  ResvTear         0         0               0         0
  ResvConf         0         0               0         0

 Errors                 Total                Since last clear
  Rcv pkt bad length    0                    0
  Rcv pkt unknown type  0                    0
  Rcv pkt bad version   0                    0
  Rcv pkt bad cksum     0                    0
  Memory alloc fail     0                    0
  Rcv pkt processing error:
    Path                0                    0
    Resv                0                    0
    PathErr             0                    0
    ResvErr             0                    0
    PathTear            0                    0
    ResvTear            0                    0
    ResvConf            0                    0
```

Syntax: show mpls rsvp statistics

The following table describes the output of the **show mpls rsvp statistics** command.

TABLE 215 Output from the show mpls rsvp statistics command

This field...	Displays...
Path	The number of Path messages sent and received. Path messages store information about the state of the path along the LSRs in the LSP.
Resv	The number of RESV messages sent and received. RESV messages include FF (Fixed Filter), WF (Wildcard Filter), and SE (Shared Explicit) messages.
PathErr	The number of PathErr messages sent and received.

TABLE 215 Output from the show mpls rsvp statistics command (Continued)

This field...	Displays...
ResvErr	The number of ResvErr messages sent and received.
PathTear	The number of PathTear messages sent and received. PathTear messages cause path states to be deleted.
ResvTear	The number of ResvTear messages sent and received. ResvTear messages cause reservation states to be deleted.
ResvConf	The number of reservation confirmation messages sent and received.
Rcv pkt bad length	The number of times a packet was not processed because it was the wrong length.
Rcv pkt unknown type	The number of times an RSVP packet was not processed because it was not one of the types defined in RFC 2205.
Rcv pkt bad version	The number of times a packet was not processed because it was an RSVP version other than 1
Rcv pkt bad cksum	The number of times a packet was not processed because of a bad RSVP checksum.
Memory alloc fail	The number of times a packet was not processed because RSVP memory allocation failed on the device.
Rcv pkt processing error	
Path	The number of Path messages received with a packet processing error.
Resv	The number of RESV messages received with a packet processing error.
PathErr	The number of PathErr messages received with a packet processing error.
ResvErr	The number of ResvErr messages received with a packet processing error.
PathTear	The number of PathTear messages received with a packet processing error.
ResvTear	The number of reservation confirmation messages received with a packet processing error.
ResvConf	The number of reservation confirmation messages received with a packet processing error.

To clear the RSVP statistics counters.

```
NetIron# clear mpls rsvp statistics
```

Syntax: clear mpls rsvp statistics

This command resets the counters listed under “Since last clear” for the **show mpls rsvp interface detail** and **show mpls rsvp statistics** commands.

Displaying information about OSPF-TE LSAs

To display information about OSPF-TE LSAs.

```
NetIron# show ip ospf database link-state opaque-area

Area ID         Type    LS ID           Adv Rtr         Seq(Hex)   Age   Cksum

       [6]   10000000 kbits/sec  [7]   10000000 kbits/sec
```

Syntax: show ip ospf database link-state opaque-area

Displaying MPLS Fast Reroute information

The following sections describe how to get information about MPLS Fast Reroute:

- "Displaying MPLS Fast Reroute LSP information"
- "Displaying RSVP session information"

Although the commands used to display MPLS and RSVP information are described in the PowerConnect *Configuration Guide*, new fields in the display present information for MPLS Fast Reroute. This section describes these new fields. For information about the other fields, see the equivalent display commands in this chapter.

Displaying MPLS Fast Reroute LSP information

To display MPLS Fast Reroute LSP information for a protected LSP that uses one-to-one (detour) backup.

```
NetIron# show mpls lsp frr_tunnel
LSP frr_tunnel, to 4.4.4.4
  From: 1.1.1.1, admin: UP, status: UP, tunnel interface: tnl4
  Times primary LSP goes up since enabled: 1
  Metric: 0, number of installed aliases: 0
  Maximum retries: 0, no. of retries: 0
  Pri. path: p1, active: yes
  Path specific attributes:
   Tunnel interface: tnl4, outbound interface: e1/1
   Setup priority: 7, hold priority: 0
   Max rate: 0 kbps, mean rate: 0 kbps, max burst: 0 bytes
   Constraint-based routing enabled: yes
   Tie breaking: random, hop limit: 0
   Explicit path hop counts: 3
    11.1.1.2 (S) -> 13.1.1.2 (S) -> 15.1.1.2 (S)
   Recorded routes:
    Protection codes: P: Local  N: Node  B: Bandwidth  I: InUse
    11.1.1.2 (PNB) -> 13.1.1.2 (PNB) -> 15.1.1.2
  Fast Reroute: one-to-one backup desired
   Bandwidth: 1024 kbps
   Detour LSP: UP, out-label: 1028, outbound interface: e1/3
```

Output that is shown in bold is unique to the **show mpls lsp** command when the LSP is configured for Fast Reroute by way of detour backup. The output is described in Table 216. Fields that are common to the output from the **show mpls lsp** command when an LSP is not configured for Fast Reroute are described in "Displaying signalled LSP status information" on page 1366.

TABLE 216 Output from the show mpls lsp command

This field...	Displays...
Fast Reroute	The method of Fast Reroute configured for this LSP. Currently only one-to-one backup is available.
Bandwidth	The bandwidth in Kilobits/sec for the bypass route. A value of 0 means that the detour route will use a best effort value for bandwidth.
Detour LSP	Indicates if the detour route is Up or Down.
out-label	The outbound label used when sending traffic over a detour LSP.
outbound interface	The physical interface on the router that is used for the detour route.

Displaying RSVP session information

To display RSVP Session information for a protected LSP.

NOTE
This section provides a brief example of the display from the **show mpls rsvp session** command. In the section titled "Example of MPLS Fast Reroute configuration" on page 1392, a detailed example of a network is given, and examples of output from the **show mpls rsvp session** command are displayed from each of the routers in the configuration, along with a descriptions of the relevant information in the displays.

```
NetIron# show mpls rsvp session name frr_tunnel
 Codes: DI:Ingress Detour  DT:Transit Detour  DM:Merged Detour
        DE:Egress Detour  RP:Repaired Session

```

For each RSVP-enabled interface, the following information is displayed

TABLE 217 Output from the show mpls rsvp interface detail command

This field...	Displays...
Explicit path hop count	The number of explicit hops used in this RSVP session.
Received RRO count	The number of Record Route Objects received on this RSVP session.
Detour Sent	Detour objects sent to the downstream node.
Detour Recvd	Detour objects received from the downstream node.
Number of PLR and Avoid Node ID pairs	Details of each detour object sent.

For each RSVP-enabled interface, the following information is displayed

TABLE 218 Output from the show mpls rsvp interface detail command

This field...	Displays...
DI	Ingress Detour. Specifies that this RSVP LSP is a detour LSP and it originates on this node (which is also a PLR of an FRR LSP).
DT	Transit Detour. Specifies that this RSVP LSP is a detour and is transiting this node.

TABLE 218 Output from the show mpls rsvp interface detail command (Continued)

This field...	Displays...
DM	Merged Detour. Specifies that this RSVP LSP is a detour LSP and it merges with another LSP (either a detour or a protected LSP) at this node (which is also a PLR for an FRR LSP).
DE	Egress Detour. Specifies that this RSVP LSP is a detour LSP and it is merging at an egress node of the protected path.
RP	Repaired Session. Specifies that this RSVP LSP is a protected LSP which has been locally repaired by the detour LSP on this node.

Syntax: show mpls rsvp session [brief | detail | *<session-name>* **}**

Using the **brief** option displays brief information about all of the RSVP sessions on the router.

Using the **detail** option displays detailed information about all of the RSVP sessions on the router.

If you specify a session name using the *<session-name>* variable, only the RSVP session specified is displayed in the detailed format.

Displaying MPLS configuration information

The **show mpls config** command lets you display all of the user-configured MPLS parameters. Using the **show mpls config** command, you can display all of the following global parameters configured on an PowerConnect router:

- ldp
- rsvp
- policy
- mpls-interface
- lsp
- path
- mpls vll
- mpls vpls
- vll local
- bypass-lsp

You can display the MPLS configuration information in any of the following modes brief, detail, and filters, as described in the sections that follow.

Displaying in the brief mode

In this mode, the information under router mpls policy, rsvp and ldp is displayed as shown in the following.

```
NetIron# show mpls config brief
router mpls
 policy
  admin-group m2 2
  traffic-eng isis level-1
  no propagate-ttl
  retry-limit 22
```

```
 rsvp
  refresh-interval 40

 ldp
  hello-timeout 12
  ka-interval 18
  advertise-labels for 5
  session 30.30.30.6 key 1 $!dZ@

end of MPLS configuration
```

Syntax: show mpls config brief

Displaying in the detail mode

In this mode, all of the MPLS global information and all of the MPLS configuration information are displayed as shown in the following.

```
NetIron# show mpls config
router mpls
 policy
  admin-group m2 2
  traffic-eng isis level-1
  no propagate-ttl
  retry-limit 22
 rsvp
  refresh-interval 40

 ldp
  hello-timeout 12
  ka-interval 18
  advertise-labels for 5
  session 30.30.30.6 key 1 $!dZ@

 mpls interfaces
  mpls-interface e1/1

end of MPLS configuration
```

Syntax: show mpls config

Displaying MPLS configuration information for a VE interface

The **show mpls config** command and **show running-config** command display specific MPLS interface configuration information. If MPLS is configured on a VE interface, the VE interface ID is displayed in the output of the **show mpls config** command and the **show running-config** command.

The **show mpls config interface** command allows you to display configuration information for an MPLS-enabled interface. You can specify a VE interface on the CLI. The following example displays CLI commands executed for interface ve 20.

```
NetIron#show mpls config interface ve 20
  mpls-interface ve 20
  ldp-enable
```

Syntax: show mpls config interface [ethernet <*slot/port*> **| pos** <*slot/port*> **| ve** <*vid*>**]**

The **ve** parameter allows you to limit the display to VE interface ID specified by the <*vid*> variable.

Displaying filtered MPLS configuration information

An individual MPLS interface, LSP, VLL, bypass, or VPLS can be specified in the **show mpls config** command to display configuration of the specified object only. The following example displays the MPLS configuration information for the LSP named “frr1”.

```
NetIron# show mpls config lsp frr1
 lsp frr1
  to 10.4.2.1
  cos 6
  ipmtu 1028
  traffic-eng max-rate 180 mean-rate 125
  metric 5
  shortcuts ospf
  frr
    bandwidth 80
    hop-limit 55
  enable
```

Syntax: **show mpls config lsp** <*lsp-name*> | **path** <*path-name*> | **interface** <*interface-name*> | **vll** <*vll-name*> | **vll-local** <*vll-local-name*> | **vpls** <*vpls-name*> | **bypass** <*bypass-name*>

The **lsp** option lets you limit the display to configuration information for the LSP specified by <*lsp-name*>.

The **path** option lets you limit the display to configuration information for the path specified by <*path-name*>.

The **interface** option allows you to limit the display to configuration information for a specified MPLS interface. The <*interface-name*> can be either a POS , Ethernet, or VE -enabled interface. A POS or Ethernet interface is specified by interface type and slot/port. For example, ethernet 3/2 specifies an Ethernet interface on port 2 of the Interface module installed in slot 3. The VE interface ID specified by the <*vid*> variable.

The **vll** option lets you limit the display to configuration information for the VLL specified by <*vll-name*>.

The **vll-local** option lets you limit the display to configuration information for the Local VLL specified by the <*vll-local-name*> variable.

The **vpls** option lets you limit the display to configuration information for the VLL specified by <*vpls-name*>.

The **bypass-lsp** option lets you limit the display to information for the bypass LSP specified by <*bypass-name*>.

When an option is used without a variable specified, the configuration parameters for the option are shown for all elements that match the option are displayed. For instance, in the following example the **lsp** option is used without a specified <*lsp-name*> variable. Consequently, the display contains the configuration information for all three LSPs configured on the router.

```
NetIron# mpls config lsp
lsp frr1
  to 10.4.2.1
  cos 6
  ipmtu 1028
  traffic-eng max-rate 180 mean-rate 125
  metric 5
  shortcuts ospf
  frr
```

```
    bandwidth 80
    hop-limit 55
  enable

lsp lsp13d
  to 10.3.3.2
  primary mu1_to_mu3
  cos 7
  traffic-eng max-rate 250 mean-rate 120
  no cspf
  enable

lsp lsp12d
  to 10.1.1.2
  cos 7
  traffic-eng max-rate 100 mean-rate 50
  enable
```

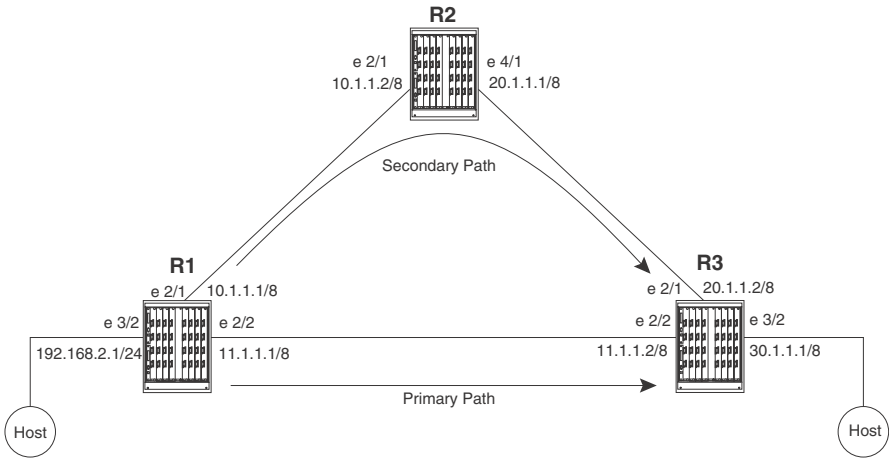
MPLS sample configurations

This section presents examples of typical MPLS configurations.

LSP with redundant paths

Figure 186 shows a signalled LSP configuration that has a primary and a secondary path. The destination for this LSP is 30.1.1.1. The primary path to this destination is through interface e 2/2, which has a direct link to interface e 2/2 on R3. If this link fails, the secondary path is established. The secondary path goes through R2.

FIGURE 186 LSP configuration with primary and secondary paths



Router R1 is the ingress LER for signalled LSP t3. Packets whose destination is 30.1.1.1 are assigned to this LSP. Two paths are configured, direct_conn and via_r2. Path direct_conn consists of a single strict node, 11.1.1.2, which is a directly connected interface on the destination LSR, R3.

Path via_r2 also consists of a single strict node, 10.1.1.2, a directly connected interface on R2. Since path via_r2 does not specify a node for R3, the hop between R2 and R3 is treated as a hop to a loose node. This means standard hop-by-hop routing is used to determine the path between R2 and R3.

Path direct_conn is the primary path for LSP t3, and path via_r2 is the secondary path. When the LSP is enabled, RSVP signalling messages set up path direct_conn. Packets assigned to this LSP use this path to reach the destination.

If path direct_conn fails, path via_r2 is set up, and packets assigned to LSP t3 then use path via_r2 to reach the destination. By default, the secondary path is not set up until the primary path fails. If you use the **standby** parameter in the configuration of the secondary path, both the primary and secondary paths are set up at the same time, although packets assigned to the LSP travel on the primary path only. If the primary path fails, the secondary path immediately carries the traffic.

Router R1

The following commands configure Router R1 in Figure 186.

```
NetIron(config)# router mpls
NetIron(config-mpls)# mpls-interface e 2/1 e 2/2
NetIron(config-mpls)# path direct_conn
NetIron(config-mpls-path)# strict 11.1.1.2
NetIron(config-mpls-path)# exit
NetIron(config-mpls)# path via_r2
NetIron(config-mpls-path)# strict 10.1.1.2
NetIron(config-mpls-path)# exit
NetIron(config-mpls)# lsp t3
NetIron(config-mpls-lsp)# to 30.1.1.1
NetIron(config-mpls-lsp)# primary direct
NetIron(config-mpls-lsp)# secondary via_r2
NetIron(config-mpls-lsp)# enable
NetIron(config-mpls-lsp)# exit
NetIron(config-mpls)# interface e 2/1
NetIron(config-e10000-2/1)# ip address 10.1.1.1 255.0.0.0
NetIron(config-e10000-2/1)# ip ospf area 1
NetIron(config-e10000-2/1)# exit
NetIron(config-mpls)# interface e 2/2
NetIron(config-e10000-2/2)# ip address 11.1.1.1 255.0.0.0
NetIron(config-e10000-2/2)# ip ospf area 1
NetIron(config-e10000-2/2)# exit
NetIron(config-mpls)# interface e 3/2
NetIron(config-if-e100-3/2)# ip address 192.168.2.1 255.255.255.0
NetIron(config-if-e100-3/2)# exit
NetIron(config)# router ospf
NetIron(config-ospf-router)# area 1
NetIron(config-ospf-router)# exit
```

Router R2

In the configuration in Figure 186, Router R2 serves as a transit LSR for path via_r2. Since path via_r2 is the secondary path for the LSP, it will be used only if the primary path fails.

```
NetIron(config)# router mpls
NetIron(config-mpls)# mpls-interface e 2/1 e 4/1
```

```
NetIron(config-mpls)# interface e 2/1
NetIron(config-e10000-2/1)# ip address 10.1.1.2 255.0.0.0
NetIron(config-e10000-2/1)# ip ospf area 1
NetIron(config-e10000-2/1)# exit
NetIron(config-mpls)# interface e 4/1
NetIron(config-e10000-4/1)# ip address 20.1.1.1 255.0.0.0
NetIron(config-e10000-4/1)# ip ospf area 1
NetIron(config-e10000-4/1)# exit
NetIron(config)# router ospf
NetIron(config-ospf-router)# area 1
NetIron(config-ospf-router)# exit
```

Router R3

In the configuration in Figure 186, Router R3 is the egress LER for LSP t3.

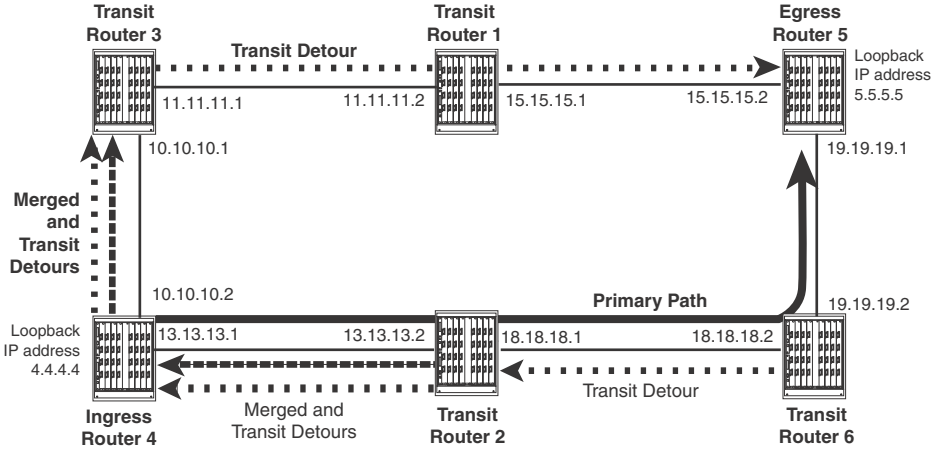
```
NetIron(config)# router mpls
NetIron(config-mpls)# mpls-interface e 2/1 e 2/2
NetIron(config-mpls)# interface pos 2/1
NetIron(config-e10000-2/1)# ip address 20.1.1.2 255.0.0.0
NetIron(config-e10000-2/1)# ip ospf area 1
NetIron(config-e10000-2/1)# exit
NetIron(config-mpls)# interface e 2/2
NetIron(config-e10000-2/2)# ip address 11.1.1.2 255.0.0.0
NetIron(config-e10000-2/2)# ip ospf area 1
NetIron(config-e10000-2/2)# exit
NetIron(config-mpls)# interface e 3/2
NetIron(config-if-e100-3/2)# ip address 30.1.1.1 255.0.0.0
NetIron(config-if-e100-3/2)# exit
NetIron(config)# router ospf
NetIron(config-ospf-router)# area 1
NetIron(config-ospf-router)# exit
```

Example of MPLS Fast Reroute configuration

This example describes an MPLS Fast Reroute Loop Configuration. It provides the configuration required on Ingress Router 4 and examples of the **show mpls rsvp session** displays for all of the routers in the configuration. These examples show how the MPLS Fast Reroute configuration of an LSP affects the RSVP session on each of the routers in the configuration.

As illustrated in Figure 187 and described in the configuration example that follows, Ingress Router 4 is configured with a strict Label Switch Path A to Egress Router 5. In this configuration, if the path is broken between Ingress Router 4 and Egress Router 5, Transit Routers 2 or 6 will take a detour path back through Ingress Router 4 and continue through Transit Routers 3 and 1 to reach Egress Router 5.

FIGURE 187 MPLS Fast Reroute Loop configuration



The following is the MPLS Fast Reroute configuration for Ingress Router 4.

```
Router4(config)# interface loopback 1
Router4(config-lbif-1)# ip address 4.4.4.4/24
Router4(config)# interface ethernet 2/1
Router4(config-if-e1000-2/1)# ip address 10.10.10.2/24
Router4(config)# interface ethernet 2/9
Router4(config-if-e1000-2/9)# ip address 13.13.13.1/24
Router4(config)# router mpls
Router4(config-mpls)# mpls-interface ethernet 2/1 ethernet 2/9
Router4(config-mpls)# path a
Router4(config-mpls-path-a)# strict 2.2.2.2
Router4(config-mpls-path-a)# strict 6.6.6.6
Router4(config-mpls)# lsp 1
Router4(config-mpls-lsp-1)# to 5.5.5.5
Router4(config-mpls-lsp-1)# primary-path a
Router4(config-mpls-lsp-1)# frr
```

Displaying RSVP session information for example network

The **show mpls rsvp session** command, provides information regarding the primary and detour routes in an MPLS RSVP Fast Reroute enabled network. Display examples are provided for the following routers in the configuration shown in Figure 187:

- Transit Router 6
- Transit Router 2
- Ingress Router 4
- Transit Router 3
- Transit Router 1
- Egress Router 5

The following examples include displays for the **show mpls rsvp session** and **show mpls rsvp session detail** commands. For a general description of the command and its output refer to "Displaying RSVP session information" on page 1384.

The Transit Router 6 display

The following display examples are from Transit Router 6. Displays are shown for the **show mpls rsvp session** and **show mpls rsvp session detail** commands.

Both displays show two paths from Ingress Router 4 at Loopback IP address 4.4.4.4. to Egress Router 5 at Loopback IP address 5.5.5.5. The (DI) path is an Ingress Detour path, and the path without a code is a protected path. The DI path is the detour path that is taken if Transit Router 6 is unable to use the primary path to Egress Router 5.

```
Router6# show mpls rsvp session
Codes: DI:Ingress Detour  DT:Transit Detour  DM:Merged Detour
       DE:Egress Detour  RP:Repaired Session
Ingress RSVP:     0 session(s)
Transit RSVP:     1 session(s)
To              From                St    Style Lbl_in  Lbl_out  LSPname
5.5.5.5         4.4.4.4(DI)         Up    SE    1024    1025     1
5.5.5.5         4.4.4.4             Up    SE    1024    3        1

Egress RSVP:      0 session(s)
```

The following example displays the output from Transit Router 6 using the **show mpls rsvp session detail** command. This command provides additional details about the paths described in the output from the **show mpls rsvp session** command.

For the DI path, one PLR and Avoid Node ID pair is shown labeled [1]. In [1], the Point of Local Repair (PLR) is at IP Address 19.19.19.2 which is an interface on Transit Router 6 and the Avoid Node is IP address 0.0.0.0. The "Explicit path hop count" field indicates that there are five hops on this path from this router to the egress to the path at routers with the following IP addresses 18.18.18.1 (Transit Router 2), 13.13.13.1 (Ingress Router 4), 10.10.10.1 (Transit Router 3), 11.11.11.2 (Transit Router 1) and 15.15.15.2 (Egress Router 5) .

For the primary path, the "Explicit path hop count" field indicates that there is one hop on this path from this router to the egress to the path to the router at IP address 19.19.19.1 (Egress Router 5). The "Fast Reroute" field indicates that the primary path has been configured for one-to-one backup.

```
Router6# show mpls rsvp session detail
Codes: DI:Ingress Detour  DT:Transit Detour  DM:Merged Detour
       DE:Egress Detour  RP:Repaired Session
Ingress RSVP:     0 session(s)
Transit RSVP:     1 session(s)
To              From                St    Style Lbl_in  Lbl_out  LSPname

The Transit Router 2 display

The following display examples are from Transit Router 2. Displays are shown for the **show mpls rsvp session** and **show mpls rsvp session detail** commands.

As for Transit Router 2, the displays show an Ingress Detour (DI) path, and a path without a code which identifies a protected path. In addition, a Merged Detour (DM) path is shown. The DM path is the detour path merged from Transit Router 6. All three paths are shown from Ingress Router 4 at Loopback IP address 4.4.4.4 to Egress Router 5 at Loopback IP address 5.5.5.5.

```
Router1# show mpls rsvp session
Codes: DI:Ingress Detour  DT:Transit Detour  DM:Merged Detour
       DE:Egress Detour  RP:Repaired Session
Ingress RSVP:     0 session(s)
Transit RSVP:     1 session(s)
To               From                St    Style Lbl_in  Lbl_out  LSPname
5.5.5.5          4.4.4.4(DI)         Up    SE    1024    1024     1
5.5.5.5          4.4.4.4             Up    SE    1024    1024     1
5.5.5.5          4.4.4.4(DM)         Up    SE    1025    1024     1

Egress RSVP:      0 session(s)
```

The following example displays the output from Transit Router 2 using the **show mpls rsvp session detail** command. This command provides additional details about the paths described in the output from the **show mpls rsvp session** command.

For the DI path, two PLR and Avoid Node ID pairs are shown labeled [1] and [2]. In [1] the Point of Local Repair (PLR) is at IP Address 18.18.18.1 which is the interface to the primary path on Transit Router 2 and the Avoid Node is IP address 18.18.18.2 on Transit Router 6. In [2] the Point of Local Repair (PLR) is at IP Address 19.19.19.2 on Transit Router 6 and the Avoid Node is IP address 0.0.0.0. The "Explicit path hop count" field indicates that there are four hops on this path from this router to the egress of the path at routers with the following IP addresses 13.13.13.1 (Ingress Router 4), 10.10.10.1 (Transit Router 3), 11.11.11.2 (Transit Router 1) and 15.15.15.2 (Egress Router 5).

For the DM path, one PLR and Avoid Node ID pair is shown labeled [1]. In [1] the Point of Local Repair (PLR) is at IP Address 19.19.19.2 which is an interface on Transit Router 6 and the Avoid Node is IP address 0.0.0.0.

For the primary path, the “Explicit path hop count” field indicates that the path has two hops from this router to the egress to the path at routers with the following IP addresses 18.18.18.2 (Transit Router 6) and 19.19.19.1 (Egress Router 5). The “Fast Reroute” field indicates that the primary path has been configured for one-to-one backup.

The Ingress Router 4 display

The following display examples are from Ingress Router 4. Displays are shown for the **show mpls rsvp session** and **show mpls rsvp session detail** commands.

Like the display for Transit Router 2, the displays show an Ingress Detour (DI) path, a path without a code which identifies a protected path and Merged Detour (DM) path. The DM path is the detour path merged from Transit Routers 2 and 6. All three paths are shown from Ingress Router 4 at IP address Loopback 4.4.4.4 to Egress Router 5 at IP address Loopback 5.5.5.5. In the case of the DM path, a reroute at either Transit Router 2 or 6 will send traffic that had begun at Ingress Router 4 back through it, and forward through Transit Routers 3 and 1 to the ultimate destination at Egress Router 5.

```
Router4# show mpls rsvp session
Codes: DI:Ingress Detour  DT:Transit Detour  DM:Merged Detour
       DE:Egress Detour  RP:Repaired Session
Ingress RSVP:     1 session(s)
To              From                St    Style Lbl_in  Lbl_out  LSPname
5.5.5.5         4.4.4.4(DI)         Up    SE    -       1028     1
5.5.5.5         4.4.4.4(DM)         Up    SE    1024    1028     1
5.5.5.5         4.4.4.4             Up    SE    -       1024     1

Transit RSVP:     0 session(s)
Egress RSVP:      0 session(s)
```

The following example displays the **show mpls rsvp session detail** output for Ingress Router 4. This command provides additional details about the paths described in the output from the **show mpls rsvp session** command.

For the DI path, three PLR and Avoid Node ID pairs are shown labeled [1], [2] and [3]. In [1] and [2] the Point of Local Repair (PLR) is at IP Address 13.13.13.1 which is the interface to the primary path on Ingress Router 4. The Avoid Node for pair [1] is IP address 13.13.13.2 on Transit Router 2 and the Avoid Node for pair [2] is IP address 18.18.18.2 on Transit Router 6. In [3] the Point of Local Repair (PLR) is at IP Address 18.18.18.1 which is the interface to the primary path on Ingress Router 2 and the Avoid Node for pair [3] is IP address 18.18.18.2 on Transit Router 6. The "Explicit path hop count" field indicates that there are three hops on the path from this router to the egress of the path at routers with the following IP addresses 10.10.10.1 (Transit Router 3), 11.11.11.2 (Transit Router 1) and 15.15.15.2 (Egress Router 5).

For the DM path, one PLR and Avoid Node ID pair is shown labeled [1]. In [1] the Point of Local Repair (PLR) is at IP Address 18.18.18.1 which is the interface to the primary path on Ingress Router 2 and the Avoid Node is IP address 18.18.18.2 on Transit Router 6.

For the primary path, the "Explicit path hop count" field indicates that there are three hops on this path from Ingress Router 4 to the egress to the path at routers with the following IP addresses 13.13.13.2 (Transit Router 2), 18.18.18.2 (Transit Router 6) and 19.19.19.1 (Egress Router 5). The "Fast Reroute" field indicates that the primary path has been configured for one-to-one backup.

The Transit Router 3 display

The following display examples come from Transit Router 3. Displays are shown for the **show mpls rsvp session** and **show mpls rsvp session detail** commands.

The display for Transit Router 3 shows a Transit Detour (DT) path. The DT path is the detour path that is an alternative to the primary path configured on Ingress Router 4 from itself to Egress Router 5. This detour path, shown from Ingress Router 4 at Loopback IP address 4.4.4.4 to Egress Router 5 at Loopback IP address 5.5.5.5, is only used if a link or router fails between the source and destination of the primary path.

```
Router3# show mpls rsvp session
Codes: DI:Ingress Detour  DT:Transit Detour  DM:Merged Detour
       DE:Egress Detour  RP:Repaired Session
Ingress RSVP:     0 session(s)
Transit RSVP:     1 session(s)
To              From             St    Style Lbl_in  Lbl_out  LSPname
5.5.5.5         4.4.4.4(DT)         Up    SE    1028    1028     1
Egress RSVP:      0 session(s)
```

The following example displays the output from Transit Router 3 using the **show mpls rsvp session detail** command. This command provides additional details about the paths described in the output from the **show mpls rsvp session** command.

For the DT path, the "Explicit path hop count:" field shows that two hops exist from this router to the egress of the path at routers with the following at IP addresses: 11.11.11.2 (Transit Router 1) and 15.15.15.2 (Egress Router 5).

```
Router3# show mpls rsvp session detail
Codes: DI:Ingress Detour  DT:Transit Detour  DM:Merged Detour
       DE:Egress Detour  RP:Repaired Session
Ingress RSVP:     0 session(s)
Transit RSVP:     1 session(s)
To              From                St    Style Lbl_in  Lbl_out  LSPname
5.5.5.5         4.4.4.4(DT)         Up    SE    1028    1028     1
  Time left in seconds (PATH refresh: 2, ttd: 141
                        RESV refresh: 25, ttd: 154)
  Tspec: peak 0 kbps rate 0 kbps size 0 bytes m 20 M 1500
  Explicit path hop count: 2
   11.11.11.2 (S) -> 15.15.15.2 (S)
  Received RRO count: 2
   Protection codes: P: Local  N: Node  B: Bandwidth  I: InUse
   11.11.11.2 -> 15.15.15.2
  PATH rcvfrom: 10.10.10.2      (e12/1         ) (MD5 OFF)
  PATH sentto:  11.11.11.2      (e11/18        ) (MD5 OFF)
  RESV rcvfrom: 11.11.11.2      (e11/18        ) (MD5 OFF)
Egress RSVP:      0 session(s)
```

The Transit Router 1 display

The following display examples are from Transit Router 1. Displays are shown for the **show mpls rsvp session** and **show mpls rsvp session detail** commands.

The display for Transit Router 1 shows a Transit Detour (DT) path.The DT path is the detour path that is an alternative to the primary path configured on Ingress Router 4 from Ingress Router 4 to Egress Router 5. This detour path shown from Ingress Router 4 at Loopback IP address 4.4.4.4 to Egress Router 5 at Loopback IP address 5.5.5.5 is only used if there is a failed link or router between the source and destination of the primary path.

```
Router1# show mpls rsvp session
Codes: DI:Ingress Detour  DT:Transit Detour  DM:Merged Detour
       DE:Egress Detour  RP:Repaired Session
Ingress RSVP:     0 session(s)
Transit RSVP:     1 session(s)
To              From             St    Style Lbl_in Lbl_out LSPname
5.5.5.5         4.4.4.4(DT)         Up    SE    1028    3        1
Egress RSVP:      0 session(s)
```

The following example displays the output from Transit Router 1 using the **show mpls rsvp session detail** command. This option provides additional details about the paths described in the output from the **show mpls rsvp session** command

For the DT path, the "Explicit path hop count" field indicates that there is one hop from this router to the egress of the path at the router at IP address 15.15.15.2 (Egress Router 5).

```
Router3# show mpls rsvp session detail
Ingress RSVP:     0 session(s)
Transit RSVP:     1 session(s)
To               From                St    Style Lbl_in  Lbl_out  LSPname

```

The Egress Router 5 display

The following display examples are from Egress Router 5. Displays are shown for the **show mpls rsvp session** and **show mpls rsvp session detail** commands.

The display for Egress Router 5, shows an Egress Detour (DE) path and a path without a code that identifies a protected path. Both paths are shown from Ingress Router 4 at Loopback IP address 4.4.4.4 to Egress Router 5 at Loopback IP address 5.5.5.5. The primary path traverses Transit Routers 2 and 6. In the case of the DE path, a reroute sends traffic through Transit Routers 3 and 1.

```
Router4# show mpls rsvp session
Codes: DI:Ingress Detour  DT:Transit Detour  DM:Merged Detour
       DE:Egress Detour  RP:Repaired Session
Ingress RSVP:     0 session(s)
Transit RSVP:     0 session(s)
Egress RSVP:      1 session(s)
To               From                St    Style Lbl_in  Lbl_out  LSPname
5.5.5.5          4.4.4.4(DE)         Up    SE    3       0        1
5.5.5.5          4.4.4.4             Up    SE    3       0        1
```

The following example displays the output from Egress Router 5 using the **show mpls rsvp session detail** command. This command provides additional details about the paths described in the output from the **show mpls rsvp session** command.

For the DE path, two PLR and Avoid Node ID pairs are shown labeled [1] and [2]. In both the Point of Local Repair (PLR) is at IP Address 13.13.13.1 which is the interface to the primary path on Ingress Router 4. The Avoid Node for pair [1] is IP address 13.13.13.2 on Transit Router 2 and the Avoid Node for pair [2] is IP address 18.18.18.2 on Transit Router 6.

The "Fast Reroute" field indicates that the primary path has been configured for one-to-one backup.

There is no "Explicit path hop count" field for either route because Egress Router 5 is the destination of the path.

```
Router5# show mpls rsvp session detail
Codes: DI:Ingress Detour  DT:Transit Detour  DM:Merged Detour
       DE:Egress Detour  RP:Repaired Session
Ingress RSVP:     0 session(s)
Transit RSVP:     0 session(s)
```

```
Egress RSVP:      1 session(s)

```

Examples of MPLS bypass LSP

This section contains **show** command output for protected LSPs and bypass LSPs. The section for bypass LSP shows information for a bypass configured on an Ethernet interface and a bypass configured on a LAG.

A **show mpls lsp** or **show mpls bypass-lsp** type of command must be entered at the ingress node of the LSP or bypass LSP, and the **show mpls rsvp session name** type of command should be used at transit nodes.

The subsections are separated into the following components:

- An interface with a bypass LSP protecting the interface, "Displaying an interface with bypass protection"
- Protected LSP configuration in an RSVP session, "Protected LSP shown in RSVP session"
- Bypass LSP shown in an RSVP session, "Bypass LSP in an RSVP session"
- An LSP that is requesting facility backup, "Displaying an LSP configured for bypass protection"
- Information when the bypass LSP is active, "A protected LSP while the bypass LSP is active"

Displaying an interface with bypass protection

This example shows that Ethernet interface 4/15 has one bypass LSP mlxe4-by. Bypass LSP mlxe4-by has, therefore, recorded at least this interface (and likely others) in its list of exclude interfaces. (Similarly, an interface can have multiple bypass LSPs protecting it. For example, the LSPs that traverse an interface might have destinations that make a single merge point impossible, so multiple bypass LSPs would be needed in this case to support different LSPs.).

```
NetIron#show mpls interface ethernet 4/15
e4/15
  Admin: Up  Oper: Up
  Maximum BW: 1000000 kbps, maximum reservable BW: 1000000 kbps

  Configured Protecting bypass lsps:
mlxe2(UP)
```

Syntax: show mpls interface <*name*>

Displaying bypass LSPs

This section has a variety of bypass LSP displays. The first example shows the running configuration. This output shows the name of the bypass LSP, its destination interface, the exclude interface e1/1 (of the protected LSP), and that the bypass LSP is enabled.

Syntax: show mpls bypass-lsp

To display any bypass LSPs that exist on the router, use the following command.

```
NetIron(config-if-e1000-2/15)#show mpls bypass-lsp
Note: LSPs marked with * are taking a Secondary Path
                              Admin Oper Tunnel   Up/Dn Retry Active
Name           To             State State Intf     Times No.   Path

    [4] 2000    [5] 2000    [6] 2000    [7] 2000
```

Syntax: show mpls bypass-lsp <*lsp_name*>

The <*lsp_name*> variable specifies the name of the LSP you want to display.

To display the detailed bypass LSP configuration under the router MPLS mode, enter the **show mpls bypass-lsp detail** command. The output from the **show mpls bypass-lsp detail** command is enhanced to display a VE interface on the CLI as shown in the following example.

```
NetIron(config-mpls)#show mpls bypass-lsp detail
LSP to10_bp, to 128.128.128.28
  From: 125.125.125.1, admin: UP, status: UP, tunnel interface(primary
path): tnl2
  Times primary LSP goes up since enabled: 1
  Metric: 0, number of installed aliases: 0
  Maximum retries: 0, no. of retries: 0
  Pri. path: NONE, up: yes, active: yes
  Setup priority: 7, hold priority: 0
  Max rate: 0 kbps, mean rate: 0 kbps, max burst: 0 bytes
  Constraint-based routing enabled: yes
  Tie breaking: random, hop limit: 0
  Active Path attributes:
   Tunnel interface: tnl2, outbound interface: ve 20
   Tunnel index: 3, Tunnel instance: 1 outbound label: 3
   Path calculated using constraint-based routing: yes
   Path calculated using interface constraint: no
   Explicit path hop count: 1
    90.90.90.28 (S)
   Recorded routes:
    Protection codes: P: Local  N: Node  B: Bandwidth  I: InUse
    90.90.90.28
  exclude interface(s): ve 54
```

Syntax: show mpls bypass-lsp detail

The **show mpls bypass-lsp wide** command allows the user to display the full bypass LSP name in a single line. Previously, a long LSP name (greater than 12 characters) was text-wrapped in multiple lines. Now, the full LSP name can be displayed in a single line as shown in the following example.

NOTE
The **show mpls bypass-lsp wide** command is supported on PowerConnect B-MLXe devices.

```
NetIron(config)#show mpls bypass-lsp wide
Note: LSPs marked with * are taking a Secondary Path
                                                        Admin Oper  Tunnel   Up/Dn Retry Active
Name                                                    To              State State Intf     Times No.   Path
by1                                                     3.3.3.3         UP    UP    tnl1     1     0     --
by2                                                     3.3.3.3         UP    UP    tnl2     1     0     --
bypasstunnelfromsanfranciscotonewyork                   3.3.3.3         UP    UP    tnl5     1     0
pathfromsanfrancisotonewyourk
```

Syntax: show mpls bypass-lsp wide

The **include** option can be used with the **show mpls bypass-lsp wide** command to filter and display specific bypass LSP name.

```
NetIron#show mpls bypass-lsp wide | include bypasstunnelfromsanfranciscotonewyork
                                                         Admin Oper Tunnel   Up/Dn Retry Active
Name                                                     To            State State Intf    Times No. Path
bypasstunnelfromsanfranciscotonewyork                    3.3.3.3         UP   UP   tnl5     1     0
pathfromsanfrancisotonewyourk
```

Syntax: show mpls bypass-lsp [**wide** [**| include** <*lsp_name*>]]

The <*lsp_name*> variable specifies the name of the LSP you want to display.

Bypass LSP in an RSVP session

Use the **show mpls rsvp session** command to display bypass LSP mlxe1-by. This example shows bypass LSP traversing a LAG, and the BYI field shows this is the bypass ingress.

```
NetIron#show mpls rsvp sess name mlxe1-by
Codes: DI:Ingress Detour DT:Transit Detour DM:Merged Detour
       DE:Egress Detour BI:Ingress Backup BM: Merged Backup BE:Egress Backup
       RP:Repaired Session BYI: Bypass Ingress

Configuring Label Distribution Protocol (LDP) 31

LDP overview

The following list displays the Label Distribution Protocol (LDP) features supported by PowerConnect B-MLXe:

- LDP
- LDP ECMP for transit LSR
- LDP Hello Interval and Hold Timeout Values
- LDP Message Authentication
- New encryption code for passwords, authentication keys, and community strings
- Option of FEC Type for Auto-discovered VPLS Peers
- MPLS Signalling: LDP support
- Resetting LDP neighbor
- LDP over RSVP (for transit LSR only)
- Displaying the LDP version
- Displaying Information about Specified LDP-Enabled Interfaces
- Displaying LDP FEC information
- Displaying information for a specified LDP FEC type
- Displaying LDP FEC summary information
- Displaying LDP FEC VC information
- Displaying information for a specified LDP FEC VC
- Displaying LDP Neighbor Connection Information
- Displaying the LDP Packet Statistics

The devices support Label Distribution Protocol (LDP) for setting up non-traffic-engineered tunnel LSPs in an MPLS network. LDP is described in RFC 3036.

When used to create tunnel LSPs, LDP allows a set of destination IP prefixes (known as a Forwarding Equivalence Class or FEC) to be associated with an LSP. Each LSR establishes a peer relationship with its neighboring LDP-enabled routers and exchanges label mapping information. This label mapping information is stored in an LDP database on each LSR. When an LSR determines that one of its peers is the next hop for a FEC, it uses the label mapping information from the peer to set up an LSP that is associated with the FEC. It then sends label mapping information to its upstream peers, allowing the LSP to extend across the MPLS network.

The devices advertise their loopback addresses to their LDP peers as a 32-bit “prefix” type FEC. When an LSR installs a label for a FEC, it also creates an MPLS tunnel route, which is then made available to routing applications. This allows each router to potentially be an ingress LER for an LSP whose destination is the device's loopback address.

The result of an LDP configuration is a full mesh of LSPs in an MPLS network, with each LDP-enabled router a potential ingress, transit, or egress LSR, depending on the destination.

The implementation supports the following aspects of LDP

Liberal label retention – Each LSR sends its peers Label Mapping messages, which map a label to a FEC. Peer LSR receiving these messages retain all of the mappings, even though they may not actually be used for data forwarding.

Unsolicited label advertisement – The LSR sends Label Mapping messages to its LDP peers even though they did not explicitly request them.

Ordered label distribution – The LSR sends a Label Mapping message to its peers only when it knows the next hop for a FEC, or is itself an egress LER for the FEC. If an LSR does not know the next hop for a FEC, and is not an egress LER for the FEC, it waits until a downstream LSR sends it a Label Mapping message for the FEC. At this point, the LSR can send Label Mapping messages for the FEC to its peers. This allows label mappings to be distributed, in an orderly fashion, starting from the egress LER and progressing upstream.

The Multi-Service IronWare software the LDP label space ID has a default value of zero which improves interoperability with routers from other venders. Also, to provide backward compatibility with Multi-Service IronWare software previous versions, a command lets you change the LDP label space ID value to 1 as described in "Resetting LDP neighbors" on page 1421.

Configuring LDP on an interface

To use LDP, a loopback address (with a 32-bit mask) ***must*** be configured on the LSR. The first loopback address configured on the device is used in its LDP identifier. If the loopback address used in the LDP identifier is removed, all LDP functions on the LSR will be shut down. LDP sessions between the LSR and its peers will be terminated, and LDP-created tunnels will be removed. If other loopback interfaces are configured on the device, the lowest-numbered loopback address will then be used as a new LDP identifier. LDP sessions and tunnels will be set up using this new LDP identifier.

To configure LDP on an interface, enter commands such as the following.

```
NetIron(config)# router mpls
NetIron(config-mpls)# mpls-interface e 1/2
NetIron(config-mpls)# ldp-enable
```

Syntax: [no] ldp-enable

NOTE
You should enable LDP on the same set of interfaces that IGP routing protocols such as OSPF and IS-IS are enabled.

Configuring an option of FEC type for auto-discovered VPLS peers

By default, Dell uses FEC 129 to send the VC label binding for auto-discovered VPLS peers. There are mixed environments where VPLS static configured peers and auto-discovered peers exist. In these environments, the following VPLS command allows you to configure FEC 128 for all VPLS. Enter the command such as the following.

```
NetIron(config)# router mpls
NetIron(config-mpls)# ldp
NetIron(config-mpls-ldp)# fec-128-for-auto-disc-peers
```

Syntax: [no] fec-128-for-auto-disc-peers

The default value is FEC 129.

Using the **no** option returns a configuration that was previously changed from the default value back to the default value.

NOTE
You must reload your system for this command to take effect.

LDP ECMP for transit LSR

NOTE
LDP ECMP for transit LSR is supported only on PowerConnect B-MLXe devices.

LDP Equal-Cost Multi-Path (ECMP) for transit LSR provides ECMP support for transit routers on an LDP LSP. The LDP LSP tunnel at ingress will continue to be a single ECMP path.

ECMP programming for LDP transit LSP creates a set of ECMP paths on the forwarding plane at any transit router. LDP LSPs transit traffic is load balanced using programmed ECMP. The number of ECMP paths that are used depends on the number of eligible paths that are available, and the maximum number of LDP ECMP paths configured by the user. The number of available paths sent to LDP are controlled by the Routing Table Manager (RTM) which is limited by IP load sharing. LDP will also enable its own load sharing limit. The lesser of the two load sharing limits will form the maximum number of ECMP paths that can be programmed on forwarding plane. For more information on configuring the maximum number of LDP ECMP paths, refer to "Changing the maximum number of LDP ECMP paths" on page 1414.

When new ECMP paths are added, or existing paths are deleted from a set of eligible ECMP paths, MPLS forwarding decides if these changes will lead to a different set of paths to be used for LDP LSP, ingress tunnel, or transit LSP. If a different set of paths is used, updates are sent to the forwarding plane. MPLS only sends an update to the forwarding plane if there is a change to the set of programmed paths. MPLS always sends the complete set of ECMP paths to the forwarding plane. If the user changes the load sharing configuration, updates are also sent to the forwarding plane. FEC updates are only generated if the new load sharing value is different from the set of ECMP paths programmed in the forwarding plane.

NOTE
LDP ECMP is not supported at the ingress router.

The ingress LDP LSP can be different from the transit LSP for the same FEC. If all ECMP paths provided by the RTM are using LDP tunneling enabled for RSVP shortcut LSP(s), then the ingress LDP tunnel is not created.

Changing the maximum number of LDP ECMP paths

To change the maximum number of LDP ECMP paths, enter the following commands under the router MPLS mode.

```
NetIron(config-mpls)# ldp
NetIron(config-mpls-ldp)# load-sharing 4
```

Syntax: load-sharing <*num*>

The <*num*> variable specifies the maximum number of LDP ECMP paths. Enter a number from 1 through 8. The default value is 1. To return to the default maximum number of LDP ECMP paths, use the **no** form of the command.

The load sharing configuration is displayed in the output of the **show mpls ldp** command.

NOTE
The configuration for load sharing is displayed only if the configured value is different from the default value.

```
NetIron#show mpls ldp
Label Distribution Protocol version 1
LSR ID: 125.125.125.1, using Loopback 1 (deleting it will stop LDP)
Hello interval: Link 5 sec, Targeted 15 sec
Hold time value sent in Hellos: Link 15 sec, Targeted 45 sec
Keepalive interval: 6 sec, Hold time multiple: 6 intervals
load-sharing 4
```

Syntax: show mpls ldp

The load sharing configuration can also be displayed in the output of the **show mpls config** command, as shown in the following example.

```
NetIron#show mpls config
router mpls
 policy
  no propagate-ttl
 ldp
  load-sharing 4
```

Syntax: show mpls config

MPLS OAM support for LDP ECMP

MPLS OAM support for traceroute at any transit router returns the list of labels used at that transit router. However, traceroute is not able to exercise all ECMP paths. The forwarding plane selects one ECMP path to forward OAM packets. All traversed labels that were returned at each transit router are displayed at the NetIron router originating the traceroute.

Display changes to commands for LDP ECMP

The output from the **show mpls forwarding** command has been updated to display all ECMP paths programmed in the forwarding plane.

NOTE
The In-lbl field will not display a value for ingress LDP LSP.

```
NetIron#show mpls forwarding
Total number of MPLS forwarding entries: 7
   Dest-prefix     In-lbl  In-intf Out-lbl Out-intf   Sig  Next-hop
 1 21.21.21.21/32                    3        e2/3    L    80.80.80.1
 2 21.21.21.21/32  1026              3        e2/3    L    80.80.80.1
 3 11.11.11.11/32                  1028       ve4     L    90.90.90.25
 4 11.11.11.11/32  1029            1028       ve4     L    90.90.90.25
 5 11.11.11.11/32  1029              3        tnnl1   L    11.11.11.11
 6 11.11.11.11/32  1029              3        tnnl2   L    11.11.11.11
 7 11.11.11.11/32  1029              3        tnnl3   L    11.11.11.11
```

Syntax: show mpls forwarding

The output from the **show mpls ldp fec prefix** command has been updated to display all available ECMP mappings on outgoing interfaces, and their corresponding next hops. When the outgoing interface is an RSVP tunnel, the RSVP LSP name is displayed as the outgoing interface in the out_if field. The following example displays multiple next hops created in LDP from ECMP.

```
NetIron#show mpls ldp fec prefix 11.11.11.11
FEC_CB: 0x362eee00, idx: 14, type: 2, pend_notif: None
 State: current, Ingr: Yes, Egr: No, UM Dist. done: Yes
 Prefix: 11.11.11.11/32
 next_hop: 90.90.90.25, out_if: ve4
 next_hop: 11.11.11.11, out_if: tunnelto12_3
 next_hop: 11.11.11.11, out_if: tunnelto12
 next_hop: 11.11.11.11, out_if: tunnelto12_2

 Downstream mappings:
 Local LDP ID        Peer LDP ID         Label     State     CB
 128.128.128.28:0    11.11.11.11:0       3         Installed 0x34db96c4(-1)
 128.128.128.28:0    125.125.125.1:0     1028      Installed 0x34db9e64(-1)

 Upstream mappings:
 Local LDP ID        Peer LDP ID         Label     CB
 128.128.128.28:0    11.11.11.11:0       1029      0x34db98ac(-1)
 128.128.128.28:0    21.21.21.21:0       1029      0x34db97b8(-1)
```

Syntax: show mpls ldp fec prefix <*IPaddress*>

The output from the **show mpls ldp path** command has been updated to display all available ECMP paths for a specified FEC. If LDP selects an RSVP tunnel as its outgoing interface, the RSVP tunnel name is displayed in the ingress interface (intf) field.

The order of fields has changed in the **show mpls ldp path** command output. The Destination route field is displayed first, followed by the Upstr-session (label) field, and the Downstr-session (label,intf) field. The Upstr-session field and the Downstr-session field display an entry for an upstream session, and a downstream session if there is an entry to be displayed. If the outgoing interface is a tunnel, the ingress interface (intf) field displays the tunnel name instead of the LSP name, as shown in the following example.

```
NetIron#show mpls ldp path
Destination route Upstr-session(label)  Downstr-session(label,intf)
11.11.11.11/24    11.11.11.11:0 (1029)  90.90.90.25:0  (1028 ve4)
                  21.21.21.21:0 (1029)  11.11.11.11:0  (3 tnnl1)
                                        11.11.11.11:0  (3 tnnl2)
                                        11.11.11.11:0  (3 tnnl3)
```

Syntax: show mpls ldp path

The **show mpls statistics label** command has been updated to display statistics for LDP ECMP paths. In the following example, packet count for all ECMP paths are collected.

```
NetIron(config-mpls)#show mpls statistics label 2/1
In-label    In-Port(s)     In-Packet Count
1024        e2/1 - e2/20       100
```

Syntax: show mpls statistics label

Setting the LDP Hello Interval and Hold Timeout values

The LDP Hello interval and Hello Hold Timeout timers are used to establish Hello Adjacency between peers. The Hello Interval is the time period between which the LSR sends out Hello messages and the Hello Hold Timeout value is the amount of time that the sending LSR maintains its record of Hellos from the receiving LSR without receipt of another Hello message.

The Hello interval and Hello Hold Timeout timer values can be obtained from the global default values, configured globally on a router, or in the case of the Hello Hold Timeout timer configured per-interface. When configuring these values the following constraints must be followed:

- the Hello Interval value must be < 32767
- the Hello Hold Timeout value must be <65535
- The Hello Hold Timeout value must be >= 2 * Hello Interval value

As described in the following sections, values can be set that determine the values used on the configured router and values sent to adjacent peers for their configuration:

- Setting the LDP Hello Interval and Hold Timeout Values
- Setting the LDP Hold Time Sent to Adjacent LSRs
- Determining the LDP Hold Time on an MPLS Interface

Setting the LDP Hello interval values

The LDP hello interval controls how often the device sends out LDP Hello messages. Hello messages are used to maintain LDP sessions between the device and its LDP peers. You can set the interval for LDP Link Hello messages (LDP Hello messages multicast to all routers on the sub-net), as well as for LDP Targeted Hello messages (LDP Hello messages unicast to a specific address, such as a VLL peer):

- **For targeted LDP sessions –** the LDP Hello Interval can only be set globally. This configuration is described in "Setting the LDP Hello Interval globally for targeted LDP sessions" on page 1417. If a Hello Interval is not set for Targeted LDP sessions, then the global default value is used.
- **For link LDP sessions –** the LDP Hello Interval can be set globally which applies to all LDP interfaces or on a per-interface basis. The LDP Hello Interval values in Link LDP sessions are determined by the following procedure in the order described below.

1. If the Hello Interval is set per-interface, that value is used. This configuration is described in "Setting the LDP Hello Interval per-Interface (link Only)" on page 1418.
2. If the Hello Interval is not set per-interface, then the value set for LDPs globally is used. This configuration is described in "Setting the LDP Hello Interval globally for link LDP sessions" on page 1417.
3. If the Hello Interval is not set either globally or per-interface, the global default value is used.

If Hello Adjacency already exists, the adjacency remains up and any new configured interval takes effect upon the expiration of the current Hello Interval timer. Consequently, the next and subsequent hello messages are sent at the new interval.

Setting the LDP Hello Interval globally

You can set a global LDP Hello Interval that applies to all LDP sessions, regardless of interface. This is performed separately for Link and Targeted LDP sessions as described in the following sections:

- Setting the LDP Hello Interval Globally for Link LDP Sessions
- Setting the LDP Hello Interval Globally for Targeted LDP Sessions

Setting the LDP Hello Interval globally for link LDP sessions

To set the interval for LDP Link Hello messages to 10 seconds, enter the following command.

```
NetIron(config-mpls)# ldp
NetIron(config-mpls-ldp)# hello-interval 10
```

Syntax: [no] hello-interval <*seconds*>

The <*seconds*> variable specifies the value in seconds of the Hello Interval that you are globally configuring for LDP Link Hello messages. The LDP hello interval can be from 1 – 32767 seconds. The default value for LDP Link Hello messages is 5 seconds.

The value set here can be overridden on a per-interface basis as described in "Setting the LDP Hello Interval per-Interface (link Only)" on page 1418.

The **no** option removes a previously configured LDP Link Hello Interval.

Setting the LDP Hello Interval globally for targeted LDP sessions

To set the interval for LDP Targeted Hello messages to 20 seconds, enter the following command.

```
NetIron(config-mpls)# ldp
NetIron(config-mpls-ldp)# hello-interval target 20
```

Syntax: [no] hello-interval target <*seconds*>

The <*seconds*> variable specifies the value in seconds of the Hello Interval that you are globally configuring for LDP Targeted messages. The LDP hello interval can be from 1 – 32767 seconds. When you set a new LDP hello interval, it takes effect immediately. The default value for LDP Targeted Hello messages is 15 seconds.

The **no** option removes a previously configured LDP Targeted Hello Interval.

NOTE
This value can only be set globally for all Targeted LDP sessions on the router. Per-interface configuration is only available for Link LDP sessions.

Setting the LDP Hello Interval per-Interface (link Only)

You can set the LDP Hello Interval on a per-Interface basis. This option is only available for Link LDP sessions. The following example configures the MPLS Interface at Ethernet port 1/1 with a **hello-interval** of 10 seconds.

```
NetIron(config)# mpls
NetIron(config-mpls)# mpls-interface ethernet 1/1
NetIron(config-mpls-if-e100-1/1)# ldp-params
NetIron(config-mpls-if-e100-1/1-ldp-params)# hello interval 10
```

Syntax: [no] hello-interval <*seconds*>

The <*seconds*> variable specifies the value in seconds of the Hello Interval that you are configuring on this MPLS interface for LDP Link Hello messages.

No default value exists for this parameter. If a value is set here, it overrides any LDP Hello Interval that was globally configured. However, if no value is set for this parameter, it defaults either to the LDP Hello Interval that was configured globally or, if no value was configured globally, to the default global value. For information about the global configuration, refer to "Setting the LDP Hello Interval globally for link LDP sessions" on page 1417.

The **no** option removes a previously configured LDP Hello Interval.

Setting the LDP hold time sent to adjacent LSRs

The LDP hold time specifies how long the device waits for its LDP peers to send a Hello message. If the device does not receive a Hello message within this time, the LDP session with the peer can be terminated. The device includes the hold time in the Hello messages it sends out to its LDP peers.

The LDP Hold Time sent in Hello messages to adjacent LSRs can be configured globally for either Link or Targeted LDP sessions, as described in the following sections:

- Setting the LDP Hello Hold Time Sent to Adjacent LSRs for Link LDP Sessions
- Setting the LDP Hello Hold Time Sent to Adjacent LSRs for Targeted LDP Sessions

Setting the LDP Hello hold time sent to adjacent LSRs for link LDP sessions

To set the hold time included in LDP Link Hello messages to 20 seconds, enter the following command.

```
NetIron(config-mpls)# ldp
NetIron(config-mpls-ldp)# hello-timeout 20
```

Syntax: [no] hello-timeout <*seconds*>

The <*seconds*> variable specifies the value in seconds of the LDP hello timeout that is sent in Hello messages to Link LDP peers. The range for this value is 1 – 65535 seconds. The default value is 15 seconds.

When you globally set a LDP hold time, the new time takes effect immediately and goes in the next Hello message sent. This hold time applies to only the hold time that the device sends to its peers; it does not affect the hold time the device uses to time out those peers. The latter is determined from the hold time that peers send to the device.

The **no** option removes a previously configured LDP Hello Timeout value and returns the value to the default.

Setting the LDP Hello hold time sent to adjacent LSRs for Targeted LDP sessions

To set the hold time included in LDP Targeted Hello messages to 60 seconds, enter the following command.

```
NetIron(config-mpls)# ldp
NetIron(config-mpls-ldp)# hello-timeout target 60
```

Syntax: [no] hello-timeout target <*seconds*>

The <*seconds*> variable specifies the value in seconds of the LDP hello timeout that is sent in Hello messages to Targeted LDP peers. The LDP hold time can be from 1 – 65535 seconds. The default value is 45 seconds.

The **no** option removes the previous LDP Hello Timeout Target value and returns the value to the default.

Determining the LDP Hold Time on an MPLS interface

An MPLS interface uses the LDP Hello Hold Time to determine how long it waits for its LDP peers to send a Hello message. How this determination is made differs for a targeted LDP session and a link LDP session, as follows:

- **For targeted LDP sessions** – The value received in Hello messages from its peers determines the time that the device waits for its LDP peers to send a Hello message. If the Timeout value received from a peer is zero, the Hold Time is set to the default period of 45 seconds.
- **For link LDP sessions** – In this case, the wait time is determined by any one of the below criteria.

1. If the Hello Hold Time is set per-interface, that value is used. That value is set as described in "Setting the LDP Hello Holdtime per-interface (link only)" on page 1420.
2. If the Hello Hold Time is not set per-interface, the hold time in the received message is used.
3. If the Hello Hold Time in the received message is 0, the default value of 15 seconds is used.

Setting the LDP Hello Holdtime per-interface (link only)

You can set the LDP Hello Holdtime on a per-interface basis. This holdtime value is sent in Hello messages from the interface. This option is available for Link LDP sessions only. The following example configuration is for the MPLS Interface at Ethernet port 1/3 with a **hello-timeout** of 18 seconds.

```
NetIron(config)# mpls
NetIron(config-mpls)# mpls-interface ethernet 1/3
NetIron(config-mpls-if-e100-1/3)# ldp-params
NetIron(config-mpls-if-e100-1/3-ldp-params)# hello-timeout 18
```

Syntax: [no] hello-timeout <*seconds*>

The value configured in the <*seconds*> variable is the LDP Hello Timeout value that will be sent in LDP Hello messages from this interface. The minimum value that can be configured for this variable is 2 * the value set for the Hello Interval.

The **no** option removes a previously configured LDP Hello Timeout value and sets the value as described in "Determining the LDP Hold Time on an MPLS interface" on page 1419.

LDP message authentication

The Multi-Service IronWare software supports LDP authentication based upon the TCP MD5 signature option specified in RFC 2385. This RFC defines a new TCP option for carrying an MD5 digest in a TCP segment. The purpose of this feature is to protect against spoofed TCP segments in a connection stream.

Configuring LDP message authentication

The PowerConnect Series routers allow configuration of an authentication key on a per LDP session basis. The LDP session can be to an adjacent peer (basic discovery) or to the targeted peer (extended discovery). This feature must be configured on both sides of an LDP peer link. To configure LDP message authentication use the following commands.

```
NetIron(config)# mpls
NetIron(config-mpls)# ldp
NetIron(config-mpls-ldp)# session 10.10.10.3 key early
```

Syntax: [no] session <*remote-ip-addr*> **key** <*string*>

The <*remote-ip-addr*> variable specifies the IP address of the LDP peer that authentication is being configured for.

The <*string*> variable specifies a text string of up to 80 characters used for authentication between LDP peers. It must be configured on both peers.

By default, **key** is encrypted. If you want the authentication key to be in clear text, insert a **0** between **key** and <*string*>.

Example

```
NetIron(config-mpls-ldp)# session 10.10.10.3 key 0 early
```

The software adds a prefix to the key string in the configuration. For example, the following portion of the code has the encrypted code "2".

```
session 1.1.1.1 key 2 $XkBTb24tb0RuXA==
```

The encrypted code can be one of the following:

- 0 = the key string is not encrypted and is in clear text
- 1 = the key string uses proprietary simple crytographic 2-way algorithm
- 2 = the key string uses proprietary base64 crytographic 2-way algorithm

Resetting LDP neighbors

This feature allows you to reset or clear an MPLS LDP neighbor session. The session will be terminated and re-established (if at least one LDP "hello" adjacency exists with the peer). As a result of LDP session termination, the following database associated with the LDP session will also be cleared. Once the session is re-established, these session specific database will be re-learned from it's peer:

- LDP downstream and upstream label database ("**show mpls ldp database ...**")
- LDP label switched path ("**show mpls ldp path ...**")
- LDP peer ("**show mpls ldp peer ...**")
- LDP created MPLS tunnels ("**show mpls ldp tunnel ...**")
- LDP FECs learned from the resetting neighbor sessions (**show mpls ldp fec ...**"). FECs are actually not cleared immediately, but it is marked that no LDP session exists.

To reset/clear an MPLS LDP neighbor session

Syntax: clear mpls ldp neighbor [all | *<peer-ip-addr>* **[label-space-id** *<label-space>***]**

If the **all** option is specified, all LDP sessions on the router will be reset, including the targeted LDP sessions.

An LDP session is uniquely referred to by *<peer-ip-addr>* **:** *<label-space>*. This command also allows you to input *<peer-ip-addr>* only and ignore *<label-space>*. In this case, all LDP sessions with the matching peer address will be reset.

Executing this command displays a warning message if the LDP session is not found corresponding to the supplied *<peer-ip-addr>* (and *<label-space>*). If an LDP session is not in operational state, resetting it will have no impact.

Resetting LDP neighbor considerations

The **clear mpls ldp neighbor** feature terminates the specified LDP sessions. The LDP sessions are automatically reestablished if at least one "hello" adjacency exists with the neighbor, and LDP configuration remains unchanged. This command allows a user to reset the following LDP sessions:

- Platform-wide label space
- Interface specific label space

When an LDP session is terminated as a result of the **clear mpls ldp neighbor** command, the switch will not generate any notification message for the neighbor. Instead, the device will unilaterally terminate the session and close the associated TCP session. The other end of the LDP session will detect this reset operation in either of the following two ways:

- TCP session is broken (half connected). The device will detect this while receiving or sending LDP messages on TCP socket fails (with fatal error), indicating that underlying TCP session is aborted by remote peer.

- Receives a new TCP connection request from the neighbor while the older session is still operational (if this is in passive role)

NOTE
Either of above events will trigger the remote end of the LDP session to tear down the session and try to reestablish. Resetting an LDP session impacts the associated VPLS/VLL sessions. Resetting an LDP session which is not in operational state will have no impact.

Validating LDP session reset

You can check the following LDP session specific parameters to validate that a session has been successfully reset:

- The LDP session state will transition from "Operational" to "Nonexistant" upon clearing it. It may quickly transition from “Nonexistant" to "Operational.” In that case, the **show mpls ldp session** [detail | A.B.C.D] will show the "Up time", and that must have been reset to zero upon clearing the session.
- The LDP session specific database (mentioned above) is cleaned upon resetting the LDP session
- The TCP port number (on the active end of the LDP session) may have been changed once the LDP session comes up after reset. In other words, the TCP port number before the reset and after the reset may be different. Use the command **show mpls ldp session** [detail | A.B.C.D] to view the TCP port number.
- Syslog will log the event of a LDP session going down and then coming back up, as a result of resetting the LDP session. Use the command **show log** to view the syslog events.

Following is an example of how to use the **show log** command to view the syslog.

```
NetIron# show log
Syslog logging: enabled (0 messages dropped, 0 flushes, 0 overruns)
    Buffer logging: level ACDMEINW, 33 messages logged
    level code: A=alert C=critical D=debugging M=emergency E=error
                I=informational N=notification W=warning

Dynamic Log Buffer (50 lines):
Sep  9 18:38:20:N:MPLS: LDP entity session 1.1.1.1:0 with peer 2.2.2.2:0 is up
Sep  9 18:38:02:N:MPLS: LDP entity session 1.1.1.1:0 with peer 2.2.2.2:0 is dow
```

The following command shows two LDP sessions with neighbor 31.234.123.64.

```
NetIron#show mpls ldp session
Peer LDP ID             State          Adj Used  My Role   Max Hold  Time Left
31.234.123.64           Operational    Link      Passive   36        33
```

The following command clears both the link and targeted LDP session with neighbor 31.234.123.64, because the <*label_space*> optional parameter has not been specified.

```
NetIron# clear mpls ldp neighbor 31.234.123.64
NetIron#
NetIron#show mpls ldp session
Peer LDP ID             State          My Role   Max Hold  Time Left
31.234.123.64           Operational    Passive   36        33
NetIron#
```

This command shows that after waiting for roughly 20 seconds (depends on the hello/keepalive timer periodicity), both the LDP sessions are reestablished.

```
NetIron# clear mpls ldp neighbor 31.234.123.64
Peer LDP ID              State          My Role   Max Hold  Time Left
31.234.123.64            Operational    Passive   36        33
```

You can also validate the **clear mpls ldp** `neighbor` command using the syslog command.

```
NetIron# show log
Syslog logging: enabled (0 messages dropped, 0 flushes, 0 overruns)
    Buffer logging: level ACDMEINW, 47 messages logged
    level code: A=alert C=critical D=debugging M=emergency E=error
                I=informational N=notification W=warning

Dynamic Log Buffer (50 lines):
Sep  9 19:23:24:N:MPLS: LDP entity session 2.2.2.2:0 with peer 31.234.123.64 is
up
Sep  9 19:23:08:N:MPLS: LDP entity session 2.2.2.2:10 with peer 31.234.123.64 is
down
Sep  9 19:23:08:N:MPLS: LDP entity session 2.2.2.2:0 with peer 31.234.123.64 is
down
```

LDP over RSVP (for transit LSR only)

LDP over RSVP (for transit LSR only) enables LDP traffic to tunnel across RSVP tunnels. The RSVP tunnel is the transit of the LDP tunnel. On PowerConnect B-MLXe, LDP over RSVP can run over all types of LSPs (for example, one-to-one or facility Fast ReRoute (FRR) LSPs, adaptive LSPs, or redundant LSPs).

NOTE
LDP over RSVP configuration (for transit LSR only) is supported on PowerConnect B-MLXe devices.

LDP over RSVP is supported for all cases except when a NetIron router acts as a Label Edge Router (LER) for both LDP and RSVP. On the transit for LDP, the RSVP tunnel (RSVP LSP with LDP tunneling enabled) is used to reach the next-hop. The RSVP tunnel is treated as a single hop, and thus external LDP FECs are not advertised to the LSRs which are part of the RSVP core.

Currently, LDP depends on the Routing Table Manager (RTM) to provide the best next-hop for a particular prefix when LDP decides which label (received from its downstream peers) should be installed. This does not change for LDP over RSVP configuration. For LDP to install a label received from a non-directly connected peer whose route is through an RSVP tunnel, LDP must receive the corresponding route from the RTM indicating that the RSVP tunnel is used to reach the next-hop.

LDP over RSVP is supported under the following conditions:

- The RTM provides MPLS with a shortcut route for a particular prefix.
- The shortcut route must be an IS-IS, OSPF, or BGP shortcut.
- The RSVP tunnel must be enabled for LDP tunneling. For more information on enabling LDP tunneling, refer to "Enabling LDP over RSVP" on page 1424.

NOTE
If an RSVP tunnel is created on ingress LSR with IS-IS or OSPF shortcuts enabled, and LDP tunneling is also enabled, then the LDP tunnel to the egress router of the RSVP tunnel is not formed. An LDP tunnel is not created at the ingress LSR if RTM selects the RSVP tunnel as the next-hop to the destination.

Previously, prefix FECs were not advertised to a targeted peer, and prefix FECs received from a targeted peer were not installed. However with LDP over RSVP support, if a targeted session is used for LDP over RSVP, prefix FECs are advertised to its targeted peer, and prefix FEC received from a targeted peer is installed.

A targeted LDP session is brought up if any one of the following configurations exist:

- A targeted peer address is set up on the egress router of an RSVP tunnel. For more information on configuring a targeted peer address, refer to "Configuring a targeted peer address" on page 1426.
- The user enables RSVP LSP with LDP tunneling configured. For more information on configuring LDP tunneling, refer to "Enabling LDP over RSVP" on page 1424.
- A Layer 2 VPN (VLL or VPLS) peer is configured.

Enabling LDP over RSVP

To enable LDP traffic to tunnel across an RSVP tunnel, first create an LSP, then enable LDP tunneling on the LSP as shown in the following example.

```
NetIron(config)# router mpls
NetIron(config-mpls)# lsp blue
NetIron(config-mpls-lsp-blue)#to 20.20.20.20
NetIron(config-mpls-lsp-blue)# ldp-tunneling
```

The following message appears on the CLI.

```
This LSP can be used for LDP tunneling if it is used as a shortcut
```

This message implies that if an RSVP tunnel is used as an ISIS or OSPF shortcut, then the shortcut must be explicitly configured.

NOTE
There is no configuration needed for BGP shortcut.

To enable ISIS shortcuts or OSPF shortcuts, enter the **shortcuts isis** command, or the **shortcuts ospf** command as shown in the following example.

```
NetIron MLX-4 Router(config-mpls-lsp-blue)#shortcuts isis level2
NetIron MLX-4 Router(config-mpls-lsp-blue)#enable
Connecting signaled LSP blue
```

Syntax: [no] ldp-tunneling

Syntax: [no] shortcuts isis level1 | level 2

Syntax: [no] shortcuts ospf

By default, LDP tunneling is disabled. The user must disable the LSP configuration to change the setting on the **ldp-tunneling** command.

NOTE
The **ldp-tunneling** command is not available under bypass LSP configuration.

To disable IS-IS shortcuts or OSPF shortcuts, enter the **no** form of the command.

The **level1** or **level2** keyword is required and indicates the level of IS-IS routing enabled on the device. The levels are:

- level1 – A level1 router routes traffic only within the area that includes the router. To forward traffic to another area, a level1 router sends the traffic to the nearest level2 router.
- level2 – A level2 router routes traffic between areas within a domain.

The LDP tunneling configuration is displayed in the output of the **show mpls lsp** command. If LDP tunneling is enabled, the line reads “yes.” If it is not enabled, the line reads “no.”

```
NetIron(config-mpls)#show mpls lsp blue
LSP blue, to 20.20.20.20
  From: 10.10.10.10, admin: UP, status: DOWN (Path not sent)
  Times primary LSP goes up since enabled: 0
  Metric: 0, number of installed aliases: 0
  Maximum retries: 0, no. of retries: 1
  Pri. path: NONE, up: no, active: no
  Setup priority: 7, hold priority: 0
  Max rate: 0 kbps, mean rate: 0 kbps, max burst: 0 bytes
  Constraint-based routing enabled: yes
  Tie breaking: random, hop limit: 0
  LDP tunneling enabled: yes
```

Syntax: show mpls lsp <*lsp_name*>

The <*lsp_name*> variable specifies the LSP name you want to display.

The LDP tunneling configuration is also displayed in the output of the **show mpls config** command, and the **show mpls config lsp** command. In the following example, LDP tunneling with ISIS shortcuts is enabled.

```
NetIron MLX-4 Router(config-mpls)#show mpls config lsp blue
 lsp blue
  to 20.20.20.20
  shortcuts isis level2
  ldp-tunneling
  enable
```

Syntax: show mpls config lsp <*lsp_name*>

The <*lsp_name*> variable specifies the LSP name you want to display.

The output from the **show mpls config** command displays a list of configured peer addresses as shown in the following example.

```
NetIron#show mpls config
router mpls
 policy
  traffic-eng isis level-2
  ingress-tunnel-accounting
 ldp
  session 7.7.7.2 key 2 $LSFVPW9iIQ==
  session 7.7.7.3 key 2 $LSFVPW9iIQ==

 bfd
  min-tx 50 min-rx 50 multiplier 3
mpls-interface e3/3
  ldp-enable
  admin-group 2

  mpls-interface e3/17
  rsvp-authentication 2 key $LSFVPW9iIQ==
  ldp-enable
```

Syntax: show mpls config

Configuring a targeted peer address

Currently, the NetIron router does not send a targeted Hello message in response to receiving a targeted Hello message from a peer that is not configured as a L2VPN peer. In the case when a L2VPN peer is not configured on a NetIron router, and the user would like to enable support for LDP over RSVP, the user must specify the IP address of the peer to bring up a targeted session. To trigger a targeted session that is set up on the egress router of an RSVP tunnel, enter the **targeted-peer** command under the MPLS LDP configuration as shown in the following example.

```
NetIron(config)# router mpls
NetIron(config-mpls)# ldp
NetIron(config-mpls-ldp)# targeted-peer 10.10.10.10
```

Syntax: [no] targeted-peer <*ip-address*>

The <*ip-address*> variable specifies the IP address of the targeted peer. To disable the configuration, enter the **no** form of the command.

NOTE
A targeted peer address is not configured on the ingress router of the RSVP tunnel because configuring LDP tunneling for the LSP automatically brings up a targeted session.

Displaying targeted peer addresses

To display a list of configured peer addresses, enter the **show mpls ldp targeted-peer** command on the CLI as shown in the following example.

```
NetIron# show mpls ldp targeted-peer
Peer_address
2.2.2.2
```

Syntax: show mpls ldp targeted-peer

TTL propagation for LDP over RSVP packets

TTL propagation for LDP over RSVP packets is controlled by the **propagate-ttl** command, and the **label-propagate-ttl** command:

- If the label operation involves the swap of the LDP label followed by the push of the RSVP label, the **label-propagate-ttl** command will control the propagation of the LDP label TTL to the RSVP label TTL. By default, the TTL is not propagated. The RSVP label TTL is set to 255. If the **label-propagate-ttl** command is configured by the user, the LDP label TTL is propagated to the RSVP label TTL.
- If the label operation involves the pop (or the removal) of the LDP label followed by the push of the RSVP label, the following two cases are considered:
  - If the LDP label is not the only label in the Layer 2 or Layer 3 VPN stack, the **label-propagate-ttl** command will control the propagation of TTL from the outer LDP label to the VC label and, in turn, from the VC label to the RSVP label. By default, the **label-propagate-ttl** command is turned off. The VC label TTL is not affected when the LDP tunnel label and the RSVP label TTL are set to 255.
  - If the LDP label is the only label in the IP over MPLS stack, the **propagate-ttl** command controls the propagation of TTL from the LDP label to the IP header and, in turn, from the IP header to the RSVP label. By default, the **propagate-ttl** command is turned on.

By default, TTL propagation is enabled for IP over MPLS traffic when an RSVP and an LDP tunnel terminate on the same node. For traceroute purposes, if an RSVP tunnel is traced, then TTL propagation should be enabled.

NOTE
For consistent behavior in all cases of TTL propagation for LDP over RSVP packets, Dell recommends that the user always turn on or turn off both the **label-propagate-ttl** command and the **propagate-ttl** command.

Enabling TTL propagation

By default, MPLS traceroute will not display the LSRs the RSVP tunnel is transiting through, except when the egress router is acting as the egress for both the LDP and the RSVP tunnel. In other words, the RSVP tunnel is treated as a single hop. The **label-propagate-ttl** command and the **propagate-ttl** command must be enabled in order to display details of the RSVP core. By default, the **propagate-ttl** command is enabled. To trace an RSVP path, enable the **label-propagate-ttl** command on all NetIron routers along the RSVP path, as shown in the following example.

```
NetIron(config)# router mpls
NetIron#(config-mpls)# policy
NetIron#(config-mpls-policy)# label-propagate-ttl
```

Syntax: [no] label–propagate-ttl

To disable the configuration, enter the **no** form of the command. By default, the **label-propagate-ttl** command is turned off. When MPLS traceroute is configured through an RSVP core, FEC validation for LDP FEC is not preformed at the transit LSR of the RSVP tunnel.

Class of Service (CoS) treatment for LDP over RSVP

The following sections describe COS treatment for LDP over RSVP (transit) for ingress RSVP and RSVP Penultimate Hop Pop (PHP).

Ingress RSVP

The internal priority of the ingress RSVP is mapped from the incoming LDP label EXP bits. If the RSVP tunnel has a COS configured, it will override the internal priority of the ingress RSVP. By default, the EXP bits in the outgoing RSVP label are mapped from the internal priority. If the **qos exp encoding off** command is configured on the outgoing interface, the RSVP label EXP bits are set to the internal priority of the ingress RSVP. The incoming LDP label EXP bits are preserved in the outgoing LDP label EXP bits irrespective of whether the **qos exp encoding** command is turned on or off on the outgoing interface.

RSVP PHP

The internal priority is mapped from the incoming RSVP label EXP bits. On the egress router of the RSVP tunnel, the outgoing LDP label EXP bits are set to the incoming LDP label EXP bits. This is irrespective of whether the **qos exp encoding** command is turned on or off on the outgoing interface.

Displaying LDP information

You can display the following information about LDP:

- The LDP version number, as well as the LSP's LDP identifier and loopback number
- Information about active LDP-created LSPs on the device
- Information about LDP-created tunnel LSPs for which this device is the ingress LER
- The contents of the LDP database
- Information about the LDP session between this LSR and its LDP peers
- Information about the connection between this LSR and its LDP peers
- Information about LDP-enabled Interfaces on the LSR

Displaying the LDP version

NOTE
The **show mpls ldp** command has changed. The Num VC FEC currently allocated field is no longer displayed in the output of the **show mpls ldp** command.

To display the LDP version number, the LSR ID and loopback number, and the LDP hello interval and hold time, enter the **show mpls ldp** command shown in the example below. T

```
NetIron(config)# show mpls ldp
Label Distribution Protocol version 1
  LSR ID: 2.2.2.2, using Loopback 1 (deleting it will stop LDP)
  Hello interval: Link 5 sec, Targeted 15 sec
  Hold time value sent in Hellos: Link 15 sec, Targeted 45 sec
  Keepalive interval: 6 sec, Hold time multiple: 6 intervals
```

Syntax: show mpls ldp

Table 219 lists the information displayed by the **show mpls ldp** command.

TABLE 219 Output from the show mpls ldp command

This field...	Displays...
Label Distribution Protocol version	The LDP version.
LSR ID	The identifier of the device and the loopback interface number being used by LDP. LDP advertises the address of this loopback interface in Address messages.
Hello interval	How often the device sends out LDP Link Hello and Targeted Hello messages.
Hold time value sent in Hellos	How long the device waits for its LDP peers to send a Hello message. The hold time is included in the Link Hello and Targeted Hello messages it sends out to its LDP peers.
Keepalive interval	The number of seconds between successive Keepalive messages send for an LDP session.
Hold time multiple	The number of Keepalive messages not received before a session is declared down.

Displaying information about LDP-created LSPs

You can display information about active LDP-created LSPs for which this device is an ingress, transit, or egress LSR.

Example

```
NetIron(config)# show mpls ldp path
Upstr-session(label)     Downstr-session(label, intf)    Destination route
33.3.3.3:0(3)            (egress)                        11.1.1.1/32
22.2.2.2:0(3)            (egress)                        11.1.1.1/32
33.3.3.3:0(1024)         22.2.2.2:0(3, e2/10)            22.2.2.2/32
22.2.2.2:0(1024)         22.2.2.2:0(3, e2/10)            22.2.2.2/32
(ingress)                22.2.2.2:0(3, e2/10)            22.2.2.2/32
33.3.3.3:0(1026)         33.3.3.3:0(3, e2/20)            33.3.3.3/32
22.2.2.2:0(1026)         33.3.3.3:0(3, e2/20)            33.3.3.3/32
(ingress)                33.3.3.3:0(3, e2/20)            33.3.3.3/32
```

Syntax: show mpls ldp path

Each line in the output of the **show mpls ldp path** command shows information about an LSP created through LDP. The command output lists the incoming and outgoing labels applied to packets in each LSP. For example, the third line in the example output indicates that MPLS packets received from upstream peer 33.3.3.3 with label 1024 are to be transmitted to downstream peer 22.2.2.2 with label 3.

NOTE
In this context, “upstream” and “downstream” shows the direction that data traffic flows in an LSP. This is opposite of the direction that labels are distributed using LDP.

Additionally, the output of this command indicates that the device has received a label for the destination IP prefix (that is, the attached route) from the downstream peer and then advertised a label for that IP prefix to the upstream peer.

Table 220 lists the information displayed by the **show mpls ldp path** command.

TABLE 220 Output from the **show mpls ldp path** command

This field...	Displays...
Upstr-session(label)	The LDP identifier of the upstream peer, as well as the incoming label. Note that upstream session information does not apply to LSPs for which this is the ingress LER. Because the device uses a per-platform label space, the incoming interface for LDP-created LSP is not relevant.
Downstr-session(label, intf)	The LDP identifier of the downstream peer, as well as the outgoing label and interface. When applicable, the ingress interface (intf) field displays a VE interface specified by the <*vid*> variable. Note that downstream session information does not apply to LSPs for which this is the egress LER. If LDP selects its outgoing interface as an RSVP tunnel, the ingress interface (intf) field displays the RSVP tunnel name.
Destination route	The destination route bound to this LSP.

Displaying LDP tunnel LSP information

To display information about LDP-created LSPs for which this device is the ingress LER, enter the following command.

```
NetIron# show mpls ldp tunnel
                Oper      Tunnel    Outbound
To              State     Intf      Intf
22.2.2.2        UP        tnl0      e3/1
33.3.3.3        UP        tnl1      e3/2
```

Syntax: show mpls ldp tunnel

The following table describes the output of the **show mpls ldp tunnel** command.

TABLE 221 Output from the **show mpls ldp tunnel** command

This field...	Displays...
To	The egress LER for the LSP.
Oper State	The operational state of the LSP. This field indicates whether the LSP has been established through LDP signalling and is capable of having packets forwarded through it.
Tunnel Intf	The MPLS tunnel interface port ID.
Outbound Intf	The outbound interface for the LSP. The outbound interface displays the egress interface of the tunnel. When applicable, the egress interface of the tunnel displays a VE interface specified by the <vid> variable.

Displaying the contents of the LDP database

You can display the contents of the LSR's LDP Label Information Base. This database contains all the labels it has learned from each of its LSR peers, as well as all of the labels it has sent to its LDP peers.

```
NetIron# show mpls ldp database
Session 1.1.1.1:0 - 2.2.2.2:0
 Downstream label database:
   Label     Prefix              State
   3         2.2.2.2/32          Installed
   1104      3.3.3.3/32          Retained
   1106      14.14.14.14/32      Retained
   1107      44.44.44.44/32      Retained
   800005    VC-FEC              Installed
 Upstream label database:
   Label     Prefix
   3         1.1.1.1/32
   1024      2.2.2.2/32
   1026      3.3.3.3/32
   1028      14.14.14.14/32
   1029      44.44.44.44/32
   800005    VC-FEC
   800006    VC-FEC
   983040    GEN ID VC-FEC
   983104    GEN ID VC-FEC
```

Syntax: show mpls ldp database

For each LDP session, the **show mpls ldp database** command displays the following information

TABLE 222 Output from the **show mpls ldp database** command

This field...	Displays...
Session	The LDP identifiers of this LSR and its peer.
Downstream label database	Information about labels received from the LDP peer
Upstream label database	Information about labels distributed by this LSR to the LDP peer. The device sends the same label for a given prefix to all of its upstream peers. In the example above, label 1028 is mapped to prefix 14.14.14.14/32. This device will send this label mapping to each of its upstream peers.
Label	The label value received from or distributed to LDP peers. It also displays the label values for VC FECs received from downstream LDP peers or advertised to up stream LDP peers.
Prefix	The destination route associated with the label. Since Prefix is not applicable to the VC-FECs, this field indicates that the label is associated with the VC FEC.
State	Whether the label is actively being used for data forwarding. This can be one of the following “Installed” indicates that the label is being used with an active LDP-created LSP to forward packets. “Retained” indicates that the label is not being used for packet forwarding. Since LSRs use Liberal Label Retention, these unused labels are retained in the database and not discarded.

Displaying LDP session information

To display information about the LDP session between this LSR and its LDP peers, enter the following command.

```
NetIron# show mpls ldp session
Peer LDP ID             State          Adj Used  My Role   Max Hold  Time Left
2.2.2.2:0               Operational    Link      Passive   36        32
3.3.3.3:0               Operational    Link      Passive   36        26
8.8.8.8:0               Operational    Targeted  Passive   36        33
14.14.14.14:0           Operational    Targeted  Passive   36        24
```

Syntax: show mpls ldp session

The following table describes the output of the **show mpls ldp session** command.

TABLE 223 Output from the **show mpls ldp session** command

This field...	Displays...
Peer LDP ID	The LDP identifier of the peer LSR. The first four octets identify the peer LSR IP address; the second two octets identify a label space on the LSR. For LSRs that use per-platform label spaces, the second two octets are always zero.
State	The current state of the LDP session between this LSR and its peer, as defined in RFC 3036. This can be "Nonexistent", "Initialized", "OpenRec", "OpenSent", or "Operational".
Adj Used	LDP adjacencies for a session: • Targeted • Link **NOTE:** When both link and targeted LDP adjacencies exist for a session, the adjacency type that is used will display Link. This is applicable on PowerConnect B-MLXe devices.
My Role	Whether this LSR is playing the “active” or “passive” role in LDP session establishment (as defined in RFC 3036). The LSR with the higher LSR ID plays the active role in LDP session establishment.
Max Hold	The number of seconds that the “Hold time remain” counter is reset to once a KeepAlive message is received from the peer.
Time Left	The amount of time, in seconds, before the LDP session times out if no KeepAlive message is received from the peer.

To display more detailed information about the LDP session between this LSR and its LDP peers, enter the **show mpls ldp session** command with the **detail** option as shown in the following.

```
NetIron# show mpls ldp session detail
Peer LDP ID: 120.120.120.2:0, Local LDP ID: 110.110.110.1:0, State: Operational
  Adj: Link, Role: Passive, Next keepalive: 4 sec, Hold time left: 37 sec
  Keepalive interval: 6 sec, Max hold time: 36 sec
  Up time: 6 min 51 sec
  MD5 Authentication Key: $MlVzZCFAbg==
  Neighboring interfaces: e2/11
  TCP connection: 110.110.110.1:646--120.120.120.2:9004, State: ESTABLISHED
  Next-hop addresses received from the peer:
    10.10.10.2  11.11.11.2  12.12.12.2  13.13.13.2  120.120.120.2
```

Syntax: show mpls ldp session detail

NOTE

The key displayed using the command, **show mpls ldp session detail** is the one currently configured for that session. This key may not be the one which is "in use" by that session as the session may have been established prior to the change in the configured key. If the session is already in the established state, any change in the authentication key will take effect during the next incarnation of the LDP session.

For each established LDP session, the command displays the following information:

TABLE 224 Output from the **show mpls ldp session detail** command

This field...	Displays...
Peer LDP ID	The LDP identifier of the peer LSR. The first four octets identify the peer LSR IP address; the second two octets identify a label space on the LSR. For LSRs that use per-platform label spaces, the second two octets are always zero.
Local LDP ID	This LSR's LDP identifier.
State	The LDP session state, as defined in RFC 3036. This can be "Nonexistent", "Initialized", "OpenRec", "OpenSent", or "Operational".
Adj	Whether the session was established using the Link adjacency (basic discovery) or the Targeted discovery (extended discovery).
Role	Whether this LSR is playing an "active" or "passive" role in session establishment.
Next keepalive	If this LDP session is established, the amount of time, in seconds, before the next KeepAlive message is sent to the active peer. If this LSR is the active peer, prior to establishing a session with the passive peer, the text "Next Initialization" is displayed instead. The "Next Initialization" value indicates, in seconds, when the next Initialization message will be sent to the passive peer.
Hold time left	The amount of time, in seconds, before the LDP session times out if no KeepAlive message is received from the peer.
Max hold time	The number of seconds that the "Hold time remain" counter is reset to once a KeepAlive message is received from the peer.
Up Time	The Up Time is displayed in days, hours, minutes, and seconds. This line appears only if the session is in Operational Up State.
Keepalive interval	The amount of time the LSR waits for an LDP PDU from the peer. If this amount of time passes without receiving an LDP PDU from the peer, the LDP session is terminated.
MD5 Authentication Key	The MD5 authentication key is displayed in an encrypted form when the user does not have the correct privileges. If the user has the correct permission, it will be displayed as clear text.
Neighboring interfaces	The interfaces where an LDP neighbor/adjacency relationship has been established with the peer. If there are multiple connections between two LDP-enabled peers, there can be multiple neighboring interfaces. When applicable, the Neighboring Interface field displays a VE interface specified by the <vid> variable.
TCP connection	The local and remote IP addresses and port numbers for the TCP connection between the peers.
State	The state of the TCP connection between the peers.
Next-hop addresses received from the peer	The next-hop addresses received from the peer in LDP address messages. The LSR uses this list of addresses to determine whether the peer is the correct next hop for a destination route. If one of the addresses in this list is the correct next hop for the route, the label received from the peer is installed for that route, allowing it to be used for data forwarding.

Displaying LDP neighbor connection information

To display information about the connection between this LSR and its LDP-enabled neighbors, enter the following command.

```
NetIron# show mpls ldp neighbor
Nbr Transport       Interface      Nbr LDP ID          Max Hold  Time Left
1.1.1.1             p4/1           1.1.1.1:0           15        14
5.5.5.5             p3/2           5.5.5.5:0           15        11
4.4.4.4             (targeted)     4.4.4.4:0           15        13
```

The **show mpls ldp neighbor** command is enhanced to include a detail option. The detail parameter includes Adjacency Up Time.

```
NetIron #show mpls ldp neighbor detail
Nbr Transport Addr: 22.22.22.1, Interface: e1/1, Nbr LDP ID: 22.22.22.1:0
 MaxHold: 44 sec, Time Left: 43 sec, Up Time: 36 min 22 sec

Nbr Transport Addr: 22.22.22.1, Interface: e1/2, Nbr LDP ID: 22.22.22.1:0
 MaxHold: 75 sec, Time Left: 74 sec, Up Time: 36 min 27 sec

Nbr Transport Addr: 33.33.33.1, Interface: e1/3, Nbr LDP ID: 33.33.33.1:0
 MaxHold: 75 sec, Time Left: 72 sec, Up Time: 36 min 22 sec

Nbr Transport Addr: 33.33.33.1, Interface: targeted, Nbr LDP ID: 33.33.33.1:0
 MaxHold: 75 sec, Time Left: 69 sec, Up Time: 35 min 36 sec
```

Syntax: show mpls ldp neighbor detail

TABLE 225 Output from the **show mpls ldp neighbor** command

This field...	Displays...
Nbr Transport	The transport address of the LDP neighbor.
Interface	The interface to which the LDP neighbor is connected. "(targeted)" indicates that the session between this device and the neighbor was established using Targeted Hello messages (that is, through extended discovery). When applicable, the Interface field displays a VE interface specified by the <vid> variable.
Nbr LDP ID	The neighbor's LDP identifier
Max Hold	The number of seconds the device waits for its LDP peers to send a Hello message.
Time Left	The amount of time, in seconds, before the LDP neighbor times out if no Hello message is received from the neighbor.
Up Time	The Up Time is the time since the LDP adjacency is established. It is displayed in days, hours, minutes, and seconds. If there is no Adjacency, then nothing is displayed

Displaying information about LDP-enabled interfaces

To display information about the LDP enabled interfaces on the LSR, enter the following command.

```
NetIron# show mpls ldp interface
                    Label-space    Nbr           Hello          Next
Interface           ID             Count         Interval       Hello
e4/1                0              1             5              --
(targeted)          0              0             15             --
```

Syntax: show mpls ldp interface

TABLE 226 Output from the **show mpls ldp interface** command

This field...	Displays...
Interface	The slot and port number of the LDP-connected interface. "(targeted)" shows information about unicast Targeted Hello messages sent to VLL peers.
Label-space ID	The label space ID. For LSRs that use per-platform label spaces, the second two octets are always zero.
Nbr Count	The number of LDP peers/adjacencies that has been established on this interface. This number can be greater than 1 if this is a multi-access network.
Hello Interval	The number of seconds between LDP Hello messages.
Next Hello	The number of seconds before the next LDP Hello message is sent (multicast) to the LDP interface (non-targeted). For a targeted interface, the LDP Hello message is unicast and, hence, for every neighbor, the next LDP Hello message is sent at a different time. In order to find out when the next LDP Hello message is sent out of any targeted adjacency, use the command **show mpls ldp neighbor**.

Displaying information about specified LDP-enabled nterface

To display information about a specific LDP enabled interface on the LSR, enter the following command.

```
NetIron# show mpls ldp interface ethernet 4/1
e4/1(Trunk1), label-space ID: 0
  Nbr count: 1
  Hello interval: 7 sec, next hello: 2 sec
  Hello timeout: 21 sec, hello timeout self: 0 sec
```

Syntax: show mpls ldp interface [ethernet <*slot/port*> **| pos** <*slot/port*>| **ve** <*vid*>**]**

TABLE 227 Output from the **show mpls ldp interface** command for a specific interface

This field...	Displays...
Interface	The slot and port number of the LDP-connected interface. The interface type refers to any one of the following: • **ethernet** <*slot/port*> to limit the display to a single ethernet port • **pos** <*slot/port*> to limt the display to a single pos port. • **ve** <*vid*> to limit the display to a VE interface ID specified by the <*vid*> variable.
Label-space ID	The label space ID. For LSRs that use per-platform label spaces, the second two octets are always zero.
Nbr Count	The number of LDP peers/adjacencies that has been established on this interface. This number can be greater than 1 if this is a multi-access network.
Hello Interval	The number of seconds between LDP Hello messages.

TABLE 227 Output from the **show mpls ldp interface** command for a specific interface

This field...	Displays...
Next Hello	The number of seconds before the next LDP Hello message is sent (multicast) to the LDP interface (non-targeted). For a targeted interface, the LDP Hello message is unicast and, hence, for every neighbor, the next LDP Hello message is sent at a different time. In order to find out when the next LDP Hello message is sent out of any targeted adjacency, use the command **show mpls ldp neighbor**.
Hello Timeout	The number of seconds that the interface waits for its LDP peers to send a Hello message. If the interface does not receive a Hello message within this time, the LDP session with the peer can be terminated.
Hello Timeout Self	The Hello Timeout Self configured for this interface. If the value for this parameter is set to 0, the Hello Timeout value is determined using the adjacent peer's sent hold timeout value. If that value is also set to 0, the global default value is used.

Displaying the LDP peer information

You can display LDP peering information as shown in the following.

```
NetIron# show mpls ldp peer
Peer LDP ID        State          Num-VLL        Num-VPLS-Peer
2.2.2.2:0          Operational    2              0
3.3.3.3:0          Operational    0              0
8.8.8.8:0          Operational    2              0
9.9.9.9:0          Unknown        2              0
14.14.14.14:0      Operational    1              0
```

Syntax: show mpls ldp peer <*peer-ip-address*> **| detail | brief]**

For each LDP session, the **show mpls ldp peer** command displays the following information

TABLE 228 Output from the **show mpls ldp peer** command

This field...	Displays...
Peer-addr	The LDP identifier of the peer LSR. The first four octets identify the peer LSR IP address; the second two octets identify a label space on the LSR. For LSRs that use per-platform label spaces, the second two octets are always zero.
State	The current state of the LDP session between this LSR and its peer.
Num-VLL	Number of VLL instances using this LDP peer.
Num-VPLS-Peer	Number of VPLS instances using this LDP peer.

To display more detailed information about the LDP peers, enter the following command.

```
NetIron#show mpls ldp peer detail
Peer LDP ID: 2.2.2.2:0, Local LDP ID: 1.1.1.1:0, State: Operational
Session Status UP, Entity Idx: 4, Targeted: No, Target Adj Added: Yes
Num VLL: 2, Num VPLS: 0
Rcvd VC-FECs:
 From 2.2.2.2: Label: 800001, VC Id: 120, Grp_Id: 0, VC Type: 4 MTU: 5000
```

```
Peer LDP ID: 8.8.8.8:0, Local LDP ID: 1.1.1.1:0, State: Operational
Session Status UP, Entity Idx: 2, Targeted: Yes, Target Adj Added: Yes
Num VLL: 2, Num VPLS: 0
Rcvd VC-FECs:
 From 8.8.8.8: Label: 16, VC Id: 19, Grp_Id: 0, VC Type: 32773, MTU: 5000
 From 8.8.8.8: Label: 18, VC Id: 18, Grp_Id: 0, VC Type: 32772, MTU 5555
```

For each LDP peer, the command displays the following information

TABLE 229 Output from the **show mpls ldp peer detail** command

This field...	Displays...
Peer LDP ID	The LDP identifier of the peer LSR. The first four octets identify the peer LSR IP address; the second two octets identify a label space on the LSR. For LSRs that use per-platform label spaces, the second two octets are always zero.
Local LDP ID	This LSR's LDP identifier.
State	The LDP session state, as defined in RFC 3036. This can be "Nonexistent", "Initialized", "OpenRec", "OpenSent", or "Operational".
Session Status	Whether the session is operationally UP or Down.
Entity Idx	This displays the LDP session entity CB index maintained by the LDP session controller.
Targeted	Whether the session was established using Targeted Hello messages (that is, through extended discovery).
Target Adj Added	Whether the targeted adjacency was initiated for this LDP peer.
Num VLL	Number of VLL instances using the LDP peer.
Num VPLS	Number of VPLS instances using the LDP peer.
Rcvd VC FECs	Displays the contents of received VC FECs
From	Peer LSR ID where the VC FEC was received from.
Label	The MPLS label associated with the VC FEC.
VC ID	The VC ID associated with the VC FEC.
Grp_ID	The Group ID associated with the VC FEC.
VC Type	The VC Type associated with the VC FEC.
MTU	The MTU value received in a VC Label Matching message from a peer.

To display detailed information about a specific LDP peer, enter the following command.

```
NetIron#show mpls ldp peer  22.22.22.22
Peer LDP ID: 22.22.22.22:0, Local LDP ID: 24.24.24.24:0, State: Operational
Session Status UP, Entity Idx: 1, Targeted: No, Target Adj Added: No
Num VLL: 0, Num VPLS: 0
Rcvd VC-FECs:
 From 5.5.5.5: Label: 100000, VC Id: 10, Grp_Id: 0, VC Type: 32773, MTU: 5000
 From 5.5.5.5: Label: 190448, VC Id: 200, Grp_Id: 0, VC Type: 32772, MTU 5555
```

For each LDP peer, the command displays the following information

TABLE 230 Output from the **show mpls ldp peer detail** command

This field...	Displays...
Peer LDP ID	The LDP identifier of the peer LSR. The first four octets identify the peer LSR IP address; the second two octets identify a label space on the LSR. For LSRs that use per-platform label spaces, the second two octets are always zero.
Local LDP ID	This LSR's LDP identifier.
State	The LDP session state, as defined in RFC 3036. This can be "Nonexistent", "Initialized", "OpenRec", "OpenSent", or "Operational".
Session Status	Whether the session is operationally UP or Down.
Entity Idx	This displays the LDP session entity CB index maintained by the LDP session controller.
Targeted	Whether the session was established using Targeted Hello messages (that is, through extended discovery).
Target Adj Added	Whether the targeted adjacency was initiated for this LDP peer.
Num VLL	Number of VLL instances using the LDP peer.
Num VPLS	Number of VPLS instances using the LDP peer.

Display considerations for LDP FEC information

The **show mpls ldp fec** command has changed to allow you to display all Layer 3 FEC information on the CLI, or specify the FEC type you want to display. When displaying the **show mpls ldp fec** command, consider the following.

- The prefix option is introduced to the **show mpls ldp fec** command. The **show mpls ldp fec prefix** command displays the total number of Layer 3 FECs. The total number of Layer 3 FECs is displayed in the Total number of prefix FECs field. For more information on this command, refer to "Displaying LDP FEC information" on page 1438.
- All options that are available under the **show mpls ldp fec** command have moved to the **show mpls ldp fec prefix** command.
- The **summary** option is introduced to the **show mpls ldp fec** command. The **show mpls ldp fec summary** command displays summarized FEC information. For more information on this command, refer to **"Displaying LDP FEC summary information"** on page 1440.
- The **vc-fec** option is renamed to **vc** option. All options that are under the **show mpls ldp vc-fec** command have moved under the **show mpls ldp fec vc** command. For more information on this command, refer to "Displaying the LDP FEC VC information" on page 1441.

Displaying LDP FEC information

To display host addresses and the total number of Layer 3 prefix FECs from the LDP FEC database, enter the following command.

```
NetIron# show mpls ldp fec prefix
Total number of prefix FECs: 2
Destination         State       Out-intf         Next-hop         Ingress Egress
125.125.125.1/32    current     e2/2             90.90.90.20      Yes     No
128.128.128.0/24    current     --               --               No      Yes
```

Syntax: show mpls ldp fec [<*IPaddress*> **[longer] | [prefix]**<*IPaddress_with_NetMask*>**] [longer]**

Using <*IPaddress*> |<*IPaddress_with_NetMask*> provides a detailed view of the specified FEC. Including the **longer** keyword means that if an IP address has been specified, display only the routes that match that IP address.The **prefix** option displays all Layer 3 FEC information.

The **show mpls ldp fec prefix** command displays the following information.

TABLE 231 Output from the **show mpls ldp fec prefix** command

This field...	Displays...
Total number of prefix FECs	The total number of Layer 3 FECs.
Destination	The IP Prefix associated with the host address or the prefix FEC type.
State	State of the FEC which indicates the FEC is currently being advertised to any LDP session (state equal to “current”). If it has no session, it will either be called “cur_no_sess” (currently no session) for local FECs or will be marked “retained” for non-local FECs.
Out-intf	For an ingress FEC, this mentions the output interface to reach to the Next-hop. The Out-Intf field displays the egress interface associated with the FEC entry. When applicable, the Out-Intf field displays a VE interface specified by the <*vid*> variable.
Next-hop	For an ingress FEC, this mentions the nexthop IP address.
Ingress	Whether the FEC is an ingress FEC.
Egress	Whether the FEC is an egress FEC.

Displaying information for a specified LDP FEC type

The **show mpls ldp fec prefix** <*IPaddress_with_NetMask*> command has changed. To display L3 FEC information for a specific FEC type, enter the following command.

```
NetIron#show mpls ldp fec prefix 125.125.125.1/32
FEC_CB: 0x29391f8c, idx: 1, type: 2, pend_notif: None
 State: current, Ingr: Yes, Egr: No, UM Dist. done: No
 Prefix: 125.125.125.1/32, next_hop: 90.90.90.20, out_if: e2/2

 Downstream mappings:
 Local LDP ID        Peer LDP ID         Label     State     CB
 128.128.128.28:0    125.125.125.1:0     3         Installe 0x29391cb0(-1)
```

Table 232 lists the output displayed for **show mpls ldp fec prefix** command.

TABLE 232 Output from the **show mpls ldp fec prefix** command

This field...	Displays...
FEC_CB	Memory address of the FEC CB.
idx	A monotonically increasing number assigned to each FEC in the LDP internal FEC tree.
type	FEC type – Prefix FEC is type 2 and Host Address is assigned type 3.
pend_notif	Any notification pending on this FEC.
State	State of the FEC which indicates the FEC is currently being advertised to any LDP session (state equal to “current”). If it has no session, it will either be called “cur_no_sess” (currently no session) for local FECs or will be marked “retained” for non-local.
Ingr	Whether the FEC is an ingress FEC.

TABLE 232 Output from the **show mpls ldp fec prefix** command (Continued)

This field...	Displays...
Egr	Whether the FEC is an egress FEC.
UM Dist	Specifies if Upstream Mapping Distribution is complete.
Prefix	The IP Prefix associated with the host address or the prefix FEC type.
next_hop	For an ingress FEC, this mentions the next- hop IP address. If LDP selects its outgoing interface as an RSVP tunnel, the next_hop field displays the RSVP tunnel destination address.
out_if	For an ingress FEC, this mentions the output interface to reach to the Next-hop. When applicable, the Out-Intf field displays a VE interface specified by the <*vid*> variable.
Downstream Mappings	Contents of the downstream mapping CB created as a result of the label mapping received from the downstream LDP peer.
Local LDP ID	Local LDP ID of the LDP session to which this downstream mapping CB belongs.
Peer LDP ID	Remote LDP ID of the LDP session to which this downstream mapping CB belongs.
Label	MPLS label received from the downstream LSR.
State	State of label. Either installed or retained.
CB	Memory address of the downstream mapping CB.

Displaying LDP FEC summary information

To display FEC summary information, enter the **show mpls ldp fec summary** command as shown in the following example.

```
NetIron#show mpls ldp fec summary
LDP FEC summary:
  Total number of prefix FECs: 8
  Total number of VC-FEC type 128: 0
  Total number of VC-FEC type 129: 0

LDP error statistics:
  Total number of route update processing errors: 0
  Total number of VC FEC processing errors: 0
```

Syntax: show mpls ldp fec summary

Table 233 lists the output displayed for the **show mpls ldp fec summary** command.

TABLE 233 Output from the **show mpls ldp fec summary** command

This field...	Displays...
LDP FEC summary	Summarized information for LDP FEC.
Total number of prefix FECs	The total number of prefix FECs in the LDP FEC database.
Total number of VC-FEC type 128	The total number of VC FECs for type 128. The FEC type for VC FEC can be 128 or 129.
Total number of VC-FEC TYPE 129	The total number of VC FECs for type 129. The FEC type for VC FEC can be 128 or 129.

This field...	Displays...
Total number of route update processing errors	The total number of route update processing errors for L3 FEC prefix.
Total number of VC FEC processing errors	The total number of L3 VC FEC internal processing errors.

Displaying the LDP FEC VC information

The **show mpls ldp vc-fec** command is renamed to **show mpls ldp fec vc** command. The output from the **show mpls ldp fec vc** command is enhanced to show the total number of VC FECs. The total number of VC FECs is displayed in the Total number of VC FECs field.

You can display a list of VC FECs from the LDP FEC database as shown in the following example.

```
NetIron#show mpls ldp fec vc
Total number of VC FECs: 2
Peer LDP ID           State      VC-ID      VC-Type FEC-Type Ingress Egress
125.125.125.1:0       current    100        4       128      Yes     Yes
125.125.125.1:0       current    1000       5       128      Yes     Yes
```

Syntax: show mpls ldp fec vc [<*vc-id*>]

The <*vc-id*> parameter provides a detailed view of the specified FEC VC. For more information on specifying the FEC VC, refer to "Displaying information for a specified LDP FEC VC" on page 1441.

The **show mpls ldp fec vc** command displays the following information.

TABLE 234 Output from the **show mpls ldp fec vc** command

This field...	Displays...
Total number of VC FECs	The total number of VC FECs.
Peer LDP ID	The remote LDP ID of the peer (or local LSR) where this VC FEC is originated from.
State	The state of the FEC which indicates the FEC is currently being advertised to any LDP session (state equal to "current"). If it has no session, it is either called "cur_no_sess" (currently no session) for local FECs or marked "retained" for non-local FECs.
VC-ID	The VC ID associated with the VC FEC.
VC-Type	The VC Type associated with the VC FEC.
FEC-Type	The number that identifies the FEC Type
Ingress	Whether the FEC in an ingress FEC.
Egress	Whether the FEC in an egress FEC.

Displaying information for a specified LDP FEC VC

The output from the **show mpls ldp fec vc** <*vc-id*> command has changed in the following:

- When a VLL or VPLS peer is up, only one FEC_CB is displayed in the output of the **show mpls ldp fec vc** <*vc-id*> command. Previously, two FEC_CBs were displayed in the output.

- The MTU enforcement field is introduced in the **show mpls ldp fec vc** <*vc-id*> command output. The MTU enforcement field indicates whether a MTU enforcement has been enabled. The MTU enforcement field, together with the Local MTU field and Remote MTU field indicates whether a MTU mismatch has occured.
- When the local and remote VC types for a specified VC ID do not match, two FEC_CBs are displayed.

The examples below describe these changes to the **show mpls ldp fec vc** <*vc-id*> command in more detail.

The following example displays VC FEC id 100 in an UP state. Since the local-mtu field and remote-mtu field both display the same MTU value of 1500 (MTU enforcement is enabled), the State field displays Installed. Local and Remote MTUs are now displayed together as part of one VC FEC_CB as shown in the example below.

```
NetIron#show mpls ldp fec vc 100
FEC_CB: 0x29391510, idx: 6, type: 128, pend_notif: None
 State: current, Ingr: Yes, Egr: Yes, UM Dist. done: Yes
 VC-Id: 100, vc-type: 4, grp-id: 0
 Local-mtu: 1500, remote-mtu: 1500, MTU enforcement: enabled

 Downstream mappings:
 Local LDP ID        Peer LDP ID         Label     State     CB
 128.128.128.28:0    125.125.125.1:0     800000    Installed 0x29391328(-1)

 Upstream mappings:
 Local LDP ID        Peer LDP ID         Label     CB
 128.128.128.28:0    125.125.125.1:0     800003    0x2939141c(-1)
```

The **show mpls ldp vc-fec** [<*vc-id*>] command displays the following information

TABLE 235 Output from the **show mpls ldp fec** command

This field...	Displays...
FEC_CB	Memory address of the FEC CB.
idx	A monotonically increasing number assigned to each FEC in the LDP internal FEC tree.
type	FEC type For VC FEC this value can be 128 or 129.
pend_notif	Any notification pending on this FEC.
State	State of the FEC which indicates the FEC is currently being advertised to any LDP session (state equal to “current”). If it has no session, it will either be called “cur_no_sess” (currently no session) for local FECs or will be marked “retained” for non-local FECs.
Ingr	Whether the FEC is an ingress FEC.
Egr	Whether the FEC is an egress FEC.
UM Dlst. done	Specifies if Upstream Mapping Distribution is complete.
VC-Id	The VC ID associated with the VC FEC.
vc-type	The VC Type associated with the VC FEC.
grp-id	The Group ID associated with the VC FEC.
Local-mtu	The local MTU for a specified VC FEC.
remote-mtu	The remote MTU for a specified VC FEC.
MTU enforcement	The user configured MTU enforcement setting that displays Enabled when a specified VC ID is up.

TABLE 235 Output from the **show mpls ldp fec** command (Continued)

This field...	Displays...
Downstream Mappings	Contents of the downstream mapping CB created as a result of the label mapping received from the downstream LDP peer.
Local LDP ID	Local LDP ID of the LDP session to which this downstream mapping CB belongs.
Peer LDP ID	Remote LDP ID of the LDP session to which this downstream mapping CB belongs.
Label	MPLS label received from the downstream LSR.
State	State of label. Either installed or retained.
CB	Memory address of the downstream mapping CB.
Upstream Mappings	Contents of the upstream mapping CB created as a result of the label mapping sent to the upstream LDP peer.
Local LDP ID	Local LDP ID of the LDP session to which this upstream mapping CB belongs.
Peer LDP ID	Remote LDP ID of the LDP session to which this upstream mapping CB belongs.
Label	MPLS label advertised to the upstream LDP LSR.
CB	Memory address of the upstream mapping CB.

The following example displays a MTU mismatch for VC ID of 100 where the VC label received from the remote peer is in a Retained state instead of an Installed state.

```
NetIron#show mpls ldp fec vc 100
FEC_CB: 0x293916f8, idx: 3, type: 128, pend_notif: None
 State: current, Ingr: Yes, Egr: Yes, UM Dist. done: Yes
 VC-Id: 100, vc-type: 4, grp-id: 0
 Local-mtu: 2000, remote-mtu: 1500, MTU enforcement: enabled

 Downstream mappings:
 Local LDP ID        Peer LDP ID         Label     State     CB
 128.128.128.28:0    125.125.125.1:0     800000    Retained  0x29391328(-1)

 Upstream mappings:
 Local LDP ID        Peer LDP ID         Label     CB
 128.128.128.28:0    125.125.125.1:0     800001    0x29391604(-1)
```

The following example displays a VC type mismatch where two VC FEC_CBs are displayed for the same VC ID of 1000. In the example, you can see that one VC type displays 5, and the other VC type displays 11. The two VC FEC_CBs are not associated with each other in any way. The VC type mismatch causes the VC label to display a Retained state instead of an Installed state.

```
NetIron#show mpls ldp fec vc 1000
FEC_CB: 0x29391234, idx: 5, type: 128, pend_notif: None
 State: retained, Ingr: Yes, Egr: Yes, UM Dist. done: No
 VC-Id: 1000, vc-type: 5, grp-id: 0, local-mtu: N/A, remote-mtu: 1500

 Downstream mappings:
 Local LDP ID        Peer LDP ID         Label     State     CB
 128.128.128.28:0    125.125.125.1:0     983040    Retained  0x29391140(-1)

FEC_CB: 0x29391510, idx: 4, type: 128, pend_notif: None
 State: current, Ingr: Yes, Egr: Yes, UM Dist. done: Yes
 VC-Id: 1000, vc-type: 11, grp-id: 0
 Local-mtu: 1500, remote-mtu: N/A, MTU enforcement: enabled

 Upstream mappings:
 Local LDP ID        Peer LDP ID         Label     CB
 128.128.128.28:0    125.125.125.1:0     983041    0x2939141c(-1)
```

Displaying the LDP packet statistics

You can display a packet statistics for packet types and packet errors, as shown in the following.

```
NetIron# show mpls ldp statistics
                      Total                Since last clear
 PacketType         Sent      Received       Sent      Received
  Link Hello         215       214           215        214
  Targeted Hello     138       110           138       110
  Init               1         1             1         1
  KeepAlive          16        18            16        18
  Notification       0         0             0         0
  Address            2         0             2         0
  AddressWithdraw    0         0             0         0
  LabelMapping       0         0             0         0
  LabelRequest       0         0             0         0
  LabelWithdraw      0         0             0         0
  LabelRelease       0         0             0         0
  LabelAbortReq      0         0             0         0

 Errors                       Total          Since last clear
  Rcv pkt bad pdu length      0              0
  Rcv pkt bad msg length      0              0
  Rcv pkt bad tlv length      0              0
  Rcv pkt notify unkn tlv     0              0
  Rcv pkt notify unkn addrfam 0              0
  Rcv pkt missing tlv         0              0
  Rcv pkt incorrect tlv       0              0
  Rcv pkt malformed tlv       0              0
  Rcv pkt bad traffic parm    0              0
  Rcv pkt partial pdu         0              0
  Rcv pkt internal error      0              0

  TCP send error              0              0
  TCP get send pkt error      0              0
  TCP memory fail             0              0
Num of TCP socket buffers: 0
```

Syntax: show mpls ldp statistics

The **show mpls ldp statistics** command displays the following information

TABLE 236 Output from the show mpls ldp statistics command

This field...	Displays...
PacketType	The type of LDP packet being counted.
Total	The number of the packets of the Type described for the row, sent and received since the router came up.
Since Last Clear	The number of the packets of the Type described for the row, sent and received since the last time a clear command was issued.
Errors	The type of packet error being counted. These errors are associated with the received packets only.
Total	The number of the errors of the Type described for the row, generated since the router came up.
Since Last Clear	The number of the errors of the Type described for the row, generated since the last time a clear command was issued.

Clearing the LDP packet statistics

You can clear the LDP Packet Statistics, as shown in the following commands.

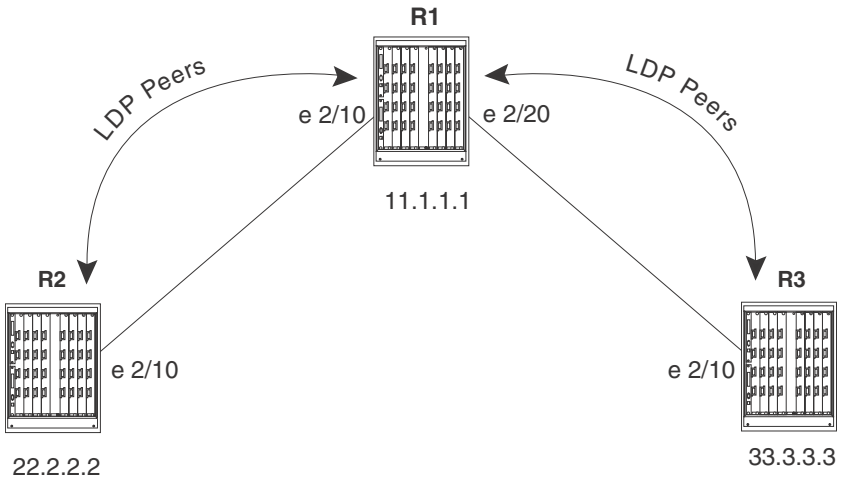
```
NetIron# clear mpls ldp statistics
```

Syntax: clear mpls ldp statistics

Sample LDP configurations

Figure 188 illustrates a sample configuration with three LDP-enabled LSRs.

FIGURE 188 Sample LDP configuration



Router R1

The following commands configure Router R1 in Figure 188.

```
R1(config)# interface loopback 1
R1(config-lbif-1)# ip address 11.1.1.1/32
R1(config-lbif-1)# exit
R1(config)# router mpls
R1(config-mpls)# mpls-interface e 2/10
R1(config-mpls)# ldp-enable
R1(config-mpls)# mpls-interface e 2/20
R1(config-mpls)# ldp-enable
R1(config-mpls)# exit
R1(config)# ip route 22.2.2.2/32 10.1.1.2
R1(config)# ip route 33.3.3.3/32 20.1.1.2
R1(config)# route-only
R1(config)# interface ethernet 2/10
R1(config-if-2/10)# enable
R1(config-if-2/10)# ip address 10.1.1.1/24
R1(config-if-2/10)# exit
R1(config)# interface ethernet 2/20
R1(config-if-2/20)# enable
R1(config-if-2/20)# ip address 20.1.1.1/24
```

Router R2

The following commands configure Router R2 in Figure 188.

```
R2(config)# interface loopback 1
R2(config-lbif-1)# ip address 22.2.2.2/32
R2(config-lbif-1)# exit
R2(config)# router mpls
R2(config-mpls)# mpls-interface e 2/10
R2(config-mpls)# ldp-enable
R2(config-mpls)# exit
R2(config)# ip route 11.1.1.1/32 10.1.1.1
R2(config)# ip route 33.3.3.3/32 10.1.1.1
R2(config)# route-only
R2(config)# interface ethernet 2/20
R2(config-if-2/20)# enable
R2(config-if-2/20)# ip address 10.1.1.2/24
R2(config-if-2/20)# exit
```

Router R3

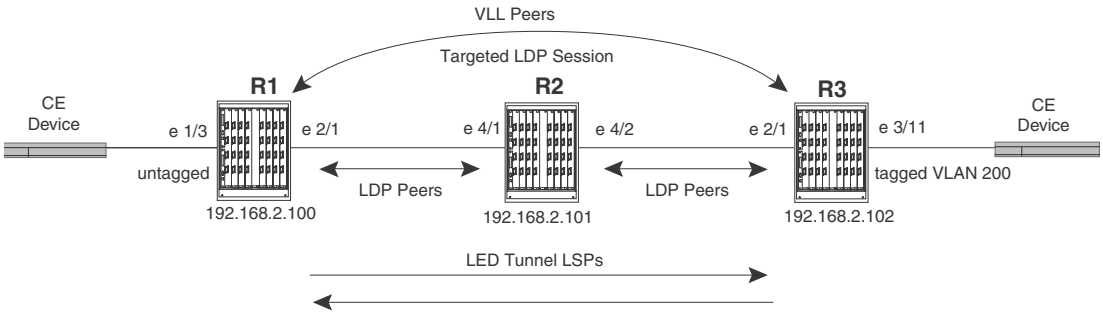
The following commands configure Router R3 in Figure 188.

```
R3(config)# interface loopback 1
R3(config-lbif-1)# ip address 33.3.3.3/32
R3(config-lbif-1)# exit
R3(config)# router mpls
R3(config-mpls)# mpls-interface e 2/10
R3(config-mpls)# ldp-enable
R3(config-mpls)# exit
R3(config)# ip route 11.1.1.1/32 20.1.1.1
R3(config)# ip route 22.2.2.2/32 20.1.1.1
R3(config)# route-only
R3(config)# interface ethernet 2/20
R3(config-if-2/20)# enable
R3(config-if-2/20)# 20.1.1.2/24
R3(config-if-2/20)# exit
```

Sample LDP configuration with VLL

Figure 189 illustrates a sample Virtual Leased Line (VLL) configuration that uses LDP tunnel LSPs.

FIGURE 189 MPLS VLL configuration with LDP tunnel LSPs



In this example, routers R1 and R3 are Provider Edge (PE) routers configured as VLL peers. R1 and R3 have established a targeted LDP session to exchange VLL label information. When this targeted LDP session is established, each router advertises its locally assigned VC label and VC ID to its VLL peer.

In addition, LDP sessions have been established between R1 – R2 and R2 – R3. LDP tunnel LSPs exist in each direction between R1 and R3. When the CE device forwards a Layer 2 packet to R1, the router assigns the packet to an LSP whose destination is R3. R1 encapsulates the packet as an MPLS packet, adding a tunnel label and the VC label advertised to the router by R3. The MPLS packet is then forwarded over the outbound interface indicated by the tunnel label to the next hop in the LSP.

When the MPLS packet reaches R2, the penultimate LSR in the tunnel LSP, R2 pops the tunnel label, leaving the packet with only the VC label, then forwards the packet to R3.

R3 examines the VC label in the packet. On R3, the VC label is mapped to the user-specified endpoint for the VLL. In this example, the endpoint consists of VLAN ID 200 and interface 3/11. R3 then pops the VC label, tags the Layer 2 packet with VLAN 200, then forwards the packet out interface 3/11.

In the opposite direction, R3 assigns traffic received from the CE device to a tunnel LSP destined for R1, pushes tunnel and VC labels onto the packets, and forwards them to the next hop in the LSP. When the packets reach R1, the router pops the VC label and forwards the Layer 2 packets out the interface indicated by the VLL endpoint. In this example, the endpoint consists of interface 1/3, so the packets are forwarded untagged out interface 1/3 to the CE device.

Router R1

The following commands configure Router R1 in Figure 189.

```
R1(config-mpls)# interface loopback 1
R1(config-lbif-1)# port-name Generic All-Purpose Loopback
R1(config-lbif-1)# ip address 192.168.2.100/32
R1(config-lbif-1)# ip ospf area 0
R1(config-lbif-1)# exit
R1(config)# router mpls
R1(config-mpls)# mpls-interface e 2/1
R1(config-mpls)# ldp-enable
R1(config-mpls)# exit
```

```
R1(config-mpls)# vll VLL_to_R3 40000
R1(config-mpls-vll)# vll-peer 192.168.2.102
R1(config-mpls-vll)# untagged e 1/3
R1(config-mpls-vll)# exit
R1(config)# ip router-id 192.168.2.100
R1(config)# router ospf
R1(config-ospf-router)# area 0
R1(config-ospf-router)# exit
R1(config-mpls)# interface e 1/3
R1(config-if-e100-1/3)# port-name VLL_endpoint
R1(config-if-e100-1/3)# enable
R1(config-if-e100-1/3)# exit
R1(config-mpls)# interface e 2/1
R1(config-e10000-2/1)# port-name Connection_to_R2
R1(config-e10000-2/1)# enable
R1(config-e10000-2/1)# ip address 192.168.37.1/30
R1(config-e10000-2/1)# ip ospf area 0
R1(config-e10000-2/1)# exit
```

Router R2

The following commands configure Router R2 in Figure 189.

```
R2(config-mpls)# interface loopback 1
R2(config-lbif-1)# port-name Generic All-Purpose Loopback
R2(config-lbif-1)# ip address 192.168.2.101/32
R2(config-lbif-1)# ip ospf area 0
R2(config-lbif-1)# exit
R2(config)# router mpls
R2(config-mpls)# mpls-interface e 4/1 e 4/2
R2(config-mpls)# ldp-enable
R2(config-mpls)# exit
R2(config)# ip router-id 192.168.2.101
R2(config)# router ospf
R2(config-ospf-router)# area 0
R2(config-ospf-router)# exit
R2(config-mpls)# interface e 4/1
R2(config-e10000-4/1)# enable
R2(config-e10000-4/1)# ip address 192.168.40.1/30
R2(config-e10000-4/1)# ip ospf area 0
R2(config-e10000-4/1)# exit
R2(config-mpls)# interface e 4/2
R2(config-e10000-4/2)# enable
R2(config-e10000-4/2)# ip address 192.168.40.9/30
R2(config-e10000-4/2)# ip ospf area 0
R2(config-e10000-4/2)# exit
```

Router R3

The following commands configure Router R3 in Figure 189.

```
R3(config-mpls)# interface loopback 1
R3(config-lbif-1)# port-name Generic All-Purpose Loopback
R3(config-lbif-1)# ip address 192.168.2.102/32
R3(config-lbif-1)# ip ospf area 0
R3(config-lbif-1)# exit
```

```
R3(config)# router mpls
R3(config-mpls)# mpls-interface e 2/1
R3(config-mpls)# ldp-enable
R3(config-mpls)# exit
R3(config-mpls)# vll VLL_to_R1 40000
R3(config-mpls-vll)# vll-peer 192.168.2.100
R3(config-mpls-vll)# vlan 200
R3(config-mpls-vll-vlan)# tagged e 3/11
R3(config-mpls-vll-vlan)# exit
R3(config-mpls-vll)# exit
R3(config)# ip router-id 192.168.2.102
R3(config)# router ospf
R3(config-ospf-router)# area 0
R3(config-ospf-router)# exit
R3(config-mpls)# interface e 3/11
R3(config-if-e100-3/11)# port-name VLL_endpoint
R3(config-if-e100-3/11)# enable
R3(config-if-e100-3/11)# exit
R3(config-mpls)# interface e 2/1
R3(config-e10000-2/1)# port-name Connection_to_R2
R3(config-e10000-2/1)# enable
R3(config-e10000-2/1)# ip address 192.168.41.1/30
R3(config-e10000-2/1)# ip ospf area 0
R3(config-e10000-2/1)# exit
```

Configuring MPLS Virtual Leased Line 32

Overview

The following list displays the MPLS Virtual Leased Line (VLL) features support by PowerConnect B-MLXe:

- MPLS Virtual Leased Line (VLL)
- MPLS VLL Packet Encoding
- QoS for VLL Traffic
- Tagged or Raw Mode for a VLL
- Dual tag support for MPLS VLL
- VLL MTU Enforcement
- VLL MTU
- Display changes to the **show mpls vll** detail command
- Local VLL
- VLAN Translation
- VPLS and VLL support - Per VLL MTU
- Dynamic LAG support for VLL endpoints
- Dual-tags for VLL-local
- MPLS Signalling: RSVP-TE support
- Traps for VLLs
- MPLS Local VLL Traps
- Disabling Syslog Messages for MPLS VLL-Local and VLL

This chapter explains how to configure **MPLS Virtual Leased Line (VLL)** on a NetIron. Virtual Leased Line is also known as Pseudo Wire Emulation as defined by the IETF PWE3 Working Group. MPLS VLL is a method for providing point-to-point Ethernet or VLAN connectivity over an MPLS domain. This functionality is outlined in the IETF documents “draft-ietf-pwe3-control-protocol-14.txt” and “draft-ietf-pwe3-ethernet-encap-08.txt”.

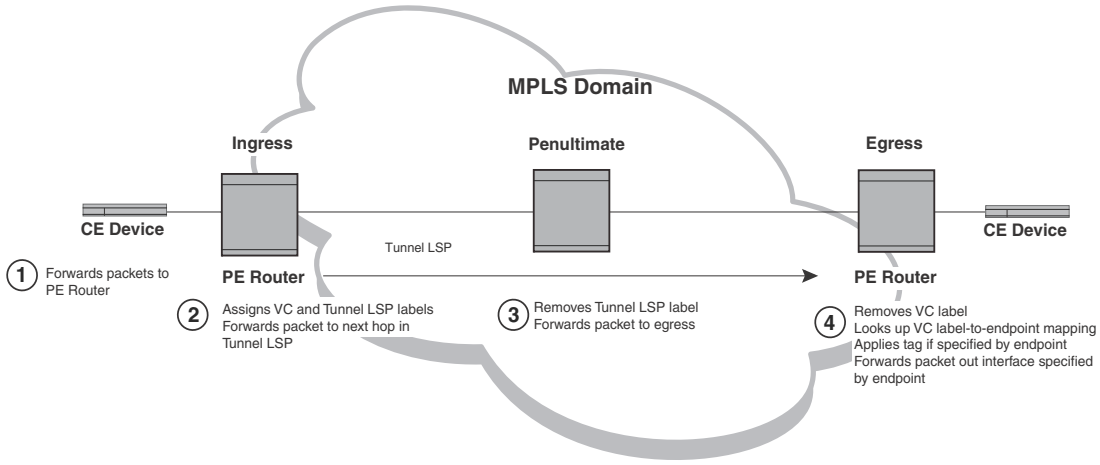
This chapter is divided into the following sections:

- “How MPLS VLL works” on page 1452 describes how packets are encapsulated and forwarded over an MPLS VLL.
- “Example 2: CoS behavior for dual-tagged to single-tagged VLL endpoints” on page 1459 describes how to set up MPLS VLLs on devices using the Command Line Interface (CLI).
- “Displaying MPLS VLL information” on page 1468 describes the commands used to display information about an MPLS VLL configuration.
- “Sample MPLS VLL configuration” on page 1477 illustrates a sample MPLS VLL configuration and lists the CLI commands used for implementing it.

How MPLS VLL works

The following diagram illustrates how packets are forwarded over an MPLS VLL.

FIGURE 190 Forwarding packets over an MPLS VLL



Packets are forwarded over an MPLS VLL as described below.

1. A Customer Edge (CE) device forwards a packet to a Label Edge Router (LER) serving as a Provider Edge (PE) router at the edge of the MPLS domain.
2. The PE router assigns the packet to an RSVP-signalled LSP whose destination is an LER (also serving as a PE router) that is connected to a CE device at the far end of the MPLS domain. The PE router at the other end of the MPLS domain is known as this PE router's ***VLL peer***. The RSVP-signalled LSP used to reach the VLL peer is known as the ***tunnel LSP***. Alternatively, an LDP-signalled, tunneled LSP can be used.

   If a Class of Service (COS) value is set for the VLL, the device selects a tunnel LSP that also has this COS value, if one is available. If no tunnel LSP with this COS value is available, the device selects a tunnel LSP with the highest configured COS value (although never higher than the COS setting for the VLL). Refer to "QoS for VLL traffic" on page 1453 for more information.

   If there are multiple tunnel LSPs that can be used to reach the VLL peer, the PE router selects one of the tunnel LSPs by using a round-robin method.

   The PE router pushes two labels onto the packet:

   - The inner ***VC label*** is used for determining what happens to the packet once it reaches the VLL peer. This label is significant only to the VLL peer.
   - The outer ***tunnel label*** is used for forwarding the packet through the MPLS domain. This label corresponds to an RSVP-signalled tunnel LSP.

   Refer to "MPLS VLL packet encoding" on page 1453 for information on the structure of packets forwarded along an MPLS VLL. After applying the two labels to the packet, the PE router forwards it to the next LSR in the tunnel LSP.
3. The penultimate LSR in the tunnel LSP removes the tunnel label and forwards the packet (now with the VC label as the top label) to the PE router at the other edge of the MPLS domain.
4. The VLL peer at the egress of the tunnel LSP examines the VC label. This VC label is mapped to an ***endpoint*** for the VLL. The endpoint of a VLL specifies what happens to packets exiting the VLL.

The endpoint can specify an untagged, dual-tagged, or single-tagged port.

- For *untagged* ports, the endpoint consists of an interface.
- For *single-tagged* ports, the endpoint consists of an interface and a VLAN ID.
- For *dual-tagged* ports, the endpoint consists of an interface and dual (outer and inner) VLAN IDs.

The egress LER removes the VC label and forwards the packet out the interface specified as the endpoint. If the endpoint is a single-tagged or dual-tagged port, the device transmits the packet with the specified VLAN ID, or with the dual tags, forwarding it out the specified interface to the CE device.

The two VLL peers advertise VC labels to each other using the ***Label Distribution Protocol (LDP)***. Each PE router attempts to initiate an LDP session with its VLL peer. After the LDP session is established, the locally assigned VC label, along with a VLL VC ID, is advertised to the VLL peer. In a similar way, the PE also learns the remotely assigned VC label from the VLL peer. Alternatively, you can configure static local and remote VC labels manually on both VLL peers; in this case, LDP is not used.

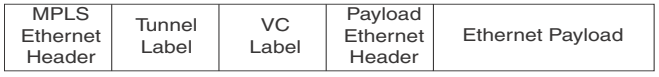
MPLS VLLs are not involved with spanning tree operations.

NOTE
If MTUs are mismatched on both sides of a VLL session, the session does not come up.

MPLS VLL packet encoding

When a packet is forwarded from the CE device, the PE router encapsulates it as an MPLS packet, applying two labels. The resulting MPLS packet has the following structure.

FIGURE 191 Structure of a packet forwarded over an MPLS VLL



The S bit in the tunnel label is zero, indicating that it is not the bottom of the stack. The VC label is significant only to the PE router at the other end of the VLL.

The Payload Ethernet header may be single-tagged or untagged.

QoS for VLL traffic

By default, packets travelling through an MPLS domain are treated equally from a QoS standpoint, in a best effort manner. However, if a Layer 2 packet has an internal priority in its 802.1q tag, or the LSP or VLL to which the packet is assigned has a configured Class of Service (COS) value, QoS can be applied to the packet in the MPLS domain. The internal priority or COS value is mapped to a value in the EXP field of the packet's MPLS header. The value in the EXP field is then mapped to an internal forwarding priority, and the packet is sent to the hardware forwarding queue that corresponds to the internal forwarding priority.

QoS for VLL traffic at the ingress LER

The following methods can be used to provide QoS to packets entering a VLL:

- Use the COS value assigned to the tunnel LSP used to reach the VLL peer.

When a tunnel LSP has a user-configured COS value, all packets in all VLLs travelling through the tunnel LSP receive the same QoS.

- Use the COS value assigned to the VLL.

  If a COS value is set for the VLL, the device selects a tunnel LSP that also has this COS value, if one is available. If no tunnel LSP with this COS value is available, the device selects a tunnel LSP with the highest configured COS value (although never higher than the COS setting for the VLL).

  If the selected tunnel LSP does not have a COS value, the VLL's configured COS value is used to provide QoS. The VLL's COS value is mapped to a value in the EXP field. This allows traffic multiple VLLs using a single tunnel LSP, traffic from each VLL can receive different QoS treatment.

- Use the priority in the packet's 802.1q tag.

  When neither the tunnel LSP nor the VLL has a configured COS value, the device examines the priority in the Layer 2 packet's 802.1q tag, if the packet has one. Consequently, Layer 2 packets with the same 802.1q priority receive the same QoS in the VLL.

- Use the configured priority of the port.

  If neither the tunnel LSP nor the VLL has a configured COS value, and the Layer 2 packet does not have an 802.1q priority, QoS can be provided based on the priority of the incoming port. A port can be assigned a priority from 0 (lowest priority) to 7 (highest priority). The default port priority is 0.

  By assigning different priorities to the ports where customer edge (CE) devices are connected (that is, the VLL endpoints), you can provide QoS to untagged Layer 2 traffic received from different customer locations.

When a packet enters a VLL, the PE router that serves as both the VLL endpoint and the ingress of a tunnel LSP pushes two labels onto the packet the inner VC label and the outer tunnel label. The packet's priority resides in the EXP field of the MPLS label header. The VC label and the tunnel label carry the same value in the EXP field.

The following table lists how a Layer 2 packet's priority is mapped to a value in the EXP field and how the EXP value is mapped to a priority queue.

Tunnel LSP configured COS or VLL configured COS or 802.1q priority or Configured port priority	Value placed in the tunnel and VC label EXP field	Priority queue
7	7	qosp7 (highest priority)
6	6	qosp6
5	5	qosp5
4	4	qosp4
3	3	qosp3
2	2	qosp2
1	1	qosp1
0	0	qosp0 (best effort)

QoS for VLL traffic at transit LSRs

At each transit LSR, the device reads the value in the tunnel label's EXP field and places the incoming EXP value in the EXP field of the outbound packet. The outbound MPLS packet is assigned to one of the eight priority queues based on the value in the EXP field. The EXP bits in the MPLS header are used to assign the packet to a priority queue as follows:

EXP Bits in tunnel label	Priority queue
7	qosp7 (highest priority)
6	qosp6
5	qosp5
4	qosp4
3	qosp3
2	qosp2
1	qosp1
0	qosp0 (best effort)

QoS for VLL traffic at the penultimate LSR

When the packet reaches the penultimate LSR in the LSP, its tunnel label is popped, leaving the VC label. The MPLS packet is placed in one of the priority queues using the value in the EXP field of the VC label. Since the VC label has the same EXP value as the tunnel label, the packet is placed in the same queue used for the tunnel LSP.

QoS for VLL traffic at the egress LER

At the VLL endpoint, the VC label is popped and the packet is forwarded as a Layer 2 packet. The packet is placed in one of the priority queues based on the contents of the EXP field in the VC label, as follows:

EXP Bits in VC label	Priority queue
6, 7	qosp3 (highest priority)
4, 5	qosp2
2, 3	qosp1
0, 1	qosp0 (best effort)

CoS behavior for VLL tagged mode and VLL raw mode

This section describes the difference in CoS behavior for VLL traffic when tagged mode or raw mode is in effect.

CoS behavior for VLL tagged mode

NOTE
This section assumes that you understand how QoS works. For details, see 9, "Configuring Quality of Service for the NetIron MLX".

Table 237 describes the expected Class of Service (CoS) behavior for VLL packets when VLL tagged mode is enabled.

TABLE 237 Expected class of service behavior for VLL tagged mode

VLL endpoints	Incoming packet		MPLS cloud		Outgoing packet	
	Outer VLAN	Inner VLAN	Tunnel/VC label (Z)	Payload tag	Outer VLAN	Inner VLAN
Dual-tagged to dual-tagged	X	Y	V or internal priority	Y	W or Y	Y
Single-tagged to dual-tagged	X	N/A		X	W or X	X
Untagged to dual-tagged	N/A	N/A		0	W or 0	0
Dual-tagged to single-tagged	X	Y		Y	W or Y	N/A

NOTE
For more specific examples of CoS behavior for tagged mode, see "Example 1: CoS behavior for dual-tagged to dual-tagged VLL endpoints" on page 1457 and "Example 2: CoS behavior for dual-tagged to single-tagged VLL endpoints" on page 1459.

Legend for Table 237

V = mapped EXP bits from internal priority (X contributes to internal priority) using the EXP encode table. Table 57 shows the default EXP encode table.

W = mapped COS from internal priority (Z contributes to internal priority) using the COS encode table

X = original outer VLAN COS

Y = original inner VLAN COS

Z = incoming EXP bits as described by Tunnel / VC label column = V or internal priority

or in the *Tunnel/VC label* column differentiates the behavior between when **qos exp encode** policy is ON (default) or OFF.

or in the *Outgoing packet Outer VLAN* column differentiates the behavior between when **qos pcp encode** policy is ON (default) or OFF.

CoS behavior for VLL raw mode

NOTE
This section assumes that you understand how QoS works. For details, see 9, "Configuring Quality of Service for the NetIron MLX".

Table 238 describes the expected Class of Service (CoS) behavior for VLL packets when VLL raw mode is in effect.

TABLE 238 Expected class of service behavior for VLL raw mode

VLL endpoints	Incoming packet		MPLS cloud		Outgoing packet	
	Outer VLAN	Inner VLAN	Tunnel/VC label (Z)	Payload tag	Outer VLAN	Inner VLAN
Dual-tagged to dual-tagged	X	Y	V or internal priority	N/A	W or Z	Z
Single-tagged to dual-tagged	X	N/A				Z
Untagged to dual-tagged	N/A	N/A				Z
Dual-tagged to single-tagged	X	Y				N/A

NOTE
For more specific examples of CoS behavior for raw mode, see "Example 1: CoS behavior for dual-tagged to dual-tagged VLL endpoints" on page 1457 and "Example 2: CoS behavior for dual-tagged to single-tagged VLL endpoints" on page 1459.

Legend for Table 238

V = mapped EXP bits from internal priority (X contributes to internal priority) using the EXP encode table. Table 53 shows the default EXP encode table.

W = mapped COS from internal priority (Z contributes to internal priority) using the COS encode table.

X = original outer VLAN COS

Y = original inner VLAN COS

Z = incoming EXP bits as described by Tunnel / VC label column = V or internal priority

or in the *Tunnel/VC label* column differentiates the behavior when **qos exp encode** policy is ON (default) or OFF.

or in the *Outgoing packet Outer VLAN* column differentiates the behavior when **qos pcp encode** policy is ON (default) or OFF.

Example 1: CoS behavior for dual-tagged to dual-tagged VLL endpoints

Table 239 shows a detailed example of the CoS behavior in a dual-tagged to dual-tagged VLL endpoint configuration. The table shows the difference in behavior for VLL tagged mode (described in Table 237) versus VLL raw mode (described in Table 238).

TABLE 239 Example CoS behavior in a dual-tagged to dual-tagged VLL endpoint configuration

Configuring MPLS VLLs

This section explains how to set up MPLS VLLs.

Creating a VLL

You create a VLL by entering VLL configuration statements on two PE routers. The two endpoints of a VLL are associated by having the same VLL VC ID on each PE router.

To create an MPLS VLL, enter commands such as the following.

```
NetIron(config-mpls)# vll foundry-sj-to-sf 40000
NetIron(config-mpls-vll)#
```

On the VLL peer (if it is a device), you would enter commands such as the following.

```
NetIron(config-mpls)# vll foundry-sf-to-sj 40000
NetIron(config-mpls-vll)#
```

Syntax: vll <*vll-name*> <*vll-vc-id*> **[cos** <*cos value*>**] [raw-mode]**

The <*vll-vc-id*> corresponds to the user-configurable ID defined in draft-ietf-pwe3-control-protocol-14.txt.

You can optionally specify a Class of Service (COS) setting for the VLL. If a COS value is set, the device selects a tunnel LSP that also has this COS value, if one is available. If no tunnel LSP with this COS value is available, the device selects a tunnel LSP with the highest configured COS value (although never higher than the COS setting for the VLL). The COS value can be between 0 – 7.

Specifying tagged or raw mode for a VLL

The default treatment for packets that are sent through a VLL is for the ingress router to add a VLAN ID tag to the payload Ethernet header. When the packet arrives at the egress router, the tag is stripped off and the packet is forwarded.

You can configure a VLL to send all packets in “raw” mode. This means that the ingress router of the VLL will not add a VLAN ID tag to the payload Ethernet header and consequently the egress router will not have to strip it off. Both the ingress and egress routers must be configured in either default (tagged mode) or raw mode. To configure a router to send or receive packets for a VLL in raw mode, enter the following command.

```
NetIron(config-mpls)# vll <vll-name> <vll-vc-id> raw-mode
```

Syntax: vll <*vll-name*> <*vll-vc-id*> **[raw-mode]**

The <*vll-name*> is the name of the VLL you want to configure raw mode for.

The <*vll-vc-id*> corresponds to the user-configurable ID defined in draft-ietf-pwe3-control-protocol-14.txt.

If **raw-mode** is specified, the VC type for signaling will be 5, otherwise it will be 4 (for tagged mode).

If **raw-mode** is not specified, the default configuration is for the ingress router to send packets with a tag, and for the egress router to strip it off before forwarding the packets.

NOTE
If there is a VC type mismatch between VLL peers, a session will not be brought up between them.

Specifying a VLL peer

The VLL peer is the PE router at the other end of the VLL. As part of VLL configuration, you specify the IP address of the VLL peer.

Each PE router must have tunnel LSP reachability to its VLL peer. Tunnel LSP reachability is defined as having at least one operational LSP tunnel with the destination (the LSP’s “to” address) matching the VLL peer’s IP address. An LSP terminating on the VLL peer but configured with a different destination address would not be considered a match.

If a PE router does not have tunnel LSP reachability to its VLL peer, or if the remote VC label is not yet available, packets from the local interface are discarded at the ingress PE router. If the local interface is administratively disabled or goes down, a VC label withdraw message is sent to the VLL peer.

By default, each PE router attempts to initiate an LDP session through extended discovery with its VLL peer, if a session is not already established. The PE router also allocates a VC label from a per-platform label range that is mapped to the local endpoint. Once the LDP session is established, the locally assigned VC label, along with the VLL VC ID is advertised to the VLL peer in a downstream-unsolicited manner. In a similar way, the PE also learns the remotely assigned VC label from the VLL peer.

Alternatively, you can configure static local and remote VC labels. In this case, no LDP session is established between the VLL peers. Note that if you use static VC labels, you must configure them on both VLL peers manually.

You specify the peer at the other end of the VLL by entering a command such as the following.

```
NetIron(config-mpls-vll)# vll-peer 192.168.2.100
```

Syntax: vll-peer <*ip-addr*> [<*static-local-vc-label*> <*static-remote-vc-label*>]

The IP address of the peer must match that of a destination for a tunnel LSP configured on the device.

Static local and remote VC label values are optional. If configured, <*static-local-vc-label*> is the VC label value expected for packets forwarded to the local physical port from the VLL peer, and <*static-remote-vc-label*> is the VC label applied to packets sent to the remote VLL peer.

Acceptable values for <*static-local-vc-label*> are 800000 – 1048575. If the label value you specify has already been assigned, a message is displayed requesting a different value.

Specifying a VLL endpoint

The endpoint of a VLL specifies what happens to packets exiting the VLL. You set the endpoint on the local PE router and this endpoint is mapped to a VC label. The VC label is advertised to the remote PE router at the other end of the VLL through LDP. The remote PE router applies this label to packets entering the VLL. When the packet reaches the end of the VLL through the MPLS uplink, the local PE router checks the mapping between the VC label and the endpoint, removes the VC label from the packet, and forwards the packet out the port specified as the endpoint.

All VLL endpoints can be dual-mode ports (tagged-untagged). An untagged endpoint port is removed from the default VLAN and cannot be added back to the default VLAN. A VLL endpoint can be tagged in multiple VLL and L2 VLANs and untagged in one other VLAN.

The Customer Edge (CE) device is connected to the PE router over an untagged, dual-tagged, or single-tagged port.

- With a *single-tagged* port, each pair (port, VLAN ID) is identified as a unique endpoint, and the packets are sent in tagged Ethernet format.
- In the case of an *untagged* port, an endpoint is identified by the physical port alone, and the packets are sent in untagged Ethernet format.
- In the case of a *dual-tagged* port, the packets contain both an outer VLAN tag and an inner VLAN tag.

Special considerations for VLL dual-tagged endpoints

Before configuring a dual-tagged endpoint, consider the following:

- An Internal Forwarding Lookup Identifier (IFL-ID) will be allocated to each MPLS VLL instance that has a dual-tagged endpoint. The ID will be displayed in the **show mpls vll detail** command output. For instances that do not have dual-tagged endpoints, the IFL-ID will be displayed as '--'.

  NOTE
  The acceptable values and configuration procedures for the system-max ifl-cam command are in the section "Configuring system max values" on page 106.

- The tag protocol identifier (TPID) of the inner VLAN tag must be 0x8100 in order to be classified as dual-tagged and recognized by dual-tagged endpoints. If the TPID is not 0x8100, the packet will be classified as a single-tagged packet.
- The same port, outer VLAN, and inner VLAN combination cannot be specified across MPLS VLL instances. For example, if a dual-tagged endpoint with vlan 100 and inner-vlan 200 is configured on port e 2/1 in MPLS VLL instance 'test', the same endpoint cannot be configured as part of another MPLS VLL instance, say 'test1'. This is also true across applications. That is, if a port, outer VLAN, and inner VLAN combination belongs to a MPLS VLL instance, it cannot simultaneously belong to a Layer 2 VLAN, Local VLL or VPLS.
- To change an existing single-tagged VLL endpoint to a dual-tagged endpoint, first delete the VLAN configuration, then configure the endpoint as dual-tagged.

- A dual-tagged VLL endpoint neither recognizes nor forwards packets that have a single tag. However, a single-tagged endpoint can recognize and forward dual-tagged packets because the endpoint treats the second tag as data.
- The port, outer VLAN, and inner VLAN combination in an incoming dual- tagged packet on a given port will be used to do an IFL CAM lookup. This lookup will yield an IFL-ID which will be used to do a MPLS-VLL CAM lookup. So for dual-tagged endpoints, the regular (port, vlan) lookup is replaced with the (port, IFL-ID) lookup.
- If only the outer VLAN is specified for a given endpoint, it is called a *less-specific* VLAN. If both the outer and inner VLAN are specified, it is called a *more-specific* VLAN (in relation to the outer VLAN).
- If a less-specific VLAN is already configured on a given port, then a more-specific VLAN with the same outer VLAN tag can also be configured on that port. Likewise, when a more-specific VLAN is already configured on a given port, then a less-specific VLAN with the same outer VLAN tag can also be configured on the port.

  In the following example, a less-specific tagged endpoint has been configured with vlan 100 on port e 2/1, and a more-specific VLAN with an outer VLAN tag of **100** and an inner vlan tag of **200** has also been configured on port e 2/1.

```
MLXe(config-mpls)#vll test1 1000
MLXe(config-mpls-vll-test1)#vlan 100
MLXe(config-mpls-vll-test1-vlan)#tag e 2/1
MLXe(config-mpls-vll-test1-if-e-2/1)#vll test2 2000
MLXe(config-mpls-vll-test2)#vlan 100 inner-vlan 200
MLXe(config-mpls-vll-test2-vlan)#tag e 2/1
```

  This applies even when the less/more-specific VLAN is configured as part of a L2 VLAN, Local VLL or VPLS.

Specifying an untagged endpoint

Untagged ports are not associated with any VLAN. A port must be a member of the default VLAN before it can be used in a VLL configuration as an untagged port. Upon configuration as the endpoint of a VLL, the port is taken out of the default VLAN. This means no local broadcast traffic includes this port. A VLL untagged port does not belong to any VLAN. If the port is currently a member of a regular VLAN or another VLL, the configuration attempt should be rejected.

NOTE
If a port is added as an untagged port into a VLL, a VLAN should not be defined under the VLL. If a VLAN is configured under the VLL, the configuration to add an untagged port will be rejected.

To specify an untagged endpoint for a VLL.

```
NetIron(config-mpls-vll)# untagged e 2/1
```

Syntax: untagged [ethernet] <*portnum*>

NOTE
Foundry Discovery Protocol (FDP) should not be enabled on an untagged VPLS or VLL endpoint.

Specifying a single-tagged endpoint

Tagged ports are configured under a VLAN ID. This VLAN ID is only meaningful for this tagged port. Another tagged port may use the same VLAN ID but the two ports are not under the same VLAN.

For tagged ports, a <*vlan-id, port*> pair constitutes a VLL endpoint. One VLL may configure a VLAN ID on one port and another VLL may reuse the same VLAN ID on another port. This capability is know as VLAN ID reuse.

As with regular VLANs, if a port is currently a member of a non-default VLAN as an untagged port, it must be returned to the default VLAN before it can be assigned to a VLL as a tagged port.

To specify a tagged endpoint for a VLL.

```
NetIron(config-mpls-vll)# vlan 200
NetIron(config-mpls-vll-vlan)# tagged e 3/11
```

Syntax: vlan <*num*>

Syntax: tagged [ethernet] <*slot/port*>

NOTE
A tagged port can be a part of one or more VLLs, and at the same time be part of one or more regular VLANs and one or more VPLSs as a tagged member.

Specifying a dual-tagged endpoint

Dual-tagged packets contain both an outer VLAN tag and an inner VLAN tag. Dual-tagged VLL endpoints enable MPLS VLL to recognize packets with two tags and make forwarding decisions based on them. A dual-tagged endpoint can receive packets with two tags and forward them to the other endpoint either untagged, single-tagged, or dual-tagged.

NOTE
Before configuring a dual-tagged endpoint, see "Special considerations for VLL dual-tagged endpoints" on page 1462.

To specify a dual-tagged endpoint for a VLL instance, enter commands such as the following:

```
NetIron(config-mpls)# vll test 100
NetIron(config-mpls-vll-test)# vlan 200 inner-vlan 300
NetIron(config-mpls-vll-test-vlan)#tagged e 3/11
```

Syntax: [**no**] **vlan** <*vlan-id*> **inner-vlan** <*vlan-id*>

Syntax: [**no**] **tagged ethernet** <*slot/port*>

The **vlan** <*vlan-id*>, which is the outer VLAN ID, can be in the range from 1 to 4094 and excludes the default VLAN.

The **inner-vlan** <*vlan-id*> can be in the range from 1 to 4095 and includes the default VLAN.

Use the **no** form of the command to remove the dual-tagged VLL VLAN configuration and its associated endpoints. For example, the command **no vlan 200 inner-vlan 300** will remove the dual-tagged VLAN and associated endpoints. The single-tagged VLAN, **vlan 200**, will not be deleted. Similarly, the command **no vlan 200** will remove the single-tagged VLAN, vlan 200, and associated endpoints. The dual-tagged VLAN, **vlan 200 inner-vlan 300**, will not be deleted.

NOTE
A tagged port can be a part of one or more VLLs, and at the same time be part of one or more regular VLANs and one or more VPLSs as a tagged member.

Viewing the VLL dual-tagged configuration

Use the **show running config** and **show mpls vll** commands to view the VLL dual-tagged configuration. The following shows an example **show running config** output. For examples and details of the **show mpls vll** commands, see "Displaying information about MPLS VLLs" on page 1468.

```
NetIron#show run
....
router mpls

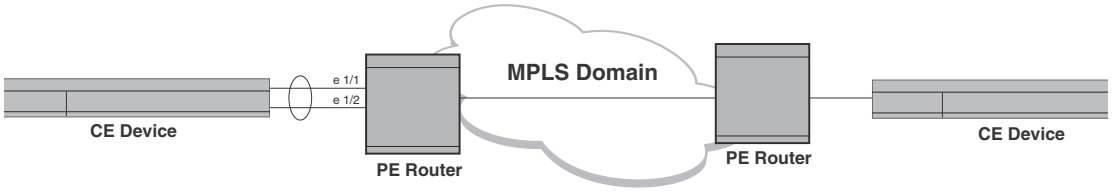
vll test 100
  vlan 100 inner-vlan 45
  tag e2
```

Specifying a LAG group as the endpoint of a VLL

The endpoint of a VLL can be a LAG group. When the endpoint of a VLL is a LAG group, the VLL traffic load is distributed to the customer edge (CE) device across all of the LAG group's ports, using a hashing mechanism described in "Hash based load sharing" on page 214.

Figure 192 illustrates a sample configuration where a LAG group of two ports serves as the endpoint of a VLL.

FIGURE 192 Specifying a LAG group as the endpoint of a VLL



To configure a LAG group like the one in Figure 192, enter commands such as the following.

```
NetIron(config)# lag red dynamic
NetIron(config-lag-red)# ports ethernet 1/1 to 1/2
NetIron(config-lag-red)# primary port 1/1
NetIron(config-lag-red)# ports ethernet 1/2
NetIron(config-lag-red)# deploy
```

To configure a VLL like the one in Figure 192, enter commands such as the following.

```
NetIron(config)# router mpls
NetIron(config-mpls)# vll test2 40000
NetIron(config-mpls-vll)# vll-peer 10.10.10.10
NetIron(config-mpls-vll)# untagged e 1/1
```

NOTES: If you first create a LAG and then configure a VLL instance, the port you specify as the VLL endpoint must also be the port you specified as the primary port of the LAG group:

- If you later delete the LAG from the configuration, only the primary port will still be a port of the VLL and all secondary ports will become normal ports.
- If you specified a tagged endpoint for the VLL instance, all of the ports in the LAG must be tagged.

- Traffic received from any port in the LAG is forwarded to the VLL instance. All traffic is matched to its VLAN.
- Both static and dynamic LAGs are supported.

Enabling VLL MTU enforcement (optional)

You can selectively enable local and remote VLL MTU mismatch checking using the following command.

```
NetIron(config)# router mpls
NetIron(config-mpls)# vll-mtu-enforcement
```

Syntax: [no] vll-mtu-enforcement

By default, MTU checking is off. You can use the **no** form of the command to disable VLL MTU checking if it is on.

NOTE
You must save the configuration and reload the software for this command to take effect.

Specifying a VLL MTU

Previously, every VLL configured on a NetIron router used the system default max-frame-size as the VLL MTU while establishing the LDP session with its peer. The system default max-frame-size is configured as described in "Setting the maximum frame size globally" on page 681. When this value is changed, the configuration needs to be saved and the router rebooted for the new value to take effect. The change in this value affects all VLLs configured on the router. This parameter is used as the max-frame-size expected on each port of the router and consequently the data plane will not accept or transmit packets larger than this size.

You can now use the **vll-mtu** command that allows you to specify an MTU value per-VLL. If an MTU value is not specified for a VLL, the router continues to use the default max-frame-size for establishing the LDP session with the peer. The MTU value configured per-VLL can be changed dynamically and takes effect immediately. Consequently, the label (if already advertised) is withdrawn from the peer and re-advertised using the new MTU. This occurs irrespective of the state of the VLL. If MTU enforcement checks are enabled and if the MTUs don't match, the VLL stays down with the reason code "MTU mismatch".

NOTE
This parameter is not enforced on the data plane. Consequently, you can still send and receive packets larger than the configured MTU.

To configure a new MTU value for a VLL, use the **vll-mtu** command as shown in the following.

```
NetIron(config-mpls)# vll foundry 40000
NetIron(config-mpls-vll-foundry)# vll-mtu 1000
```

Syntax: [no] vll-mtu <*mtu-value*>

The <*mtu-value*> variable can be set to any value between 64 - 9190.

Generating traps for VLLs

You can enable and disable SNMP traps for VLLs. VLL traps are enabled by default.

To enable VLL traps after they have been disabled, enter the following command.

```
NetIron(config)# snmp-server enable traps mpls vll
```

Syntax: [no] snmp-server enable traps mpls vll

Use the **no** form of the command to disable VLL traps.

MPLS VLL behavior with other features

This section describes the interaction of MPLS VLL with the features sFlow, IFL CAM, and Layer 2 ACLs.

sFlow

sFlow sampling is supported for VLL packets received from customer interfaces. sFlow is not supported for packets received from MPLS uplinks. The following describes the behavior for sFlow for VLL packets received from customer endpoints:

- If the endpoint is untagged, the default VLAN ID in the sFlow sample is used for both the incoming and outgoing VLAN fields in the sFlow sample collection.
- If the endpoint is tagged, the tag is used as both the incoming and outgoing VLAN in the sFlow sample collection.
- If the endpoint is dual-tagged, 4096 is used as the incoming VLAN to indicate that the packet is dual-tagged. If the VLL is in raw-mode, the outer VLAN of the packet is used as the outgoing VLAN ID in the sFlow sample collection. If the VLL is in tagged-mode, the inner VLAN ID of the packet is used as the outgoing VLAN ID in the sFlow sample collection.

  Note that if the endpoint is dual-tagged, the sFlow packet will not contain VLL- or MPLS-specific information.

Table 241 illustrates the above points.

TABLE 241 Source and destination VLAN in an sFlow sampled VLL packet

Endpoint	Source VLAN	Destination VLAN
Untagged	Default VLAN	Default VLAN
Single-tagged	Incoming VLAN	Incoming VLAN
Dual-tagged	4096	Raw mode: Incoming outer VLAN Tagged mode: Incoming inner VLAN

IFL CAM

For dual-tagged VLL instances, IFL CAM entries are used for the service lookup. The default system value for IFL CAM is 8192, which can be modified up to a maximum of 81920 entries using the CLI command **system-max ifl-cam** <*number*>. For more information about modifying the number of IFL CAM entries supported, refer to "Configuring system max values" on page 106.

Layer 2 ACLs

When the port and VLAN combination of a Layer 2 ACL matches with any VLL endpoint, the ACL is applied. For dual-tagged VLL endpoints, the Layer 2 ACL is applied based on the port and outer VLAN combination, if it is configured.

Displaying MPLS VLL information

You can display the following information about the MPLS VLL configuration on the device:

- Information about individual MPLS VLLs configured on the device
- Information about detailed MPLS VLLs configured on the device
- Information about LDP sessions between VLL peers
- Information about VLL Endpoint Statistics
- Information about packets sent between VLL endpoints and MPLS uplinks

Displaying information about MPLS VLLs

Use the following command to display information about MPLS VLLs.

```
NetIron# show mpls vll
Name    VC-ID   Vll-peer      End-point                          State  Tunnel-LSP
test    10      11.11.11.11   tag vlan 2    e 1/10               UP     tn17
test2   100     --            tag vlan 100 inner-vlan 45  e2/1   DOWN
```

Syntax: show mpls vll

NOTE
Show commands have been enhanced to include the full MPLS name. Previously, the MPLS name was truncated because it exceeded the character length. Now, the MPLS name is text wrapped to display the full name.

For each MPLS VLL on the device, the following information is displayed.

TABLE 242 Output from the show mpls vll command

This field...	Displays...
Name	The configured name of the VLL.
VC-ID	The user-configurable ID as defined in draft-ietf-pwe3-control-protocol-14.txt.
Vll-peer	The remote PE router. This should be the same as the LSP destination for the LSPs that the VLL is transported over.

TABLE 242 Output from the show mpls vll command (Continued)

This field...	Displays...
End-point	How packets are forwarded once they reach the egress LER. This can be one of the following • "untagged <*portnum*>" – Forward the packet out the specified port as untagged. • "tag VLAN <*vlan-id*> <*portnum*>" – Tag the packet with the specified VLAN ID and forward the packet out the specified port. • tag VLAN <*vlan-id*> inner-vlan <*vlan-id*> – Tag the packet with the specified outer and inner VLAN IDs and forward the packet out the specified port. • "undefined" – An endpoint has not been configured for this VLL
State	The current state of the VLL. This can be either UP or DOWN. Data can be forwarded over the VLL only when the state is UP.
Tunnel-LSP	The name of the RSVP-signalled LSP that has been selected to carry the VLL traffic through the MPLS domain

Displaying detailed information about MPLS VLLs

NOTE
The display changes to the **show mpls vll detail** command output are supported on .

To display detailed information about the VLLs configured on the device, use the **show mpls vll detail** command. The **show mpls vll detail** command has changed. The following DOWN states (with their respective reasons), are introduced in the output of the **show mpls vll detail** command. For more information on the DOWN states, refer to Table 243 on page 1472.

- The state, DOWN - PW is Down (Reason: Out of VC labels)
- The state, DOWN - PW is Down (Reason: LDP session is down)

NOTE: The state, DOWN - no LDP session to vll-peer is removed from the output, and replaced with the state, DOWN - PW is Down (Reason: LDP session is down).

- The state, DOWN - PW is Down (Reason: Out of Memory)
- The state, DOWN - PW is Down (Reason: Waiting for Remote VC label)
- The state, DOWN - PW is Down (Reason: MTU mismatch Local- MTU <mtu-value>, Remote-MTU <mtu-value>)
- The state, DOWN - PW is Down (Reason: VC type mismatch, Local VC type: <vc-type>, Remote VC type: <vc-type>)

NOTE: The state, DOWN - VC Type Mismatch in VC signalling, Local VC type <vc-type>, Remote VC type <vc-type>is removed from the output, and replaced with the state, DOWN - PW is Down (Reason: VC type mismatch, Local VC type:<vc-type>, Remote VC type: <vc-type>).

For example, the state, DOWN - Pseudo Wire (PW) is Down (Reason: MTU mismatch Local-MTU 1500, Remote -MTU 1400) indicates that PW is down because the MTU values between the local MTU and the remote MTU are not equal, as shown in the example below.

```
NetIron# show mpls vll detail
VLL VLL1 VC-ID 1001
State:     DOWN -PW is Down (Reason: MTU mismatch Local-MTU 1500, Remote-MTU
1400)
End-point: tagged vlan 1001 e 2/20
IFL-ID:    --
Vll-peer:  21.21.21.21
Local VC type:   tag                Remote VC type:   --
Local label:                        Remote label:     --
Local group-id:  0                  Remote group-id:  --
Local VC MTU:   1500                Remote VC MTU:   1400
COS:             --                 Tunnel LSP:      LSP_MLXe21 (tnl0)
```

The example below displays state, DOWN - PW is Down (Reason: LDP session is down) for a single-tagged VLL instance.

```
NetIron# show mpls vll detail
VLL VLL1 VC-ID 1001
State:     DOWN -PW is Down (Reason: LDP session is down)
End-point: tagged vlan 1001 e 2/20
IFL-ID:    --
Vll-peer:  21.21.21.21
Local VC type:    tag                 Remote VC type:    --
Local label:      --                  Remote label:      --
Local group-id:    0                  Remote group-id:   --
Local VC MTU:    1500                 Remote VC MTU:     --
COS:              --                  Tunnel LSP:        LSP_MLXe21 (tnl0)
```

The UP state is introduced in the output of the **show mpls vll detail** command. The UP state indicates that VLL is operational and packets are able to flow. The following example displays an output of a dual-tagged VLL instance in an UP state.

```
NetIron# show mpls vll detail
VLL VLL1 VC-ID 1001
State:      UP
End-point: tagged vlan 1001 e 2/20
IFL-ID:          --
Vll-peer:  21.21.21.21
Local VC type:     tag                    Remote VC type:   tag
Local label:      800001                  Remote label:     800002
Local group-id:    0                      Remote group-id:  0
Local VC MTU:     1500                    Remote VC MTU:    1500
COS:               --                     Tunnel LSP:       LSP_MLXe21 (tnl0)
```

The DOWN states, Waiting for PW Up, and Waiting for VC Withdrawal Completion is introduced in the output of the **show mpls vll detail** command, and are described in more detail below.

- The state, DOWN - Waiting for PW Up indicates that VLL is waiting for MPLS to bring up the session.
- The state, DOWN - Waiting for VC Withdrawal Completion indicates that PW is down, and VLL is waiting for MPLS to withdraw the labels that VLL has requested.

The following example below displays the state, Down - Waiting for PW Up.

```
NetIron# show mpls vll detail
VLL VLL1 VC-ID 1001
State:     DOWN -Waiting for PW Up
End-point: tagged vlan 1001 e 2/20
IFL-ID:    --
Vll-peer:  21.21.21.21
Local VC type:   tag            Remote VC type:   --
Local label:     --             Remote label:     --
Local group-id:  0              Remote group-id:  --
Local VC MTU:   1500            Remote VC MTU:    --
COS:            --              Tunnel LSP:       LSP_MLXe21 (tnl0)
```

Syntax: show mpls vll detail | *<vll-name>*

For each configured VLL, the command displays the following information in Table 263.

TABLE 243 Output from the show mpls vll detail command

This field...	Displays...
state	The current state of the VLL. This can be one of the following • "UP" VLL is operational - packets can flow. • "DOWN - configuration incomplete" A required configuration statement is missing. • "DOWN - endpoint port to CE is down" The physical endpoint port that should be connected to the Customer Edge device is down due to a link outage or is administratively disabled. • "DOWN - no tunnel LSP to vll-peer" Cannot find a working LSP. • "DOWN - PW is Down (Reason: LDP session is down)" LDP session is not yet ready. • "DOWN - Waiting for PW Up" VLL is waiting for MPLS to bring up the session. • "DOWN - Waiting for VC withdrawal Completion" PW is down, and VLL is waiting for MPLS to withdraw the labels that VLL has requested. • "DOWN - PW is Down (Reason: Out of VC labels)" PW is down; VC labels are not available. • "DOWN - PW is Down (Reason: Out of Memory)" PW is down; there is not sufficient memory available. • "DOWN - PW is Down (Reason: Waiting for Remote VC label)" PW is down; waiting for remote peer's VC label to be advertised. • "DOWN - waiting for VC label binding from vll-peer" The device has advertised its VC label binding to the VLL peer, but has not yet received the peer's VC label binding. • "DOWN - PW is Down (Reason: MTU mismatch Local- MTU <mtu-value>, Remote-MTU <mtu-value>)" PW is down and the MTU values for the local and remote peers are not equal. • "DOWN - PW is Down (Reason: VC type mismatch, Local VC type: <*vc-type*>, Remote VC type: <*vc-type*>" – The session cannot be brought up because the VC types of the local and remote peers are not equal. The possible values for the <*vc-type*> variable are 5 for raw mode or 4 for tagged mode.
End-point	How packets are forwarded once they reach the egress LER. This can be one of the following: • "untagged <*portnum*>" - Forward the packet out the specified port as untagged. • "tagged VLAN <*vlan_id*> <*portnum*>" - Tag the packet with the specified VLAN ID and forward the packet out the specified port. • "tagged VLAN <*vlan-id*> inner-vlan <*vlan-id*>" – Tag the packet with the specified outer and inner VLAN IDs and forward the packet out the specified port. • "undefined" - An endpoint has not been configured for this VLL.
IFL-ID	The Internal Forwarding Lookup Indentifier (IFL-ID) that is allocated to each Local VLL instance that has at least one dual-tagged endpoint. For instances that do not have dual-tagged endpoints, the IFL-ID is displayed as "--".
Vll-peer	The remote PE router. This should be the same as the LSP destination for the LSPs that the VLL is transported over.
Local VC Type	Indicates whether the local VC is in Raw-mode or Tagged-mode.
Remote VC Type	Indicates whether the remote VC is in Raw-mode or Tagged-mode.
Local Label	The VC label value locally allocated for this VLL. Packets forwarded from the VLL peer to this device are expected to contain this label. This is the label that is advertised to the VLL peer through LDP.

TABLE 243 Output from the show mpls vll detail command (Continued)

This field...	Displays...
Remote Label	The VC label allocated by the VLL peer and advertised to this device through LDP. The device applies this label to outbound MPLS packets sent to the VLL peer.
Local Group-id	The VLL group-ID (defined in draft-martini-l2circuit-trans-mpls-07.txt) advertised to the VLL peer through LDP. In this release, this is always zero.
Remote Group-id	The VLL group-ID selected and advertised by the VLL Peer.
Local VC MTU	The MTU value configured for this local VC.
Remote VC MTU	The MTU value advertised from the VLL peer.
COS	The optional COS setting for the VLL. If a COS value is set, the device will attempt to select a tunnel LSP that also has this COS value. The COS value can be between 0 - 7.
Tunnel LSP	The name, as well as internal tunnel index number, of the tunnel LSP selected for the VLL.

In a situation when MPLS may run out local resources, an error state is displayed in the **show mpls vll detail** command output. The errors states, DOWN - VC binding Failed, and DOWN - VC withdrawal Failed are displayed in the examples below. To recover from this state, the user is required to delete the failed peer and reconfigure it.

```
NetIron# show mpls vll detail
VLL VLL1 VC-ID 1001
State:     DOWN -VC binding Failed
End-point: tagged vlan 1001 e 2/20
IFL-ID:    --
Vll-peer:  21.21.21.21
Local VC type:  tag                Remote VC type:   --
Local label:    --                 Remote label:     --
Local group-id: 0                  Remote group-id:  --
Local VC MTU:  1500                Remote VC MTU:    --
COS:           --                  Tunnel LSP:       LSP_MLXe21 (tnl0)
```

The example below displays the state, DOWN - VC withdrawal failed.

```
NetIron# show mpls vll detail
VLL VLL1 VC-ID 1001
State:     DOWN -VC withdrawal Failed
End-point: tagged vlan 1001 e 2/20
IFL-ID:    --
Vll-peer: 21.21.21.21
Local VC type:   tag              Remote VC type:   --
Local label:     --               Remote label:     --
Local group-id:  0                Remote group-id:  --
Local VC MTU:   1500              Remote VC MTU:    --
COS:            --                Tunnel LSP:       LSP_MLXe21 (tnl0)
```

VLL will generate the following warning messages. MPLS will also generate a warning message, and it will be displayed on the console as shown in the example below.

```
WARNING: VLL Id 1 with Peer 1.1.1.1 is placed in VC Bind failure state due to MPLS
resource failure
```

```
WARNING: VLL Id 2 with Peer 2.2.2.2 is placed in VC Withdraw failure state due to
MPLS resource failure
```

Displaying LDP information

To display information about the state of the LDP connection between the device and VLL peers, enter the following command.

```
NetIron# show mpls ldp peer
Peer LDP ID State Num-VLL Num-VPLS-Peer
11.11.11.11:0 Operational 32008 0
13.13.13.13:0 Operational 0 0
```

Syntax: show mpls ldp peer

For each VLL peer, the command displays the following information:

TABLE 244 Output from the show mpls ldp target-peer command

This field...	Displays...
Peer-addr	The IP addresses of VLL peers.
State	The state of the LDP session with the VLL peer. This can be one of the following "Unknown" LDP session establishment has not started for this peer, normally because no Hello messages have been received from the peer. In this situation, that peer will not show up in the output of the **show mpls ldp session** command. "Nonexistent", "Initialized", "OpenRec", "OpenSent", or "Operational" LDP session states, as defined in RFC 3036.

To display information about LDP sessions between the device and VLL peers.

```
NetIron# show mpls ldp session
Peer LDP Ident: 192.168.2.100:1, Local LDP Ident: 11.1.1.1:1
  Active: no, State: Operational
  TCP connection: 11.1.1.1:646--22.2.2.2:9001, State: ESTABLISHED
  Addresses bound to peer LDP Ident:
    1.1.1.2
    10.1.1.2
    20.1.1.2
    22.2.2.2
```

Syntax: show mpls ldp session [*<label-space-id>* **| detail | brief]**

For each established LDP session, the command displays the following information.

TABLE 245 Output from the show mpls ldp session command

This field...	Displays...
Peer LDP Ident	The VLL peer's LDP identifier, consisting of the LSR ID and label space ID.
Local LDP Ident	The device's LDP identifier.
Active	Whether this LSR is playing an active role in session establishment.
State	The LDP session state, as defined in RFC 3036. This can be "Nonexistent", "Initialized", "OpenRec", "OpenSent", or "Operational".

TABLE 245 Output from the show mpls ldp session command (Continued)

This field...	Displays...
TCP connection, state	The TCP local or remote IP address, port and state.
Addresses bound to peer LDP Ident	IP addresses carried in the VLL peer's LDP Address messages.

To display information about LDP sessions between a specified router and VLL peers.

```
NetIron# #show mpls ldp session 22.22.22.22
Peer LDP ID: 22.22.22.22:0, Local LDP ID: 24.24.24.24:0, State: Operational
  Adj: Link, Role: Active, Next keepalive: 0 sec, Hold time left: 30 sec
  Keepalive interval: 6 sec, Max hold time: 36 sec
  Neighboring interfaces: e1/4
  TCP connection: 24.24.24.24:9012--22.22.22.22:646, State: ESTABLISHED
  Next-hop addresses received from the peer:
    22.22.22.22  40.40.40.1  10.10.10.2
```

The command displays the following information.

TABLE 246 Output from the show mpls ldp session command

This field...	Displays...
Peer LDP Ident	The VLL peer's LDP identifier, consisting of the LSR ID and label space ID.
Local LDP Ident	The device's LDP identifier.
State	The LDP session state, as defined in RFC 3036. This can be "Nonexistent", "Initialized", "OpenRec", "OpenSent", or "Operational".
Adj	The type of adjacency formed with a peer. Possible values are Link, or Targeted.
Role	This can be either of the following values Active or Passive.
Next keepalive	The number of seconds after which a "Hello" message is sent to a peer.
Hold time left	The number of seconds after which a session can be terminated if a "Hello" message is not received from the peer within this time.
Keepalive interval	The frequency within which LDP "Hello" messages are sent out.
Max hold time	The length of time the device waits for a "Hello" message from its peer before terminating the session.
Neighboring interfaces	The physical interfaces on which the adjacency to the neighbor is formed.
TCP connection, state	The TCP local or remote IP address, port and state.
Next-hop addresses received from the peer	IP addresses carried in the VLL peer's LDP Address messages.

Displaying VLL endpoint statistics

You can display VLL Endpoint traffic statistics to see the forwarding counters for each VLL configured on the system. The display is shown so that, for a given port range that receives traffic, it shows the number of packets arriving from the customer endpoint and the number of packets arriving from the MPLS core and going to the customer interface.

To display all VLL traffic statistics on a NetIron router, enter the following command.

```
NetIron# show mpls statistics vll
VLL-Name       VLL Port(s)    VLL-Ingress-Pkts  VLL-Egress-Pkts
---------      ----------     --------------    ------------
VLL1           e1/1           100               100
VLL2           e1/4           100               100
```

NOTE
The VLL name is repeated for each module from where the statistics are collected, to be displayed on the Management console.

To display VLL traffic statistics for a VLL instance specified by its VLL name, enter the following command.

```
NetIron# show mpls statistics vll vll1
VLL-Name       VLL Port(s)    VLL-Ingress-Pkts  VLL-Egress-Pkts
---------      ----------     --------------    ------------
VLL1           e1/1           100               100
```

To display VLL traffic statistics for a VLL instance specified by its VLL ID, enter the following command.

```
NetIron# show mpls statistics vll 4
VLL-Name       VLL Port(s)    VLL-Ingress-Pkts  VLL-Egress-Pkts
---------      ----------     --------------    ------------
VLL1           e1/1           100               100
```

Syntax: show mpls statistics vll [<*vll-name*> | <*vll-id*>]

The <*vll-name*> variable is the configured name for a VLL instance.
The <*vll-id*> variable is the ID of a VLL instance.

For following information is displayed in the **show mpls statistics vll** command.

TABLE 247 Output from the **show mpls vll command**

This field...	Displays...
VLL-Name	The configured name of the VLL instance.
VLL-Ports	The port where the traffic is monitored.
VLL-Ingress-Pkts	Packets arriving from the Customer Endpoint.
VLL-Egress-Pkts	Packets arriving from the MPLS core and going to the customer interface

Clearing VLL traffic statistics

To clear the entries stored for all VLL statistics, enter a command such as the following.

```
NetIron# clear mpls statistics vll
```

Syntax: clear mpls statistics vll [<*vll-name*> | <*vll-id*>]

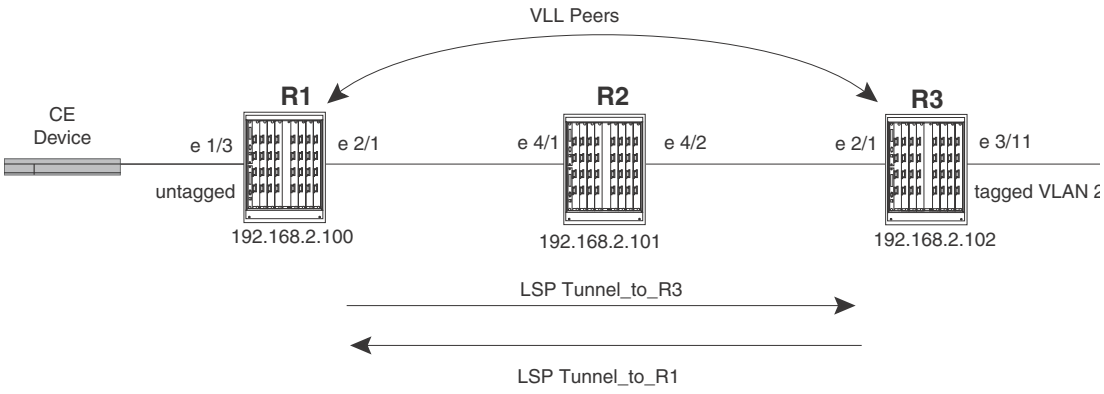
The <*vll-name*> variable is the configured name for a VLL instance.

The <*vll-id*> variable is the ID of a VLL instance.

Sample MPLS VLL configuration

Figure 193 depicts a sample VLL configuration.

FIGURE 193 MPLS VLL configuration



In this example, routers R1 and R3 are Provider Edge (PE) routers configured as VLL peers. R1 and R3 have established an LDP session to exchange VLL label information. When the LDP session is established, each router advertises its locally assigned VC label and VC ID to its VLL peer.

RSVP-signalled (tunnel) LSPs have been established in each direction between the two routers. When the CE device forwards a Layer 2 packet to R1, the router assigns the packet to an RSVP-signalled LSP whose destination is R3. R1 encapsulates the packet as an MPLS packet, adding a tunnel label and the VC label advertised to the router by R3. The MPLS packet is then forwarded over the outbound interface indicated by the tunnel label to the next hop in the LSP.

When the MPLS packet reaches R2, the penultimate LSR in the tunnel LSP, R2 pops the tunnel label, leaving the packet with only the VC label, then forwards the packet to R3.

R3 examines the VC label in the packet. On R3, the VC label is mapped to the user-specified endpoint for the VLL. In this example, the endpoint consists of VLAN ID 200 and interface 3/11. R3 then pops the VC label, tags the Layer 2 packet with VLAN 200, then forwards the packet out interface 3/11.

In the opposite direction, R3 assigns traffic received from the CE device to an RSVP-signalled LSP destined for R1, pushes tunnel and VC labels onto the packets, and forwards them to the next hop in LSP. When the packets reach R1, the router pops the VC label and forwards the Layer 2 packets out the interface indicated by the VLL endpoint. In this example, the endpoint consists of interface 1/3, so the packets are forwarded untagged out interface 1/3 to the CE device.

Router R1

The following commands configure Router R1 in Figure 193.

```
NetIron(config)# ip router-id 192.168.2.100
NetIron(config)# router ospf
NetIron(config-ospf-router)# area 0
NetIron(config-ospf-router)# exit
NetIron(config)# router mpls
NetIron(config-mpls)# mpls-interface e 2/1
```

```
NetIron(config-mpls)# policy

NetIron(config-if-e1000-2/1)# ip ospf area 0
NetIron(config-if-e1000-2/1)# exit
```

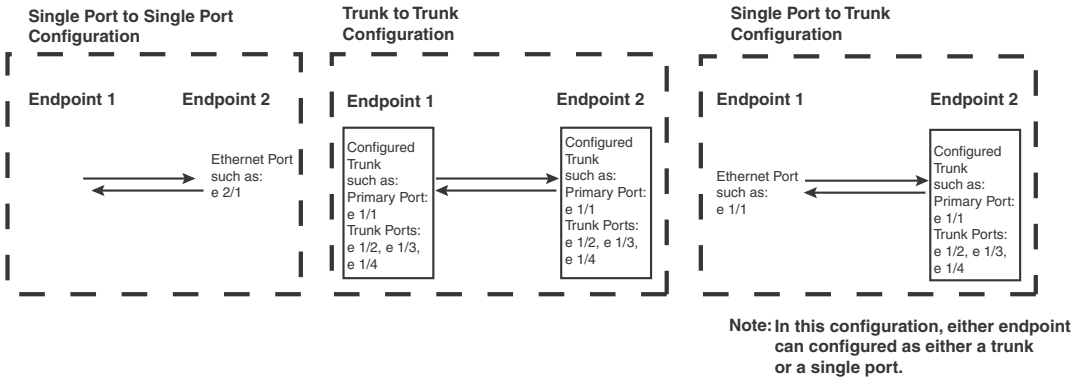
Local VLL

Local VLL is used to create a Virtual Leased Line (VLL) circuit with endpoints in the same NetIron router. A Local VLL can be configured between two ports in a router, two LAGs in a router or between a port and a LAG as shown in Figure 194. Each entity (port or LAG) is identified as either “Endpoint 1” or Endpoint 2”.

NOTE
LAGs supported include server LAGs and per-packet server LAGs. LACP LAGs are not supported.

FIGURE 194 Local VLL port and LAG configurations



NOTE
When configuring a LAG as an endpoint, only the primary port of the LAG is specified in the Local VLL configuration.

NOTE
Packets that arrive on an interface with the same destination MAC address as the interface are forwarded in hardware just like packets with other destination addresses.

The endpoints connected to the Local VLL can be untagged or tagged as members of the same or different VLANs. Using this function of Local VLL, a router can receive packets with a particular tag or no tag on one endpoint and forward them to the Local VLL's other endpoint which may be untagged or tagged with a different VLAN tag. When so configured, the tags within the packets are changed to reflect the configuration of the egress port as they leave the router.

Local VLL configuration examples

Local VLL supports traffic flows between any combination of single-tagged, untagged, and dual-tagged ports. Some scenarios are described and illustrated in the following configuration examples.

Example of a Local VLL configured for single-tagged VLAN traffic on both ports

In Figure 195 the Local VLL named "Test1" contains Ethernet ports 1/1 and 2/1. Port 1/1 is a member of VLAN 100 and port 2/1 is a member of VLAN 200. Because both ports belong to Local VLL "Test1" traffic tagged with VLAN 100 will be able to reach nodes within VLAN 200 and traffic tagged with VLAN 200 will be able to reach nodes within VLAN 100. Traffic that ingresses on port 1/1 must have a tag with the value "100" and will egress on port 2/1 with a tag value of "200". Traffic that ingresses on port 2/1 must have a tag with the value "200" and will egress on port 2/1 with a tag value of "100".

FIGURE 195 Local VLL "Test1" with 2 tagged VLANs

```
NetIron(config)# router mpls
NetIron(config-mpls)# vll-local test1
NetIron(config-mpls-vll-lo-test1)# vlan 100
NetIron(config-mpls-vll-lo-test1-vlan)# tagged ethernet 1/1
NetIron(config-mpls-vll-lo-test1-vlan)# vlan 200
NetIron(config-mpls-vll-lo-test1-vlan)# tagged ethernet 2/1
```

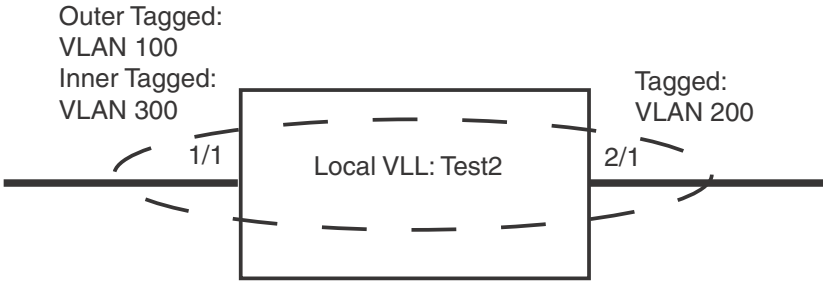
Example of a Local VLL configured for dual-tagged and single-tagged VLAN traffic

You can configure a Local VLL with ports that are configured for dual tags. In a dual-tagged configuration, the packets contain an outer tag and an inner tag. One or both of the VLANs configured for the Local VLL will have an inner VLAN configured in addition to the default outer VLAN.

Under this configuration, a router can receive packets with a two tags on one endpoint and forward them to the Local VLLs other endpoint either untagged, tagged with a single tag or tagged with an inner and and outer VLAN tag. Where dual-tagging is used within a Local VLL, the system allocates an Internal Lookup Indentifier (IFL-ID) for the Local VLL instance.

In Figure 196 the Local VLL named "Test2" contains Ethernet ports 1/1 and 2/1. Port 1/1 is a member of VLAN 100 and is configured to accept packets with an inner VLAN tag value of 300. Port 2/1 is a member of VLAN 200. Because both ports belong to Local VLL "Test2" traffic tagged with outer VLAN tag 100 and inner VLAN tag 300 will be able to reach nodes within VLAN 200 and traffic tagged with VLAN 200 will be able to reach nodes within VLAN 100. Traffic that ingresses on port 1/1 must have an outer tag with the value "100" and an inner tag with the value "300" and will egress on port 2/1 with a tag value of "200". Traffic that ingresses on port 2/1 must have a tag with the value "200" and will egress on port 1/1 with an inner tag value of "100" and an outer tag value of "300".

FIGURE 196 Local VLL "Test2" with 1 single-tagged VLAN and 1 dual-tagged VLAN



```
NetIron(config)# system-max ifl-cam 16384
NetIron(config)# router mpls
NetIron(config-mpls)# vll-local test2
NetIron(config-mpls-vll-lo-test1)# vlan 100 inner-vlan 300
NetIron(config-mpls-vll-lo-test1-vlan)# tagged ethernet 1/1
NetIron(config-mpls-vll-lo-test1-vlan)# vlan 200
NetIron(config-mpls-vll-lo-test1-vlan)# tagged ethernet 2/1
```

A shown in the following example, you can use the **show mpls vll-local detail** command to see that an IFL-ID has been created for this Local VLL instance.

```
NetIron#show mpls vll-local detail
VLL test2 VLL-ID 1 IFL-ID 4096
  State: UP
  End-point 1:      tagged  vlan 100   inner-vlan 300    e 1/1
                    COS: --
  End-point 2:      tagged  vlan 200   e 2/1
                    COS: --
```

Example of a Local VLL configured for single-tagged and untagged VLAN traffic

In Figure 197 the Local VLL named “Test3” contains Ethernet ports 1/1 and 2/1. Port 1/1 is a member of VLAN 100 and port 2/1 is untagged. Because both ports belong to Local VLL “Test3, traffic tagged with VLAN 100 will be able to reach nodes attached to the untagged port and traffic from the untagged port will be able to reach nodes within VLAN 100.

FIGURE 197 Local VLL “Test3” with 1 tagged VLAN and 1 untagged port

```
NetIron(config)# router mpls
NetIron(config-mpls)# vll-local test3
NetIron(config-mpls)# untagged ethernet 2/1
NetIron(config-mpls-vll-lo-test1)# vlan 100
NetIron(config-mpls-vll-lo-test1-vlan)# tagged ethernet 1/1
```

Local VLL QoS

You can optionally specify Class of Service (COS) on a per-endpoint (EP) basis. This COS value applies to inbound traffic on the endpoint. If a COS value is not specified, the port’s configured priority and the packet’s 802.1p priority are used to determine the internal priority, as described for the following traffic flows.

Untagged Endpoint 1 (EP1) to Untagged Endpoint 2 (EP2).

1. If available, use the configured COS value on untagged EP1 otherwise go to step 2.

2. If there is a configured port priority on untagged EP1 use that priority; otherwise go to step 3.
3. If there is neither a COS value or priority configured (as described in steps 1 and 2), the default “best effort” priority is used.

Tagged Endpoint 1 (EP1) to Tagged Endpoint 2 (EP2) .

1. If available, use the configured COS value on tagged EP1 otherwise go to step 2.
2. The 802.1p priority of incoming packets on the tagged EP1 is merged with the port priority of EP1.

The 802.1p priority for packets outbound from EP2 is determined as described in 9, “Configuring Quality of Service for the NetIron MLX”.

Untagged Endpoint 1 (EP1) to Tagged Endpoint 2 (EP2).

1. If available, use the configured COS value on untagged EP1 otherwise go to step 2.
2. If there is a configured port priority on untagged EP1 use that priority; otherwise go to step 3.
3. If there is neither a COS value or priority configured (as described in steps 1 and 2), the default “best effort” priority is used.

The 802.1p priority for packets outbound from EP2 is determined as described in 9, “Configuring Quality of Service for the NetIron MLX”.

Tagged Endpoint 1 (EP1) to Untagged Endpoint 2 (EP2).

1. If available, use the configured COS value on tagged EP1 otherwise go to step 2.
2. The 802.1p priority of incoming packets on the tagged EP1 is merged with the port priority of EP1.

Double-Tagged Endpoint 1 (EP1) to Double-Tagged Endpoint 2 (EP2).

1. The internal priority is determined as described in 9, “Configuring Quality of Service for the NetIron MLX”.
2. If Vll-local COS is configured, this value overrides internal priority.
3. By default, the outgoing outer VLAN COS is mapped from the internal priority by use of the egress encoding map. The internal priority does not affect the outgoing inner VLAN COS.
4. The outgoing outer VLAN COS is preserved if “qos pcp encode-policy off” is configured on the outgoing interface.
5. The outgoing inner VLAN COS is preserved—it is the same as the incoming packet’s inner VLAN COS.

Single-Tagged Endpoint 1 (EP1) to Double-Tagged Endpoint 2 (EP2).

1. The internal priority is determined as described in 9, “Configuring Quality of Service for the NetIron MLX”.
2. If Vll-local COS is configured, this value overrides internal priority.
3. The outgoing outer VLAN COS is mapped from internal priority through use of the egress encoding map by default. The internal priority does not affect the outgoing inner VLAN COS.

4. The outgoing outer VLAN COS is preserved if “qos pcp encode-policy off” is configured on the outgoing interface.
5. The outgoing inner VLAN COS is the COS in the incoming packet.

Untagged Endpoint 1 (EP1) to Double-Tagged Endpoint 2 (EP2).

1. The internal priority is determined as described in 9, “Configuring Quality of Service for the NetIron MLX”.
2. If Vll-local COS is configured, this value overrides internal priority.
3. The outgoing outer VLAN COS is mapped from internal priority through the use of the egress encoding map by default. The internal priority does not affect the outgoing inner VLAN COS.
4. The outgoing outer VLAN COS is 0 if “qos pcp encode-policy off” is configured on the outgoing interface.
5. The outgoing inner VLAN COS would be 0.

Double-Tagged Endpoint 1 (EP1) to Single-Tagged Endpoint 2 (EP2).

1. The internal priority is determined as described in 9, “Configuring Quality of Service for the NetIron MLX”.
2. If Vll-local COS is configured, its value overrides internal priority.
3. By default, the outgoing VLAN COS is mapped from the internal priority by use of the egress encoding map.
4. The outgoing VLAN COS is equal to the incoming, inner VLAN COS if “qos pcp encode-policy off” is configured on the outgoing interface.

CoS behavior for Local VLL

NOTE
This section assumes that you understand how QoS works. For details, see For details, see 9, “Configuring Quality of Service for the NetIron MLX”.

Table 248 describes the expected Class of Service (CoS) behavior for VLL packets when Local VLL is in effect.

TABLE 248 Expected class of service behavior for Local VLL

Local VLL endpoints	Incoming packet		Outgoing packet	
	Outer VLAN	Inner VLAN	Outer VLAN	Inner VLAN
Dual-tagged to dual-tagged	X	Y	X’ or X	Y
Single-tagged to dual-tagged	X	N/A	X’ or X	X
Untagged to dual-tagged	N/A	N/A	X’ or 0	0
Dual-tagged to single-tagged	X	Y	X’ or Y	N/A

Legend for Table 248

X = original outer VLAN CoS

Y = original inner VLAN CoS

X' = mapped CoS from internal priority (X contributes to internal priority) using CoS encode table

Configuring Local VLL

Configuring Local VLL uses the following procedures:

- "Local VLL configuration"
- "Specifying Local VLL endpoints"
- "Configuring Local VLL QoS (optional)"

Local VLL configuration

Local VLL is configured under router mpls as shown.

```
NetIron(config)# router mpls
NetIron(config-mpls)# vll-local test1
```

Syntax: [no] vll-local <*vll-name*>

Specifying Local VLL endpoints

Local VLL can be configured between any combination of untagged, single-tagged, and dual-tagged endpoints.

The following sections describe how to configure VLL Endpoints:

Configuring an untagged endpoint

To configure untagged port 1/1 into Local VLL instance "test1" use the following commands.

```
NetIron(config)# router mpls
NetIron(config-mpls)# vll-local test1
NetIron(config-mpls-vll-test1)# untagged ethernet 1/1
```

Syntax: [no] untagged ethernet <*slot/port*>

Configuring a single-tagged endpoint

Tagged ports are configured under a VLAN ID. This ID is only meaningful for the tagged port.

For tagged ports, a <*vlan-id, port*> pair constitutes a VLL endpoint. if a port is currently a member of a non-default VLAN as an untagged port, it must be returned to the default VLAN before it can be assigned to a VLL as a tagged port.

To configure tagged port 1/2 with VLAN 200 into Local VLL instance "test1" use the following commands.

```
NetIron(config)# router mpls
NetIron(config-mpls)# vll-local test1
NetIron(config-mpls-vll-lo-test1)# vlan 200
NetIron(config-mpls-vll-lo-test1-vlan)# tagged ethernet 1/2
```

Syntax: vlan <*VLAN-ID*>

The range for **VLAN ID** is 1 – 4094. (This parameter range excludes the default VLAN ID.)

Syntax: [no] tagged ethernet <*slot/port*>

Configuring a dual-tagged endpoint

Dual-tagged ports are configured under a VLAN ID. The main difference between single and dual tagged configuration is that in the dual-tagged configuration, a parameter for **inner-vlan** is configured.

Considerations when configuring the Local VLL with dual tagged endpoints

Before configuring a Local VLL to operate with Dual Tagged Endpoints, you must consider the following:

- The System Max value for IFL CAM must be changed from its default value of 0 (which does not support this feature) to a higher value. The available values for this parameter as well as the procedure required to change it are described in "Configuring system max values" on page 106.
- Only one dual-tag endpoint can exist on the same port per instance.
- The inner VLAN of the dual-tag endpoint cannot be configured dynamically. In other words, an existing single-tag VLL endpoint cannot be changed to a dual tag VLL endpoint on the fly. You must delete the single-tag VLL endpoint before configuring a dual-tag endpoint.
- A dual tag VLL endpoint neither recognizes nor forwards packets that have a single tag. However, a single-tag endpoint can recognize and forward dual tag packets because the endpoint treats the second tag as data.
- If only the outer VLAN is specified for a given endpoint, the VLAN is called a less-specific VLAN. Similarly, if both the outer and inner VLANs are specified, the VLAN is called a more-specific VLAN (in relation to the outer VLAN).
- If a less-specific VLAN is already configured on a given port, then a more-specific VLAN with the same outer VLAN tag can be configured on that port. In the following example, a less-specific, tagged endpoint has been configured with VLAN 100 on port e 2/1, and a more-specific endpoint with outer-VLAN value of "100" and an inner-VLAN value of "200" is configured on port e 2/1.

  ```
  NetIron(config-mpls)#vll-local test1
  NetIron(config-mpls-vll-lo-test1)#vlan 100
  NetIron(config-mpls-vll-lo-test1-vlan)#tag e 2/1
  NetIron(config-mpls-vll-lo-test1-if-e-2/1)#vlan 100 inner-vlan 200
  NetIron(config-mpls-vll-lo-test1-vlan)#tag e 2/1
  NetIron(config-mpls-vll-lo-test1-vlan)#
  ```

  The result of this example is that single-tagged packets received on port 2/1 with VLAN ID value of "100" and double-tagged packets with an outer-VLAN value of "100" and inner-VLAN of any value other than "200" are sent back out from port 2/1 with outer-VLAN value of "100" and an inner-VLAN value of "200". Dual-tagged packets received on port 2/1 with an outer-VLAN value of "100" and an inner-VLAN value of "200" are sent back out from port 2/1 as single-tagged packets with a VLAN value of "100".

- In any given Local VLL instance, two dual-tag endpoints on the same port are not allowed. The Error messages displayed in **bold** in the following two configuration examples describe this restriction.

```
NetIron(config-mpls)#vll-local test3
NetIron(config-mpls-vll-lo-test3)#vlan 100 inner-vlan 400
NetIron(config-mpls-vll-lo-test3-vlan)#tag e 2/3
NetIron(config-mpls-vll-lo-test3-if-e-2/3)#vlan 100 inner-vlan 500
NetIron(config-mpls-vll-lo-test3-vlan)#tag e 2/3
Error - VLL test3 already has a dual tag end-point on port 2/3 - another dual
tag endpoint on the same port not allowed.
NetIron(config-mpls)#vll-local test4
NetIron(config-mpls-vll-lo-test3)#vlan 1000 inner-vlan 400
NetIron(config-mpls-vll-lo-test3-vlan)#tag e 2/3
NetIron(config-mpls-vll-lo-test3-if-e-2/3)#vlan 2000 inner-vlan 500
NetIron(config-mpls-vll-lo-test3-vlan)#tag e 2/3
Error - VLL test4 already has a dual tag end-point on port 2/3 - another dual
tag endpoint on the same port not allowed.
```

To support dual tags, the VLAN CLI command in the Local VLL configuration mode has a parameter that lets you configure dual tag endpoints.

```
NetIron(config)# router mpls
NetIron(config-mpls)# vll-local test1
NetIron(config-mpls-vll-lo-test1)# vlan 200 inner-vlan 300
NetIron(config-mpls-vll-lo-test1-vlan)# tagged ethernet 1/2
```

Syntax: [no] vlan <*VLAN-ID*> inner-vlan <*Inner-VLAN-ID*>

The range for **VLAN-ID** is 1 – 4094. (This parameter range excludes the default VLAN ID.)

The range for **inner-VLAN-ID** is 1 – 4095. (This parameter range does not exclude the default VLAN ID.)

Configuring Local VLL QoS (optional)

You can configure a Class of Service (COS) value for either a tagged or untagged port. If the COS value is configured, it is used to determine traffic priority as described in "Local VLL QoS" on page 1482.

To set a COS value for an untagged port use the following command.

```
NetIron(config)# router mpls
NetIron(config-mpls)# vll-local test1
NetIron(config-mpls-vll-test1)# untagged ethernet 1/1
NetIron(config-mpls-if-e1000-1/1)# cos 3
```

To set a COS value for an tagged port use the following command.

```
NetIron(config)# router mpls
NetIron(config-mpls)# vll-local test1
NetIron(config-mpls-vll-test1)# vlan 200
NetIron(config-mpls-vll-vlan)# tagged 1/2
NetIron(config-mpls-if-e1000-1/2)# cos 4
```

Syntax: [no] cos <*cos-value*>

The <*cos-value*> can be set to a priority between 0 - 7.

Displaying Local VLL information

You can display the following information about the Local VLL configuration on a NetIron router:

- Information about individual Local VLLs configured on the router

- Information about VLL Endpoint Statistics

Displaying information about Local VLLs

To display brief information about Local VLLs.

```
NetIron# show mpls vll-local
Name         VLL-ID    End-point1                      End-point2          State
foundrylong   1        tag vlan 100  e 5/12            undefined           DOWN
vlllocalfou
ndrylongvll
localfoundr
ylongvlloc
alfoundry

test          2      tag vlan 200 inner-vlan 50 e 2/1  tag vlan 200 e 2/2  UP
NetIron
```

Syntax: show mpls vll-local

For each Local VLL on the device, the following information is displayed.

TABLE 249 Output from the show mpls vll-local brief command

This field...	Displays...
Name	The configured name of the Local VLL.
VLL-ID	The VLL ID.
End-point	How packets are forwarded out of the egress port of the Local VLL. This can be one of the following: • "untagged <*portnum*>" – Forward the packet out the specified port as untagged. • "tag VLAN <*vlan_id*> <*portnum*>" – Tag the packet with the specified VLAN ID and forward the packet out the specified port. • "undefined" – An endpoint has not been configured for this Local VLL • "inner-vlan" – Describes the inner-VLAN tag for an end-point that is configured for dual-tagging.
State	The current state of the Local VLL. This can be either UP or DOWN. Data can be forwarded over the Local VLL only when the state is UP.

To display detailed information about a specific Local VLL configured on the device.

```
NetIron# show mpls vll-local detail
VLL test-1 VLL-ID 1 IFL-ID --
  State: UP
  End-point 1:      untagged e 2/2
                    COS: --
  End-point 2:      untagged e 2/13
                    COS: --
VLL test-2 VLL-ID 2 IFL-ID --
  State: UP
  End-point 1:      tagged  vlan 2500  e 2/10
                    COS: --
  End-point 2:      tagged  vlan 2500  e 2/9
                    COS: --
VLL test-3 VLL-ID 3 IFL-ID --
  State: UP
  End-point 1:      tagged  vlan 2501  e 2/10
                    COS: 6
  End-point 2:      tagged  vlan 2501  e 2/9
                    COS: 5
Vll test-4 VLL-ID 4 IFL-ID 4096
  State: UP
    End-point 1:    tagged  vlan 100   inner-vlan 45 e 2/1
                    COS: --
    End-point 2:    tagged  vlan 100  e 2/3
                    COS: --
```

Syntax: show mpls vll-local detail | *<vll-name>*

The detail parameter displays detailed information for all Local VLLs in the router while specifying a particular VLL using the *<vll-name>* option limits the display to the specified Local VLL.

For each configured Local VLL, the command displays the following information in addition to the information described in Table 249.

TABLE 250 Output from the show mpls vll-local detail command

This field...	Displays...
IFL-ID	The Internal Forwarding Lookup Indentifier that is allocated to each Local VLL instance that has at least one dual tag endpoint. For instances that do not have dual tag endpoints, the IFL-ID is displayed as "--".
state	The current state of the VLL. This can be one of the following: • "UP": Local VLL is operational - packets can flow. • "DOWN - configuration incomplete": A required configuration statement is missing. • "DOWN - endpoint port is down": The physical endpoint port is down due to a link outage or is administratively disabled.

TABLE 250 Output from the show mpls vll-local detail command (Continued)

This field...	Displays...
End-point	How packets are forwarded out of the egress port of the Local VLL. This can be one of the following: • "u"ntagged <*portnum*>" – Forward the packet out the specified port as untagged. • "tag VLAN <*vlan_id*> <*portnum*>" – Tag the packet with the specified VLAN ID and forward the packet out the specified port. • "undefined" – An endpoint has not been configured for this Local VLL • "inner-vlan" – Describes the inner-VLAN tag for an end-point that is configured for dual-tagging.
COS	The optional COS setting for the Local VLL. If a COS value is set, the COS value can be between 0 - 7.

Displaying Local VLL endpoint statistics

To view the forwarding counters for each Local VLL configured on the system, you can display Local VLL Endpoint traffic statistics. The display is shown such that for a given port range that receives traffic, how many packets are arriving from the customer endpoint.

NOTE
When the forwarding cam is full, the vll-local software forwarded packets are not accounted in vll-local statistics.

To display all VLL traffic statistics on a NetIron router, enter the following command.

```
NetIron# show mpls stat vll-local
VLL-Name       End-point 1/2       VLL Port(s)      VLL-Ingress-Pkts
-------------- ----------------  --------------    ----------------
test             End-point1          e2/3-2/4         835192705
                 End-point2          e2/3-2/4         838181595
test1            End-point1          e2/3-2/4         544017
                 End-point2          e2/3-2/4         544017
test3            End-point1          e2/1             544022
                 End-point2          e2/2             544022
```

To display VLL traffic statistics for a VLL instance specified by its VLL name, enter the following command.

```
NetIron# show mpls stat vll-local test
VLL-Name       End-point 1/2       VLL Port(s)         VLL-Ingress-Pkts
---------       -----------------     ---------------       -----------------
test           End-point1          e2/3-2/4            0
               End-point2          e2/3-2/4            0
```

To display Local VLL traffic statistics for a VLL instance specified by its VLL ID, enter the following command.

```
NetIron# show mpls stat vll-local 4
VLL-Name       End-point 1/2       VLL Port(s)         VLL-Ingress-Pkts
---------       ---------------       --------------       ------------------
test3          End-point1          e2/1                0
               End-point2          e2/2                0
```

Syntax: show mpls statistics vll-local [<*vll-name*> | <*vll-id*>]

The <*vll-name*> variable is the configured name for a Local VLL instance.
The <*vll-id*> variable is the ID of a VLL instance.

For following information is displayed in the **show mpls statistics vll** command:

TABLE 251 Output from the **show mpls vll-local command**

This field...	Displays...
VLL-Name	The configured name of the Local VLL instance.
End-point 1/2	Either the End-point1 or End-point2 of the Local VLL instance
VLL Ports	The port or ports that are assigned to the end point. If there are multiple ports, they are members of a trunk.
VLL-Ingress-Pkts	Packets arriving on the specified end point from outside the Local VLL.

Clearing the VLL traffic statistics

To clear the entries stored for all Local VLL statistics, enter a command such as the following.

```
NetIron# clear mpls statistics vll-local
```

Syntax: clear mpls statistics vll-local

Enabling MPLS Local VLL traps

You can enable trap notification to be sent for Local VLLs by entering the following command.

```
NetIron(config)# snmp-server enable trap mpls vll-local
```

Syntax: [no] snmp-server enable trap mpls vll-local

Refer to the *IronWarre MIB Reference* for MPLS VLL trap notifications.

Disabling Syslog messages for MPLS VLL-local and VLL

Transitions of VLL local instances from an up state to a down state and vice versa are logged by default. You can disable the logging of these events by entering the following command.

```
NetIron(config)# no logging enable mpls
```

Syntax: [no] logging enable mpls

Similarly, the generation of Syslog message for MPLS VLL events are enabled by default. You can disable the logging of these event by entering the following command.

```
NetIron(config)# no logging enable mpls vll
```

Syntax: [no] logging enable mpls vll

Refer to Table 454 on page 2299 for the Syslog messages generated.

Configuring MPLS Virtual Private LAN Services 33

Overview

This chapter explains how to configure Virtual Private LAN Services (VPLS). VPLS is a method for carrying Layer 2 frames between customer edge (CE) devices across an MPLS domain. The implementation supports VPLS as described in the IETF RFC 4762 (Virtual Private LAN Services over MPLS Using LDP Signaling).

NOTE
VPLS should not be used if Foundry Discovery Protocol (FDP) is configured.

The following list displays the Virtual Private LAN Services (VPLS) features supported by PowerConnect B-MLXe:

- Virtual Private LAN Services (VPLS)
- Per-VPLS MAC Table Limit
- Maximum Number of MAC Entries for a VPLS instance
- LSP to Reach a Peer within a VPLS instance
- LSP Load Balancing for VPLS Traffic
- Dual tag support for VPLS and Local VPLS
- VPLS Broadcast/Multicast/Unknown-Unicast Packet Limiting
- Flooding Layer2 BPDUs in VPLS
- VPLS Tagged mode
- VPLS CPU Protection
- VLAN Translation
- VPLS MTUs
- Dynamic LAG support for VPLS endpoints
- Flooding Layer 2 BPDUs with a VPLS Instance
- VPLS MTU Enforcement
- VPLS Local Switching
- MPLS VPLS Traps
- Disabling Syslog Messages for MPLS VPLS
- Local VPLS
- VC label allocation managed by MPLS
- VPLS LDP
- VPLS FID sharing

How VPLS works

Virtual Private LAN Services (VPLS) enhances the point-to-point connectivity defined in the Draft-Martini IETF documents by specifying a method for virtual circuits (VCs) to provide point-to-multipoint connectivity across the MPLS domain, allowing traffic to flow between remotely connected sites as if the sites were connected by a Layer 2 switch.

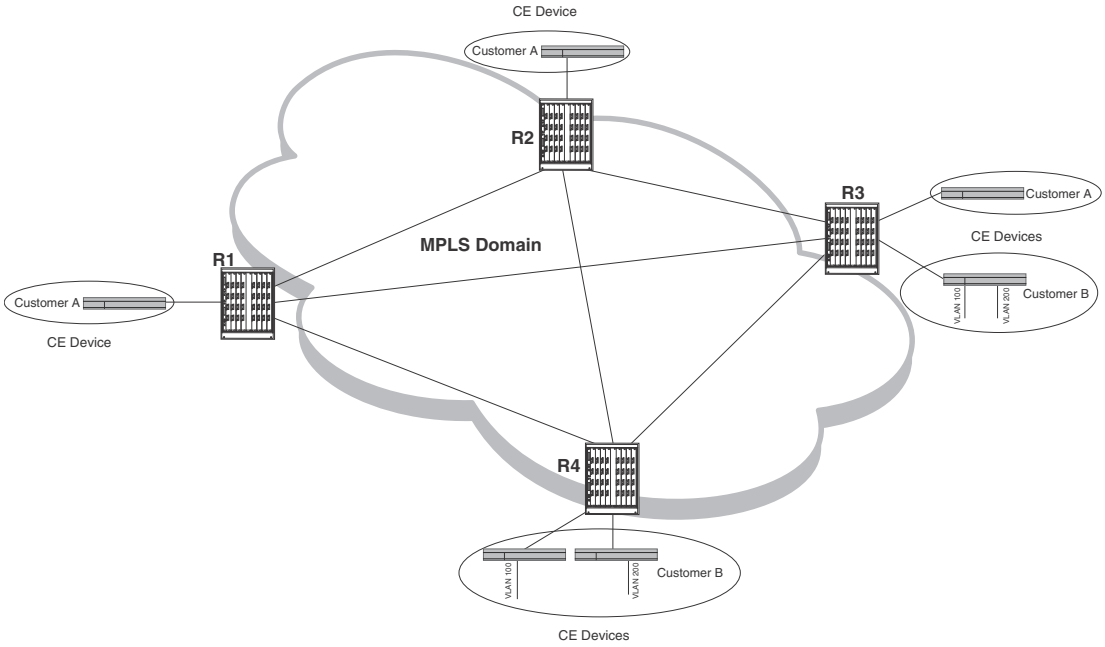
VPLS can be used to transport Ethernet frames to and from multiple, geographically dispersed sites belonging to a customer Virtual Private Network (VPN). The Provider Edge (PE) devices connecting the customer sites provide functions similar to a Layer 2 switch. The PE devices learn the MAC addresses of locally connected customer devices, flood broadcast and unknown unicast frames to other PE devices in the VPN, and create associations between remote MAC addresses and the VC Label Switch Patchs (LSPs) used to reach them.

Figure 198 shows an illustration of a VPLS configuration with two customer VPNs. Two separate VPLS instances have been created, one for Customer A's VPN and one for Customer B's VPN. A VPLS instance consists of a full mesh of VC LSPs between the customers' PE devices. In the example, Customer A's VPLS instance consists of VC LSPs between routers R1, R2, and R3. Customer B's VPLS instance consists of VC LSPs between routers R3 and R4. Because VC LSPs are unidirectional, separate VC LSPs exist in each direction between each of the PE devices. When Label Distribution Protocol (LDP) is enabled on the MPLS interfaces on the PE devices, the VC LSPs are established automatically through LDP when you specify the VPLS peers on the PE devices.

Alternatively, LSPs can be established using Resource ReSerVation Protocol- Traffic Engineering (RSVP-TE) by manually configuring LSPs to all PE devices. The same LSP from one PE to another PE can be shared by multiple VPLS instances for traffic belonging to different customers. In this case, traffic belonging to different customers has the same tunnel label, but different VC labels. If more than one LSP exists from one PE to another PE for multiple VPLS instances, traffic belonging to the different VPLS instances can be load-balanced across the LSPs. In this case, traffic belonging to the different VPLS instances has different tunnel and VC labels.

In Figure 198, the VPLS instance for Customer A links its CE devices so that they appear to be a single Layer 2 broadcast domain. The VPLS instance for Customer B has two VLANs configured within the VPLS instance, VLAN 100 and VLAN 200. The VPLS instance for Customer B has two endpoints on PE device R4. Unlike a Virtual Leased Line (VLL), a VPLS instance can have multiple endpoints. The PE device performs local and remote VLAN tag translation, so that multiple VLANs can be specified under a single VPLS instance.

FIGURE 198 Sample VPLS configuration



A PE device in the VPLS configuration operates like a standard Layer 2 switch, in that it performs MAC address learning, flooding, and forwarding for the CE devices in each VPLS instance. For example, when PE device R1 receives a Layer 2 frame with a given MAC destination address from Customer A's CE device, it looks up the MAC address in a Layer 2 forwarding table that records associations between MAC addresses and VC LSPs. This forwarding table is known as the *VPLS MAC database.*

If the MAC address is found in the VPLS MAC database, the PE device finds the associated VC LSP, encapsulates the frame as an MPLS packet, and pushes an inner VC label and outer tunnel label onto the packet. The packet is then sent over a tunnel LSP to the VC peer. If the MAC address is not found in the VPLS MAC database, the frame is flooded to all of the PE devices and locally connected CE devices (except for the CE device that originated the frame) in the customer's VPLS instance. When a response is received, an entry for the MAC address and the VC from which it arrived is added to the VPLS MAC database. Subsequent frames targeting the MAC address are not flooded to the other devices in the VPLS instance. In this way, the PE device learns the MAC addresses of the remotely connected customer devices. MAC addresses received at the local VPLS endpoints are also learned in the VPLS MAC database for the VPLS instance.

The PE devices do not run Spanning Tree Protocol (STP) over the MPLS domain. The full mesh of PE devices in a VPLS configuration allows one PE device to reach any other PE device in the VPN in exactly one hop, with no transit PE devices in between. The PE devices apply a split horizon rule when forwarding frames within the VPN. When a PE receives a customer frame from a VC LSP, it can forward the frame only to a directly attached customer device, not to another VC LSP. This allows the VPLS instance to have a loop-free topology without having to run STP.

NOTE
Packets that arrive on an interface with the same destination MAC address as the interface are forwarded in hardware just like packets with other destination addresses.

Configuring VPLS instances

This section explains how to set up VPLS instances.

Creating a VPLS instance

You create a VPLS instance by entering VPLS configuration statements on two or more PE routers. The endpoints of a VPLS instance are associated by having the same VPLS Virtual Circuit Identifier (VCID) on each PE router.

To create a VPLS instance, enter commands such as the following.

```
NetIron(config)# router mpls
NetIron(config-mpls)# vpls v1 100
NetIron(config-mpls-vpls-v1)#
```

On the VPLS peers (if they are devices), you would enter commands such as the following.

```
NetIron(config)# router mpls
NetIron(config-mpls)# vpls v1 100
NetIron(config-mpls-vpls-v1)#
```

Syntax: **vpls** <*name*> <*vpls-vcid*> [**cos** <*cos-value*>] [**max-mac** <*max-mac-entries*>]

The **vpls** <*name*> variable specifies the VPLS instance name.

The <*vpls-vcid*> variable is the VPLS ID number of the VPLS instance. The <*vpls-vcid*> variable can take a value in the range of 1 through 4294967294.

You can optionally specify a Class of Service (CoS) setting for the VPLS instance. If a CoS value is set, the device selects a tunnel LSP that also has the CoS value if one is available. If no tunnel LSP with this CoS value is available, the device selects a tunnel LSP with the highest configured CoS value (although never higher than the CoS setting for the VPLS instance). The CoS value has a range from 0 through 7.

Setting a per-VPLS MAC table limit

In previous versions of the IronWare Multi-Service software, you could set the maximum size of the VPLS MAC database and set a soft limit on the amount of memory resources available for each VPLS from the VPLS MAC database. While this soft limit helped optimize the amount of resources for each VPLS instance, it did not restrict an individual instance of a VPLS from learning more entries than the amount set for the specified VPLS instance. In practice, it would allow an instance to grow its individual entries up to the amount available in the VPLS MAC database. Under these circumstances, an individual VPLS instance could consume all of the resources and starve other VPLS instances.

You can configure a maximum number of MAC entries that can be learned for a specified VPLS instance. This number cannot be exceeded. This limit can be configured at any time, although operation is more robust if you configure the limit at the same time that you configure the VPLS instance.

Configuring the maximum number of MAC entries for a VPLS

To configure a maximum number of MAC entries available to a VPLS instance, enter commands such as the following.

```
NetIron(config)# router mpls
NetIron(config-mpls)# vpls v1 100 max-mac 3000
```

Syntax: vpls <*name*> <*vpls-vcid*> **[cos** <*cos-value*>**] [max-mac** <*max-mac-entries*>**]**

The <*name*> variable is the name of the VPLS instance for which you are configuring the maximum number of MAC entries.

The <*vpls-vcid*> variable is the VPLS ID number of the VPLS instance for which you are configuring the maximum number of MAC entries. The <*vpls-vcid*> variable can take a value in the range of 1 through 4294967294.

You can optionally specify a Class of Service (CoS) setting for the VPLS instance. If a CoS value is set, the device selects a tunnel LSP that also has this CoS value, if one is available. If no tunnel LSP with this CoS value is available, the device selects a tunnel LSP with the highest configured CoS value (although never higher than the CoS setting for the VPLS instance). The CoS value has a range from 0 through 7.

The <*max-mac-entries*> variable specifies the maximum number of MAC entries that can be learned for the VPLS instance. The <*max-mac-entries*> value can range from 1 to global VPLS MAC database size.

Specifying the maximum size of the VPLS MAC database

The VPLS MAC database serves as a Layer 2 forwarding table that associates local MAC addresses with CE devices and remote MAC addresses with VC LSPs used to reach the remote CE devices. The minimum, maximum, and default values for this parameter are described in Table 15. This number represents the total number of MAC addresses that can be learned for all VPLS instances configured on the device.

You can globally specify a different maximum size for the VPLS MAC database by entering a command such as the following.

```
NetIron(config)# system-max vpls-mac 4096
```

Syntax: system-max vpls-mac <*number-of-entries*>

NOTE
You must reload your system for the **system-max vpls-mac** command to take effect.

Clearing the contents of the VPLS MAC database

To clear the entries stored in the VPLS MAC database belonging to a VPLS instance, enter a command such as the following.

```
NetIron# clear mac vpls name v1
```

Syntax: clear mac vpls name <*name*> **| id** <*vpls-vcid*> **| ethernet** <*portnum*> **| label** <*label*>

The **name** <*name*> parameter clears all entries associated with the named VPLS instance.

The **id** <*vpls-vcid*> parameter clears all entries associated with the specified VPLS VCID.

The **ethernet** <*portnum*> parameter clears all local MAC entries on the specified port.

The **label** <*label*> parameter clears all entries associated with a local VC label.

Specifying the maximum number of VPLS instances on the device

The minimum, maximum and default values for this parameter are described in Table 15. The configured maximum number of VPLS instances has an effect on the size of the label range for each VPLS instance. The label range is the set of labels that the VPLS instance can assign to its peers for use as the peer's local VC label.

The product of the maximum number of VPLS instances and the label range will always equal 65536. This means that if the maximum number of VPLS instances is 2048, then the label range is 32; if the maximum number of VPLS instances is 8192, then the label range is 8; and so on.

To change the maximum number of number of VPLS instances to 8192, enter the following command.

```
NetIron(config)# system-max vpls-num 8192
```

Syntax: system-max vpls-num <*number-of-VPLS-instances*>

NOTE
You must reload your system for this command to take effect.

You can display the configured maximum number of VPLS instances, as well as the size of the label range, with the **show mpls vpls summary** command.

Specifying VPLS peers

NOTE
Starting with release 04.0.00, the implementation of *BGP-based auto-discovery for VPLS* (also called *VPLS auto-discovery*) eliminates the need for manual configuration of VPLS peers for every VPLS instance configured on the device. For details, refer to chapter 34, "Configuring BGP-Based Auto-Discovery for VPLS".

As part of the VPLS configuration, you specify the IP address of each VPLS peer. VPLS requires a full mesh of tunnel LSPs; each PE router must have tunnel LSP reachability to each of its VPLS peers. Tunnel LSP reachability is defined as having at least one operational RSVP- or LDP-signalled LSP with the destination (the 'to" address of the LSP) matching the VPLS peer's IP address. An LSP terminating on the VPLS peer but configured with a different destination address would not be considered a match.

By default, each PE router attempts to initiate an LDP session through extended discovery with its VPLS peers, if a session is not already established. Each VPLS instance is allocated a range of 32 labels. The PE router assigns one label in the range to each of its peers to be used as the peer's local VC label. If there are more than 32 peers in the VPLS instance, an additional label range is automatically allocated to the VPLS instance. The size of the label range depends on the configured maximum number of VPLS instances on the device. Refer to "Specifying the maximum number of VPLS instances on the device" on page 1498 for more information.

Once the LDP session is established, the PE device advertises the local VC label, along with the VPLS ID, to its VPLS peers in a downstream-unsolicited manner. In a similar way, the PE also learns the remotely assigned VC labels from its VPLS peers.

To specify three remote VPLS peers within a VPLS instance, enter a command such as the following.

```
NetIron(config-mpls-vpls-v1)# vpls-peer 192.168.2.100 192.168.2.101 192.168.2.102
```

Syntax: vpls-peer <*ip-addr*> [<*ip-addr*>...]

The IP address of each VPLS peer must match that of a destination for a tunnel LSP configured on the device.

Setting the VPLS VC mode

The PowerConnect B-MLXe routers support the following VPLS VC modes, which determine whether or not VLAN tags are carried across the MPLS cloud:

- Raw mode – This is the default VC mode. When this mode is in effect, the VLAN tag information in the original payload *is not* carried across the MPLS cloud.
- Tagged mode – When tagged mode is enabled, the VLAN tag information in the original payload is carried across the MPLS cloud.

VPLS raw mode

By default, VPLS packets are sent to remote peers over the MPLS cloud in *raw mode*. This means that no VLAN tag information in the payload is carried across the MPLS cloud. In raw mode, the VLAN priority (Class of Service) of the original (incoming) packets is lost once the packets are sent through the cloud.

NOTE
If desired, you can enable the device to preserve the VLAN tag information in the payload and carry it across the MPLS cloud to remote peers. For more information, see "VPLS tagged mode" on page 1500.

CoS behavior for VPLS raw mode

NOTE
This section assumes that you understand how QoS works. For details, see "Configuring Quality of Service for the NetIron MLX" on page 283.

Table 252 describes the expected Class of Service (CoS) behavior for VPLS packets when VPLS raw mode is in effect.

TABLE 252 Expected class of service behavior for VPLS raw mode

VPLS endpoints	Incoming packet		MPLS cloud		Outgoing packet	
	Outer VLAN	Inner VLAN	Tunnel/VC label (Z)	Payload tag	Outer VLAN	Inner VLAN
Dual-tagged to dual-tagged	X	Y	V or internal priority	N/A	W or Z	Z
Single-tagged to dual-tagged	X	N/A				Z
Untagged to dual-tagged	N/A	N/A				Z
Dual-tagged to single-tagged	X	Y				N/A

Legend for Table 252

V = Mapped EXP bits from internal priority (X contributes to internal priority) using the EXP encode table. Table 57 shows the default EXP encode table.

W = Mapped CoS from internal priority (Z contributes to internal priority) using the CoS encode table.

X = Original outer VLAN CoS.

Y = Original inner VLAN CoS.

Z = Incoming EXP bits as described by the *Tunnel / VC label* column = V or internal priority.

- The *Tunnel/VC label* column differentiates the behavior when **qos exp encode** policy is ON (default) or OFF.
- The *Outgoing packet Outer VLAN* column differentiates the behavior when **qos pcp encode** policy is ON (default) or OFF.

VPLS tagged mode

VPLS tagged mode enables the preservation of the VLAN tag information in the payload. In VPLS tagged mode, the VLAN priority of the original (incoming) packets is carried across the MPLS cloud to remote peers.

By default, VPLS packets are sent across the MPLS cloud in raw mode. To use VPLS tagged mode, enable it per VPLS instance on both sides of the communicating edge routers. When this feature is enabled, the VLAN tag is determined as follows:

- If the original packet has one VLAN tag, the payload tag will be the (outer) VLAN tag of the original packet.
- If the original packet has dual VLAN tags, the payload tag will be the inner VLAN tag of the original packet.
- If the original packet is untagged, the payload tag will be the configured VLAN on the VPLS untagged endpoint, and the CoS will be 0.
- If the original packet has an I-component Service Identifier (ISID) tag, the payload tag will be the unmodified ISID tag.

For more information about CoS behavior for VPLS tagged mode, see Table 253 on page 1501.

VPLS tagged mode must be enabled on both sides of the communicating edge routers. If the VPLS VC type does not match, the remote peer will not transition into operational state. Because each remote peer has its own operational state, the impact may differ from one remote peer to another, depending on its current state. The remote peer state can be categorized into two general categories, as follows:

- *Remote peer in operational state* – If the remote peer is in operational state, a VC withdraw message and a new VC bind message will be sent to the remote peer to tear down the current VC binding and to communicate the new VC type, respectively. This scenario assumes that the remote router is also a Dell router running the same code level. The VC tear-down and re-bind should cause the remote peer to transition its peer state to “VC Parameter Check” state, because its own VC type will now be mismatched with that of the new VC type received. Once the same tagged mode configuration is also applied to the remote router, the peer state for both routers should transition into operational state. As part of the VC tear-down, the hardware forwarding entries on the Interface module (LP) will be cleaned up. When the peer transitions to operational state, its hardware forwarding entries will be reprogrammed based on its tagged mode setting.

- *Remote peer not in operational state* – The category indicates that the VC has not yet been formed with the VPLS peer on the remote router. Remote peers may be in this category for many reasons (for example, “No local port defined”, “No Tunnel”, “No LDP Session”, “VC Parameter Check”, and so on). In this scenario, there is no need to tear down the VC binding. When the VPLS tagged mode configuration changes, most of the peers in this category will not change their operational state or perform any actions triggered by this configuration change. For remote peers that are in the state “VC Parameter Check” state because of a VC type mismatch, the configuration change will trigger the sending of a VC bind message with the new VC type to the remote router. If the remote peer’s VC type becomes compatible due to this configuration change and there is no other VC parameter mismatch, then the state of the remote peer will transition to operational state.

To enable VPLS tagged mode, see “Configuring VPLS tagged mode” on page 1511.

CoS behavior for VPLS tagged mode

NOTE
This section assumes that you understand how QoS works. For details, see “Configuring Quality of Service for the NetIron MLX” on page 283.

Table 253 describes the expected Class of Service (CoS) behavior for VPLS packets when VPLS tagged mode is enabled.

TABLE 253 Expected class of service behavior for VPLS tagged mode

VPLS endpoints	Incoming packet		MPLS cloud		Outgoing packet	
	Outer VLAN	Inner VLAN	Tunnel/VC label (Z)	Payload tag	Outer VLAN	Inner VLAN
Dual-tagged to dual-tagged	X	Y	V or internal priority	Y	W or Y	Y
Single-tagged to dual-tagged	X	N/A		X	W or X	X
Untagged to dual-tagged	N/A	N/A		0	W or 0	0
Dual-tagged to single-tagged	X	Y		Y	W or Y	N/A

Legend for Table 253

V = Mapped EXP bits from internal priority (X contributes to internal priority) using the EXP encode table. Table 58 shows the default EXP encode table.

W = Mapped CoS from internal priority (Z contributes to internal priority) using the CoS encode table.

X = Original outer VLAN CoS.

Y = Original inner VLAN CoS.

Z = Incoming EXP bits as described by the *Tunnel / VC label* column = V or internal priority.

- The *Tunnel/VC label* column differentiates the behavior between when **qos exp encode** policy is ON (default) or OFF.
- The *Outgoing packet Outer VLAN* column differentiates the behavior between when **qos pcp encode** policy is ON (default) or OFF.

QoS for VPLS traffic

By default, packets travelling through an MPLS domain are treated equally from a QoS standpoint, in a best effort manner. However, if a Layer 2 packet has an internal priority in its 802.1q tag, or the LSP or VPLS to which the packet is assigned has a configured Class of Service (COS) value, QoS can be applied to the packet in the MPLS domain. The internal priority or COS value is mapped to a value in the EXP field of the packet's MPLS header. The value in the EXP field is then mapped to an internal forwarding priority, and the packet is sent to the hardware forwarding queue that corresponds to the internal forwarding priority.

QoS for VPLS traffic at the ingress LER

The following methods can be used to provide QoS to packets entering a VPLS:

- Use the COS value assigned to the tunnel LSP used to reach the VPLS peer.

  When a tunnel LSP has a user-configured COS value, all packets in all VPLS travelling through the tunnel LSP receive the same QoS.

- Use the COS value assigned to the VPLS.

  If a COS value is set for the VPLS, the device selects a tunnel LSP that also has this COS value, if one is available. If no tunnel LSP with this COS value is available, the device selects a tunnel LSP with the highest configured COS value (although never higher than the COS setting for the VPLS).

  If the selected tunnel LSP does not have a COS value, the VPLS configured COS value is used to provide QoS. The VPLS COS value is mapped to a value in the EXP field. This allows traffic multiple VPLS using a single tunnel LSP, traffic from each VPLS can receive different QoS treatment.

- Use the priority in the packet's 802.1q tag.

  When neither the tunnel LSP nor the VPLS has a configured COS value, the device examines the priority in the Layer 2 packet's 802.1q tag, if the packet has one. Consequently, Layer 2 packets with the same 802.1q priority receive the same QoS in the VPLS.

- Use the configured priority of the port.

  If neither the tunnel LSP nor the VPLS has a configured COS value, and the Layer 2 packet does not have an 802.1q priority, QoS can be provided based on the priority of the incoming port. A port can be assigned a priority from 0 (lowest priority) to 7 (highest priority). The default port priority is 0.

  By assigning different priorities to the ports where customer edge (CE) devices are connected (that is, the VPLS endpoints), you can provide QoS to untagged Layer 2 traffic received from different customer locations.

When a packet enters a VPLS, the PE router that serves as both the VPLS endpoint and the ingress of a tunnel LSP pushes two labels onto the packet the inner VC label and the outer tunnel label. The packet's priority resides in the EXP field of the MPLS label header. The VC label and the tunnel label carry the same value in the EXP field.

The following table lists how a Layer 2 packet's priority is mapped to a value in the EXP field and how the EXP value is mapped to a priority queue.

Tunnel LSP configured COS or VPLS configured COS or 802.1q priority or Configured port priority	Value placed in the tunnel and VC label EXP field	Priority queue
7	7	qosp7 (highest priority)
6	6	qosp6
5	5	qosp5
4	4	qosp4
3	3	qosp3
2	2	qosp2
1	1	qosp1
0	0	qosp0 (best effort)

Specifying an LSP to reach a peer within a VPLS

You can specify the LSPs that can be used to reach a peer within a VPLS. You can specify up to four Resource ReSerVation Protocol (RSVP) LSPs per VPLS peer. VPLS subsequently selects one of the LSPs configured to reach the specified peer. Any of the configured LSPs can be used, and the order of configuration is not relevant to the selection of the LSP. If none of the assigned LSPs is operational, the VPLS session with the peer is down. An LSP is considered down when the LSP's primary, secondary, and detour paths are all down.

RSVP LSPs must be pre-configured prior to their assignment to the VPLS peer. Additionally, the VPLS peer's IP address must match the target IP address of any RSVP LSPs assigned to it. If these addresses do not match, the configuration will be rejected. An LSP that is assigned to any VPLS will not be allowed to be deleted from the configuration unless the VPLS LSP assignment is deleted first. If no LSPs have been assigned to a VPLS peer, the existing mechanism is used to select an appropriate LSP for the peer.

When LSP assignment is configured, ignore the configured COS of the LSP, and ignore the VPLS to select an LSP for the VPLS peer. However, traffic sent on the LSP will use the CoS of the LSP. If LSP load balancing is enabled for a VPLS peer, traffic is load-balanced on all assigned LSPs that are operational.

To specify LSPs for a VPLS peer within a VPLS instance, enter a command such as the following.

```
NetIron(config-mpls-vpls-v1)# vpls-peer 192.168.2.100 lsp t1 t2 t3 t4
```

Syntax: vpls-peer <*ip-address*> **lsp** <*lsp1*> [<*lsp2*> <*lsp3*> <*lsp4*>]

The <*ip-address*> variable specifies the IP address of the VPLS peer to which you want to assign LSPs.

The <*lsp1*> <*lsp2*> <*lsp3*> <*lsp4*> variables are the names of the LSPs that you want to assign to the VPLS peer. You can assign up to four LSPs to a peer using this command. If a VPLS peer is not assigned any LSPs, the default mechanisms for selecting an LSP for the VPLS peer are used.

LSP load balancing for VPLS traffic

In a VPLS instance, traffic from one VPLS peer to another is forwarded over an MPLS tunnel LSP. If more than one tunnel LSP exists from the device to a VPLS peer, the device can select multiple tunnel LSPs to forward VPLS traffic to the peer. Known unicast traffic is load-balanced across the selected tunnel LSPs. Broadcast and unknown unicast traffic is always sent over a single tunnel LSP, however.

For VPLS LSP load-balancing, select an LSP based on a hash-index which is calculated as follows:

NOTE
For VPLS traffic, source and destination MAC addresses come from the inner customer Ethernet header.

- **Layer-2, non-IPv4, and IPv6 packets:** Source MAC address and destination MAC address.
- **IPv4, non-TCP/UDP packets**: Source MAC address and destination MAC address, source IP address and destination IP address.
- **IPv4 TCP packets:** Source MAC address and destination MAC address, source IP address and destination IP address, and TCP source port and TCP destination port.
- **IPv4 UDP packets:** Source MAC address and destination MAC address, source IP address and destination IP address, and UDP source port and UDP destination port.
- **IPv6 non-TCP/UDP packets**: Source MAC address and destination MAC address, source IP address and destination IP address.
- **IPv6 TCP packets:** Source MAC address and destination MAC address, source IP address and destination IP address, and TCP source port and TCP destination port.
- **IPv6 UDP packets:** Source MAC address and destination MAC address, source IP address and destination IP address, and UDP source port and UDP destination port.

A tunnel LSP's eligibility for load balancing depends on whether CoS values are defined for the VPLS instance and the tunnel LSP:

- If the VPLS instance does not have a CoS value defined, then all tunnel LSPs to the peer are eligible for load balancing.
- If a VPLS instance has a CoS value defined, and at least one tunnel LSP to the peer has a CoS value less than or equal to the VPLS instance CoS value, then all tunnel LSPs with the highest CoS value less than or equal to the VPLS instance CoS value are eligible for load balancing.
- If a VPLS instance has a CoS value defined, and none of the tunnel LSPs to the peer has a CoS value less than or equal to the VPLS instance CoS value, then all tunnel LSPs to the peer that do not have a CoS value are eligible for load balancing.

NOTE
The LSP's picked for load-balancing must have the same COS values. For example: If COS of LSP1 = 4, LSP2 = 4, LSP3 = 2, LSP4 =2, LSP5 = 1 and VPLS instance COS = 3. Then traffic is load balanced with LSP3 and LSP4 which has same COS values.

LSP load balancing

The device evenly distributes VPLS traffic across tunnel LSPs.

In early software releases, VPLS traffic was unevenly balanced across tunnel LSPs if exactly three tunnels were used for load balancing. For example, for tunnels A, B, and C, VPLS traffic might be distributed among the tunnels as follows: A: 50%, B: 25%, and C: 25%.

Now, the tunnels are fully utilized. Using the same example above, VPLS traffic might be distributed among tunnels A, B, and C as follows: A: 33.3%, B: 33.3%, and C: 33.3%. These percentages are based on a fully distributed hash index generated by the incoming traffic. Actual distribution percentages may vary and are based on the hash index.

Configuring LSP load balancing for VPLS traffic

To configure a VPLS instance to load balance known unicast traffic sent to a VPLS peer across multiple tunnel LSPs, enter a command such as the following.

```
NetIron(config-mpls-vpls-v1) vpls-peer 192.168.9.210 load-balance
```

Syntax: [**no**] **vpls-peer** <*ip-addr*> [**load-balance**]

NOTE
To disable the LSP load balancing, you must delete the VPLS peer with the **no vpls-peer** command, then re-enter the **vpls-peer** command without the **load-balance** option.

NOTE
To disable LSP load balancing when VPLS auto-discovery is enabled on the device, refer to "Disabling load balancing" on page 1550.

In the prior example, when the **load-balance** option is specified, VPLS traffic originating from the device and sent to peer 192.168.9.210 is load balanced across eligible tunnel LSPs whose destination is the peer.

Specifying the endpoint of a VPLS instance

When you configure the VPLS endpoint, you specify what happens to packets exiting the VPLS instance, which VLAN the packet belongs to, as well as whether it is transmitted from the PE device to the CE device over a dual-tagged, single-tagged, or untagged port. You can also specify a server Link Aggregation Group (LAG) group as the endpoint of a VPLS instance.

A VPLS instance can be configured between any combination of dual-tagged, single-tagged, and untagged endpoints. For dual-tagged ports, traffic flows between the dual-tagged endpoint and the MPLS cloud are also supported for traffic switched between a local endpoint and remote peers.

NOTE
Unless VPLS tagged mode is enabled, VPLS will operate in raw mode, meaning no VLAN tags will be carried across the MPLS cloud to remote peers. For more information, see "Configuring VPLS tagged mode" on page 1511.

The Customer Edge (CE) device is connected to the PE router over one or more dual-tagged, single-tagged, or tagged ports.

- With a *single-tagged* port, each pair (port, VLAN ID) is identified as a unique endpoint. If VPLS raw mode is in effect, the tag is of significance between the CE and the PE and is not sent across the MPLS cloud. If VPLS tagged mode is enabled, the tag will be sent across the MPLS cloud.

- In the case of an *untagged* port, an endpoint is identified by the physical port alone, and the packets are sent in untagged Ethernet format within the MPLS payload.
- In the case of a *dual-tagged* port, the packets contain both an outer VLAN tag and an inner VLAN tag. In this configuration, an endpoint can receive packets with two tags and forward them to the other endpoint either single-tagged or dual-tagged. If VPLS tagged mode is enabled, the inner VLAN tag will be sent across the MPLS cloud.

All VPLS endpoints can be dual mode ports (tagged-untagged). An untagged endpoint port is removed from the default VLAN ID 1 and cannot be added back to the default VLAN. A VPLS endpoint can be tagged in multiple VPLS and Layer 2 VLANs and untagged in one other VLAN.

Special considerations for dual-tagged endpoints

Before configuring a dual-tagged VPLS endpoint, consider the following:

- The tag protocol identifier (TPID) of the inner VLAN tag must be 0x8100 be classified as dual-tagged and recognized by dual-tagged endpoints. If the TPID is not 0x8100, the packet will be classified as a single-tagged packet.
- The TPID of the outer VLAN tag must be the port's configured tag type (the default tag type is 0x8100).
- The System Max value for the Internal Forwarding Lookup (IFL) CAM partition must not be set to 0 (zero). If it is set to zero, an informational message such as the following will be displayed.

```
NetIron(config-mpls)#vpls test 10
NetIron(config-mpls-vpls-test10)#vlan 100 inner-vlan 200
NetIron(config-mpls-vpls-test_10-vlan-100-inner-vlan-200)#tagged Ethernet 2/1
Note – The system-max size for the Internal Forwarding Lookup CAM is 0.
Please use the command 'system-max ifl-cam' to specify a size.
```

  The informational message only warns that the configuration should be changed. It does not cause the system to reject the VPLS configuration. For example, in the sample case, the dual-tagged endpoint configuration of vlan 100 inner-vlan 200 on port ethernet 2/1 has been accepted assuming the port, outer VLAN, and inner VLAN combination has not already been assigned elsewhere.

NOTE
The acceptable values and configuration procedures for the **system-max ifl-cam** command are in the section "Configuring system max values" on page 106.

- When the IFL CAM partition on the Interface module exceeds a configured threshold, there will be a warning log message which is similar to the way other CAM partitions are handled currently. The system will not generate any logs if it cannot program the IFL CAM because of exhaustion of an IFL CAM resource.
- If an outer VLAN is specified for a given endpoint, it is called a less-specific VLAN. If both an outer VLAN and inner VLAN are specified, it is called a more-specific VLAN (in relation to the outer VLAN).
- Similar to single-tagged endpoints, the outgoing VLANs for a dual-tagged endpoint are based solely on the outgoing endpoint configuration, and not on the incoming packet VLAN values.

- The same port, outer VLAN, and inner VLAN combination cannot be specified across VPLS instances. For example, if a dual-tagged endpoint with VLAN 100 and inner VLAN 200 is configured on port ethernet 2/1 on VPLS instance “test”, same endpoint cannot be configured as part of another VPLS instance (for example, “test 1”).This is also true across applications. If a port, outer VLAN, and inner VLAN combination belongs to a VPLS instance, it cannot simultaneously belong to a Layer 2 VLAN, local VLL, or VLL.
- When CPU protection is enabled for a VPLS instance, the system will not support a configuration with two different dual-tagged VPLS VLANs as part of the same VPLS instance. Consider the following configuration example.

```
NetIron(config)#router mpls
NetIron(config-mpls)#vpls test 10
NetIron(config-mpls)#cpu-protection
NetIron(config-mpls-vpls-test)#vlan 10 inner-vlan 20
NetIron(config-mpls-vpls-test-vlan-10-20)#tagged eth 2/1
NetIron(config-mpls-vpls-test-vlan-10)#exit
NetIron(config-mpls-vpls-test)#vlan 10 inner-vlan 30
NetIron(config-mpls-vpls-test-vlan-10-30)#tagged eth 2/1
Error - VPLS port 2/1 cannot be shared by multiple end-points when CPU
protection is enabled. Remove CPU protection for VPLS 10 to make this
configuration change.
```

  Similarly, CPU protection cannot be enabled for a VPLS instance that has a port configured under two different dual-tagged VPLS VLANs. Consider the following configuration example.

```
NetIron(config)#router mpls
NetIron(config-mpls)#vpls test 10
NetIron(config-mpls-vpls-test)#vlan 10 inner-vlan 20
NetIron(config-mpls-vpls-test-vlan-10-20)#tagged eth 2/1
NetIron(config-mpls-vpls-test-vlan-10)#exit
NetIron(config-mpls-vpls-test)#vlan 30 inner-vlan 40
NetIron(config-mpls-vpls-test-vlan-30-40)#tagged eth 2/1
NetIron(config-mpls-vpls-test-vlan-20)#exit
NetIron(config-mpls-vpls-test)#cpu-protection
Error - Cannot configure CPU protection for VPLS 10 as multiple end-points
share the same physical port.
```

  The restrictions exist because packets are hardware-forwarded when CPU protection is enabled. In this case, source port suppression cannot be properly performed if there are multiple endpoints on the same physical interface.

Specifying an untagged endpoint

To specify an untagged endpoint for a VPLS instance, enter commands such as the following.

```
NetIron(config-mpls)# vpls v1 40000
NetIron(config-mpls-vpls-v1)# vlan 100
NetIron(config-mpls-vpls-v1-vlan-100)# untagged ethernet 2/1
```

Syntax: [no] untagged [ethernet] <*portnum*>

NOTE
Foundry Discovery Protocol (FDP) should not be enabled on an untagged VPLS or VLL endpoint.

Specifying a single-tagged endpoint

Tagged ports are configured under a VLAN ID. A VPLS instance can have multiple ports configured under the same VLAN ID, and can have ports configured under different VLAN IDs. Another VPLS instance can reuse the same VLAN ID on other physical ports. Because the VLANs are configured under different VPLS instances, they are different VPLS VLANs even though they use the same VLAN ID.

To specify a tagged endpoint for a VPLS instance, enter commands such as the following:

```
NetIron(config-mpls)# vpls v1 40000
NetIron(config-mpls-vpls-v1)# vlan 200
NetIron(config-mpls-vpls-v1-vlan-200)# tagged ethernet 3/11
```

Syntax: vlan <*num*>

Syntax: [no] tagged ethernet <*slot/port*>

Specifying a dual-tagged endpoint

Dual-tagged ports are configured with two VLAN IDs. A VPLS instance can have multiple ports configured under the same dual-tagged VLAN ID, and can have ports configured under different VLAN IDs. Another VPLS instance can reuse the same VLAN ID on other physical ports. Because the VLANs are configured under different VPLS instances, they are different VPLS VLANs even though they use the same VLAN ID.

NOTE
Before configuring a dual-tagged endpoint, see "Special considerations for dual-tagged endpoints" on page 1506.

To specify a dual-tagged endpoint for a VPLS instance, use the following commands.

```
NetIron(config-mpls)# vpls v1 40000
NetIron(config-mpls-vpls-v1)# vlan 200 inner-vlan 300
NetIron(config-mpls-vpls-v1-vlan-200)# tagged ethernet 3/11
```

Syntax: [no] vlan <*VLAN-ID*> **inner-vlan** <*VLAN-ID*>

Syntax: [no] tagged ethernet <*slot/port*>

The **vlan** <*VLAN-ID*> variable, which is the outer VLAN ID, can be in the range from 1 through 4094 and excludes the default VLAN.

The **inner-vlan** <*VLAN-ID*> variable, can be in the range from 1 through 4095 and includes the default VLAN.

Use the **no** form of the command to remove the dual-tagged VPLS VLAN configuration and its associated endpoints. For example, the command **no vlan 200 inner-vlan 300** will remove the dual-tagged VLAN and associated endpoints. The single-tagged VLAN, **vlan 200**, will not be deleted. Similarly, the command **no vlan 200** will remove the single-tagged VLAN, **vlan 200**, and associated endpoints. The dual-tagged VLAN, **vlan 200 inner-vlan 300**, will not be deleted.

Example of dual-tagged endpoints mapped to different VPLS instances

The following example shows two dual-tagged endpoints on the same physical interface with the same outer VLAN ID and different inner VLAN IDs mapped to different VPLS instances.

```
NetIron(config-mpls)#vpls test_10 10
NetIron(config-mpls-vpls-test_10)#vlan 100 inner-vlan 200
```

```
NetIron(config-mpls-vpls-test_10-vlan-100-inner-vlan-200)#tagged ethernet 2/1
NetIron(config-mpls-vpls-test_10-vlan-100-inner-vlan-200)#exit
NetIron(config-mpls-vpls-test_10)#exit
NetIron(config-mpls)#vpls test_20 20
NetIron(config-mpls-vpls-test_20)#vlan 100 inner-vlan 300
NetIron(config-mpls-vpls-test_20-vlan-100-inner-vlan-300)#tagged ethernet 2/1
NetIron(config-mpls-vpls-test_20-vlan-100-inner-vlan-300)#exit
```

Example of dual-tagged endpoints mapped to the same VPLS instance

The following example shows two dual-tagged endpoints on the same physical interface with the same outer VLAN ID and different inner VLAN IDs mapped to the same VPLS instance.

```
NetIron(config-mpls)#vpls test 10
NetIron(config-mpls-vpls-test)#vlan 100 inner-vlan 200
NetIron(config-mpls-vpls-test-vlan-100-inner-vlan-200)#tagged ethernet 2/1
NetIron(config-mpls-vpls-test-vlan-100-inner-vlan-200)#exit
NetIron(config-mpls-vpls-test)#vlan 100 inner-vlan 300
NetIron(config-mpls-vpls-test-vlan-100-inner-vlan-300)#tagged ethernet 2/1
```

In the above example, if packets are received with outer VLAN ID 100 and no inner VLAN ID, the packets will not be handled as part of VPLS instance 10.

Example of a less-specific and more-specific VLAN mapped to different VPLS instances

The following example shows a less-specific VLAN and more-specific VLAN (with the same outer VLAN ID) of the same port in different VPLS instances.

```
NetIron(config-mpls)#vpls test_10 10
NetIron(config-mpls-vpls-test_10)#vlan 100
NetIron(config-mpls-vpls-test_10-vlan-100)#tagged ethernet 2/1
NetIron(config-mpls-vpls-test_10-vlan-100)#exit
NetIron(config-mpls-vpls-test_10)#exit
NetIron(config-mpls)#vpls test_20 20
NetIron(config-mpls-vpls-test_20)#vlan 100 inner-vlan 300
NetIron(config-mpls-vpls-test_20-vlan-100-inner-vlan-300)#tagged ethernet 2/1
NetIron(config-mpls-vpls-test_20-vlan-100-inner-vlan-300)#exit
```

Example of a less-specific and more-specific VLAN mapped to the same VPLS instance

The following example shows a less-specific VLAN and more-specific VLAN (with the same outer VLAN ID) of the same port in the same VPLS instance.

```
NetIron(config-mpls)#vpls test_10 10
NetIron(config-mpls-vpls-test_10)#vlan 100
NetIron(config-mpls-vpls-test_10-vlan-100)#tagged ethernet 2/1
NetIron(config-mpls-vpls-test_10-vlan-100)#exit
NetIron(config-mpls-vpls-test_10)#vlan 100 inner-vlan 300
NetIron(config-mpls-vpls-test_10-vlan-100-inner-vlan-300)#tagged ethernet 2/1
NetIron(config-mpls-vpls-test_10-vlan-100-inner-vlan-300)#exit
```

In the above example, if packets are received on interface ethernet 2/1 with outer VLAN ID 100 and an inner VLAN ID other than 300, the packets will be handled as part of VPLS instance 10. In this case, the inner VLAN is treated as payload.

Specifying a LAG group as the endpoint of a VPLS instance

The endpoint of a VPLS instance can be a static or a dynamic LAG. When the endpoint of a VPLS instance is a LAG, the VPLS traffic load is distributed to the CE device across all of the LAG's ports by way of a hashing mechanism that utilizes the source and destination MAC addresses.

For example, to configure a LAG, enter commands such as the following.

```
NetIron(config)# lag blue dynamic
NetIron(config-lag-blue)# ports ethernet 1/1 to 1/2
NetIron(config-lag-blue)# primary-port 1/1
```

To configure a VPLS instance that uses the LAG defined as the endpoint by the previous example commands, enter the commands as in the following example.

```
NetIron(config)# router mpls
NetIron(config-mpls)# vpls test1 40000
NetIron(config-mpls-vpls-test1)# vpls-peer 10.10.10.10
NetIron(config-mpls-vpls-test1)# vlan 200
NetIron(config-mpls-vpls-test1)# tagged e 1/1
```

NOTES: If you first create a LAG and then configure a VPLS instance, the port you specify as the VPLS endpoint must also be the port you specified as the primary port of the LAG group:

- If you first configure a VPLS instance and then create a LAG, all ports of the LAG must be specified as endpoints of the VPLS instance. The VPLS instance will use all the ports of the LAG.
- If you later delete the LAG from the configuration, all ports in the LAG become independent endpoints in the VPLS instance.
- If you specified a tagged endpoint for the VPLS instance, all of the ports in the LAG must be tagged.
- Traffic received from any port in the LAG is forwarded to the VPLS instance. All traffic is matched to its VLAN.

Support for VPLS endpoints within a Topology group

You can configure VPLS VLANs into Topology groups so that you can use any of the following protocols within a VPLS VLAN:

- Spanning Tree Protocol (STP)
- Rapid Spanning Tree Protocol (RSTP)
- Foundry Metro Ring Protocol (MRP)
- Virtual Switch Redundancy Protocol (VSRP)

Instructions for configuring VPLS VLANs into Topology groups are provided in the chapter 16, "Topology Groups" in the section titled "Adding VPLS VLANs to topology groups" on page 546.

Flooding Layer 2 BPDUs in VPLS

By default, Layer 2 STP and Per VLAN Spanning Tree (PVST) Bridge Protocol Data Units (BPDUs) entering a VPLS endpoint are not transparently flooded within the VPLS instance. The BPDUs are dropped when they enter the VPLS endpoint. The user can change this default behavior to not block BPDUs and transparently flood them within the VPLS instance, by configuration on a per-physical-port basis. Because the BPDU block option is configurable per physical interface, it will affect all VPLS instances that have endpoints on that interface.

To flood BPDUs in VPLS, use the following command.

```
NetIron(config)# interface ethernet 1/1
NetIron(config-if-e10000-1/1)# no vpls-bpdu-block
```

Syntax: [no] vpls-bpdu-block

Specifying the VPLS VC type

NOTE
This is a global setting that will affect all VPLS instances, except those in VPLS tagged mode. You must save the configuration and reload the software to place the change into effect.

The default VC type for all VPLS instances is set to 0x5 or “Ethernet”. For compatibility with previous versions, the VC type can be changed to 0xB or “Ethernet VPLS”. The VC type must match between peers for the VPLS session to be established.

NOTE
When VPLS tagged mode is enabled for a VPLS instance, the VC type for that instance will be set to 0x04 or “Ethernet Tagged”, regardless of the global VPLS VC type setting.

To change the VPLS VC type, use the following command at the MPLS configuration level.

```
NetIron(config-mpls)# vpls-vc-type-ethernet-vpls
VPLS VC type will be 0xB (Ethernet VPLS) after you save to config and reboot
```

Syntax: [no] vpls-vc-type-ethernet-vpls

Configuring VPLS tagged mode

This section describes how to enable, disable, and view the configuration details of VPLS tagged mode. For details about how VPLS tagged mode works, see “VPLS tagged mode” on page 1500.

Enabling VPLS tagged mode

To enable VPLS tagged mode, first create the VPLS instance if it does not already exist, and then enter commands such as the following at the MPLS VPLS configuration level of the CLI.

```
NetIron(config-mpls)#vpls test 100
NetIron(config-mpls-vpls-test)#vc-mode tagged
```

Syntax: vc-mode tagged

Disabling VPLS tagged mode

Except for VPLS instances on which ISID is configured, use the **no vc-mode tagged** command to disable VPLS tagged mode. For VPLS instances with an ISID configuration, first remove the ISID configuration, then disable VPLS tagged mode.

If you attempt to disable VPLS tagged mode on a VPLS instance with ISID, the system will display the following error message.

```
NetIron(config-mpls-vpls-test)#no vc-mode tagged
Error – Cannot remove tagged-mode setting while VPLS ISID configuration exists
```

Syntax: no vc-mode tagged

Viewing the VPLS tagged mode configuration

Use the **show running config** and **show mpls vpls detail** commands to view the VPLS tagged mode configuration. The following shows an example **show running config** output. For examples and details of the **show mpls vpls detail** command, see "Enabling MPLS VPLS traps" on page 1518.

```
NetIron(config-mpls)#vpls test 100
NetIron(config-mpls-vpls-test)#vc-mode tagged

NetIron#show running config
....
router mpls

vpls test 100
  vc-mode tagged
  vpls-peer 100.100.100.100
  vlan 100 inner-vlan 45
    tag e 2/1
vpls name_raw 3
  vpls-peer 200.200.200.200
```

In the above example, **vc-mode tagged** indicates that VPLS tagged mode is enabled on **vpls test 100**, whereas **vpls name_raw 3** is in VPLS raw mode.

VPLS CPU protection

The VPLS CPU protection feature protects the CPU of the line card from being overwhelmed by excessive VPLS packets that would require the CPU's attention, including unknown unicast, multicast packets, and packets requiring source-MAC learning. Once this feature is enabled, all VPLS multicast traffic will be hardware-flooded. Furthermore, when the CPU is too busy, this feature will hardware-flood unknown unicast traffic, as well as reduce the rate of source-MAC learning traffic to the line card CPU, so that the line card CPU will have enough resources to handle other types of packets.

Configuration Considerations

Note the following configuration rules before enabling VPLS CPU protection.

- VPLS CPU protection cannot be concurrently enabled with IGMP snooping on a VPLS instance.
- CPU protection cannot be enabled for a VPLS instance that has a port configured under two different VPLS VLANs. Similarly, when CPU protection is enabled for a VPLS instance, the system will not support a configuration with two different VPLS VLANs as part of the same VPLS instance.
- If VPLS FID usage reaches 100%, CPU protection will be temporarily disabled until adequate FID resources are available.

Configuring adequate CAM resources

NOTE
Beginning with release 03.8.00, the Multi-Service IronWare software has been enhanced to support the dynamic growth of the protocol and flooding sub-partitions in the L2 CAM to grant them a higher priority. Because of this enhancement, the **system-max hw-flooding** command is no longer required and has been retired from the software.

When using VPLS CPU protection, you must have adequate CAM resources available. Each endpoint and each uplink port requires a single CAM entry. Also, if an endpoint is a LAG port, one entry is required for each port in the LAG. To determine the number of entries required on your system, add the number of VPLS endpoints, ports within a LAG port used as an endpoint, and uplink ports. Use this number with the **system-max hw-flooding** command to provide adequate CAM resources.

By default, 8 CAM entries are available. To configure a larger number, you must use the following command.

```
NetIron(config)# system-max hw-flooding 40
```

Syntax: [no] system-max hw-flooding <*number*>

The <*number*> variable is the number of CAM entries that you want to make available.

NOTE
You must reload your system for the **system-max** command to take effect.

Configuring VPLS CPU protection

VPLS CPU protection can be configured in either of the following two ways:

- Globally – This enables VPLS CPU protection to affect all VPLS instances on the router.
- Per-VPLS – This enables VPLS CPU protection on one or more specified VPLS instances.

Configuring VPLS CPU protection globally

VPLS CPU protection can be enabled for all VPLS instances on a router. To enable VPLS CPU protection on all VPLS instances, enter the following command.

```
NetIron(config)# router mpls
NetIron(config-mpls) vpls-cpu-protection
```

Syntax: [no] vpls-cpu-protection

Configuring VPLS CPU protection per VPLS

VPLS CPU protection can be enabled per VPLS instance. To enable VPLS CPU protection on a specified VPLS instance, enter the following command.

```
NetIron(config)# router mpls
NetIron(config-mpls) vpls test 1
NetIron(config-mpls-vpls-test)# cpu-protection
```

Syntax: [no] cpu-protection

VPLS Broadcast, multicast, and unknown unicast packet limiting

This feature limits the number of broadcast, multicast, and unknown unicast packet packets that are flooded into the network. You can limit the number of broadcast, multicast, and unknown unicast packet that are flooded by the LP CPU on all VPLS instances.

You can limit the number of packets that are flooded by the LP CPU on VPLS instances using the following command.

```
NetIron(config)# router mpls
NetIron(config-mpls) vpls-policy
    cpu-broadcast-limit 100000
    cpu-multicast-limit 200000
    cpu-unknown-unicast-limit 300000
```

Syntax: [no] vpls-policy | [no] cpu-broadcast-limit <*number*> |[no] cpu-multicast-limit <*number*>| [no]cpu-unknown-unicast-limit <*number*>]

The <*number*> variable refers to the packet limits for broadcast, multicast, and unknown unicast packets.

CPU packet limiting

The CPU limiting feature affects the packets being flooded into VPLS endpoints as well as remote peers. The CPU packet limiting is as follows:

- When VPLS policy parameters are configured in the MP, the LP CPU acts on those configuration parameters and limits the number of packets of a specific type up to the configured limit.
- Once the number of packets for a given type exceeds the limit, the LP CPU drops the packets before flooding into the VPLS instance.
- When a packet is dropped, the drop-reason-code is incremented accordingly.
- Counters are reset and start counting the packets again after one second.
- Known unicast packets forwarded by the LP CPU will not be counted as drops as those packets will be sent directly to the next hop and not flooded. This can happen in CAM full scenarios.

Interaction with VPLS CPU protection

The interaction with VPLS CPU protection is as follows:

- When the VPLS CPU protection feature is enabled, multicast and broadcast packets are normally forwarded in hardware using a flooding entry after Source MAC Address (SA) learning. Most of the unicast packets will be forwarded in hardware as well, and packets will be sent to the CPU for flooding in a rate-limiting fashion depending upon CPU utilization.
- When VPLS CPU protection is configured along with the packet-limiting feature, the packets with CPU protection will be subjected to CPU limiting. In other words, the packets coming to the CPU for VPLS with CPU protection may be dropped with the CPU limiting feature enabled.

Multicast traffic processing

The multicast traffic processing is as follows:

- If a multicast packet limit is configured, multicast data packets will not be differentiated from multicast protocol packets.
- All the packets will be subjected to packet limitations and may be dropped if they exceed per-second multicast packet limits.
- Multicast snooping packets and IEEE 802.1ag packets may be affected as well.

Layer 2 control traffic behavior on VPLS endpoints

This section describes the layer 2 control traffic behavior on VPLS endpoints.

802.1x Protocol packets on a VPLS endpoint

802.1x does not support VPLS endpoints.

Cisco Discovery Protocol packets

Cisco Discovery Protocol (CDP) cannot be configured on a VPLS endpoint port and a VPLS endpoint cannot be configured on a physical port that has CDP enabled. This restriction is enforced by the CLI. If a VPLS endpoint receives any CDP traffic, this traffic will be transparently flooded within the VPLS.

The behavior of CDP control packets is as follows:

- If CDP is globally enabled on the device, and the **priority force** command is configured on an incoming port, the VPLS local switched packets will be sent out with a priority of 7.
- If CDP is not enabled on the device, packets are switched locally according to the priority in the configured **qos exp encode** command or **qos pcp encode-policy** command.

Foundry Discovery Protocol packets

Foundry Discovery Protocol (FDP) cannot be configured on a VPLS endpoint port and a VPLS endpoint cannot be configured on a physical port that has FDP enabled. This restriction is enforced by the CLI. If a VPLS endpoint receives any FDP traffic, this traffic will be transparently flooded within the VPLS.

The behavior of FDP control packets is as follows:

- If FDP is globally enabled on the device and **priority force** command is configured on an incoming port, the VPLS local switched packets will be sent out with a priority of 7.
- If FDP is not enabled on the device, packets are switched locally according to the priority in the configured **qos exp encode** command or **qos pcp encode-policy** command.

Uni-directional Link Detection packets

Uni-directional Link Detection (UDLD) cannot be configured on a VPLS endpoint port and a VPLS endpoint cannot be configured on a physical port that has UDLD enabled. This restriction is enforced by the CLI. If a VPLS endpoint receives any UDLD traffic, this traffic will be dropped by the router at ingress. However, if the VPLS has CPU protection enabled, this traffic will be hardware-flooded intermittently.

Flooding Layer 2 BPDUs with a VPLS instance

By default, Layer 2 Spanning Tree Protocol (STP) and Per VLAN Spanning Tree (PVST) BPDUs entering a VPLS endpoint are not transparently flooded within the VPLS instance. The BPDUs are dropped when they enter the VPLS endpoint. The user can change this default behavior to not block BPDUs and transparently flood them within the VPLS instance, by configuration on a per-physical-port basis.

To flood BPDUs with a VPLS, use the following command.

```
NetIron(config)# interface ethernet 1/1
NetIron(config-if-e10000-1/1)#no vpls-bpdu-block
```

Syntax: [no] vpls-bpdu-block

Specifying a VPLS MTU

The **vpls-mtu** command allows you to specify an MTU value per VPLS instance. The newly configured VPLS MTU takes effect immediately to refresh or re-establish the VPLS sessions with peers in the following manner:

- If the VPLS session is Operational and the VPLS's MTU is changed by configuration, bring down the peer, we send a label withdraw message to the peer, followed by the current VC binding message.
- If the VPLS session is not Operational and the VPLS's MTU is changed by configuration and the current state of the peer is VC-Parameter-MTU-Mismatch, the peer is brought UP if the MTU is equal, and a VC withdraw message is sent to clean up the old binding on the peer, and then a VC binding message is sent with the newly configured MTU. If the current state of the peer is anything other than VC-Parameter-MTU-Mismatch, the VPLS's configured MTU is changed.
- When a VC binding is received from a peer and VPLS MTU enforcement is enabled, the received MTU is compared with the VPLS's MTU. if they are not equal, the peer is kept in the VC-Parameter-MTU-Mismatch state, and otherwise made Operational. If the MTU enforcement is disabled, the peer's MTU is saved and the peer is made Operational irrespective of the MTU values.

To configure a new MTU value for a VPLS instance, use the **vpls-mtu** command as shown in the following example.

```
NetIron(config-mpls)# vpls dell 40000
NetIron(config-mpls-vpls-dell)# vpls-mtu 1000
```

Syntax: [no] vpls-mtu <*mtu-value*>

The <*mtu-value*> variable can be set to any value between 64 through 9190.

If you use the **no** parameter to remove the configured MTU value for a VPLS instance, that instance's MTU becomes one of two possible values:

- If a global default MTU has been configured, then the MTU for this VPLS instance becomes that global maximum frame size minus 26.
- If no global default exists, the MTU is 1500.

For example, if you remove the MTU value for the VPLS named Dell, and the global default maximum frame size is 5000, then the MTU for VPLS Dell becomes 4974 (5000 – 26 = 4974).

NOTE
This MTU parameter is not enforced on the data plane (hardware). Consequently, packets larger than the configured MTU can still be sent or received.

Configuring VPLS MTU enforcement

You can set the device to enforce the VPLS MTU value when establishing control sessions with peers. This is done globally on the router using the **vpls-mtu-enforcement** command.

```
NetIron(config)# router mpls
NetIron(config-mpls)# vpls-mtu-enforcement
```

Syntax: [no] vpls-mtu-enforcement

NOTE
The **vpls-mtu-enforcement** command is global to all VPLS instances. It requires a reload to take effect.

Configuring VPLS local switching

VPLS local switching is enabled by default, so packets received on a VPLS endpoint are flooded or forwarded to other VPLS endpoints belonging to the VPLS instance. This mode of operation does not require any configuration.

Using the **no vpls-local-switching** command, you can disable VPLS local switching. With VPLS local switching disabled, packets will only be flooded to the VPLS peers in a VPLS instance and not to the other VPLS endpoints belonging to that instance. Also, unicast traffic will be discarded if it is received on a VPLS endpoint and is meant to go out on another VPLS endpoint.

You can disable VPLS local switching behavior on a per-VPLS basis using the **no vpls-local-switching** command.

```
NetIron(config)# router mpls
NetIron(config-mpls)# vpls test 100
NetIron(config-mpls-vpls-test)# no vpls-local-switching
```

Syntax: [no] vpls-local-switching

Once the **no vpls-local-switching** command has been used to disable VPLS local switching, you can use the command without the **no** option to turn VPLS local switching on.

Special considerations

When using the VPLS local switching feature, consider the following:

- When you toggle this option, all the MAC addresses that were learned on the VPLS endpoints are flushed and re-learned.
- This option does not affect IGMP/PIM snooping. Multicast traffic continues forwarding only to those VPLS endpoints and peers from which a Join for the (S,G) is requested, regardless of the status of the local switching option.
- IEEE 802.1ag packets will follow the local switching option. In other words, packets are forwarded or flooded to other VPLS endpoints if local switching is enabled and discarded if local switching is disabled.

Enabling MPLS VPLS traps

You can enable traps that will be generated for MPLS VPLS by entering the following command.

```
NetIron(config)# snmp-server enable trap mpls vpls
```

Syntax: [no] snmp-server enable trap mpls vpls

Refer to the *IronWare MIB Reference* for MPLS VPLS trap notifications.

Disabling Syslog messages for MPLS VPLS

The generation of Syslog messages for MPLS VPLS and MPLS VLL Local is enabled by default. If you want to disable the logging of these events, enter the following command.

```
NetIron(config)# no logging enable mpls
```

Syntax: [no] logging enable mpls

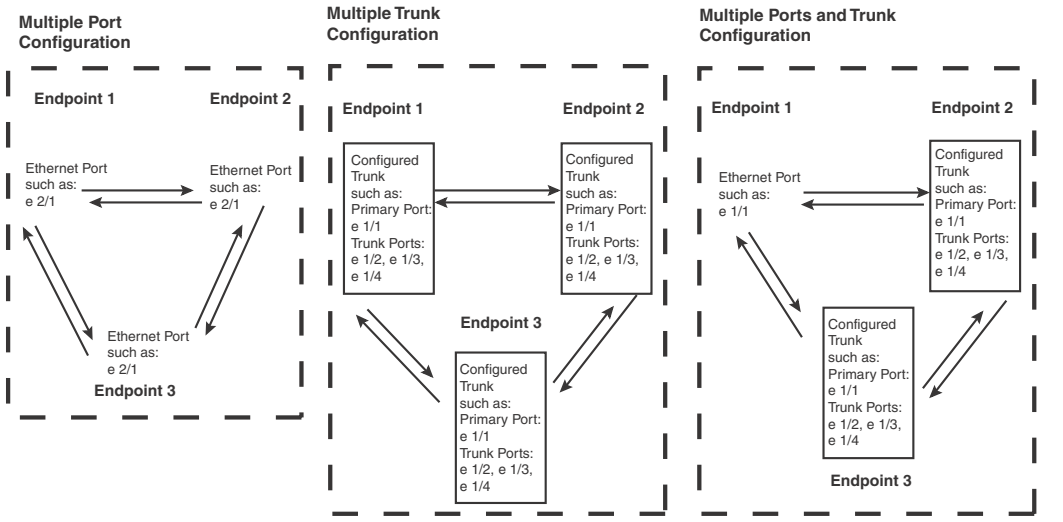
Refer to Table 454 on page 2299 for a list of Syslog messages for MPLS.

Local VPLS

Local VPLS is used to create a VPLS circuit with endpoints in the same device. A Local VPLS can be configured between two or more ports in a router, two or more LAGs in a router, or between a port and a LAG as shown in Figure 199. Each entity (port or LAG) is identified as “Endpoint 1”, Endpoint 2” or “Endpoint 3”.

NOTE
Trunks supported include server LAGs and per-packet server LAGs. Link Aggregation Control Protocol (LACP) LAGs are not supported.

FIGURE 199 Local VPLS port and LAG configurations



Note: In this configuration, any endpoint can configured as either a trunk or a single port.

NOTE
When configuring a LAG as an endpoint, only the primary port of the LAG is specified in the Local VPLS configuration.

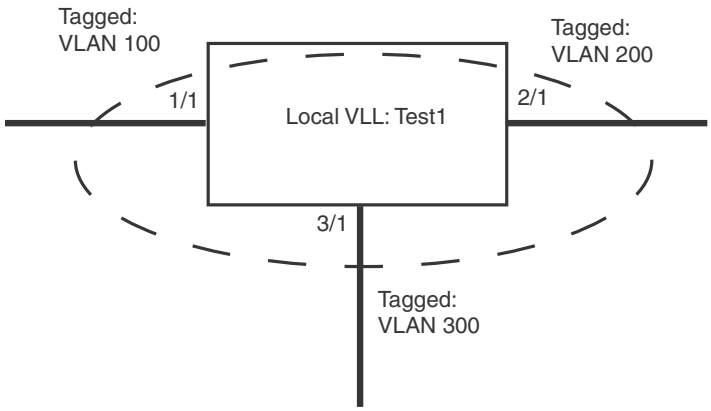
NOTE
Packets that arrive on an interface with the same destination MAC address as the interface are forwarded in hardware just like packets with other destination addresses.

The endpoints connected to the Local VPLS can be untagged, dual tagged, or single-tagged as members of the same or different VLANs. Using this function of Local VPLS, a router can receive packets with particular tags or no tag on one endpoint and forward them to the Local VPLS's other endpoint, which may be untagged, dual-tagged, or single-tagged with a different VLAN tag. When so configured, the tags within the packets are changed to reflect the configuration of the egress port as they leave the router.

Example Local VPLS configuration

In Figure 200 the Local VPLS named "Test1" contains Ethernet ports 1/1, 2/1, and 3/1. Port 1/1 is a member of VLAN 100, port 2/1 is a member of VLAN 200, and port 3/1 is a member of VLAN 300. Because all of the ports belong to Local VPLS "Test1", traffic tagged with any of the configured tags (100, 200, or 300) can reach traffic within any of the three VLANs. For example, traffic that ingresses on port 1/1 must have a tag with the value "100" and will egress on port 2/1 with a tag value of "200" or egress on port 3/1 with a tag value of "300".

FIGURE 200 Local VPLS "Test1" with three tagged VLANs



```
NetIron(config)# router mpls
NetIron(config-mpls)# vpls-test1 5000
NetIron(config-mpls-vpls-test1)# vlan 100
NetIron(config-mpls-vpls-test1-vlan-100)# tagged ethernet 1/1
NetIron(config-mpls-vpls-test1-vlan-100)# vlan 200
NetIron(config-mpls-vpls-test1-vlan-200)# tagged ethernet 2/1
NetIron(config-mpls-vpls-test1-vlan-200)# vlan 300
NetIron(config-mpls-vpls-test1-vlan-300)# tagged ethernet 3/1
```

CoS behavior for Local VPLS

NOTE
This section assumes that you understand how QoS works. For details, see "Configuring Quality of Service for the NetIron MLX" on page 283.

Table 254 describes the expected Class of Service (CoS) behavior for VPLS packets when Local VPLS is in effect.

TABLE 254 Expected class of service behavior for Local VPLS

Local VPLS endpoints	Incoming packet		Outgoing packet	
	Outer VLAN	Inner VLAN	Outer VLAN	Inner VLAN
Dual-tagged to dual-tagged	X	Y	X' or X	Y
Single-tagged to dual-tagged	X	N/A	X' or X	X
Untagged to dual-tagged	N/A	N/A	X' or 0	0
Dual-tagged to single-tagged	X	Y	X' or Y	N/A

Legend for Table 254

X = Original outer VLAN CoS.

Y = Original inner VLAN CoS.

X= Mapped CoS from internal priority (X contributes to internal priority) using CoS encode table.

Specifying Local VPLS endpoints

Local VPLS can be configured between any combination of dual-tagged, single-tagged, and untagged endpoints.

The following procedures describe how to configure VPLS endpoints:

- "Configuring an untagged endpoint"
- "Configuring a single-tagged endpoint"
- "Configuring a dual-tagged endpoint"

Configuring an untagged endpoint

To configure untagged port 1/1 into Local VPLS instance "test1", use the following commands.

```
NetIron(config)# router mpls
NetIron(config-mpls)# vpls test1 5000
NetIron(config-mpls-vpls-test1)# untagged ethernet 1/1
```

Syntax: [no] untagged ethernet <*slot/port*> <*vpls-id*>

The <*vpls-id*> variable variable is the ID of a VPLS instance.

Configuring a single-tagged endpoint

Tagged ports are configured under a VLAN ID. This VLAN ID is only meaningful for the tagged port.

For tagged ports, a <*vlan-id, port*> variable pair constitutes a VPLS endpoint. If a port is currently a member of a non-default VLAN as an untagged port, it must be returned to the default VLAN before it can be assigned to a VPLS as a tagged port.

To configure a tagged port 1/2 with VLAN 200 into Local VPLS instance "test1", use the following commands.

```
NetIron(config)# router mpls
NetIron(config-mpls)# vpls test1
NetIron(config-mpls-vpls-test1)# vlan 200
NetIron(config-mpls-vpls-test1-vlan-200)# tagged ethernet 1/2
```

Syntax: vlan <*VLAN-ID*>

The range for <*VLAN ID*> from 1 through 4094. (This parameter range excludes the default VLAN ID.)

Syntax: [no] tagged ethernet <*slot/port*>

The <*slot/port*> variable specifies the port that is a tagged ethernet port.

Configuring a dual-tagged endpoint

A dual-tagged endpoint enables packets to have both an outer VLAN tag and an inner VLAN tag. In this configuration, an endpoint can receive packets with two tags and forward them to the other endpoint either untagged, single-tagged, or dual-tagged.

NOTE
Dual-tagged endpoints for Local VPLS follow the same configuration rules as do endpoints of a VPLS instance. Before configuring a dual-tagged endpoint, see "Special considerations for dual-tagged endpoints" on page 1506.

To configure a dual-tagged endpoint for Local VPLS, use the following commands.

```
NetIron(config)# router mpls
NetIron(config-mpls)# vpls test1
NetIron(config-mpls-vpls-test1)# vlan 200 inner-vlan 300
NetIron(config-mpls-vpls-test1-vlan-200)# tagged ethernet 1/2
```

Syntax: [no] vlan <*VLAN-ID*> **inner-vlan** <*VLAN-ID*>

Syntax: [no] tagged ethernet <*slot/port*>

The **vlan** <*VLAN-ID*> variable, which is the outer VLAN ID, can be in the range from 1 through 4094 and excludes the default VLAN ID.

The **inner-vlan** <*VLAN-ID*> variable can be in the range from 1 through 4095 and includes the default VLAN ID.

Use the **no** form of the command to remove the dual-tagged VPLS VLAN configuration and its associated endpoints. For example, the command **no vlan 200 inner-vlan 300** will remove the dual-tagged VLAN and associated endpoints. The single-tagged VLAN, **vlan 200**, will not be deleted. Similarly, the command **no vlan 200** will remove the single-tagged VLAN, **vlan 200**, and associated endpoints. The dual-tagged VLAN, **vlan 200 inner-vlan 300,** will not be deleted.

Displaying VPLS information

You can display the following information about the VPLS configuration on the device:

- VPLS summary information
- Information about individual VPLS instances configured on the device
- Detailed information about VPLS instances
- Information about a specified VPLS ID or VPLS name
- Information about VPLS instances that are not fully operational
- The contents of the VPLS MAC database for a VPLS instance
- The VPLS MAC database entries on the Managment Processor (MP)
- VPLS traffic statistics
- VPLS CPU protection configuration status

Display considerations for VPLS information

The VPLS information that is displayed in the output of the **show mpls vpls** commands has changed. Previously, when a VPLS was created, a range of VC labels was allocated to the VPLS instance. Now, there is no pre-allocation of VC label ranges to a VPLS instance.

NOTE
This change is supported on PowerConnect B-MLXe devices.

The range of the allocated VC labels is no longer displayed in the output of the following **show mpls vpls** commands. Refer to the subsequent sections for more information on changes to the **show mpls vpls** command outputs:

- **show mpls vpls brief** - "Displaying information about VPLS instances" on page 1523
- **show mpls vpls detail** - "Displaying detailed information about VPLS instances" on page 1524
- **show mpls vpls down** - "Displaying information about VPLS instances that are not operational" on page 1531
- **show mpls vpls id** - "Displaying information about a specified VPLS ID or VPLS name" on page 1528
- **show mpls vpls summary** - "Displaying VPLS summary information" on page 1523

Displaying VPLS summary information

The **show mpls vpls summary** command has changed. The VC label allocation range size field is no longer displayed in the output of the **show mpls vpls summary** command.

You can display a summary of VPLS information, including the number of VPLS instances, number of VPLS peers, maximum size of the VPLS MAC database, VPLS raw mode, and the values of the VPLS global MTU, and the value of the remote VC MTU.

```
NetIron# show mpls vpls summary
Virtual Private LAN Service summary:
Total VPLS configured: 3, maximum number of VPLS allowed: 4096
Total VPLS peers configured: 1, total peers operational: 1
Maximum VPLS macentries allowed: 8192, currently installed: 3
VPLS global raw mode VC-Type is Ethernet (0x5)
VPLS global MTU is 1500, MTU enforcement is OFF
Global CPU protection: OFF
MVIDs in use: 1 of 1 total allocated
```

Syntax: show mpls vpls summary

Displaying information about VPLS instances

The **show mpls vpls brief** command has changed. The Num VC-label field is no longer displayed in the output of the **show mpls vpls brief** command.

To display information about VPLS instances configured on the device, enter the following command.

```
NetIron#show mpls vpls brief

                        Num   Num     Ports   Num    Peers          CPU  VC
Name          Id        Vlans Ports   Up      Peers  Up     IFL-ID  Prot Mode
====          ==        ===== =====   =====   =====  =====  ======  ==== ======
1             1         2     2       2       1      1      4096    OFF  TAGGED
2             2         1     0       0       1      0       n/a    OFF  RAW
3             3         2     6       4       2      1       n/a    OFF  RAW
```

Syntax: show mpls vpls brief

Table 255 lists the output displayed by the **show mpls vpls brief** command.

TABLE 255 Output from the **show mpls vpls brief** command

Field	Description
Name	The configured name of the VPLS instance.
Id	The ID of this VPLS instance.
Num Vlans	The total number of single-tagged and dual-tagged VLANs associated with this VPLS instance.
Num Ports	The number of ports in this VPLS instance.
Ports Up	The number of ports in this VPLS instance that are up.
Num Peers	The number of VPLS peers this device has for this VPLS instance.
Peers Up	The number of VPLS peers with which a VC connection is completely operational.
IFL-ID	The Internal Forwarding Lookup Identifier (IFL-ID) for dual-tagged VLAN ports in this VPLS instance.
CPU Prot	Whether CPU protection configured on this VPLS instance is ON or OFF.
VC Mode	The VC mode for the VPLS instance: • Raw – The VLAN tag information in the original payload is not carried across the MPLS cloud. • Tagged – The VLAN tag information in the original payload is carried across the MPLS cloud.

Displaying detailed information about VPLS instances

The **show mpls vpls detail** command has changed. The total VC labels allocated field is no longer displayed in the output of the **show mpls vpls detail** command.

To display more detailed information about each VPLS instance, enter the following command.

```
NetIron#show mpls vpls detail
VPLS 3, Id 3, Max mac entries: 8192
 Total vlans: 2, Tagged ports: 2 (1 Up), Untagged ports 0 (0 Up)
 IFL-ID: n/a
  Vlan 500
   Tagged: ethe 1/3
  Vlan 600
   Tagged: ethe 1/4
 VC-Mode: Raw
 Total VPLS peers: 1 (1 Operational)
 Peer address: 21.21.21.21, State: Operational, Uptime: 1 min
  Tnnl in use: tnl0(3)
  LDP session: Up, Local VC lbl: 983040, Remote VC lbl: 983040
  Local VC MTU: 1500, Remote VC MTU: 9174
  Local VC-Type: Ethernet(0x05), Remote VC-Type: Ethernet(0x05)
 CPU-Protection: OFF [Resource FID Failure, Retry in 18 seconds (approximate)]
 Local Switching: Enabled
 Mutlicast Snooping: Disabled
```

Syntax: show mpls vpls detail

Table 256 lists the output displayed by the **show mpls vpls detail** command.

TABLE 256 Output from the **show mpls vpls detail** command

Field	Description
VPLS	The configured name of the VPLS instance.
Id	The ID of this VPLS instance.
Max mac entries	The maximum number of MAC address entries that can be learned for this VPLS instance. This is a soft limit only and can be exceeded if there is space available in the VPLS MAC database.
Total vlans	The number of VLANs that are translated for this VPLS instance.
Tagged ports	The total number of tagged ports that are associated with VLANs in this VPLS instance, as well as the number of these ports that are up.
Untagged ports	The total number of untagged ports that are associated with VLANs in this VPLS instance, as well as the number of these ports that are up.
IFL-ID	The Internal Forwarding Lookup Identifier (IFL-ID) for dual-tagged ports in the VPLS instance.
Vlan	The ID of each VLAN in this VPLS instance.
Tagged	The numbers of the tagged ports in each VLAN.
Untagged	The numbers of the untagged ports in each VLAN.
VC-Mode	The VC mode for the VPLS instance: • Raw – The VLAN tag information in the original payload is not carried across the MPLS cloud. • Tagged – The VLAN tag information in the original payload is carried across the MPLS cloud.
Total VPLS peers	The number of VPLS peers this device has for this VPLS instance, as well as the number of these VPLS peers with which this device has an LDP session.
Peer address	The IP address of the VPLS peer.

TABLE 256 Output from the **show mpls vpls detail** command (Continued)

Field	Description
State	The current state of the connection with the VPLS peer. This can be one of the following states: • Operational – The VPLS instance is operational. Packets can flow between the device and the peer. • Wait for functional local ports – The physical endpoint port that should be connected to the Customer Edge device is down due to a link outage or is administratively disabled. • Wait for LSP tunnel to Peer – The device cannot find a working tunnel LSP. • Wait for PW Up (Wait for LDP session to Peer)– The LDP session is not yet ready. • Wait for PW Up (Wait for remote VC label) - The device has advertised its VC label binding to the VPLS peer, but has not yet received the peer's VC label binding. • Wait for PW Up (VC type mismatched) – A session is not formed because the VC type does not match with its peer's VC type. • Wait for PW Up (MTU mismatched) – The MTU sent to a peer is derived from the router's global setting by the following formula: (*system-mtu* minus 26 bytes). If a *system-mtu* value is not configured, a default value of 1500 is sent. • Wait for PW Up (Wait for LPD session to Peer) - The LDP session to the peer is down. • Wait for PW Up (No Label Resource) - When configuring a new VPLS peer, the maximum amount of VC labels that can be supported may exceed 64K, and cause the configuration to be rejected. The maximum amount of VC labels available for VPLS instances is equal to 64K.
Uptime	The time in minutes that the entry has been operational.
Tnnl in use	The tunnel LSP used to reach the VPLS peer. If VPLS traffic to the peer is load balanced across multiple tunnel LSPs, the tunnel LSPs used to reach the peer are displayed.
LDP session	The state of the LDP session between this device and the VPLS peer.
Local VC lbl	The VC label value locally allocated for this peer for this VPLS instance. Packets forwarded from the VPLS peer to this device are expected to contain this label. This is the label that is advertised to the VPLS peer through LDP.
Remote VC lbl	The VC label allocated by the VPLS peer and advertised to this device through LDP. The device applies this label to outbound MPLS packets sent to the VPLS peer.
Local VC MTU	The MTU value locally configured for this peer.
Remote VC MTU	The MTU value configured for the remote VPLS peer.
Local VC-Type	The VC type for this peer.
Remote VC-Type	The VC type for the remote VPLS peer.
CPU-Protection	Whether CPU protection configured on this VPLS instance is ON or OFF.
Local Switching	Whether local switching behavior on a per-VPLS basis is enabled or disabled.

The Wait for LDP session to Peer state is no longer displayed in the output of the **show mpls vpls detail** command. The Wait for Pseudo Wire (PW) Up (Wait for LDP session to Peer) state is now displayed, and replaces the existing state. The total VC labels allocated field is also removed from the output. In the following example, the LDP session to the remote peer is down. The Local VC lbl field will displays N/A (not applicable).

```
NetIron#show mpls vpls detail
VPLS NO_LDP, Id 500, Max mac entries: 8192
 Total vlans: 1, Tagged ports: 1 (1 Up), Untagged ports 0 (0 Up)
  IFL-ID: 4101
  Vlan 880 inner-vlan 35
   Tagged: ethe 8/2
 VC-Mode: Tagged
 Total VPLS peers: 1 (0 Operational)
Peer address: 66.66.66.66, State: Wait for PW Up (Wait for LDP session to Peer)
  Tnnl in use: tnl5(6)
  LDP session: Down, Local VC lbl: N/A, Remote VC lbl: N/A
  Local VC MTU: 1500, Remote VC MTU: 0,
  LOCAL VC-Type: Ethernet Tagged (0x04), Remote VC-Type: UNKNOWN
 CPU-Protection: OFF
 Local Switching: Enabled
```

The maximum number of VC labels available for VPLS instances is equal to 64K. When configuring a new VPLS peer, the total number of VPLS peers will exceed 64K, and will cause the configuration to be rejected. The following error message is displayed on the console.

```
NetIron(config-mpls-vpls-1)#vpls-peer 23.23.23.23
Error - Unable to create vpls peer 23.23.23.23 for VPLS 1 due to no VC label
resource.
```

The Wait for PW Up (No label Resource) state is introduced in the output of the **show mpls vpls detail** command. In the following example, the Wait for PW Up (No label Resource) state is highlighted.

```
NetIron#show mpls vpls detail
VPLS waiting_for_remote_label, Id 400, Max mac entries: 8192
 Total vlans: 1, Tagged ports: 1 (1 Up), Untagged ports 0 (0 Up)
  IFL-ID: 4100
  Vlan 900 inner-vlan 245
   Tagged: ethe 7/1
 VC-Mode: Tagged
 Total VPLS peers: 1 (0 Operational)
 Peer address: 55.55.55.55, State: Wait for PW Up (No Label Resource)
  Tnnl in use: tnl4(5)
  LDP session: Up, Local VC lbl: N/A, Remote VC lbl: N/A
  Local VC MTU: 1500, Remote VC MTU: 0,
  LOCAL VC-Type: Ethernet Tagged (0x04), Remote VC-Type: UNKNOWN
 CPU-Protection: OFF
 Local Switching: Enabled
```

When the system runs out of memory, a warning message is displayed on the console. To recover from this state, the user is required to delete the failed peer and reconfigure it. VPLS generates the following warning messages.

```
WARNING: VPLS id 3 Peer IP Address: 21.21.21.21 is placed in VC Bind Failure state
due to low system memory.
```

```
WARNING: VPLS id 3 Peer IP Address: 11.11.11.11  is placed in VC Withdraw Failure
state due to low system memory.
```

Displaying information about a specified VPLS ID or VPLS name

The **show mpls vpls id** <*vpls-id*> command displays detailed information about a specified VPLS ID. The **show mpls vpls name** <*vpls-name*> command displays detailed information about a VPLS name. The output of the **show mpls vpls id** <*vpls-id*> command, and the output of the **show mpls vpls name** <*vpls-name*> command display the same information for a configured VPLS instance. The display changes that are described below are applicable to both the **show mpls vpls id** <*vpls-id*> command, and **show mpls vpls name** <*vpls-name*> command.

When the remote peer is in an operational state, the total VC labels allocated field is no longer displayed in the output of the **show mpls vpls id** <*vpls-id*> command, as shown in the following example.

```
NetIron#show mpls vpls id 3
VPLS name_raw, Id 3, Max mac entries: 8192
 Total vlans: 1, Tagged ports: 3 (3 Up), Untagged ports 0 (0 Up)
  IFL-ID: 4097
  Vlan 300 inner-vlan 500
   Tagged: ethe 3/1 ethe 3/11 ethe 3/13
 VC-Mode: Raw
 Total VPLS peers: 1 (1 Operational)
 Peer address: 200.200.200.200, State: Operational, Uptime: 1 hr 10 min
  Tnnl in use: tnl1(4)
  LDP session: Up, Local VC lbl: 983072, Remote VC lbl: 983072
  Local VC MTU: 1500, Remote VC MTU: 1500
  LOCAL VC-Type: Ethernet (0x05), Remote VC-Type: Ethernet (0x05)
 CPU-Protection: OFF
 Local Switching: Enabled
```

When a VC type mismatch occurs, the output from the **show mpls vpls id** <*vpls-id*>command will now display the Wait for PW Up (VC type mismatched) state. The Wait for VC parameter check (VC type mismatched) state is no longer displayed. The total VC labels allocated field is also removed from the output. In the following example, a VC type mismatch has occurred, and the PW is down. The local VC MTU and the remote VC MTU are not known by VPLS so there is no information to display. The Local VC lbl field, the Remote VC lbl field, and the Remote VC MTU field display N/A (non applicable).

```
NetIron#show mpls vpls id 200
VPLS vc_mismatched, Id 200, Max macentries: 8192
Total vlans: 1, Tagged ports: 1 (1 Up), Untagged ports 0 (0 Up)
IFL-ID: 4098
Vlan200 inner-vlan145
Tagged: ethe2/1
VC-Mode: Tagged
Total VPLS peers: 1 (0 Operational)
Peer address: 33.33.33.33, State: Wait for PW Up (VC type mismatched)
Tnnlin use: tnl0(2)
LDP session: Up, Local VC lbl: N/A, Remote VC lbl: N/A
Local VC MTU: 1500, Remote VC MTU: N/A
LOCAL VC-Type: Ethernet Tagged (0x04), Remote VC-Type: Ethernet (0x05)
```

When a MTU mismatch occurs, the output from the **show mpls vpls id** <*vpls-id*> command will now display the Wait for PW Up (MTU mismatched) state. The Wait for VC parameter check (MTU mismatched) state is no longer displayed. The total VC labels allocated field is also removed from the output. In the following example, a MTU mismatch has occurred, and the PW is down. The Local VC lbl field and the Remote VC lbl field display N/A (not applicable).

NOTE
When both the VC type and MTU are mismatched, only the output from the VC type mismatch is displayed on the console.

```
NetIron#show mpls vpls id 300
VPLS mtu_mismatched, Id 300, Max macentries: 8192
Total vlans: 1, Tagged ports: 1 (1 Up), Untagged ports 0 (0 Up)
IFL-ID: 4099
Vlan100 inner-vlan145
Tagged: ethe1/1
VC-Mode: Tagged
Total VPLS peers: 1 (0 Operational)
Peer address: 44.44.44.44, State: Wait for PW Up (MTU mismatched)
Tnnlin use: tnl3(3)
LDP session: Up, Local VC lbl: N/A, Remote VC lbl: N/A
Local VC MTU: 1500, Remote VC MTU: 2500,
LOCAL VC-Type: Ethernet Tagged (0x04), Ethernet Tagged (0x04)
```

The Wait for remote VC label from Peer state is no longer displayed in the output of the **show mpls vpls id** <*vpls-id*> command. The Wait for PW Up (Wait for remote VC label) state is now displayed, and replaces the existing state. The total VC labels allocated field is also removed from the output. In the following example, the PW is down and it is waiting for the VC label of the remote peer to be advertised to the VPLS peer. The Local VC lbl field and the Remote VC MTU field will display N/A (non applicable).

```
NetIron#show mpls vpls id 400
VPLS waiting_for_remote_label, Id 400, Max macentries: 8192
Total vlans: 1, Tagged ports: 1 (1 Up), Untagged ports 0 (0 Up)
IFL-ID: 4100
Vlan900 inner-vlan245
Tagged: ethe7/1
VC-Mode: Tagged
Total VPLS peers: 1 (0 Operational)
Peer address: 55.55.55.55, State: Wait for PW Up (Wait for remote VC label)
Tnnlin use: tnl4(5)
LDP session: Up, Local VC lbl: N/A, Remote VC lbl: N/A
Local VC MTU: 1500, Remote VC MTU: N/A,
LOCAL VC-Type: Ethernet Tagged (0x04), Remote VC-Type: UNKNOWN
```

The Wait for PW Up (VC Bind in Progress) state is introduced in the output of the **show mpls vpls id** <*vpls-id*> command. The total VC labels allocated field is removed from the output. In the following example, the PW is down, and local VC binding is still in progress. The Local VC lbl field and the Remote VC MTU field display N/A (non applicable).

```
NetIron#show mpls vpls id 400
VPLS waiting_for_remote_label, Id 400, Max macentries: 8192
Total vlans: 1, Tagged ports: 1 (1 Up), Untagged ports 0 (0 Up)
IFL-ID: 4100
Vlan900 inner-vlan245
Tagged: ethe7/1
VC-Mode: Tagged
Total VPLS peers: 1 (0 Operational)
Peer address: 55.55.55.55, State: Wait for PW Up (VC Bind in Progress)
Tnnlin use: tnl4(5)
LDP session: Up, Local VC lbl: N/A, Remote VC lbl: N/A
Local VC MTU: 1500, Remote VC MTU: N/A,
LOCAL VC-Type: Ethernet Tagged (0x04), Remote VC-Type: UNKNOWN
```

The **show mpls vpls id** <*vpls-id*> command displays the tunnel LSPs that are being used to forward VPLS traffic from the device to the peer. If VPLS traffic to a peer is being load balanced across multiple tunnel LSPs, then the command lists the tunnel LSPs used for load balancing, as shown in the example below.

```
NetIron# show mpls vpls id 5
VPLS test5, Id 5, Max mac entries: 2048
 Total vlans: 1, Tagged ports: 1 (1 Up), Untagged ports 0 (0 Up)
  Vlan 50
   Tagged: ethe 5/3
 VC-Mode: Raw
 Total VPLS peers: 1 (1 Operational)
 Peer address: 5.5.5.5, State: Operational, Uptime: 28 min
  Tnnl (load balance): tnl0(3) tnl2(3) tnl1(3)
  LDP session: Up, Local VC lbl: 983040, Remote VC lbl: 983040
```

Syntax: show mpls vpls id <*vpls-id*>

Syntax: show mpls vpls name <*vpls-name*>

The <*vpls-id*> variable is the ID of a VPLS instance. The <*vpls-name*> variable is the name of a VPLS instance.

Displaying VPLS CPU protection configuration status

The **show mpls vpls id** command has changed. The total VC labels allocated field is no longer displayed in the output of the **show mpls vpls id** command.

To see the VPLS CPU protection configuration status for a specified VPLS, use the **show mpls vpls id** command.

```
NetIron(config)# show mpls vpls id 1
VPLS test1, Id 1, Max mac entries: 2048
 Total vlans: 1, Tagged ports: 1 (0 Up), Untagged ports 1 (1 Up)
  Vlan 2
   Tagged: ethe 5/4
   Untagged: ethe 2/2
 Total VPLS peers: 1 (0 Operational)
 Peer address: 1.1.1.1, State: Wait for remote VC label from Peer
  Tnnl: tnl0(3), LDP session: Up, Local VC lbl: 983040, Remote VC lbl: N/A
 CPU-Protection: ON,  MVID: 0x000,  VPLS FID: 0x00000205
```

The CPU protection status is highlighted in the previous example. It can be either on or off. If CPU protection status is enabled on the VPLS but is temporarily off due to unavailable FID resources, the following message is shown in the CPU-Protection field:

```
CPU-Protection: OFF [Resource FID Failure, Retry in 18 seconds (approximate)]
```

Syntax: show mpls vpls id [<*vpls-id*>]

The <*vpls-id*> variable is the ID of a VPLS instance.

Displaying information about VPLS instances that are not operational

The **show mpls vpls down** command has changed. The Num VC-label field is no longer displayed in the output of the **show mpls vpls down** command.

To display information about VPLS instances that are not fully operational, enter the following command.

```
NetIron#show mpls vpls down
The following VPLS'es are not completely operational:
                      Num     Num     Ports   Num     Peers
Name          Id      Vlans   Ports   Up      Peers   Up
test1         1       1       1       1       1       0
test2         2       1       2       1       1       0
test3         3       1       1       1       1       0
test4         4       1       2       1       1       0
```

Syntax: show mpls vpls down

Displaying the contents of the VPLS MAC database

The VPLS MAC database stores entries associating remote MAC addresses with VC LSPs and local MAC addresses with CE devices. When a PE device receives a Layer 2 frame from an attached CE device with a given destination MAC address, the PE device looks up the MAC address in the VPLS MAC database and assigns the frame to the associated VC LSP. Each VPLS instance configured on the PE device has a separate VPLS MAC database.

Displaying VPLS MAC database entries on the Management Processor

To display the entire VPLS MAC database on the Management Processor (MP), enter the following command.

```
NetIron# show mac vpls
Total VPLS mac entries in the table: 10 (Local: 5, Remote: 5)

                              Vlan:Inner-Vlan
VPLS MAC Address    L/R Port      /Peer       Age
==== ===========    === ====  =========       ===
1    0016.0100.1601 R   5/1   3.3.3.3         0
1    0010.0100.1003 L   5/3   2               0
1    0016.0100.1603 R   5/1   3.3.3.3         0
1    0010.0100.1005 L   5/3   2               0
1    0010.0100.1002 L   5/3   2               0
1    0016.0100.1605 R   5/1   3.3.3.3         0
1    0016.0100.1602 R   5/1   3.3.3.3         0
1    0010.0100.1004 L   5/3   2               0
1    0010.0100.1001 L   5/3   2               0
1    0016.0100.1604 R   5/1   3.3.3.3         0
1    0000.0201.0201 L   5/4   100:200         0
```

If a given remote VPLS MAC address is learned on multiple uplink interfaces, the Port field in the output of the **show mac vpls** command indicates “Mult.” instead of a port number. For example, this abbreviation might appear when all of the following are true:

- The remote PE establishes multiple LSPs to this router.
- Packets from a remote VPLS MAC address are load balanced across these LSPs.
- The packets arrive on different MPLS uplink interfaces at this router.

```
NetIron#show mac vpls
Total VPLS mac entries in the table: 2274 (Local: 8, Remote: 2266)

                                 Vlan:Inner-Vlan
VPLS  MAC Address     L/R Port      /Peer       Age
====  ===========     === ====  =========       ===
3     0012.f29b.d419  L   4/2   3               0
504   0060.2d00.0067  R   Mult. 10.99.42.253    0
504   00c0.f033.b24c  R   Mult. 10.99.42.253    0
504   0080.ad73.6185  R   1/1   10.99.42.253    375
504   00e0.c900.40cf  R   Mult. 10.99.42.253    0
504   0015.7719.d7f4  R   Mult. 10.99.42.253    0
504   00c0.f044.d58b  R   Mult. 10.99.42.253    0
504   0010.5a5c.5a3b  R   Mult. 10.99.42.253    0
504   00c0.f044.d696  R   Mult. 10.99.42.253    0
```

To see details for all the ports on which a remote VPLS MAC address has been learned, use the **show mac mpls vpls** <*mac-address*> command.

To display the VPLS MAC database on the MP for a VPLS instance specified by its VPLS ID, enter the following command.

```
NetIron# show mac vpls 1
Total MAC entries for VPLS 1: 10 (Local: 5, Remote: 5)

                                Vlan:Inner-Vlan
VPLS MAC Address    L/R Port      /Peer       Age
==== ===========    === ====  =========       ===
1    0016.0100.1601 R   5/1   3.3.3.3         0
1    0010.0100.1003 L   5/3   2               0
1    0016.0100.1603 R   5/1   3.3.3.3         0
1    0010.0100.1005 L   5/3   2               0
1    0010.0100.1002 L   5/3   2               0
1    0016.0100.1605 R   5/1   3.3.3.3         0
1    0016.0100.1602 R   5/1   3.3.3.3         0
1    0010.0100.1004 L   5/3   2               0
1    0010.0100.1001 L   5/3   2               0
1    0016.0100.1604 R   5/1   3.3.3.3         0
1    0000.0201.0201 L   5/4   100:200         0
```

To display a specific entry in the VPLS MAC database on the MP, enter the following command.

```
NetIron# show mac vpls 1 0016.0100.1601
    VPLS: 1         MAC:  0016.0100.1601     Age:     0
    Remote MAC      Port: ethe 5/1           Peer:    3.3.3.3
Trunk slot mask: 00000000
```

Syntax: show mac vpls [<*vpls-id*> [<*mac-address*>]]

The <*vpls-id*> variable is the ID of a VPLS instance. If you specify the VPLS ID, you can also specify a particular entry in the VPLS MAC database by adding the optional <*mac-address*> variable.

Table 257 lists the output displayed by the **show mac vpls** command.

TABLE 257 Output from the **show mac vpls** command

Field	Description
Total VPLS mac entries in the table	The number of MAC addresses that have been learned in the database.
Local	The number of locally learned entries in the database.
Remote	The number of remotely learned entries in the database.
VPLS	The VC ID of the VPLS instance.
MAC Address	The MAC address of the entry.
L/R	Whether the entry was learned from local endpoints (L), or was learned from a remote VPLS peer (R).
Port	The port number for the entry.
Vlan:Inner-VLAN/Peer	For Local entries, the VLAN ID for the port; for dual-tagged VLANs, the outer VLAN ID followed by the inner VLAN ID; for Remote entries, the IP address of the VPLS peer.
Age	The age of the entry. The value on the MP is zero because the aging occurs on line card processors.

NOTE
The information displayed in the SA-CAM and DA-CAM index fields is not relevant for day-to-day management of the device. The information is used by engineering and technical support staff for debugging purposes.

Displaying VPLS traffic statistics

You can display VPLS traffic statistics, to view the forwarding counters for each VPLS configured on the system. The output shows a given port range that receives traffic, how many packets are sent out on local CE device endpoints, and how many are sent out of LSP tunnels to remote PE devices. If the port is a 10G port, a single port is displayed. If the module is a 40x1G module, a range of 10 1G ports is displayed.

NOTE
When CPU protection is on, flooded traffic received from an endpoint is not accounted by the VPLS statistics for endpoint-out packets even though they are locally switched.

To display all VPLS traffic statistics on a router, enter the following command.

```
NetIron# show mpls statistics vpls
VPLS-Name      In-Port(s)     Endpt-Out-Pkts    Tnl-Out-Pkts
---------      ----------     --------------    ------------
test2          e1/1           0                 0
               e1/2           0                 0
               e1/3           0                 0
               e1/4           0                 0
test2          e2/1 - e2/10   0                 0
               e2/11 - e2/20  0                 0
               e2/21 - e2/30  0                 0
               e2/31 - e2/40  0                 0
test3          e1/1           0                 0
               e1/2           0                 0
               e1/3           0                 0
               e1/4           0                 0
test3          e2/1 - e2/10   0                 0
               e2/11 - e2/20  0                 0
               e2/21 - e2/30  0                 0
               e2/31 - e2/40  0                 0
test4          e1/1           0                 0
               e1/2           0                 0
               e1/3           0                 0
               e1/4           0                 0
test4          e2/1 - e2/10   0                 0
               e2/11 - e2/20  0                 0
               e2/21 - e2/30  0                 0
               e2/31 - e2/40  0                 0
test4          e5/1           10354120822       0
               e5/2           0                 0
               e5/3           0                 2992416134
               e5/4           0                 0
```

NOTE
The VPLS name is repeated for each module from which the statistics are collected, to be displayed on the MP console.

To display VPLS traffic statistics for a VPLS instance specified by its VPLS name, enter the following command.

```
NetIron# show mpls statistics vpls test4
VPLS-Name      In-Port(s)     Endpt-Out-Pkts    Tnl-Out-Pkts
---------      ----------     --------------    ------------
test4          e1/1           0                 0
               e1/2           0                 0
               e1/3           0                 0
               e1/4           0                 0
test4          e2/1 - e2/10   0                 0
               e2/11 - e2/20  0                 0
               e2/21 - e2/30  0                 0
               e2/31 - e2/40  0                 0
test4          e5/1           10828448712       0
               e5/2           0                 0
               e5/3           0                 3025869251
               e5/4           0                 0
```

To display VPLS traffic statistics for a VPLS instance specified by its VPLS ID, enter the following command.

```
NetIron# show mpls statistics vpls 4
VPLS-Name      In-Port(s)     Endpt-Out-Pkts    Tnl-Out-Pkts
---------      ----------     --------------    ------------
test4          e1/1           0                 0
               e1/2           0                 0
               e1/3           0                 0
               e1/4           0                 0
test4          e2/1 - e2/10   0                 0
               e2/11 - e2/20  0                 0
               e2/21 - e2/30  0                 0
               e2/31 - e2/40  0                 0
test4          e5/1           10828448712       0
               e5/2           0                 0
               e5/3           0                 3025869251
               e5/4           0                 0
```

Syntax: show mpls statistics vpls [<*vpls-name*> | <*vpls-id*>]

The <*vpls-name*> variable is the configured name for a VPLS instance.

The <*vpls-id*> variable is the ID of a VPLS instance.

Table 258 lists the output displayed by the **show mpls statistics vpls** command.

TABLE 258 Output from the **show mpls statistics vpls** command

Field	Description
VPLS-Name	The configured name of the VPLS instance.
In-Port(s)	The port where the traffic is received.
Endpt-Out-Pkts	The number of packets transmitted out of local endpoints.
Tnl-Out-Pkts	The number of packets transmitted out of LSP tunnels.

Clearing VPLS traffic statistics

To clear the entries stored for all VPLS statistics, enter the following command.

```
NetIron# clear mpls statistics vpls
```

Syntax: clear mpls statistics vpls [<*vpls-name*> | <*vpls-id*>]

The <*vpls-name*> variable is the configured name for a VPLS instance.

The <*vpls-id*> variable is the ID of a VPLS instance.

The support enables simplified interactions between MPLS and VPLS with regard to VPLS peer FSM transitions. The LDP integration is supported on all platforms.

VPLS LDP

Displaying the VPLS peer FSM state with LDP support

You can display the various VPLS peer FSM states with the LDP integration on the device using the **show mpls vpls** commands.

Table 259 provides a description of all the peer FSM states with the LDP support.

TABLE 259 PEER FSM state description

Peer FSM state name	state description
Wait for functional local ports	No functional local endpoints.
Wait for LSP tunnel to Peer	No LSP tunnels available to reach the remote peer.
Wait for PW UP (Wait for LDP Session)	LDP session to remote peer is down.
Wait for PW UP (Wait for remote VC label)	PW is down (waiting for remote peer's VC label.)
Wait for PW UP (VC type Mismatched)	PW is down (VC type mismatched).
Wait for PW UP (MTU Mismatched)	PW is down (MTU mismatched).
Wait for PW UP (VC Bind In Progress)	PW is down (Local VC binding in progress).
Operational	PW is up and operational.
Wait Withdraw Done ...	Waiting for VC withdraw completion (internal intermediate states).
VC BIND Failure State	VC binding failed. User intervention required.
VC Withdraw Failure State	VC withdraw failed. User intervention required.

User intervention is required to recover from the VC Bind Failure state, and the VC Withdraw Failure state. To recover, you must delete the failed peer and then add it back. These failure states may occur during extreme conditions when the system runs out of memory to issue ITC requests. When these failures are detected, VPLS generates the following syslog messages accordingly.

```
WARN: VPLS id X Peer IP Address: aa.bb.cc is placed in VC Bind Failure state due
to low system memory.
WARN: VPLS id Y Peer IP Address: dd.ee.ff  is placed in VC Withdraw Failure state
due to low system memory.
```

VC type mismatched

The following example shows the output for the LDP integration for a VC type mismatched case.

```
NetIron# show mpls vpls id 200
VPLS vc_mismatched, Id 200, Max mac entries: 8192
 Total vlans: 1, Tagged ports: 1 (1 Up), Untagged ports 0 (0 Up)
  IFL-ID: 4098
  Vlan 200 inner-vlan 145
   Tagged: ethe 2/1
 VC-Mode: Tagged
 Total VPLS peers: 1 (0 Operational)
 Peer address: 33.33.33.33, State: Wait for PW Up (VC type mismatched)
  Tnnl in use: tnl0(2)
  LDP session: Up, Local VC lbl: N/A, Remote VC lbl: N/A
  Local VC MTU: 1500, Remote VC MTU: N/A
  LOCAL VC-Type: Ethernet Tagged (0x04), Remote VC-Type: Ethernet (0x05)
 CPU-Protection: OFF
 Local Switching: Enabled
```

The local VC label and remote VC label display will be performed only if the Peer is in Operational state. Else, it will display N/A for these fields.

The remote VC Type will be the same as the local VC type if the peer state is Operational, else, it will be shown as N/A.

MTU mismatched

The following example shows the output for the LDP integration for a MTU mismatched case.

```
NetIron# show mpls vpls id 300
VPLS mtu_mismatched, Id 300, Max mac entries: 8192
 Total vlans: 1, Tagged ports: 1 (1 Up), Untagged ports 0 (0 Up)
  IFL-ID: 4099
  Vlan 100 inner-vlan 145
   Tagged: ethe 1/1
 VC-Mode: Tagged
 Total VPLS peers: 1 (0 Operational)
 Peer address: 44.44.44.44, State: Wait for PW Up (MTU mismatched)
  Tnnl in use: tnl3(3)
  LDP session: Up, Local VC lbl: N/A, Remote VC lbl: N/A
  Local VC MTU: 1500, Remote VC MTU: 2500,
  LOCAL VC-Type: Ethernet Tagged (0x04), Ethernet Tagged (0x04)
 CPU-Protection: OFF
Local Switching: Enabled
```

No remote VC label

The following example shows the output for the LDP integration for a no remote VC label case.

```
NetIron# show mpls vpls id 400
VPLS waiting_for_remote_label, Id 400, Max mac entries: 8192
 Total vlans: 1, Tagged ports: 1 (1 Up), Untagged ports 0 (0 Up)
  IFL-ID: 4100
  Vlan 900 inner-vlan 245
   Tagged: ethe 7/1
 VC-Mode: Tagged
 Total VPLS peers: 1 (0 Operational)
 Peer address: 55.55.55.55, State: Wait for PW Up (Wait for remote VC label)
  Tnnl in use: tnl4(5)
  LDP session: Up, Local VC lbl: N/A, Remote VC lbl: N/A
  Local VC MTU: 1500, Remote VC MTU: 0,
  LOCAL VC-Type: Ethernet Tagged (0x04), Remote VC-Type: UNKNOWN
 CPU-Protection: OFF
 Local Switching: Enabled
```

LDP session down

The following example shows the output for the LDP integration for an LDP session down case.

```
NetIron# show mpls vpls detail
VPLS NO_LDP, Id 500, Max mac entries: 8192
 Total vlans: 1, Tagged ports: 1 (1 Up), Untagged ports 0 (0 Up)
  IFL-ID: 4101
  Vlan 880 inner-vlan 35
   Tagged: ethe 8/2
 VC-Mode: Tagged
 Total VPLS peers: 1 (0 Operational)
 Peer address: 66.66.66.66, State: Wait for PW Up (Wait for LDP session to
Peer)
  Tnnl in use: tnl5(6)
  LDP session: Down, Local VC lbl: N/A, Remote VC lbl: N/A
  Local VC MTU: 1500, Remote VC MTU: 0,
  LOCAL VC-Type: Ethernet Tagged (0x04), Remote VC-Type: UNKNOWN
 CPU-Protection: OFF
 Local Switching: Enabled
```

No local label resource

The following example shows the output for the LDP integration for a no local label resource case.

```
NetIron# show mpls vpls detail
VPLS waiting_for_remote_label, Id 400, Max mac entries: 8192
 Total vlans: 1, Tagged ports: 1 (1 Up), Untagged ports 0 (0 Up)
  IFL-ID: 4100
  Vlan 900 inner-vlan 245
   Tagged: ethe 7/1
 VC-Mode: Tagged
 Total VPLS peers: 1 (0 Operational)
 Peer address: 55.55.55.55, State: Wait for PW Up (No Label Resource)
  Tnnl in use: tnl4(5)
  LDP session: Up, Local VC lbl: N/A, Remote VC lbl: N/A
  Local VC MTU: 1500, Remote VC MTU: 0,
  LOCAL VC-Type: Ethernet Tagged (0x04), Remote VC-Type: UNKNOWN
 CPU-Protection: OFF
 Local Switching: Enabled
```

MPLS LDP show commands

If there are issues with the peer VC labels (local or remote), MTU values, or VC type, other than using the vpls show command as documented in previous sections, one can also use the **mpls ldp show** command to compare the PW VC information.

Using the show mpls ldp vc x command

Here is an example of the **show mpls ldp fec vc** command where the remote peer is in the Operational state.

```
NetIron#show mpls ldp fec vc 1
FEC_CB: 0x34ff85a8, idx: 50, type: 128, pend_notif: None
 State: current, Ingr: Yes, Egr: Yes, UM Dist. done: Yes
 VC-Id: 1, vc-type: 4, grp-id: 0
 Local-mtu: 2000, remote-mtu: 1500, MTU enforcement: disabled
 Downstream mappings:
 Local LDP ID        Peer LDP ID         Label     State     CB
 21.21.21.21:0       11.11.11.11:0       983041    Installed 0x34eb2140(-1)
 Upstream mappings:
 Local LDP ID        Peer LDP ID         Label     CB
 21.21.21.21:0       11.11.11.11:0       983040    0x34eb2510(-1)
```

Configuring BGP-Based Auto-Discovery for VPLS 34

Overview

The following list displays the BGP-Based Auto-Discovery for VPLS features supported by PowerConnect B-MLXe:

- BGP-Based Auto-Discovery for VPLS

This chapter describes how to configure the PowerConnect device to automatically discover Virtual Private LAN Services (VPLS) endpoints that are part of the same VPLS domain.

VPLS is a method for carrying Layer 2 frames between Customer Edge (CE) devices across a Multi-Protocol Label Switched (MPLS) domain. Information about VPLS, how it works, and how to manually configure it is discussed in the 33, "Configuring MPLS Virtual Private LAN Services".

The implementation of ***BGP-based auto-discovery for VPLS*** (also called ***VPLS auto-discovery***) eliminates the need for manual configuration of VPLS peers for every VPLS instance configured on the device. The implementation complies with the Internet draft *draft-ietf-l2vpn-signaling-08*. Using the services of Border Gateway Protocol version 4 (BGP4) and Label Distribution Protocol (LDP), VPLS auto-discovery enables a device to automatically discover other VPLS Provider Edge (PE) devices that are part of the same VPLS domain, and to detect and converge when other PE routers are added to or removed from the VPLS domain.

Terms introduced in this chapter

BGP-based auto-discovery for VPLS – Also called ***VPLS auto-discovery***, this feature enables automatic discovery of VPLS Provider Edge (PE) devices that are part of the same VPLS domain, and the ability to detect and converge when other PE routers are added to or removed from the VPLS domain.

BGP L2VPN VPLS Routing Information Base (RIB) – Also called the **BGP L2VPN RIB**, this is the database that contains information about VPLS endpoints that are automatically discovered through VPLS auto-discovery.

L2VPN VPLS address family or **L2VPN address family** – This is the BGP-based auto-discovery mechanism used to distribute information about VPLS endpoints. Information is stored in the BGP L2VPN VPLS Routing Information Base.

Label Switch Router (LSR) ID – This is the router ID. LDP assigns the default loopback address as the router ID. Since VPLS auto-discovery uses the services of LDP, a valid loopback address must be configured on the PowerConnect before VPLS auto-discovery can be enabled.

Route Distinguisher (RD) – The address qualifier used within a single Internet Service Provider's (ISP's) Multi-Protocol Label Switching (MPLS) network. The qualifier is used to distinguish the distinct Virtual Private Network (VPN) routes of separate customers who connect to the service provider.

Route Target (RT) Extended Community – Defines the import and export policies applied to a VPLS instance. Each VPLS instance is associated with one or more route target extended communities.

Subsequent Address Family Identifier (SAFI) – An ID number that provides additional information about the NLRI type for a given attribute.

VPLS Virtual Circuit Identifier (VPLS VCID) or ***VPLS ID*** – Identifies the endpoints of a VPLS instance. All Provider Edge (PE) routers that are part of the same VPLS instance have the same VPLS VCID.

How BGP-based auto-discovery for VPLS works

The devices use the services of LDP and BGP4 to automatically discover VPLS endpoints that are part of the same VPLS domain. To enable the PowerConnect to distribute information about VPLS endpoints, you must configure a L2VPN VPLS address family, activate BGP peering on the L2VPN VPLS address family, then enable BGP-based auto-discovery for VPLS. When BGP L2VPN VPLS update messages are exchanged between PE routers, the device can start discovering VPLS peer addresses.

For every VPLS instance on which BGP-based auto-discovery is enabled, the device automatically generates a Route Distinguisher (RD) value based on the BGP Autonomous System (AS) number and the VPLS Virtual Circuit Identifier (VCID) for PE routers. The RD Is an address qualifier used by the PE router to distinguish VPN routes of separate customers. Also, if not manually configured, the device automatically generates import and export route targets that define the policies that each VPLS instance will use. A local VPLS endpoint Network Layer Reachability Information (NLRI) and import route-target tree are also created and sent to BGP peers with the L2VPN VPLS capability.

When the device receives information about a VPLS endpoint, it checks if its extended community matches any locally-configured VPLS import route targets. If a match is found, information about the VPLS endpoint is stored in the BGP L2VPN routing table and a notification is sent to VPLS for peering information. Once VPLS receives the information, it creates a VPLS peer and starts a peering session.

When VPLS auto-discovery is disabled for a VPLS instance, the system removes all auto-discovered peers for the VPLS instance from the configuration. It then removes the route (local VPLS endpoint address) from the BGP L2VPN route table and sends a “withdrawn” message to VPLS peers, prompting them to remove the route and to disable VPLS auto-discovery. Finally, the system updates the route target tree and sends a route refresh message for the L2VPN VPLS address family.

About the L2VPN VPLS address family

The ***L2VPN VPLS address family*** is an integral part of BGP-based auto-discovery for VPLS, in that it is the mechanism used by BGP4 to distribute information about VPLS endpoints. The L2VPN address family is configured at the BGP configuration level of the CLI and supports the VPLS Subsequent Address Family Identifier (SAFI), an address qualifier that provides additional information about the Network Layer Reachability Information (NLRI) type for a given attribute.

BGP4 uses the L2VPN address family to build the BGP L2VPN Routing information Base (RIB). The L2VPN database is updated each time a Layer 2 Virtual Forwarding Instance (VFI) is configured.

Information about configuring the L2VPN Address Family is in the section “Configuring the L2VPN VPLS address family and activating the BGP4 peering session” on page 1551.

Feature limitations and configuration notes

Consider teh following feature limitations and configuration naotes:

- VPLS should not be used if FDP is enabled.
- VPLS auto-discovery and manual configuration of VPLS peers are supported together on the same device. However they are not supported together on the same VPLS instance.

Scalability

The following section describes the scalability:

- The maximum number of BGP4 peers that can support the L2VPN VPLS address family is equal to the maximum number of BGP4 peers supported on the device.
- The maximum number of VPLS instances that can support BGP-based auto-discovery for VPLS is equal to the maximum number of VPLS instances supported on the device.
- The maximum number of BGP-based auto-discovered peers supported per VPLS instance is equal to the maximum number of unique VPLS or VLL peers or number of VPLS peers supported on the device. If the system exceeds the default or manually-configured maximum number of VPLS peers supported on the device, any new peering for VPLS auto-discovery is rejected.

NOTE
For more information about setting the maximum number of VPLS instances and peers on the device, refer to "Specifying the maximum number of VPLS instances on the device" on page 1498.

Configuring BGP-based auto-discovery for VPLS

It is recommended that you perform the configuration tasks in the order listed in Table 260. Performing the tasks in the recommended sequence minimizes CPU consumption and route flapping. Except where noted as "optional", the configuration tasks in the table are required for VPLS auto-discovery.

TABLE 260 Configuration tasks for VPLS auto-discovery

Configuration task		See...
1	Configure a loopback address	"Configuring a loopback interface" on page 1544
2	Enable BGP4 and assign a local Autonomous System (AS) number	"Configuring BGP4 to support VPLS auto-discovery" on page 1545
3	Enable MPLS and configure LDP	To configure MPLS, refer to the 30, "Configuring MPLS Traffic Engineering". To configure LDP, refer to the 31, "Configuring Label Distribution Protocol (LDP)".
4	Configure VPLS: • Create a VPLS instance • Define the route target (optional) • Enable load balancing (optional)	"Configuring VPLS to support auto-discovery" on page 1547

TABLE 260 Configuration tasks for VPLS auto-discovery

Configuration task		See...
5	Enable VPLS auto-discovery	"Enabling VPLS auto-discovery" on page 1550
6	Configure the L2VPN VPLS address family and activate BGP4 peering	"Configuring the L2VPN VPLS address family and activating the BGP4 peering session" on page 1551

After performing the configuration steps listed in Table 260, you can observe the L2VPN VPLS address family routes, neighbor summary, and VPLS auto-discovery peering. Refer to "Displaying VPLS auto-discovery information" on page 1556.

Configuring a loopback interface

You must configure a loopback address on the PowerConnect before enabling VPLS auto-discovery.

This section contains the following topics:

- "About loopback interfaces and the router ID"
- "Changes that occur when a loopback interface is deleted"
- "Adding a loopback interface"
- "Viewing the loopback Interface"

About loopback interfaces and the router ID

In most configurations, a PowerConnect has multiple IP addresses, usually configured on different interfaces. As a result, a PowerConnect's identity to other devices varies depending on the interface to which the other device is attached. BGP4 identifies a PowerConnect by just one of the IP addresses configured on the device, regardless of the interfaces that connect the devices. This IP address is the ***router ID*** also known as the Label Switched Router (LSR) ID.

LDP uses the default loopback address as the router ID. Since VPLS auto-discovery uses the services of LDP, a valid loopback address must be configured on the PowerConnect before VPLS auto-discovery can be enabled. If a loopback address is not configured, the LDP router ID will be NULL and VPLS auto-discovery will not function.

If there are several loopback addresses configured on the device, the default loopback address is the IP address configured on the lowest-numbered loopback interface on the PowerConnect. For example, if you configure loopback interfaces 1, 2, and 3 as follows, the default router ID is 9.9.9.9/24.

```
Loopback interface 1, 9.9.9.9/24
Loopback interface 2, 4.4.4.4/24
Loopback interface 3, 1.1.1.1/24
```

Changes that occur when a loopback interface is deleted

If a loopback interface is deleted while VPLS auto-discovery is enabled, and more than one loopback interface is configured on the device, the PowerConnect uses the IP address configured on the next lowest numbered loopback interface as the router ID. For example, using the following configuration, if loopback interface 1 is deleted, the PowerConnect uses loopback interface 2. Thus, the successive router ID is 4.4.4.4/24. The system will remove all existing VPLS routes for 9.9.9.9/24 and obtain new routes for 4.4.4.4/24.

```
Loopback interface 1, 9.9.9.9/24
```

```
Loopback interface 2, 4.4.4.4/24
```

If a loopback interface is deleted from the configuration while VPLS auto-discovery is enabled, and there are no other valid loopback interfaces, the system will disable LDP and VPLS auto-discovery.

Adding a loopback interface

To add a loopback interface, enter commands such as the following.

```
NetIron(config)# int loopback 1
NetIron(config-lbif-1)# ip address 10.1.1.4/24
```

Syntax: [no] interface loopback <*num*>

Use the **no** form of the command to delete a loopback interface. Also refer to "Changes that occur when a loopback interface is deleted"in the following section.

The <*num*> value can be a number from 1 – 64.

Viewing the loopback Interface

Use the **show mpls ldp** command to view the loopback interface and router ID in use on the router. Refer to "Displaying information about LDP" on page 1573.

Configuring BGP4 to support VPLS auto-discovery

BGP4 must be enabled on the device and a local ***Autonomous System*** (AS) number must be assigned before VPLS auto-discovery can be enabled.

This section includes configuration details for the following BGP-related tasks:

- How to enable BGP4 and assign the local AS number
- How to change or clear the local AS number when VPLS auto-discovery is enabled
- How to disable BGP4 when VPLS auto-discovery is enabled

NOTE
This section provides minimal information about configuring BGP4 neighbors, peer groups, and other essential BGP-related configuration tasks, because its focus is to provide information about configuring BGP to support VPLS auto-discovery. For more information about essential configuration tasks for BGP4, refer to 26, "Configuring BGP4 (IPv4)".

Enabling BGP4 and assigning the local AS number

In a VPLS configuration, all PEs in the same VPLS domain must be configured with the same AS number. To assign a local AS number to the PowerConnect device, enter commands such as the following.

```
NetIron(config)#router bgp
BGP4: Please configure 'local-as' parameter in order to enable BGP4.
NetIron(config-bgp)#local-as 10
NetIron(config-bgp)#neighbor 10.1.1.1 remote-as 10
```

These commands enable BGP4, set the local AS number to 10, and add the IP address of the remote neighbor (10.1.1.1) to the IPv4 multi-protocol BGP neighbor table of the local router.

Syntax: [no]router bgp

Syntax: [no] local-as <*number*>

Syntax: [no] neighbor <*IPv4-address*> **remote-as** <*number*>

For local-as <*number*>, specify the AS number in which the router you are configuring resides.

For <*IPv4-address*>, enter the IP address of the remote neighbor.

For remote-as <*num*>, enter the AS number.

Changing or clearing the local AS number when VPLS auto-discovery is enabled

If VPLS auto-discovery is enabled on the device and you want to clear or change the BGP local AS number, you must first disable VPLS auto-discovery, then clear the local AS number. If you attempt to clear or change the local AS number while VPLS auto-discovery is enabled, the console will display the following message.

```
NetIron(config-bgp)#no router bgp
Error:  VPLS instances with BGP auto-discovery exist, remove auto-discovery
configuration first!
```

To clear the BGP local AS number when VPLS auto-discovery is enabled, enter commands such as the following.

```
NetIron(config)#router mpls
NetIron(config-mpls)#vpls c1 10
NetIron(config-mpls-vpls-c1)#no auto-discovery
NetIron(config-mpls-vpls-c1)#router bgp
NetIron(config-bgp)#no local-as 10
BGP is no longer operational
```

Syntax: [no] auto-discovery

Syntax: [no] local-as <*num*>

Disabling BGP4 when VPLS auto-discovery is enabled

If VPLS auto-discovery is enabled on the device and you want to disable BGP4, first disable VPLS auto-discovery, then disable BGP4 at the VPLS instance level of the CLI. If you attempt to disable BGP4 while VPLS auto-discovery is enabled, the console will display the following message.

```
NetIron(config-bgp)#no router bgp
Error:  There are VPLS instances with BGP auto-discovery enabled, disable
auto-discovery first!
```

NOTE
If VPLS auto-discovery is not enabled on the device, you can disable BGP simply by entering the CLI command **no router bgp** at the global CONFIG level of the CLI.

To disable BGP4 when VPLS auto-discovery is enabled, enter commands such as the following.

```
NetIron(config)#router mpls
NetIron(config-mpls)#vpls c1 10
NetIron(config-mpls-vpls-c1)#no auto-discovery
NetIron(config-mpls-vpls-c1)#no router bgp
router bgp mode now disabled.  All bgp config data will be lost when writing to
flash!!
```

Syntax: [no] auto-discovery

Syntax: [no] router bgp

NOTE
When BGP is disabled, the system also removes the BGP local AS number from the configuration.

Configuring VPLS to support auto-discovery

This section describes how to configure VPLS to support BGP-based auto-discovery. It includes the following configuration details:

- "Creating a VPLS instance"
- "Defining the route target for a VPLS instance (optional)"
- "Enabling and disabling load balancing for a VPLS instance (optional)"

NOTE
This section provides minimal information about configuring VPLS and other related configuration tasks, because its focus is to provide information about configuring VPLS to support BGP-based auto-discovery. For more information about essential configuration tasks for VPLS, refer to 33, "Configuring MPLS Virtual Private LAN Services".

Creating a VPLS instance

To create a VPLS instance, enter VPLS configuration statements on two or more PE routers.

On the PE routers, enter commands such as the following.

```
NetIron(config)# router mpls
NetIron(config-mpls)#mpls-interface ethernet 1/1
NetIron(config-mpls)# vpls CustomerA 10
NetIron(config-mpls-vpls-CustomerA)#
```

On the VPLS peers (if they are Dell devices), enter commands similar to the above.

```
NetIron(config)# router mpls
NetIron(config-mpls)#mpls-interface ethernet 6/1
NetIron(config-mpls)# vpls CustomerA 10
NetIron(config-mpls-vpls-CustomerA)#
In the above configurations, the endpoints of the VPLS instance are associated by
having the same Virtual Circuit Identifier (VCID) of 10 on each PE router.
```

Syntax: [no] router mpls

Syntax: [no]mpls-interface ethernet [<*slot-num*>/]<*portnum*>

Syntax: [no] vpls <*name*> <*vpls-vcid*>

The **router mpls** command enables MPLS. Enter the **no** form of the command to disable it.

The **mpls-interface ethernet** command specifies the interface on which to create the VPLS instance.

The **vpls** <*name*> parameter specifies the VPLS instance name. The name can be up to 64 alphanumeric characters.

The <*vpls-vcid*> parameter specifies the VCID for the BGP L2VPNVPLS instance. The endpoints of a VPLS instance are associated by having the same VCID on each PE router. Enter a number in the range 1 – 4294967294.

Defining the route target for a VPLS instance (optional)

NOTE
If you opt to manually define a route target, it is recommended that you do so before enabling VPLS auto-discovery.

The ***route target*** extended community for VPLS auto-discovery defines the import and export policies that a VPLS instance will use. The export route target sets an extended community attribute number that is appended to all routes that are exported from the VPLS instance. The import route target value sets a filter that determines the routes that will be accepted into the VPLS instance. Any route with a value in its import route target contained in its extended attributes field matching the value in the VPLS instance's import route target will be accepted. Otherwise the route will be rejected.

In a configuration with VPLS auto-discovery, configuring a route target is optional. If you do not manually configure one, the system will automatically generate the import and export route target for each VPLS instance configured on the PowerConnect device when VPLS auto-discovery is enabled. A manually-configured route target takes precedence over one that is automatically generated by VPLS auto-discovery. If all manually-configured route targets are removed from a VPLS instance while VPLS auto-discovery is enabled, the system will automatically generate a new route target for the VPLS instance.

The PowerConnect supports up to 16 unique import and export route targets per VPLS instance. If you attempt to configure more than 16, the system will display the following error message.

```
Error: Maximum number of Import RT for a VPLS instance is 16!
Error: Maximum number of Export RT for a VPLS instance is 16!
```

To define an import route target of 3:6 and an export route target of 3:8 for a VPLS instance, enter the following commands.

```
NetIron(config)#router mpls
NetIron(config-mpls)#vpls c1
NetIron(config-mpls-vpls-c1)#route-target import 3:6
NetIron(config-mpls-vpls-c1)#route-target export 3:8
```

Syntax: [no] route-target [both | import | export] <*ASN:num*> **|** <*IP-address:num*>

The **both** parameter specifies both import and export values will apply to the specified route target for the VPLS instance where this command is applied. This is the default state and will apply if no specific value for this parameter is set.

The **import** parameter specifies that routes with route-target extended community attributes matching the specified route-target can be imported into the VPLS instance where this command is applied.

The **export** parameter specifies the route-target extended community attributes that are attached to routes exported from the specified VPLS instance.

The <*ASN:num*> parameter identifies the route as an ASN relative. This number is the local ASN number followed by a colon (:) and a unique arbitrary number.

The <*IP-address:num*> parameter identifies the route as an IP-address relative. This number is the local IP address followed by a colon (:) and a unique arbitrary number.

Viewing the route target for a VPLS instance

Use the **show mpls vpls name** command to view the route targets for a VPLS instance. Refer to "Displaying information about VPLS auto-discovery and load balancing" on page 1571.

Enabling and disabling load balancing for a VPLS instance (optional)

This section describes how to enable and disable load balancing for a VPLS instance on which VPLS auto-discovery is enabled. When load balancing is enabled, the PowerConnect will automatically load balance traffic to all auto-discovered peers.

You can configure a VPLS instance to load balance known unicast traffic sent to auto-discovered VPLS peers across multiple tunnel LSPs. The CLI commands for enabling and disabling load balancing differ depending on whether VPLS auto-discovery is enabled on the VPLS instance. Follow the appropriate procedures in this section.

NOTE
To enable load balancing on VPLS peers that are manually created, refer to "LSP load balancing for VPLS traffic" on page 1504.

NOTE
The PowerConnect load balances traffic for auto-discovered VPLS peers, the same as for manually-created VPLS peers. For details about how traffic is load balanced from one VPLS peer to another, refer to "LSP load balancing for VPLS traffic" on page 1504.

Enabling load balancing when VPLS auto-discovery is disabled

To enable VPLS auto-discovery and load balancing of traffic sent to auto-discovered VPLS peers, enter commands such as the following:

NOTE
Before enabling VPLS auto-discovery, make sure you have completed the configuration tasks listed in Table 260 on page 1543.

```
NetIron(config)#router mpls
NetIron(config-mpls)#vpls c1 10
NetIron(config-mpls-vpls-c1)#auto-discovery load-balance
```

Syntax: [no] auto-discovery load-balance

To disable load balancing, refer to "Disabling load balancing".

Enabling load balancing when VPLS auto-discovery is enabled

If VPLS auto-discovery is enabled for a VPLS instance and you wish to enable load balancing, you must first disable VPLS auto-discovery, then re-enable it with the **load-balancing** option. If you attempt to enable load balancing when VPLS auto-discovery is enabled, the console will display the following message.

```
NetIron(config-mpls-vpls-c1)#auto-discovery load-balance
Error:  Please disable auto-discovery before make change!
```

To enable load balancing for a VPLS instance that has VPLS auto-discovery enabled, enter commands such as the following.

```
NetIron(config)#router mpls
NetIron(config-mpls)#vpls c1 10
NetIron(config-mpls-vpls-c1)#no auto-discovery
NetIron(config-mpls-vpls-c1)#auto-discovery load-balance
```

The above commands disable VPLS auto-discovery for VPLS instance "c1", then re-enable VPLS auto-discovery with the **load-balance** option.

Syntax: [no] auto-discovery

Syntax: [no]auto-discovery load-balance

Disabling load balancing

To disable load balancing when VPLS auto-discovery is enabled on the device, first disable VPLS auto-discovery, then re-enable it without the **load-balancing** option.

```
NetIron(config)#router mpls
NetIron(config-mpls)#vpls c1 10
NetIron(config-mpls-vpls-c1)#no auto-discovery load-balance
NetIron(config-mpls-vpls-c1)#auto-discovery
```

Syntax: [no]auto discovery load-balance

Syntax: [no]auto-discovery

Viewing the load balancing configuration

Use the **show mpls vpls name** command to view If VPLS traffic to the peer is load balanced across tunnel LSPs, and the tunnel LSPs used to reach the peer. Refer to "Displaying information about VPLS auto-discovery and load balancing" on page 1571

Enabling VPLS auto-discovery

NOTE
Before enabling VPLS auto-discovery, make sure you have completed the configuration tasks listed in Table 260 on page 1543.

To enable auto-discovery for a VPLS instance, enter commands such as the following.

```
NetIron(config)#router mpls
NetIron(config-mpls)#vpls c1
NetIron(config-mpls-vpls-c1)#auto-discovery
```

These commands enable MPLS, then change the CLI configuration level from the global MPLS level to the configuration level for the VPLS instance "c1". The **auto-discovery** command enables auto-discovery for this VPLS instance.

Syntax: [no] auto-discovery

Use the **no** form of the command to disable VPLS auto-discovery.

Configuration notes

Consider the following configuration notes while enabling VPLS auto-discovery:

- If you attempt to enable VPLS auto-discovery without first adding a loopback interface, the following error message will display on the console.

  ```
  NetIron(config-mpls-vpls-c2)auto-discovery
  Error: Please configure a loopback address for LDP first!
  ```

  To add a loopback interface, follow the configuration instructions in "Configuring a loopback interface" on page 1544.

- If you attempt to enable VPLS auto-discovery without first configuring the BGP AS number, the following error message will display on the console.

```
NetIron(config-mpls-vpls-c2)auto-discovery
Error: Cannot configure auto-discovery before configuring BGP-AS number!
```

To configure the BGP AS number, follow the configuration instructions in "Configuring BGP4 to support VPLS auto-discovery" on page 1545.

Configuring the L2VPN VPLS address family and activating the BGP4 peering session

This section describes how to configure the L2VPN VPLS address family and activate BGP4 peering. More information about the L2VPN VPLS address family is in the section "About the L2VPN VPLS address family" on page 1542

NOTE
It is recommended that you activate peering on the L2VPN VPLS address family after performing steps 1 – 5 in Table 260. Otherwise, you will need to clear the entire peering session.

To configure the L2VPN VPLS address family, enter commands such as the following.

```
NetIron(config)#router bgp
NetIron(config-bgp)#address-family l2vpn vpls
NetIron(config-bgp-l2vpn-vpls)#neighbor 10.10.1.1 activate
NetIron(config-bgp-l2vpn-vpls)#exit
```

Syntax: [no]address-family l2vpn vpls

Syntax: [no]neighbor *<IPv4-address>* | *<peer group name>* activate | remote-as | send-community extended

The **activate** command enables the exchange and updating of routes within the L2VPN VPLS address family.

The **send-community extended** command enables the sending of extended community attributes to this neighbor.

Clearing the BGP L2VPN route table

You can clear routes from the BGP L2VPN route table with or without resetting the BGP session. Use the appropriate commands in this section.

Clearing the BGP L2VPN route table and resetting BGP

NOTE
This section describes how to clear routes from the BGP L2VPN route table and reset the BGP session. If you do not want to reset the BGP session while clearing routes, refer to "Clearing the BGP L2VPN route table without resetting the BGP session" on page 1552.

You can clear routes from the BGP L2VPN route table that were exchanged by the PowerConnect and:

- All BGP4 neighbors

- A specific neighbor
- A specific peer group

To clear and reset all BGP4 routes from the BGP L2VPN route table, enter the following command.

```
NetIron# clear ip bgp l2vpn vpls neighbor all
```

To clear and reset BGP4 routes exchanged by the PowerConnect and a *specific neighbor*, enter a command such as the following.

```
NetIron# clear ip bgp l2vpn vpls neighbor 10.10.10.1
```

To clear and reset BGP4 routes exchanged by the PowerConnect and a *specific peer group*, enter a command such as the following.

```
NetIron# clear ip bgp l2vpn vpls neighbor peergroup1
```

Syntax: clear ip bgp neighbor all | <*ip-addr*> **|** <*peer-group-name*>

The all | <*ip-addr*> | <*peer-group-name*> | <*as-num*> specifies the neighbor.

The <*ip-addr*> parameter specifies a neighbor by its IP interface with the PowerConnect.

The <*peer-group-name*> specifies all neighbors in a specific peer group.

Clearing the BGP L2VPN route table without resetting the BGP session

When clearing all BGP4 routes from the BGP L2VPN route table, you can place policy changes into effect without resetting the BGP session. To do so, enter a command such as the following.

```
NetIron(config-bgp)# clear ip bgp l2vpn vpls neighbor all soft in
```

This command updates the inbound routes in the BGP L2VPN route table by comparing the route policies against the route updates that the PowerConnect has stored. The command does not request additional updates from the neighbor or otherwise affect the session with the neighbor.

Syntax: clear ip bgp l2vpn vpls neighbor all | <*ip-addr*> **|** <*peer-group-name*> **soft [in | out]**

The **soft** parameter performs a soft reset of the neighbor session, which does not affect the session with the neighbor.

The **in** parameter updates inbound routes.

The **out** parameter updates outbound routes.

NOTE
If you do not specify “in”, the command applies to both inbound and outbound updates.

Example configuration

The following shows a typical VPLS auto-discovery configuration.

PowerConnect1 configuration

The following commands are entered on PowerConnect1.

```
NetIron(config)# int loopback 1
NetIron(config-lbif-1)# ip address 10.1.1.1/24
NetIron(config-lbif-1)#exit
NetIron(config)#router bgp
BGP4: Please configure 'local-as' parameter in order to enable BGP4.
NetIron(config-bgp)#local-as 10
NetIron(config-bgp)#neighbor 10.1.1.2 remote-as 10
NetIron(config-bgp)#exit
NetIron(config)# router mpls
NetIron(config-mpls)#mpls-interface ethernet 1/1
NetIron(config-mpls)# vpls C1 10
NetIron(config-mpls-vpls-C1)#auto-discovery
NetIron(config-mpls)#exit
NetIron(config-mpls)# vpls C2 20
NetIron(config-mpls-vpls-C2)#auto-discovery
NetIron(config-mpls-vpls-C2)#exit
NetIron(config-mpls)#exit
NetIron(config)#router bgp
NetIron(config-bgp)#address-family l2vpn vpls
NetIron(config-bgp-l2vpn-vpls)#neighbor 10.1.1.2 activate
NetIron(config-bgp-l2vpn-vpls)#exit-address-family
NetIron(config-bgp)#exit
NetIron(config)#
```

PowerConnect2 configuration

The following commands are entered on PowerConnect2, a peer of PowerConnect1.

```
NetIron(config)# int loopback 1
NetIron(config-lbif-1)# ip address 10.1.1.2/24
NetIron(config-lbif-1)#exit
NetIron(config)#router bgp
BGP4: Please configure 'local-as' parameter in order to enable BGP4.
NetIron(config-bgp)#local-as 10
NetIron(config-bgp)#neighbor 10.1.1.1 remote-as 10
NetIron(config-bgp)#exit
NetIron(config)# router mpls
NetIron(config-mpls)#mpls-interface ethernet 1/1
NetIron(config-mpls)# vpls C1 10
NetIron(config-mpls-vpls-C1)#auto-discovery
NetIron(config-mpls)#exit
NetIron(config-mpls)# vpls C2 20
NetIron(config-mpls-vpls-C2)#auto-discovery
NetIron(config-mpls-vpls-C2)#exit
NetIron(config-mpls)#exit
NetIron(config)#router bgp
NetIron(config-bgp)#address-family l2vpn vpls
NetIron(config-bgp-l2vpn-vpls)#neighbor 10.1.1.1 activate
NetIron(config-bgp-l2vpn-vpls)#exit-address-family
NetIron(config-bgp)#exit
NetIron(config)#
```

After applying the above commands, you can use various **show** commands to display information about the VPLS auto-discovery configuration. In the **show** command examples that follow, the lines in bold type indicate the information specific to the VPLS auto-discovery configuration.

NOTE
The **show mpls vpls name** command has changed. The total VC labels allocated field is no longer displayed in the output of the **show mpls vpls name** command.

For field definitions of the **show ip bgp neighbor** command output, refer to "Displaying summary neighbor information" on page 1107. For field definitions of the **show ip bgp l2vpn vpls** command output, refer to "Displaying VPLS auto-discovery information" on page 1556.

```
NetIron1#show ip bgp nei 10.1.1.2

Displaying VPLS auto-discovery information

You can display the following information about the VPLS auto-discovery configuration:

- L2VPN VPLS address family and associated routes
- VPLS auto-discovered peers
- Load balancing status for VPLS auto-discovered peers
- LDP configuration, including the loopback interface and router ID

Displaying information about BGP L2VPN VPLS routes

You can use the **show ip bgp l2vpn vpls** command with the parameters listed in Table 261 to view information related to BGP L2VPN VPLS routes.

TABLE 261 Parameters for CLI command show ip bgp l2vpn vpls

Parameter	Displays...	For details, see...
<A.B.C.D or A.B.C.D/L> (route IP address)	The BGP L2VPN VPLS routes for a particular IP route address	page 1559
attribute-entries	AS-path attribute entries	page 1560

TABLE 261 Parameters for CLI command show ip bgp l2vpn vpls

Parameter	Displays...	For details, see...
neighbors	Details about TCP and BGP neighbor connections	page 1562
rd	Details about the route distinguisher	page 1567
routes	Information about BGP L2VPN VPLS routes	page 1568
summary	A summary of the BGP L2VPN VPLS neighbor status	page 1570

Viewing all BGP L2VPN VPLS routes

The **show ip bgp l2vpn vpls** command displays all of the BGP L2VPN VPLS routes. The following shows example output.

```
NetIron1#show ip bgp l2vpn vpls
Total number of BGP L2VPN VPLS Routes: 4
Status codes: s suppressed, d damped, h history, * valid, > best, i  internal, S
stale
Origin codes: i - IGP, e - EGP, ? - incomplete
    Network          Next Hop    Metric LocPrf Weight Path
Route Distinguisher: 10:10
*>  1.1.1.1/32      0.0.0.0     0    100   65535  i
*i  2.2.2.2/32      0.0.0.0     0    100   0      i

Route Distinguisher: 10:20
*>  1.1.1.1/32      0.0.0.0     0    100   65535  i
*i  2.2.2.2/32      0.0.0.0     0    100   0      i
```

Syntax: show ip bgp l2vpn vpls

Table 262 defines the fields shown in the above example output.

TABLE 262 Output for the show ip bgp l2vpn vpls command

This field...	Displays
Total number of BGP L2VPN VPLS Routes	The number of BGP4 routes in the BGP L2VPN VPLS route table.
Status codes	A list of the characters the display uses to indicate the route's status. The status code appears in the left column of the display, to the left of each route: • s (suppressed) – This route was suppressed during aggregation and thus is not advertised to neighbors. • d (damped) – This route has been dampened (by the route dampening feature), and is currently unusable. • h (history) – Route dampening is configured for this route, and the route has a history of flapping and is unreachable now. • * (valid) – The next-hop of this route can be resolved by the routing table. • > (best) – BGP4 has determined that this is the optimal route to the destination. • i (internal) – The route was learned through BGP4. • S (stale) – This route is stale and will be cleaned up.
Origin codes	A list of the characters the display uses to indicate the route's origin. The origin code appears to the right of the AS path (Path field). The origin code can be one of the following: • i - IGP – The routes with this set of attributes came to BGP4+ through IGP • e - EGP – The routes with this set of attributes came to BGP4+ through EGP. • ? - incomplete – The routes came from an origin other than IGP or EGP. For example, they may have been redistributed from OSPF or RIP. **NOTE:** When BGP4 compares multiple routes to a destination to select the best route, IGP is preferred over EGP and both are preferred over INCOMPLETE.
Route Distinguisher	A unique ID that is prepended on any address being routed or advertised from a Virtual Routing and Forwarding (VRF) instance. The RD can be defined as either ASN-relative or IP address-relative as described: • ASN-relative - Composed of the local ASN number followed by a ":" (colon) and a unique arbitrary number. For example: 3:6 • IP address-relative - Composed of the local IP address followed by a ":" (colon) and a unique arbitrary number.
Network	The IP address and network mask of the destination network of the route.
Next Hop	The IP address of the next-hop router.
Metric	The cost of the routes that have this set of attributes.
LocPrf	The degree of preference for this route relative to other routes in the local AS. When the BGP4+ algorithm compares routes on the basis of local preferences, the route with the higher local preference is chosen. The preference can have a value from 0 – 4294967295.

TABLE 262 Output for the show ip bgp l2vpn vpls command (Continued)

This field...	Displays
Weight	The value that this route associates with routes from a specific neighbor. For example, if the router receives routes to the same destination from two BGP4 neighbors, the router prefers the route from the neighbor with the larger weight
Path	The AS path for the route.

Viewing BGP L2VPN VPLS routes for a particular IP route address

The **show ip bgp l2vpn vpls** <*IP route address*>**>** command displays the BGP L2VPN VPLS routes for a particular IP route address.

```
mu2(config-lbif-1)#show ip bgp l2vpn vpls 10.1.1.1
Total number of BGP L2VPN VPLS Routes: 1
Status codes: s suppressed, d damped, h history, * valid, > best, i internal, S
stale
Origin codes: i - IGP, e - EGP, ? - incomplete
    Network           Next Hop        Metric LocPrf Weight Path
Route Distinguisher: 10:10
*>  3.3.3.3/32        0.0.0.0         0      100    65535  i
```

Syntax: show ip bgp l2vpn vpls <*IP route address*>

Field definitions for the **show ip bgp l2vpn vpls** <*IP route address*> command are the same as for **show ip bgp l2vpn vpls**. Refer to Table 262.

Viewing BGP L2VPN VPLS route attribute entries

Use the **show ip bgp l2vpn vpls attribute-entries** command to view attribute entries for BGP L2VPN VPLS routes.

```
NetIron1#show ip bgp l2vpn vpls attribute-entries
        Total number of BGP Attribute Entries: 4 (2)

Syntax: show ip bgp l2vpn vpls attribute-entries

Table 263 defines the fields shown in the above example output.

TABLE 263 Output for the show ip bgp l2vpn vpls attribute-entries command

This field...	Displays
Total number of BGP Attribute Entries	The number of routes contained in this router's BGP L2VPN VPLS route table.
Next Hop	The IP address of the next hop router for routes that have this set of attributes.
Metric	The cost of the routes that have this set of attributes.

TABLE 263 Output for the show ip bgp l2vpn vpls attribute-entries command (Continued)

This field...	Displays
Origin	The source of the route information. The origin can be one of the following: • EGP – The routes with this set of attributes came to BGP through EGP. • IGP – The routes with this set of attributes came to BGP through IGP. • INCOMPLETE – The routes came from an origin other than one of the above. For example, they may have been redistributed from OSPF or RIP. **NOTE:** When BGP4 compares multiple routes to a destination to select the best route, IGP is preferred over EGP and both are preferred over INCOMPLETE.
Originator	The originator of the route in a route reflector environment.
Cluster List	The route-reflector clusters through which this set of attributes has passed.
Aggregator	Aggregator information: • AS `Number` shows the AS in which the network information in the attribute set was aggregated. This value applies only to aggregated routes and is otherwise 0. • `Router-ID` shows the router that originated this aggregator.
Atomic	Indicates whether the network information in this set of attributes has been aggregated *and* this aggregation has resulted in information loss. **NOTE:** Information loss under these circumstances is a normal part of BGP4 and does not indicate an error.
Local Pref	The degree of preference for routes that use this set of attributes relative to other routes in the local AS.
Communities	The communities to which routes with this set of attributes belong.
Extended Community	The extended community attributes.
AS Path	The AS path through which routes with this set of attributes have passed. The local AS is shown in parentheses.
Address	This field is an internal value used for debugging purposes only.
Links	This field in an internal value used for debugging purposes only.
Reference Counts	This field is an internal value used for debugging purposes only.

Viewing neighbor connections

Use the **show ip bgp l2vpn vpls neighbors** command to view the details of TCP and BGP neighbor connections.

```
NetIron1#show ip bgp l2vpn vpls neighbors
    Total number of BGP Neighbors: 1
1   IP Address: 10.1.1.2, AS: 10 (IBGP), RouterID: 2.2.2.2, VRF: default-vrf
    State: ESTABLISHED, Time: 0h15m47s, KeepAliveTime: 60, HoldTime: 180
       KeepAliveTimer Expire in 49 seconds, HoldTimer Expire in 148 seconds
    Minimal Route Advertisement Interval: 0 seconds
       RefreshCapability: Received
    Messages:    Open    Update  KeepAlive Notification Refresh-Req
       Sent    : 3       2       19        0            0
       Received: 1       2       18        0            0
    Last Update Time: NLRI       Withdraw          NLRI       Withdraw
                  Tx: 0h15m47s   ---           Rx: 0h15m47s   ---
    Last Connection Reset Reason: Hold Timer Expired
    Notification Sent:     Unspecified
    Notification Received: Unspecified
    Neighbor NLRI Negotiation:
      Peer Negotiated IPV4  unicast  capability
      Peer Negotiated L2VPN VPLS address family
      Peer configured for IPV4 unicast  Routes
      Peer configured for L2VPN VPLS address family
    Neighbor AS4 Capability Negotiation:
    As-path attribute count: 2
    TCP Connection state: ESTABLISHED, flags:00000044 (0,0)
     Maximum segment size: 1460
    TTL check: 0, value: 0, rcvd: 64

```

Syntax: show ip bgp l2vpn vpls neighbors

TABLE 264 Output for the show ip bgp l2vpn vpls neighbors command

This field...	Displays...
Total Number of BGP Neighbors	The number of BGP neighbors configured.
IP Address	The IP address of the neighbor.
AS	The AS number to which the neighbor belongs.
EBGP or IBGP	Whether the neighbor session is an IBGP session, an EBGP session, or a confederation EBGP session: • EBGP – The neighbor is in another AS. • EBGP_Confed – The neighbor is a member of another sub-AS in the same confederation. • IBGP – The neighbor is in the same AS.
RouterID	The neighbor's router ID.

TABLE 264 Output for the show ip bgp l2vpn vpls neighbors command (Continued)

This field...	Displays...
VRF	• default-vrf – The L2VPN is only applicable to the global default VRF instance.
State	The state of the router's session with the neighbor. The states are from this router's perspective of the session, not the neighbor's perspective. The state values are based on the BGP4 state machine values described in RFC 1771 and can be one of the following for each router: • IDLE – The BGP4 process is waiting to be started. Usually, enabling BGP4 or establishing a neighbor session starts the BGP4 process. • ADMND – The neighbor has been administratively shut down. • CONNECT – BGP4 is waiting for the connection process for the TCP neighbor session to be completed. • ACTIVE – BGP4 is waiting for a TCP connection from the neighbor. **NOTE:** If the state frequently changes between CONNECT and ACTIVE, there may be a problem with the TCP connection. • OPEN SENT – BGP4 is waiting for an Open message from the neighbor. • OPEN CONFIRM – BGP4 has received an OPEN message from the neighbor and is now waiting for either a KEEPALIVE or NOTIFICATION message. If the router receives a KEEPALIVE message from the neighbor, the state changes to Established. If the message is a NOTIFICATION, the state changes to Idle. • ESTABLISHED – BGP4 is ready to exchange UPDATE messages with the neighbor.
State (cont'd)	Operational States: Additional information regarding the operational states of the BGP states described above may be added as described in the following: • (+) – Indicates that there is more BGP data in the TCP receiver queue. • (-) – indicates that the session has gone down and the software is clearing or removing routes. • (*) – indicates that the inbound or outbound policy is being updated for the peer. • (s) – indicates that the peer has negotiated restart, and the session is in a stale state. • (r) – indicates that the peer is restarting the BGP connection, through restart. • (^) – On the standby MP indicates that the peer is in the ESTABLISHED state and has received restart capability (in the primary MP). • (<) – Indicates that the router is waiting to receive the "End of RIB" message from the peer.
Time	The amount of time this session has been in its current state.
KeepAliveTime	The keep alive time, which specifies how often this router sends keep alive messages to the neighbor.
HoldTime	The hold time, which specifies how many seconds the router will wait for a KEEPALIVE or UPDATE message from a BGP4 neighbor before deciding that the neighbor is dead.
Minimal Route Advertisement Interval	The minimum time elapse between route advertisements to the same neighbor.
RefreshCapability	Indicates whether this PowerConnect has received confirmation from the neighbor that the neighbor supports the dynamic refresh capability.

TABLE 264 Output for the show ip bgp l2vpn vpls neighbors command (Continued)

This field...	Displays...
Messages Sent	The number of messages this router has sent to the neighbor. The display shows statistics for the following message types: • Open • Update • KeepAlive • Notification • Refresh-Req
Messages Received	The number of messages this router has received from the neighbor. The message types are the same as for the Message Sent field.
Last Update Time	The last time updates were sent and received for the following: • NLRIs • Withdraws

Last Connection Reset Reason	The reason the previous session with this neighbor ended. The reason can be one of the following:
	• Reasons described in the BGP specifications:
	  • Message Header Error
	  • Connection Not Synchronized
	  • Bad Message Length
	  • Bad Message Type
	  • OPEN Message Error
	  • Unsupported Version Number
	  • Bad Peer AS Number
	  • Bad BGP Identifier
	  • Unsupported Optional Parameter
	  • Authentication Failure
	  • Unacceptable Hold Time
	  • Unsupported Capability
	  • UPDATE Message Error
	  • Malformed Attribute List
	  • Unrecognized Well-known Attribute
	  • Missing Well-known Attribute
	  • Attribute Flags Error
	  • Attribute Length Error
	  • Invalid ORIGIN Attribute
	  • Invalid NEXT_HOP Attribute
	  • Optional Attribute Error
	  • Invalid Network Field
	  • Malformed AS_PATH
	  • Hold Timer Expired
	  • Finite State Machine Error
	  • Rcv Notification

TABLE 264 Output for the show ip bgp l2vpn vpls neighbors command (Continued)

This field...	Displays...

Last Connection Reset Reason (cont'd)	• Reasons specific to the implementation:
	  • Reset All Peer Sessions
	  • User Reset Peer Session
	  • Port State Down
	  • Peer Removed
	  • Peer Shutdown
	  • Peer AS Number Change
	  • Peer AS Confederation Change
	  • TCP Connection KeepAlive Timeout
	  • TCP Connection Closed by Remote
	  • TCP Data Stream Error Detected

Notification Sent	If the router sends a NOTIFICATION message to the neighbor, the message contains an error code corresponding to one of the following errors. Some errors have subcodes that clarify the reason for the error. Where applicable, the subcode messages are listed underneath the error code messages.
	• Message Header Error:
	  • Connection Not Synchronized
	  • Bad Message Length
	  • Bad Message Type
	  • Unspecified
	• Open Message Error:
	  • Unsupported Version
	  • Bad Peer As
	  • Bad BGP Identifier
	  • Unsupported Optional Parameter
	  • Authentication Failure
	  • Unacceptable Hold Time
	  • Unspecified
	• Update Message Error:
	  • Malformed Attribute List
	  • Unrecognized Attribute
	  • Missing Attribute
	  • Attribute Flag Error
	  • Attribute Length Error
	  • Invalid Origin Attribute
	  • Invalid NextHop Attribute
	  • Optional Attribute Error
	  • Invalid Network Field
	  • Malformed AS Path
	  • Unspecified
	• Hold Timer Expired
	• Finite State Machine Error
	• Cease
	• Unspecified

Notification Received	If the router receives a NOTIFICATION message from the neighbor, the message contains an error code corresponding to one of the following errors. Some errors have subcodes that clarify the reason for the error. Where applicable, the subcode messages are listed underneath the error code messages. See above.

TABLE 264 Output for the show ip bgp l2vpn vpls neighbors command (Continued)

This field...	Displays...
Neighbor NLRI Negotiation	The state of the NLRI negotiation with the neighbor. For example: • Peer negotiated IPv4 unicast capability • Peer negotiated L2VPN VPLS address family • Peer configured for IPv4 unicast routes • Peer configured for L2VPN VPLS address family
Neighbor AS4 Capability Negotiation	Whether this neighbor enabled 4 bytes ASN capability,
As-path attribute count	The number of unique path attributes learned from this neighbor.
TCP Connection state	The state of the connection with the neighbor. The connection can have one of the following states: • LISTEN – Waiting for a connection request. • SYN-SENT – Waiting for a matching connection request after having sent a connection request. • SYN-RECEIVED – Waiting for a confirming connection request acknowledgment after having both received and sent a connection request. • ESTABLISHED – Data can be sent and received over the connection. This is the normal operational state of the connection. • FIN-WAIT-1 – Waiting for a connection termination request from the remote TCP, or an acknowledgment of the connection termination request previously sent. • FIN-WAIT-2 – Waiting for a connection termination request from the remote TCP. • CLOSE-WAIT – Waiting for a connection termination request from the local user. • CLOSING – Waiting for a connection termination request acknowledgment from the remote TCP. • LAST-ACK – Waiting for an acknowledgment of the connection termination request previously sent to the remote TCP (which includes an acknowledgment of its connection termination request). • TIME-WAIT – Waiting for enough time to pass to be sure the remote TCP received the acknowledgment of its connection termination request. • CLOSED – There is no connection state.
Maximum segment size	The TCP maximum segment size.
TTL check	The TCP TTL check.
Byte Sent	The number of bytes sent.
Byte Received	The number of bytes received.
Local host	The IP address of the PowerConnect.
Local port	The TCP port the PowerConnect is using for the BGP4 TCP session with the neighbor.
Remote host	The IP address of the neighbor.
Remote port	The TCP port the neighbor is using for the BGP4 TCP session with the PowerConnect.
ISentSeq	The initial send sequence number for the session.
SendNext	The next sequence number to be sent.
TotUnAck	The number of sequence numbers sent by the PowerConnect that have not been acknowledged by the neighbor.

TABLE 264 Output for the show ip bgp l2vpn vpls neighbors command (Continued)

This field...	Displays...
TotSent	The number of sequence numbers sent to the neighbor.
ReTrans	The number of sequence numbers that the PowerConnect retransmitted because they were not acknowledged.
UnAckSeq	The current acknowledged sequence number.
IRcvSeq	The initial receive sequence number for the session.
RcvNext	The next sequence number expected from the neighbor.
SendWnd	The size of the send window.
TotalRcv	The number of sequence numbers received from the neighbor.
DupliRcv	The number of duplicate sequence numbers received from the neighbor.
RcvWnd	The size of the receive window.
SendQue	The number of sequence numbers in the send queue.
RcvQue	The number of sequence numbers in the receive queue.
CngstWnd	The number of times the window has changed.

Viewing information for a route distinguisher

Use the **show ip bgp l2vpn vpls rd** command to view information for a particular route distinguisher.

```
NetIron#show ip bgp l2vpn vpls rd 10:10
Total number of BGP Routes: 2
Status codes: s suppressed, d damped, h history, * valid, > best, i internal, S
stale
Origin codes: i - IGP, e - EGP, ? - incomplete
    Network            Next Hop        Metric LocPrf Weight Path
*>  1.1.1.1/32         0.0.0.0         0      100    65535  i
*i  2.2.2.2/32         0.0.0.0         0      100    0      i
```

Syntax: show ip bgp l2vpn vpls rd

TABLE 265 Output for the show ip bgp l2vpn vpls rd command

This field...	Displays
Total number of BGP Routes	The number of BGP4 routes the PowerConnect has installed in the BGP L2VPN VPLS route table.
Status codes	A list of the characters the display uses to indicate the route's status. Refer to "Status codes" on page 1558.
Origin codes	A list of the characters the display uses to indicate the route's origin. Refer to "Origin codes" on page 1558.
Network	The IP address and network mask of the destination network of the route.
Next Hop	The IP address of the next-hop router.
Metric	The cost of the route.
LocPrf	The degree of preference for this route relative to other routes in the local AS. When the BGP4+ algorithm compares routes on the basis of local preferences, the route with the higher local preference is chosen. The preference can have a value from 0 – 4294967295.

TABLE 265 Output for the show ip bgp l2vpn vpls rd command (Continued)

This field...	Displays
Weight	The value that this route associates with routes from a specific neighbor. For example, if the router receives routes to the same destination from two BGP4 neighbors, the router prefers the route from the neighbor with the larger weight.
Path	The AS path for the route.

Viewing information about BGP L2VPN VPLS routes

Use the **show ip bgp l2vpn vpls routes** command to view information about BGP L2VPN VPLS routes.

```
NetIron1#show ip bgp l2vpn vpls routes
Total number of BGP Routes: 4
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED

         AS_PATH:
```

Syntax: **show ip bgp l2vpn vpls routes**

TABLE 266 Output for the show ip bgp l2vpn vpls routes command

This field...	Displays
Total number of BGP Routes	The number of BGP4 routes the PowerConnect has installed in the BGP4 route table.
Status	A list of the characters the display uses to indicate the route's status. The status code appears in the last column of the display, to the right of each route. The route's status can be one or more of the following: • A: AGGREGATE – The route is an aggregate route for multiple networks. • B: BEST – BGP4 has determined that this is the optimal route to the destination. • b NOT-INSTALLED-BEST – The routes received from the neighbor are the best BGP4 routes to their destinations, but were nonetheless not installed in the IP route table because the PowerConnect received better routes from other sources (such as OSPF, RIP, or static IP routes). • C: CONFED_EBGP – The route was learned from a neighbor in the same confederation and AS, but in a different sub-AS within the confederation. • D: DAMPED – This route has been dampened (by the route dampening feature), and is currently unusable. • E: EBGP – The route was learned from another AS BGP neighbor. • F: FILTERED – The route was filtered from the BGP route table. • H: HISTORY – Route dampening is configured for this route, and the route has a history of flapping and is unreachable now. • I: IBGP – The route was learned from the same AS BGP neighbor. • L: LOCAL – The route originated on this PowerConnect. • M: MULTIPATH – BGP4 load sharing is enabled and this route was selected as one of the best ones to the destination. The best route among the multiple paths also is marked with "B". • m: NOT-INSTALLED-MULTIPATH – The software was not able to install the route in the IP route table. • S: SUPPRESSED – This route was suppressed during aggregation and thus is not advertised to neighbors. • s: STALE – This is a stale route and will be cleaned up.
Route Distinguisher	A unique ID that is prepended on any address being routed or advertised from a Virtual Routing and Forwarding (VRF) instance. The RD can be defined as either ASN-relative or IP address-relative as described: • ASN-relative - Composed of the local ASN number followed by a ":" (colon) and a unique arbitrary number. For example: 3:6 • IP address-relative - Composed of the local IP address followed by a ":" (colon) and a unique arbitrary number.
Prefix	The IP address and network mask of the destination network of the route.
AS_PATH	The BGP AS_PATH path attribute.
Next Hop	The IP address of the next-hop router.
Metric	The cost of this route.
LocPrf	The degree of preference for this route relative to other routes in the local AS. When the BGP4+ algorithm compares routes on the basis of local preferences, the route with the higher local preference is chosen. The preference can have a value from 0 – 4294967295.

TABLE 266 Output for the show ip bgp l2vpn vpls routes command (Continued)

This field...	Displays
Weight	The value that this route associates with routes from a specific neighbor. For example, if the router receives routes to the same destination from two BGP4 neighbors, the router prefers the route from the neighbor with the larger weight.
Status	The route's status. Refer to "Status" on page 1569.

Viewing a summary of BGP neighbor status

Use the **show ip bgp l2vpn vpls summary** command to view BGP4 summary information.

```
NetIron1#show ip bgp l2vpn vpls summary
  BGP4 Summary
  Router ID: 1.1.1.1   Local AS Number: 10
  Confederation Identifier: not configured
  Confederation Peers:
  Maximum Number of IP ECMP Paths Supported for Load Sharing: 1
  Number of Neighbors Configured: 1, UP: 1
  Number of Routes Installed: 4, Uses 344 bytes
  Number of Routes Advertising to All Neighbors: 2, Uses 88 bytes
  Number of Attribute Entries Installed: 4, Uses 376 bytes
  Neighbor Address  AS#        State   Time     Rt:Accepted Filtered Sent     ToSend
  10.1.1.2          10          ESTAB   0h 7m21s    2        0        2        0
```

Syntax: show ip bgp l2vpn vpls summary

TABLE 267 Output for the show ip bgp l2vpn vpls summary command

This field...	Displays
Router ID	The PowerConnect's router ID.
Local AS Number	The BGP4 AS number to which the router belongs.
Confederation Identifier	The AS number of the confederation to which the PowerConnect belongs.
Confederation Peers	The numbers of the local ASs contained in the confederation. This list matches the confederation peer list you configure on the PowerConnect.
Maximum Number of IP ECMP Paths Supported for Load Sharing	The maximum number of route paths across which the device can balance traffic to the same destination.
Number of Neighbors Configured	The number of BGP4 neighbors configured on this PowerConnect, and currently in established state.
Number of Routes Installed	The number of BGP4 routes in the router's BGP4 route table and the route or path memory usage.
Number of Routes Advertising to All Neighbors	The total of the RtSent and RtToSend columns for all neighbors and the amount of memory used by these routes.
Number of Attribute Entries Installed	The number of BGP4 route-attribute entries in the router's route-attributes table and the amount of memory used by these entries.
Neighbor Address	The IP addresses of this router's BGP4 neighbors.
AS#	The AS number.
State	Refer to "State" on page 1563.mmd
Time	The time that has passed since the state last changed.

TABLE 267 Output for the show ip bgp l2vpn vpls summary command (Continued)

This field...	Displays
Rt: Accepted	The number of routes received from the neighbor that this router installed in the BGP4 route table. Usually, this number is lower than the RoutesRcvd number. The difference indicates that this router filtered out some of the routes received in the UPDATE messages.
Filtered	The routes or prefixes that have been filtered out: • If soft reconfiguration is enabled, this field shows how many routes were filtered out (not placed in the BGP4 route table) but retained in memory. • If soft reconfiguration is not enabled, this field shows the number of BGP4 routes that have been filtered out.
Sent	The number of BGP4 routes that the PowerConnect has sent to the neighbor.
ToSend	The number of routes the PowerConnect has queued to send to this neighbor.

Displaying information about VPLS auto-discovery and load balancing

The **show mpls vpls name** command has changed. The total VC labels allocated field is no longer displayed in the output of the **show mpls vpls name** command.

To display detailed information about a specified VPLS name, enter the following command.

```
NetIron#show mpls vpls name c1
VPLS c1, Id 10, Max mac entries: 8192
 Total vlans: 0, Tagged ports: 0 (0 Up), Untagged ports 0 (0 Up)
 Total VPLS peers: 1 (0 Operational)
 auto-discovery enabled, RD 10:10
 export RT   10:10
 import RT   10:10
 Peer address: 2.2.2.2 (auto-discovered), State: Wait for functional local ports
  Tnnl in use: (load balance): None
  LDP session: Up, Local VC lbl: 983040, Remote VC lbl: N/A
  Local VC MTU: 1500, Remote VC MTU: 0
 CPU-Protection: OFF
 Local Switching: Enabled
```

Syntax: show mpls vpls name <*name*>

TABLE 268 Output for the show mpls vpls name command

This field...	Displays
VPLS	The configured name of the VPLS instance.
Id	The VCID of this VPLS instance.
Max mac entries	The maximum number of MAC address entries that can be learned for this VPLS instance. This is a soft limit only and can be exceeded if there is space available in the VPLS MAC database.
Total VLANs	The number of VLANs that are translated for this VPLS instance.

TABLE 268 Output for the show mpls vpls name command (Continued)

This field...	Displays
Tagged ports	The total number of tagged ports that are associated with VLANs in this VPLS instance, as well as the number of these ports that are up.
Untagged ports	The total number of untagged ports that are associated with VLANs in this VPLS instance, as well as the number of these ports that are up.
Total VPLS peers	The number of VPLS peers this device has for this VPLS instance, as well as the number of these VPLS peers with which this device has an LDP session.
auto-discovery enabled	Indicates that VPLS auto-discovery is enabled for this VPLS instance.
RD	The Route Distinguisher assigned to the VPLS instance.
export RT	The export route for the VPLS instance.
import RT	The import route for the VPLS instance.
Peer address	The IP address of the VPLS peer. When VPLS auto-discovery is enabled for the VPLS instance, "(auto-discovered)" appears after the IP address.
State	The current state of the connection with the VPLS peer. The VC label allocation is now managed by MPLS. This can be one of the following: • **Operational** – The VPLS instance is operational. Packets can flow between the device and the peer. • **Wait for functional local ports** – The physical endpoint port that should be connected to the Customer Edge device is down due to a link outage or is administratively disabled. • **Wait for LSP tunnel to Peer** – Cannot find a working tunnel LSP. • **Wait for LDP session to Peer** – The LDP session is not yet ready. • **Wait for PW Up (Wait for remote VC label)**– The device has advertised its VC label binding to the VPLS peer, but has not yet received the peer's VC label binding. • **Wait for PW Up (VC type mismatched)** – A session is not formed because the VC type does not match with its peer's VC type. • **Wait for PW Up (MTU mismatched)** – A session will not be formed and this message will be displayed. The MTU sent to a peer is derived from the router's global setting by the following formula: (system-mtu minus 26 bytes). If a system-mtu value is not configured, a default value of 1500 is sent. • **Wait for PW Up (Wait for LPD session to Peer) -** The LDP session to the peer is down. • **Wait for PW Up (No Label Resource)** - When configuring a new VPLS peer, the maximum amount of VC labels that can be supported may exceed 64K, and cause the configuration to be rejected.The maximum amount of VC labels available for VPLS instances is equal to 64K.
Tnnls in use	The tunnel LSP used to reach the VPLS peer. If VPLS traffic to the peer is load balanced across multiple tunnel LSPs, the tunnel LSPs used to reach the peer are displayed. When load balancing for auto-discovered VPLS peers is enabled for the VPLS instance, "(load balance)" also appears in this line.
LDP session	The state of the LDP session between this device and the VPLS peer.
Local VC lbl	The VC label value locally allocated for this peer for this VPLS instance. Packets forwarded from the VPLS peer to this device are expected to contain this label. This is the label that is advertised to the VPLS peer through LDP.
Remote VC lbl	The VC label allocated by the VPLS peer and advertised to this device through LDP. The device applies this label to outbound MPLS packets sent to the VPLS peer.
Local VC MTU	The MTU value locally configured for this peer.

TABLE 268 Output for the show mpls vpls name command (Continued)

This field...	Displays
Remote VC MTU	The MTU value configured for the remove VPLS peer.
CPU-protection	Indicates whether CPU protection is enabled (ON) or disabled (OFF) for this VPLS instance.
Local Switching	Indicates whether local switching is enabled or disabled for this VPLS instance.

Displaying information about LDP

To display information about LDP, including the router ID and loopback interface in use, enter the **show mpls ldp** command.

```
NetIron(config-lbif-1)#show mpls ldp
Label Distribution Protocol version 1
  LSR ID: 3.3.3.3, using Loopback 2 (deleting it will stop LDP)
  Hello interval: Link 5 sec, Targeted 15 sec
  Hold time value sent in Hellos: Link 15 sec, Targeted 45 sec
  Keepalive interval: 6 sec, Hold time multiple: 6 intervals
  Num VC FEC currently allocated: 0
```

Field definitions for the **show mpls ldp** command are in the section "Displaying the LDP version" on page 1428.

Syntax: **show mpls ldp**

IP over MPLS 35

Overview

One of the benefits that MPLS offers service providers is the ability to take advantage of MPLS traffic engineering capabilities to efficiently utilize the service provider network bandwidth, to control traffic placement, as well as to achieve fast network resiliency. This is accomplished through IP-over-MPLS features.

PowerConnect B-MLXe supports the following IP over MPLS features:

- IP over MPLS
- BGP Shortcut with optional LSP metrics
- IS-IS Shortcuts
- ECMP forwarding for IP over MPLS
- LDP Route Injection
- QoS Mapping Between IP Packets and MPLS
- Using Traffic Engineered LSPs Within an AS
- OSPF Shortcuts
- BGP Shortcut Enhancement

The following sections describe some of the procedures and considerations required when configuring a device to carry IP traffic over an MPLS network:

- "BGP shortcuts" – This feature directs BGP to resolve a route nexthop to a MPLS LSP when one is available.
- "LDP route injection" – This feature allows you to make selected customer routes available though LDP created LSP tunnels.
- "Using traffic-engineered LSPs within an AS" – This section describes how CoS values are determined for packets through an LSP.

BGP shortcuts

In a typical configuration, BGP considers only IP routes when building a routing table. If an MPLS network uses BGP to propagate routes, BGP must consider whether the MPLS tunnels are viable routes. The BGP shortcut feature forces BGP to use an MPLS tunnel as the preferred route to a destination network if one is available. You can also force BGP to include LSP metrics for best-route computations.

When configured on an MPLS edge router, BGP computes routes to destinations available through other edge routers. When BGP determines that a route is available through an edge router that is reachable through an MPLS tunnel, a BGP shortcut directs BGP to place the MPLS tunnel in the routing table as the preferred BGP route.

You can globally enable the BGP shortcut feature and optional inclusion of LSP metrics on a router. With the BGP shortcut feature enabled, the router first attempts to resolve BGP routes with an MPLS tunnel, and can optionally consider LSP metrics. If the BGP attempt at route resolution is unsuccessful, the router defaults to the IPv4 routing table.

Key algorithms

This section describes the behavior of the system in three contexts:

- **Next-hop MPLS disabled:** Only IP routing tables are used to resolve routes for the routing table.
- **Next-hop MPLS enabled:** LSP with a fixed metric of 1 is used to resolve the routes. For routes that cannot be resolved, the system uses the routing table.
- **Next-hop MPLS with LSP metric consideration:** When BGP resolves the next hop with LSP, it uses the LSP metric as the IGP cost for that next hop. If any of the possible paths are through an LSP, then only LSPs are chosen. The IGP cost of each next hop is then compared, and only IGP cost paths with the lowest values are considered for ECMP.

Native IP forwarding

If next-hop MPLS is disabled, BGP uses the default BGP decision process and native IP forwarding to build BGP EMCP routes.

Next-hop MPLS

For each unique BGP next hop, if next-hop MPLS is enabled, BGP first determines if an LSP can be used to resolve the route. If BGP can resolve the route, it does not check the native IP routing table.

For each BGP next hop, if the route is resolved by LSP, then all possible LSPs with the same lowest-metric value are selected. After this selection, BGP internally sets this next hop IGP cost to 1 (rather than the true LSP metric) to force it to be the preferred hop over a hop resolved by native IP.

For each BGP next hop, the IGP cost is compared, and the least-value IGP cost for the next hop or hops are used to install them in the routing table.

When the router installs a BGP route in the RTM, it uses a BGP metric, not the IGP metric (IGP cost.)

Next-hop MPLS comparing LSP metrics

With the option enabled to compare LSP metrics, after BGP resolves a next hop with LSP, it uses the LSP metric as the IGP cost for that next hop. Thereafter, all of the next hops IGP costs are compared, and only the IGP cost paths with the lowest values are considered for ECMP. If any of these paths is an LSP, then only LSP paths are taken.

You have the flexibility to choose a native IP path over an LSP path if they have different BGP next-hops, and the native IP path has a lower IGP cost.

NOTE
Enabling or disabling the LSP metric option takes effect immediately: BGP automatically recalculates the existing BGP routes.

To configure BGP shortcuts and optionally compare LSP metrics, use the **next-hop-mpls** command in BGP configuration mode, as in the following example.

```
NetIron(config)# router bgp
NetIron(config-bgp)# next-hop-mpls compare-lsp-metric
```

Syntax: [no] next-hop-mpls [compare-lsp-metric]

For the next-hop-mpls command, when you use the no form with the optional compare-lsp-metric parameter, only this optional parameter is deleted, so the global next-hop MPLS enable remains the same. To disable both the optional LSP-metric compare and the global next-hop MPLS, use the no form of the command but without the optional compare-lsp-metric parameter.

Examples of next-hop MPLS

This section illustrates how to configure a BGP shortcut by enabling next-hop MPLS. It also illustrates the optional parameter—the consideration of LSP metrics:

- Enabling next-hop MPLS (LSP metric becomes fixed at 1)
- Enabling compare-LSP-metric (so IGP metric is compared with user-configurable LSP metric)
- Disabling next-hop MPLS

Enable next-hop MPLS using the next-hop-mpls command, as the following example illustrates. The follow-up show command of the running configuration indicates the global enabling of this feature.

```
NetIron(config-bgp)#next-hop-mpls
NetIron(config-bgp)#show ip bgp config
Current BGP configuration:
router bgp
 local-as 10
 neighbor 10.1.1.2 remote-as 20
 neighbor 20.1.1.2 remote-as 20
 address-family ipv4 unicast
 next-hop-mpls
 exit-address-family
 address-family ipv4 multicast
 exit-address-family
 address-family ipv6 unicast
 exit-address-family
```

Syntax: [no] next-hop-mpls [compare-lsp-metric]

Enable the router to use the compare LSP metric. The running configuration reflects the global configuration on one line.

```
NetIron(config-bgp)#next-hop-mpls compare-lsp-metric
NetIron(config-bgp)#show ip bgp config
Current BGP configuration:
router bgp
 local-as 10
 neighbor 10.1.1.2 remote-as 20
 neighbor 20.1.1.2 remote-as 20
 address-family ipv4 unicast
 next-hop-mpls compare-lsp-metric
 exit-address-family
 address-family ipv4 multicast
 exit-address-family
 address-family ipv6 unicast
 exit-address-family
```

Syntax: [no] next-hop-mpls [compare-lsp-metric]

This series of examples shows how an IP-only routing table resolution for BGP is affected first by the enabling of next-hop MPLS and then by the enabling of LSP-metric comparison. The tasks for these examples are:

- Specify metrics for three LSPs. The existing LSPs in this example are to2, to22, and to2_sec. As a precondition for this example, their metrics are changed to 10, 20, and 10.
- Enable BGP ECMP, then check the routing table. The destination IP address for this example is 8.8.8.1/32. The routing table shows that native IP-forwarding is used.
- Enable next-hop MPLS and observe the effect on the route to 8.8.8.1/32.
- Enable LSP-metric comparison and note that, because of the metric for LSP to22, it has no effect on the routing table.
- Change the metric for an LSP (to2 in this example).
- Disable LSP-metric compare and check the consequences.
- Disable global next-hop MPLS

Specifying metrics

This step specifies metrics for three LSPs.

```
NetIron(config-bgp)#router mpls
NetIron(config-mpls)#lsp to2
NetIron(config-mpls-lsp-to2)#disable
NetIron(config-mpls-lsp-to2)#to 10.1.1.2
NetIron(config-mpls-lsp-to2)#from 10.1.1.1
NetIron(config-mpls-lsp-to2)#metric 10
NetIron(config-mpls-lsp-to2)#enable
Connecting signaled LSP to2
exit
....
NetIron(config-mpls)#lsp to22
NetIron(config-mpls-lsp-to22)#disable
NetIron(config-mpls-lsp-to22)#to 10.1.1.2
NetIron(config-mpls-lsp-to22)#from 10.1.1.1
NetIron(config-mpls-lsp-to22)#metric 20
NetIron(config-mpls-lsp-to22)#enable
Connecting signaled LSP to22
exit
....
NetIron(config-mpls)#lsp to2_sec
NetIron(config-mpls-lsp-to2_sec)#diable
NetIron(config-mpls-lsp-to2_sec)#to 20.1.1.2
NetIron(config-mpls-lsp-to2_sec)#from 20.1.1.1
NetIron(config-mpls-lsp-to2_sec)#metric 10
NetIron(config-mpls-lsp-to2_sec)#enable
Connecting signaled LSP to2_sec
exit
NetIron(config-mpls)#show mpls lsp
                              Admin Oper  Tunnel   Up/Dn Retry Active
Name           To             State State Intf     Times No.   Path
to2            10.1.1.2       UP    UP    tnl0     1     0     --
to2_sec        20.1.1.2       UP    UP    tnl2     1     0     --
to22           10.1.1.2       UP    UP    tnl1     1     0     --
```

Syntax: [**no**]**metric** <*num*>

Enable BGP ECMP

This example shows BGP ECMP being enabled and the check of the routing table manager (RTM) by the **show ip route** command. The destination for this example is 8.8.8.8/32, and native IP forwarding is in effect.

```
NetIron(config-mpls)#router bgp
NetIron(config-bgp)#maximum 5
NetIron(config-bgp)#show ip route
Total number of IP routes: 5
Type Codes - B:BGP D:Connected I:ISIS O:OSPF R:RIP S:Static; Cost - Dist/Metric
ISIS Codes - L1:Level-1 L2:Level-2
OSPF Codes - i:Inter Area 1:External Type 1 2:External Type 2 s:Sham Link
        Destination        Gateway         Port        Cost          Type Uptime

5       8.8.8.2/32         10.1.1.2        eth 1/1     20/0          B    0m1s
        8.8.8.2/32         20.1.1.2        eth 1/2     20/0          B    0m1s
```

Enable next-hop MPLS

In this example, the next-hop MPLS is enabled, and the **show ip route** command is used to check the RTM.

```
NetIron(config-bgp)#next-hop-mpls
NetIron(config-bgp)#show ip route
Total number of IP routes: 4
Type Codes - B:BGP D:Connected I:ISIS O:OSPF R:RIP S:Static; Cost - Dist/Metric
ISIS Codes - L1:Level-1 L2:Level-2
OSPF Codes - i:Inter Area 1:External Type 1 2:External Type 2 s:Sham Link
        Destination        Gateway         Port        Cost          Type Uptime
1       1.1.1.1/32         DIRECT          loopback 1  0/0           D    10m4s
2       2.2.3.3/32         DIRECT          loopback 2  0/0           D    10m4s
3       5.5.5.5/32         10.1.1.10       eth 1/1     1/1           S    9m53s
4       8.8.8.1/32         10.1.1.2        lsp to2     20/0          B    0m1s
        8.8.8.1/32         20.1.1.2        lsp to2_sec 20/0          B    0m1
5       8.8.8.2/32         10.1.1.2        lsp to2     20/0          B    0m1s
        8.8.8.2/32         20.1.1.2        lsp to2_sec 20/0          B    0m1s
```

Syntax: [no] **next-hop-mpls** [**compare-lsp-metric**]

Enable LSP-metric comparison

For this example, LSP-metric comparison is enabled and the consequences are checked in the RTM. In this case, LSPs to2 and to2_sec already provide the best route, so this display does not differ from the example in which next-hop MPLS is enabled. Note that to22 is not displayed because its metric is 20, but the metric of to2 (to the same destination) is only 10 and so represents the chosen LSP.

```
NetIron(config-bgp)# next-hop-mpls compare-lsp-metric
NetIron(config-bgp)# show ip route
Total number of IP routes: 5
Type Codes - B:BGP D:Connected I:ISIS O:OSPF R:RIP S:Static; Cost - Dist/Metric
ISIS Codes - L1:Level-1 L2:Level-2
OSPF Codes - i:Inter Area 1:External Type 1 2:External Type 2 s:Sham Link
        Destination        Gateway         Port        Cost          Type Uptime
1       1.1.1.1/32         DIRECT          loopback 1  0/0           D    11m30s
2       2.2.3.3/32         DIRECT          loopback 2  0/0           D    11m30s
3       5.5.5.5/32         10.1.1.10       eth 1/1     1/1           S    11m19s
4       8.8.8.1/32         10.1.1.2        lsp to2     20/0          B    0m1s
        8.8.8.1/32         20.1.1.2        lsp to2_sec 20/0          B    0m1s
5       8.8.8.2/32         10.1.1.2        lsp to2     20/0          B    0m1s
        8.8.8.2/32         20.1.1.2        lsp to2_sec 20/0          B    0m1s
```

Syntax: [no] next-hop-mpls [compare-lsp-metric]

Changing the metric for an LSP

In the next example, the metric for LSP to2 is changed to a value (20) that causes the system to remove it from the routing table, so only LSP to2_sec to 8.8.8.1/32 remains. This output illustrates this result.

```
NetIron(config-mpls)# lsp to2
NetIron(config-mpls-lsp-to2)# disconnect
Disconnecting signaled LSP
NetIron(config-mpls-lsp-to2)# metric 20
NetIron(config-mpls-lsp-to2)# enable
Connecting signaled LSP to2
NetIron(config-mpls)# show ip route
Total number of IP routes: 5
Type Codes - B:BGP D:Connected I:ISIS O:OSPF R:RIP S:Static; Cost - Dist/Metric
ISIS Codes - L1:Level-1 L2:Level-2
OSPF Codes - i:Inter Area 1:External Type 1 2:External Type 2 s:Sham Link
        Destination        Gateway         Port        Cost          Type Uptime
1       1.1.1.1/32         DIRECT          loopback 1  0/0           D    12m23s
2       2.2.3.3/32         DIRECT          loopback 2  0/0           D    12m23s
3       5.5.5.5/32         10.1.1.10       eth 1/1     1/1           S    12m12s
4       8.8.8.1/32         20.1.1.2        lsp to2_sec 20/0          B    0m6s
5       8.8.8.2/32         20.1.1.2        lsp to2_sec 20/0          B    0m6s
```

Disabling LSP-metric compare and checking the consequences

For the last example related to next-hop MPLS, disable LSP-metric compare using the **no** form of the **next-hop-mpls** command and include the **compare-lsp-metric** option.

NOTE

When you use the **no** form with the optional **compare-lsp-metric** parameter for the **next-hop-mpls** command, only this optional parameter is deleted, so global next-hop-mpls enable remains the same. To disable both the optional LSP-metric compare and the global next-hop-mpls, use the **no** form of the **next-hop-mpls** command without the optional parameter.

Because global next-hop MPLS remains enabled and the LSP metrics are no longer a factor, all the LSPs are displayed in the routing table since BGP considers them to have equal cost.

```
NetIron(config-bgp)# no next-hop-mpls compare-lsp-metric
NetIron(config-bgp)# show ip route
Total number of IP routes: 5
Type Codes - B:BGP D:Connected I:ISIS O:OSPF R:RIP S:Static; Cost - Dist/Metric
ISIS Codes - L1:Level-1 L2:Level-2
OSPF Codes - i:Inter Area 1:External Type 1 2:External Type 2 s:Sham Link
        Destination        Gateway         Port        Cost          Type Uptime
1       1.1.1.1/32         DIRECT          loopback 1  0/0           D    12m58s
2       2.2.3.3/32         DIRECT          loopback 2  0/0           D    12m58s
3       5.5.5.5/32         10.1.1.10       eth 1/1     1/1           S    12m47s
4       8.8.8.1/32         10.1.1.2        lsp to2     20/0          B    0m1s
        8.8.8.1/32         10.1.1.2        lsp to22    20/0          B    0m1s
        8.8.8.1/32         20.1.1.2        lsp to2_sec 20/0          B    0m1s
5       8.8.8.2/32         10.1.1.2        lsp to2     20/0          B    0m1s
        8.8.8.2/32         10.1.1.2        lsp to22    20/0          B    0m1s
        8.8.8.2/32         20.1.1.2        lsp to2_sec 20/0          B    0m1s
```

Syntax: [no] next-hop-mpls [compare-lsp-metric]

Disabling global next-hop MPLS

Disable global next-hop MPLS and check the RTM to see that native IP-forwarding has been restored.

```
NetIron(config-bgp)# no next-hop-mpls
NetIron(config-bgp)# show ip route
Total number of IP routes: 5
Type Codes - B:BGP D:Connected I:ISIS O:OSPF R:RIP S:Static; Cost - Dist/Metric
ISIS Codes - L1:Level-1 L2:Level-2
OSPF Codes - i:Inter Area 1:External Type 1 2:External Type 2 s:Sham Link
        Destination        Gateway         Port        Cost          Type Uptime
1       1.1.1.1/32         DIRECT          loopback 1  0/0           D    9m46s
2       2.2.3.3/32         DIRECT          loopback 2  0/0           D    9m46s
3       5.5.5.5/32         10.1.1.10       eth 1/1     1/1           S    9m35s
4       8.8.8.1/32         10.1.1.2        eth 1/1     20/0          B    0m1s
        8.8.8.1/32         20.1.1.2        eth 1/2     20/0          B    0m1s
5       8.8.8.2/32         10.1.1.2        eth 1/1     20/0          B    0m1s
        8.8.8.2/32         20.1.1.2        eth 1/2     20/0          B    0m1s
```

Syntax: [no] next-hop-mpls [compare-lsp-metric]

LDP route injection

An MPLS edge router is typically connected to a customer network that is not configured for MPLS. If the edge router is then connected to the MPLS core through LSP tunnels that have been created by LDP, only routes to the loopback address of the edge router are available for routing through the LSP tunnels. In practice, this means that routes to and from the customer network are unavailable to the MPLS network.

The LDP route injection feature allows you to make routes available from the customer network through LSPs that have been created by LDP. You can filter routes that you want to allow through the MPLS network using an ACL, and then apply that ACL to the **advertise-labels for** command. The routes injected will then be accessible over the MPLS network.

To direct the device to inject non-loopback routes into LDP while restricting the routes injected through reference to an ACL, enter the following command.

```
NetIron(config)# router mpls
NetIron(config-mpls)# ldp
NetIron(config-mpls-ldp)# advertise-labels for 30
```

Syntax: advertise-labels for <*access-list*>

The <*access-list*> variable refers to the number of the access list that filters for the routes you want to use for label binding.

Considerations when using LDP route injection

1. You can directly change the LDP route injection filter without deleting a previously configured one. The change automatically applies and triggers LDP route re-injections.
2. Any change to a referenced ACL automatically applies to LDP route injection filtering and triggers LDP route re-injection.
3. If no LDP route injection filter is configured, by default LDP acquires all local loopback addresses.
4. If the ACL referenced by the LDP route injection filter is not configured, it is an implicit deny. All local routes are denied.
5. Both number-based and name-based ACLs can be used. Because only prefix-based filtering is applied, use of a standard ACL is preferred.
6. The LDP route injection filter is only applied on local route injection. Learned remote binding is not filtered.

LDP route injection example

This example describes how to use LDP route injection to inject routes 1.2.2.2/32 and 5.5.5.2/32 into the LDP label information database.

1. the **show ip interface** command displays IP addresses of loopback interfaces in router MLXe-1.

```
MLXe-1# show ip interface
Interface       IP-Address      OK?  Method    Status    Protocol  VRF
eth 1/1         20.0.0.1        YES  NVRAM     up        up        default
eth 1/2         120.0.0.1       YES  NVRAM     up        up        default
loopback 3      3.3.3.3         YES  NVRAM     up        up        default
loopback 5      5.5.5.5         YES  manual    up        up        default
```

2. By default, the LDP label information database only contains labels learned for IP addresses of loopback interfaces, as demonstrated in this example, where only prefixes 3.3.3.3/32 and 5.5.5.5/32 are displayed by the **show mpls ldp database** command.

```
MLXe-1# show mpls ldp database
Session 3.3.3.3:0 - 5.5.5.2:0
 Downstream label database:
   Label     Prefix              State
   1024      3.3.3.3/32          Retained
 Upstream label database:
   Label     Prefix
   3         3.3.3.3/32
   3         5.5.5.5/32
```

3. The **show ip route** command displays routes available to ports on router MLXe-1.

```
MLXe-1# show ip route
Total number of IP routes: 9
 Type Codes - B:BGP  D:Connected  S:Static  R:RIP  O:OSPF;   Cost - Dist/Metr
       Destination        Gateway         Port        Cost       Type
1      1.2.2.2/32         20.0.0.2        eth 1/1     1/1        S
2      3.3.3.3/32         DIRECT          loopback 3  0/0        D
3      5.5.5.0/24         20.0.0.2        eth 1/1     1/1        S
4      5.5.5.1/32         20.0.0.2        eth 1/1     1/1        S
5      5.5.5.2/32         20.0.0.2        eth 1/1     110/2      O
6      5.5.5.5/32         DIRECT          loopback 5  0/0        D
7      5.5.6.2/32         20.0.0.2        eth 1/1     1/1        S
8      20.0.0.0/24        DIRECT          eth 1/1     0/0        D
9      120.0.0.0/24       DIRECT          eth 1/2     0/0        D
```

4. In this example, a filter is configured to inject route 1.2.2.2/32.

```
MLXe-1(config)# access-list 30 permit 1.2.2.2/32
MLXe-1(config)# router mpls
MLXe-1(config-mpls)# ldp
MLXe-1(config-mpls-ldp)# advertise for 30
```

5. As shown, the 1.2.2.2/32 has been injected into the LDP Label information database.

```
MLXe-1# show mpls ldp database
Session 3.3.3.3:0 - 5.5.5.2:0
 Downstream label database:
   Label     Prefix              State
 Upstream label database:
   Label     Prefix
   3         1.2.2.2/32
```

6. In this example a second filter is configured to inject route 5.5.5.2/32.

```
MLXe-1(config)#access-list 30 permit 5.5.5.2/32
```

7. As shown, route 5.5.5.2/32 has been injected into the LDP label information database.

```
MLXe-1(config)# show mpls ldp database
Session 3.3.3.3:0 - 5.5.5.2:0
 Downstream label database:
   Label     Prefix              State
 Upstream label database:
   Label     Prefix
   3         1.2.2.2/32
   3         5.5.5.2/32
```

Displaying routes through LSP tunnels

Once a network has been enabled to allow routes through LSP tunnels, the routes will appear in the IP routing table. In the following example, the **show ip route** command displays a table that contains routes through LSP tunnels. In this example, routes 7 - 8 and 10 - 14 are LDP tunnels.

```
NetIron# show ip route
Total number of IP routes: 1027
 Type Codes - B:BGP  D:Connected  S:Static  R:RIP  O:OSPF;   Cost -
Dist/Metric
        Destination        Gateway         Port        Cost       Type
1       1.1.1.1/32         DIRECT          loopback 1  0/0        D
2       1.1.2.1/32         DIRECT          loopback 2  0/0        D
3       1.1.3.1/32         DIRECT          loopback 3  0/0        D
4       2.2.2.2/32         11.0.0.2        eth 1/1     110/10     O
5       3.3.3.3/32         11.0.0.2        eth 1/1     110/12     O
        3.3.3.3/32         11.8.0.2        eth 1/4     110/12     O
6       4.4.4.4/32         11.8.0.2        eth 1/4     110/10     O
7       5.5.1.5/32         5.5.5.5         lsp(LDP)    200/0      B
8       5.5.3.5/32         5.5.5.5         lsp(LDP)    200/0      B
9       5.5.5.5/32         11.0.0.2        eth 1/1     110/13     O
        5.5.5.5/32         11.8.0.2        eth 1/4     110/13     O
10      6.6.1.6/32         6.6.6.6         lsp(LDP)    200/0      B
11      6.6.2.6/32         6.6.6.6         lsp(LDP)    200/0      B
12      6.6.3.6/32         6.6.6.6         lsp(LDP)    200/0      B
13      6.6.4.6/32         6.6.6.6         lsp(LDP)    200/0      B
14      6.6.5.6/32         6.6.6.6         lsp(LDP)    200/0      B
15      6.6.6.6/32         11.0.0.2        eth 1/1     110/14     O
        6.6.6.6/32         11.8.0.2        eth 1/4     110/14     O
```

Using traffic-engineered LSPs within an AS

In addition to traffic destined to travel outside an AS, Dell routers can forward internal AS traffic into LSP tunnels. This feature allows you to configure a signalled LSP to serve as a shortcut between nodes in an AS. In a shortcut LSP, OSPF includes the LSP in the SPF calculation. If OSPF determines that the LSP shortcut is the best path to a destination, it installs a route into the IP routing table, specifying the LSP tunnel interface as the outbound interface, as well as the coxt of the LSP. Only LSPs configured to router IDs can be considered as shortcuts. If the LSP goes down or is administratively disabled, the LSP tunnel route is removed from the main routing table.

The cost of the LSP is the user-configured metric for the LSP. If there is no user-configured metric, the underlying IP cost of the LSP is used. For example, if the IP cost of the best underlying path between two routers is 2, and there is an LSP configured between these two routers, the cost of the LSP is 2. Once an LSP is used as a next hop for a destination, the cost of the LSP can be used to calculate other destinations that can use the LSP egress node as next hop. This allows traffic for addresses downstream from the LSP egress node (including prefixes of the egress node) to use the LSP shortcut.

If OSPF is already using an LSP tunnel route to an Area Border Router (ABR), all inter-area routes through that ABR use the LSP as the next hop, provided there are no other better paths to the destination (paths through other ABRs). An LSP to a destination outside an area is not used by OSPF in the calculation of inter-area routes.

Only signalled LSPs can be used as OSPF shortcuts. RSVP packets, used to establish and maintain signalled LSPs, are never forwarded into LSP tunnels.

Refer to “Creating OSPF shortcuts over an LSP tunnel” on page 1585 for more information.

IS-IS shortcuts over an LSP tunnel

Refer to "IS-IS shortcuts" on page 1586 for details about creating IS-IS shortcuts over an LSP tunnel.

Creating OSPF shortcuts over an LSP tunnel

This feature allows you to forward traffic to destinations within an OSPF routing domain through an LSP tunnel, which optimizes available bandwidth by choosing LSPs where multiple paths exist to the same OSPF destination. When an LSP is configured as an OSPF shortcut, OSPF includes the LSP in the SPF calculation. If OSPF determines that the LSP shortcut is the best path to a destination, it adds a route to the IP routing table, specifying the LSP tunnel interface as the outbound interface, along with the cost of the LSP. Only LSPs configured to router ID are considered as shortcuts. If the LSP goes down or is administratively disabled, or the **shortcuts ospf** command is removed from the configuration, the LSP tunnel route is removed from the main routing table.

LSPs used for this feature must originate and terminate within the same OSPF area. When configured, OSPF directs routes that are reachable from the egress router of a shortcut-enabled LSP to an LSP tunnel as the outgoing interface.

To configure this feature, point the LSP to the router ID of the egress router where traffic will be forwarded. You must also configure the LSP with the **shortcuts ospf** command.

The following configuration of LSP "tunnel1" specifies the egress router with a router ID of 2.2.2.2 and enables it for OSPF shortcuts.

```
NetIron(config)# router mpls
NetIron(config-mpls)# lsp tunnel1
NetIron(config-mpls-lsp)# to 2.2.2.2
NetIron(config-mpls-lsp)# shortcuts ospf
NetIron(config-mpls-lsp)# enable
```

Syntax: [no] **shortcuts ospf**

This feature points OSPF routes to routes from the configured egress router of the LSP tunnel. By way of the LSP interface, the ingress router points to routes on the egress router (including downstream external or summary routes). To view these routes, enter the **show ip route** command as shown in the following example.

```
NetIron# show ip route
Total number of IP routes: 5
Type Codes - B:BGP D: Connected I:ISIS S: Static R:RIP O: OSPF; Cost - Dist/Metri
       Destination        Gateway        Port          Cost       Type

1      2.2.2.0/24         2.2.2.2        lsp tunnel1   110/10     O2
2      5.5.5.0/24         11.1.1.2       eth 1/1       110/2      O
3      15.15.15.15/32     3.3.3.3        lsp l1        110/10     O2
4      78.0.0.0/8         11.1.1.2       eth 1/1       110/10     O2
5      192.85.1.0/24      11.1.1.2       eth 1/1       110/2      O
```

In this example, Type "O2" routes are OSPF routes from outside the OSPF area.

You can set the next hop for a static route to the egress router of an LSP tunnel if the destination route is contained in the MPLS routing table, as described in "Static route to an LSP tunnel interface" on page 727.

IS-IS shortcuts

This section describes IS-IS shortcuts and how to configure them on an MPLS router with traffic engineering (TE) capabilities.

Overview

The IS-IS Shortcuts feature enables an MPLS TE path (LSP tunnel) to serve as a shortcut through the network to a destination based on the cost of the path (metric). Traffic is forwarded through the LSP tunnel to destinations within the IS-IS routing domain. This feature helps optimize available bandwidth by choosing paths using LSPs where multiple paths exist to the same destination.

When IS-IS shortcuts are enabled on an LSP tunnel, IS-IS includes the LSP in the SPF calculation. If IS-IS determines that the LSP shortcut is the best path to a destination, it adds the route to the IP routing table, specifying the LSP tunnel interface as the outbound interface, including the cost of the LSP. Only LSPs configured to a router ID are considered as shortcuts. If the LSP goes down or is administratively disabled, or if the **shortcuts isis** command is removed from the configuration, the IS-IS LSP tunnel routes are removed from the main routing table.

Determining the cost of an IS-IS shortcut

IS-IS uses the following information to determine the cost of an IS-IS shortcut:

- The ***announce metric***, if announce is enabled
- If announce is not enabled, IS-IS uses the LSP metric configured under the LSP configuration mode, for example:

  ```
  NetIron(config-mpls-lsp)#metric <value>
  ```

- If no LSP metric is configured, IS-IS uses the native IGP cost, plus or minus the ***relative metric***
- If there is no relative metric, IS-IS uses the native IGP cost

The announce metric and relative metric are described in detail in the following sections.

The announce metric

When IS-IS shortcuts are enabled on an LSP tunnel, the MPLS router does not announce (advertise) the IS-IS shortcuts unless specifically configured to do so. When announce is enabled, you can optionally specify an announce metric, which is used to compute the LSP cost of the IS-IS shortcut. If an announce metric is not explicitly configured, IS-IS uses a default metric value of 10.

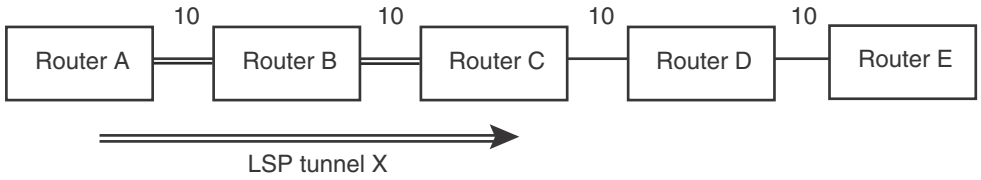
To configure an announce metric for IS-IS shortcuts, refer to "“Configuring the announce metric” on page 1589".

The relative metric

When announce is not enabled and an LSP metric is not explicitly configured under the LSP configuration mode of the CLI, the ***relative metric*** is used to compute the LSP cost, which is the native IGP cost, plus or minus the relative metric.

The relative metric is optionally specified when IS-IS shortcuts are enabled, and is used to make an LSP tunnel less or more preferred over other paths. The default relative metric value is zero (0), but can be configured to be a positive or negative number. A positive number disables an LSP tunnel from participating in the SPF calculation. A negative number ensures that the LSP tunnel is preferred over native IGP paths in the SPF calculation. Figure 201 shows an example of this configuration.

FIGURE 201 SPF calculation adjustment using the relative metric



In this example, if there are no IS-IS shortcuts, Router A adds routes in the routing table for routers C, D, and E with the metrics 20, 30, and 40, respectively. If an IS-IS shortcut is configured on LSP tunnel X and the relative metric is –5 (minus 5), router A installs the same routes in the routing table with the metrics 15, 25, and 35, respectively, over the LSP tunnel X.

To configure the device to use a relative metric value other than 0, refer to "Configuring the relative metric" on page 1589.

Why LSP tunnels may be excluded from the SPF calculation

LSP tunnels may be excluded in SPF calculations in the following cases:

- The system did not find mapping between the LSP tunnel destination (the To address) and the IS-IS system ID.
- There is no IS-IS native route to the LSP tunnel destination.
- The IS-IS native route has a better metric than the LSP tunnel.
- Another shortcut has a better metric than the LSP tunnel.

Configuration notes

Consider the following configuration notes:

- IS-IS shortcuts require MPLS and IS-IS Traffic Engineering (TE) to be enabled. For details about IS-IS TE, refer to "IS-IS Link State Protocol data units with TE extensions for MPLS interfaces" on page 1299. To enable IS-IS TE, refer to "Enabling IS-IS LSPs with TE extensions for MPLS interfaces" on page 1322.
- IS-IS does not use an LSP tunnel as a shortcut if the To address of the tunnel is not the router ID of the destination router.
- Where multiple IS-IS shortcuts have the same cost, IS-IS installs LSP tunnel-based ECMP routes.

Configuration tasks

It is recommended that you perform the configuration tasks in the order listed in Table 269.

TABLE 269 Configuration tasks for IS-IS shortcuts

Configuration task		Default behavior	See...
1	Enable IS-IS shortcuts	Disabled	"Enabling and disabling IS-IS shortcuts"
2	Optionally enable announce on the LSP	Disabled	"Enabling IS-IS shortcut advertisements"
3	If announce is enabled, optionally configure the announce metric	When announce is enabled, the system uses either the default metric value of 10, or the explicitly-configured announce metric value.	"Configuring the announce metric"
4	Optionally configure the relative metric	The default value is 0 (zero).	"Configuring the relative metric"

After performing the configuration steps listed in Table 269, you can observe the IS-IS routes that use IGP shortcuts. For more information, refer to "Show command support" on page 1593.

Enabling and disabling IS-IS shortcuts

To enable IS-IS shortcuts on an LSP tunnel, enter commands such as the following, starting at the MPLS level of the CLI.

```
NetIron MLX(config-mpls)# lsp tomu3
NetIron MLX(config-mpls-lsp-tomu3)# shortcuts isis level2
NetIron MLX(config-mpls-lsp-tomu3)# enable
Connecting signaled LSP tomu3
```

These commands enable IS-IS shortcuts on the **tomu3** LSP tunnel.

Syntax: [**no**] **shortcuts isis level1** | **level 2**

Enter the **no** form of the command to disable IS-IS shortcuts.

The **level1** or **level2** keyword is required and indicates the level of IS-IS routing enabled on the device. The levels are:

- level1 – A level1 router routes traffic only within the area that includes the router. To forward traffic to another area, a level1 router sends the traffic to the nearest level2 router.
- level2 – A level2 router routes traffic between areas within a domain.

NOTE
The IS-IS traffic engineering level should match the shortcut level configuration.

Enabling IS-IS shortcut advertisements

When announce is enabled, the tunnel information is advertised in an IS neighbor TLV, which is stored in the IS-IS database.

To enable announce, enter the following command on an LSP that is not yet enabled.

```
NetIron MLX(config-mpls-lsp-tomu3)# shortcuts isis level2 announce
```

If the tunnel is enabled, disable it before enabling announce, then re-enable the tunnel. For example.

```
NetIron MLX(config-mpls-lsp-tomu3)# disable
Disconnecting signaled LSP tomu3
NetIron MLX(config-mpls-lsp-tomu3)# shortcuts isis level2 announce
NetIron MLX(config-mpls-lsp-tomu3)# enable
Connecting signaled LSP tomu3
```

These commands enable the system to advertise IS-IS shortcuts. Since an announce metric is not explicitly specified in this example, IS-IS uses the default announce metric of 10. To configure an announce metric other than 10, refer to "Configuring the announce metric".

Syntax: [no] **shortcuts isis level1** | **level2 announce**

Enter the **no** form of the command to disable advertisement of IS-IS shortcuts. IS-IS shortcuts are still enabled, but will no longer be advertised in the IS-IS database.

Configuring the announce metric

The announce metric is described in "The announce metric" on page 1586.

To configure an announce metric, enter a command such as the following at the MPLS LSP level of the CLI.

```
NetIron MLX(config-mpls-lsp-tomu3)# shortcuts isis level2 announce
announce-metric 20
```

Syntax: [no] **shortcuts isis level1** | **level2 announce announce-metric** <*num*>

Enter the **no** form of the command to return to the default announce metric value of 10. IS-IS shortcuts will still be enabled, however the **no** form of the command simply reverts to the default announce metric.

For <*num*>, enter a value from 1 – 16777215. The default is 10.

The announce metric is displayed in the output of the **show isis shortcuts** command. If the LSP tunnel is not announced, a – (dash) is displayed in the announce metric field.

Configuring the relative metric

The relative metric is described in "The relative metric" on page 1586.

If announce is not enabled and a metric is not explicily configured under the LSP configuration mode of the CLI, the ***relative metric*** is used to compute the shortcut cost.

To configure the relative metric, enter a command such as the following at the MPLS LSP level of the CLI.

```
NetIron MLX(config-mpls-lsp-tomu3)# shortcuts isis level2 relative-metric -5
```

This command sets the relative metric value to -5. The LSP cost is determined by subtracting 5 from the native IGP cost to reach the tunnel destination. Using this example, if the native IGP cost is 10, the relative metric value -5 sets the LSP cost to 5.

NOTE
The shortcut cost will never be a value less than 1. For example, if the native IGP cost is 10 and the relative metric is -15, the shortcut cost will be 1, not -5.

Syntax: [no] **shortcuts isis level1** | **level2 relative-metric +** | **–** <*num*>

Enter the **no** form of the command to return to the default native IGP path metric. IS-IS shortcuts will still be enabled. The **no** form of the command simply removes the relative-metric value from the configuration.

The **+** or **–** sign is required. **+** denotes a positive number. – denotes a negative number.

For <*num*>, enter a value from 1 – 16777215. The default is 0 (zero).

The metric used in the SPF calculation is displayed in the output of the **show isis shortcuts** command. If the LSP tunnel is not used in the SPF calculation, a – (dash) is displayed in the SPF metric field.

Example configurations

This section includes example configurations and relevant **show** command outputs both before and after IS-IS shortcuts are enabled.

The following display shows an IS-IS route configuration *before* IS-IS shortcuts are installed.

NOTE
For a description of the output fields, refer to "Displaying the IP route table" on page 763 in 19, "Configuring IP".

```
PowerConnect(config-mpls-lsp-tomu3)# show ip route isis
Type Codes - B:BGP D:Connected I:ISIS O:OSPF R:RIP S:Static; Cost - Dist/Metric
ISIS Codes - L1:Level-1 L2:Level-2
OSPF Codes - i:Inter Area 1:External Type 1 2:External Type 2 s:Sham Link
        Destination        Gateway         Port        Cost          Type Uptime

1       0.0.0.0/0          10.1.1.2        eth 1/1     115/21        IL2  0m23s
2       20.1.1.0/24        10.1.1.2        eth 1/1     115/20        IL2  0m23s
3       30.1.1.0/24        10.1.1.2        eth 1/1     115/10        IL2  0m23s
4       40.1.1.1/32        10.1.1.2        eth 1/1     115/10        IL2  0m23s
5       40.2.2.2/32        10.1.1.2        eth 1/1     115/10        IL2  0m23s
6       100.1.0.0/16       DIRECT          drop        115/10        IL1  3m37s
7       200.1.1.1/32       10.1.1.2        eth 1/1     115/20        IL2  0m23s
```

The following example shows IS-IS shortcut configuration.

```
NetIron MLX(config-mpls)# lsp tomu3
NetIron MLX(config-mpls-lsp-tomu3)# metric 1
NetIron MLX(config-mpls-lsp-tomu3)# shortcuts isis level2
NetIron MLX(config-mpls-lsp-tomu3)# enable
Connecting signaled LSP tomu3
```

The following display shows the IS-IS route configuration *after* the shortcut configuration is applied. The bold text indicates that the routes are now using shortcuts. Compare this output with the output generated before the shortcut configuration was applied.

```
mu1(config-mpls)# show ip route isis
Type Codes - B:BGP D:Connected I:ISIS O:OSPF R:RIP S:Static; Cost - Dist/Metric
ISIS Codes - L1:Level-1 L2:Level-2
OSPF Codes - i:Inter Area 1:External Type 1 2:External Type 2 s:Sham Link
        Destination        Gateway         Port        Cost          Type Uptime

1       0.0.0.0/0          30.1.1.1        lsp tomu3   115/2         IL2  0m2s
2       20.1.1.0/24        30.1.1.1        lsp tomu3   115/11        IL2  0m2s
3       30.1.1.0/24        30.1.1.1        lsp tomu3   115/1         IL2  0m2s
4       40.1.1.1/32        30.1.1.1        lsp tomu3   115/1         IL2  0m2s
5       40.2.2.2/32        30.1.1.1        lsp tomu3   115/1         IL2  0m2s
6       100.1.0.0/16       DIRECT          drop        115/10        IL1  3m54s
7       200.1.1.1/32       30.1.1.1        lsp tomu3   115/1         IL2  0m2s
```

The following example shows an IS-IS shortcut configuration with route advertisements enabled.

```
NetIron MLX(config-mpls)# lsp tomu3
NetIron MLX(config-mpls-lsp-tomu3)# disable
Disconnecting signaled LSP tomu3
NetIron MLX(config-mpls-lsp-tomu3)# shortcuts isis level2 announce
NetIron MLX(config-mpls-lsp-tomu3)# enable
Connecting signaled LSP tomu3
```

In the output for this configuration, the bold text indicates that the device uses the extended TLV fields to advertise the shortcut in an IS adjacency TLV. If route advertisements are not enabled, this text would not appear in the output.

```
PowerConnect(config-mpls)# show isis database mu1.00-00 detail

```

Clearing IS-IS shortcuts

When you clear IS-IS shortcuts, IS-IS attempts to remap the LSP To address to IS-IS system ID. Clearing shortcuts is useful when the mapping between the To address and System ID must be refreshed once the LSP tunnel is being used in the SPF calculation.

NOTE
This is not a common operation.

To clear IS-IS shortcuts from the configuration, use one of the following CLI commands at any level of the CLI:

- **clear isis shortcut** – This command clears all IS-IS shortcuts from the configuration.

- **clear isis shortcut lsp** <*lsp-name*> – This command clears IS-IS shortcuts for the specified LSP.

Syntax: clear isis shortcut [**lsp** <*lsp-name*>]

Show command support

Use the following **show** commands to display information about IS-IS shortcuts:

- **show isis shortcuts** – Displays information about all IS-IS shortcuts configured on the router.
- **show isis shortcuts lsp** <*lsp-name*> – Displays information about all IS-IS shortcuts configured for a specified LSP.
- **show isis shortcuts detail** – Displays detailed information about all IS-IS shortcuts that are UP, such as the system ID and matching To address of the tunnel, configured metric values, and the time period for which the LSP has been an IS-IS shortcut.
- **show isis shortcuts lsp** <*lsp-name*> **detail** – Displays detailed information about all IS-IS shortcuts for a specified LSP, such as the system ID and matching To address of the tunnel, configured metric values, and the time period for which the LSP has been an IS-IS shortcut.
- **show isis** – Enhanced output indicates whether or not IS-IS shortcuts are configured, the number of shortcuts configured, how many are UP, and how many are advertised.
- **show isis debug** – Shows debugging information for IS-IS shortcuts. For more information, refer to the *PowerConnect B-MLXe Diagnostic Reference*.

NOTE
Only LSPs that are UP (administratively and operationally enabled in the MPLS domain) are kept in the database and displayed in the **show** command outputs. LSPs that are down are not kept in the database and are not displayed in the command outputs.

Displaying general information about IS-IS shortcuts

The **show isis shortcuts** command displays information about all IS-IS shortcuts configured on the device.

```
PowerConnect# show isis shortcuts
Configured: 3, Up: 2, Announced: 1
Name               To                Metric              Announce    Tunnel
                                  (SPF/Announce)                       Intf
lsp tomu2         40.1.1.1            10/-                 No         tnl1
lsp tomu3         30.1.1.1            -/-                  Yes        tnl2
lsp toolong       200.1.1.1           10/10                Yes        tnl3
toreachmu3
```

Syntax: show isis shortcuts [**lsp** <*lsp-name*>]

The optional **lsp** parameter displays information about IS-IS shortcuts for a specific LSP.

Table 270 describes the fields shown in this output.

TABLE 270 Output for the **show is-is shortcuts** command

This field...	Displays
Configured	The number of IS-IS shortcuts configured.
Up	The number of IS-IS shortcuts that are UP.

TABLE 270 Output for the **show is-is shortcuts** command (Continued)

This field...	Displays
Announced	The number of IS-IS shortcuts that are advertised.
Name	The name of the IS-IS shortcut. If the name is longer than 11 characters, it wraps to the next line.
To	The LSP endpoint address.
Metric (SPF or Announce)	The metric used in the SPF calculation or the metric used in the advertisement of the IS adjacency TLV. The SPF metric can be one of the following: • The metric configured at the MPLS LSP configuration level. • The native IGP metric plus or minus (+ or -) the relative metric configured with the **shortcuts isis** command. • The native IGP metric. • A dash (-) denotes that the tunnel is not used in SPF calculations. The Announce metric can be one of the following: • 10 (the default announce metric) • The metric configured with the **announce-metric** keyword • A dash denotes that the tunnel is not used in the IS adjacency TLV advertisement.
Announce	Indicates whether or not IS-IS shortcuts are advertised: • Yes – IS-IS shortcuts are advertised. • No – IS-IS shortcuts are not advertised.
Tunnel Intf	The tunnel index of the LSP. This is assigned by MPLS whenever an LSP is created.

Displaying detailed information about IS-IS shortcuts

The **show isis shortcuts detail** command displays detailed information about IS-IS shortcuts, including:

- The system ID and matching To address of the tunnel
- Configured metric values
- How long the LSP has been an ISIS shortcut

The following shows output from this command.

```
PowerConnect# show isis shortcuts lsp tomu2 detail
lsp tomu2
 To 40.1.1.1, Used by SPF (10), Not Announced
  LSP metric: 10, Relative Metric: -, Announce Metric: -
  ISIS System Id for 40.1.1.1 is mu2.00-00
  Not announced due to configuration
  Last notification from MPLS received 0h0m35s ago.
```

NOTE
The LSP name in this output is not wrapped.

Syntax: show isis shortcuts detail | **lsp** <*lsp-name*> **detail**

The optional **lsp** parameter displays detailed information about IS-IS shortcuts for a specific LSP.

Table 270 defines the fields shown in this output.

TABLE 271 Output for the **show isis shortcuts detail** command

This field...	Displays
<*name*>	The name of the IS-IS shortcut.
To	This line contains the following information: • The LSP endpoint address • Whether or not this LSP is used in the SPF calculation. This field displays either **Used by SPF** or **Not Used by SPF**. • Whether or not the announce metric is used
LSP metric	This field displays one of the following: • The metric value configured at the MPLS LSP configuration level of the CLI • A dash (-), which denotes that the LSP metric is not configured.
Relative metric	This field displays one of the following: • The relative metric value configured with the **shortcuts isis** command • A dash (-), which denotes that the relative metric is not configured.
Announce metric	This field displays one of the following: • The announce metric value configured with the **shortcuts isis** command • A dash (-) which denotes that the announce metric is not configured.
ISIS System Id	The matching IS-IS system ID for the LSP endpoint.
Not used by SPF due to	If the tunnel is not used by SPF, one of the following reasons is noted: • **Not used by SPF due to no ISIS system-id mapping to** <*router-ID*>. No mapping exists between the LSP tunnel destination and the IS-IS System ID. • **Not used by SPF due to no ISIS native route to LSP** <*tunnel destination*>. There is no IS-IS native route to the LSP tunnel destination. • **Not used by SPF due to ISIS alternate path preferred to this tunnel**. An alternate path has a better metric than the LSP tunnel.
Not announced due to configuration	Indicates that announce is not configured.
Last notification from MPLS received	The last time (in hours, minutes, seconds) a status notification was received from MPLS.

Displaying IS-IS shortcut statistics

The **show isis** command output includes the following information about IS-IS shortcuts:

- Whether or not IS-IS shortcuts are enabled
- The number of IS-IS shortcuts configured
- How many IS-IS shortcuts are UP
- How many IS-IS shortcuts are advertised

The information is displayed at the bottom of the **show isis** display output. For example:

```
NetIron# show isis
(truncated for brevity)...
ISIS Shortcuts: 20 configured, 10 are up, and 10 are announced
```

Or

```
NetIron# show isis
(truncated for brevity)...
No isis shortcuts configured
```

ECMP forwarding for IP over MPLS

ECMP hardware forwarding is supported for IP over MPLS packets when an outgoing interface is configured as a physical port *and* a VE interface, or configured on an MPLS tunnel. When multiple routes use ECMP to reach a destination, hardware ECMP is automatically enabled. ECMP load sharing for IP over MPLS is supported for 2-8 tunnels, with a default of 4 tunnels.

ECMP hardware forwarding is not supported for dynamic mode. Hitless upgrade for ECMP hardware forwarding is not supported.

For ECMP hardware forwarding, all outgoing interface paths must configured in the same VRF, and must belong to an MPLS tunnel. A hash value is computed for a packet when it is received by XPP. XPP uses the hash value to select a PRAM that forwards the packet to the destination. An ECMP PRAM block consists of 8 PRAMs. The hash value for each outgoing packet on a customer edge router interface is calculated based on source MAC address, destination MAC address, VLAN ID, source IP address, destination IP address, IP protocol field, TCP or UDP source port, and TCP or UDP destination port.

The hash value for each incoming packet on the route target is calculated based on the source MAC address, destination MAC address, VLAN ID, source IP address, destination IP address, IP protocol field, TCP or UDP source port, TCP or UDP destination port, and a VC label for an MPLS packet.

QoS mapping between IP packets and MPLS

The 3-bit EXP field in the MPLS header can be used to define a Class of Service (CoS) value for packets the traverse an LSP. The CoS value specifies a priority for MPLS packets.

There are two ways that a CoS value can be applied to packets that traverse an MPLS network through an LSP:

- A CoS value is manually configured for the LSP, as described in "Setting a Class of Service value for the LSP" on page 1341. This is the default operation.
- No CoS value is set for an LSP, and the Type of Service (ToS) field in the IP header is used. In this situation, the device copies the first three bits in the ToS field of the packet to the CoS (EXP) field in the MPLS header. The ToS value maps to one of the four priority queues on the device.

Configuring BGP or MPLS VPNs 36

Overview

PowerConnect B-MLXe supports the following BGP or MPLS VPN features:

- Defining a VRF Routing Instance
- MPLS Forwarding
- Generating Traps for VRFs
- Route Distinguisher to a VRF
- Automatic Route Filtering
- Assigning a VRF Routing Instance to a LAG Interface
- Cooperative Route Filtering
- Importing and Exporting Route Maps in a VRF
- Defining an External Community with a Route Map
- VPNv4 Route Reflector
- BGP VRF Load Sharing
- ECMP forwarding for IP VPN
- Autonomous System Number Override
- Allow Routes with its own AS Number
- Defining an External Community
- LSPs per VRF
- OSPF Sham Links
- OSPF on a PE Device to Redistribute BGP-VPNv4 Routes
- Adding a Static ARP Entry for a VRF
- Configuring an IP Static Interface Route Across VRFs
- IP TTL to MPLS TTL Propagation in an IPVPN
- Static Route within the VRF Context
- Backup Virtual Router for VRF Using VRRPE
- Ping and Traceroute for Layer-3 VPNs
- Displaying BGP or MPLS VPNv4 Information

This chapter describes how to configure BGP or MPLS VPNs on devices. BGP or MPLS VPNs as defined by RFC 2547 can be used by internet service providers to provide remote wide-area connectivity services using an MPLS Domain for data traffic and IBGP to distribute routing information. Each customer network can be completely segregated from every other customer network while sharing the same infrastructure.

This chapter is divided into the following sections:

- "What is a BGP or MPLS VPN" provides a basic description of BGP VPNs and an example. This section also lists the IETF RFCs and Internet Drafts supported by the implementation of BGP or MPLS VPNs.
- "BGP or MPLS VPN components and what they do" explains the software and hardware components that make up BGP or MPLS VPNs, including Customer Edge Router (CE), Provider Edge Routers (PE) and Virtual Routing and Forwarding (VRF) tables.
- "BGP or MPLS VPN operation" explains basic concepts about BGP or MPLS VPNs, including how routes are advertised and discovered, how the VRF manages packet forwarding, and how LSPs are employed to switch traffic across a MPLS Domain.
- "Configuring BGP VPNs on a PE" describes how to configure a BGP or MPLS VPN. In this section, the basic configuration steps of a BGP VPN are described.
- "Displaying BGP or MPLS VPNv4 information", "Displaying BGP or MPLS VRF information", and "Displaying additional BGP or MPLS VPN information" provide information about the display command you can use to manage a BGP or MPLS VPNv4 network.
- "BGP or MPLS VPN sample configurations" provide detailed examples of network configurations and examples of feature configurations.

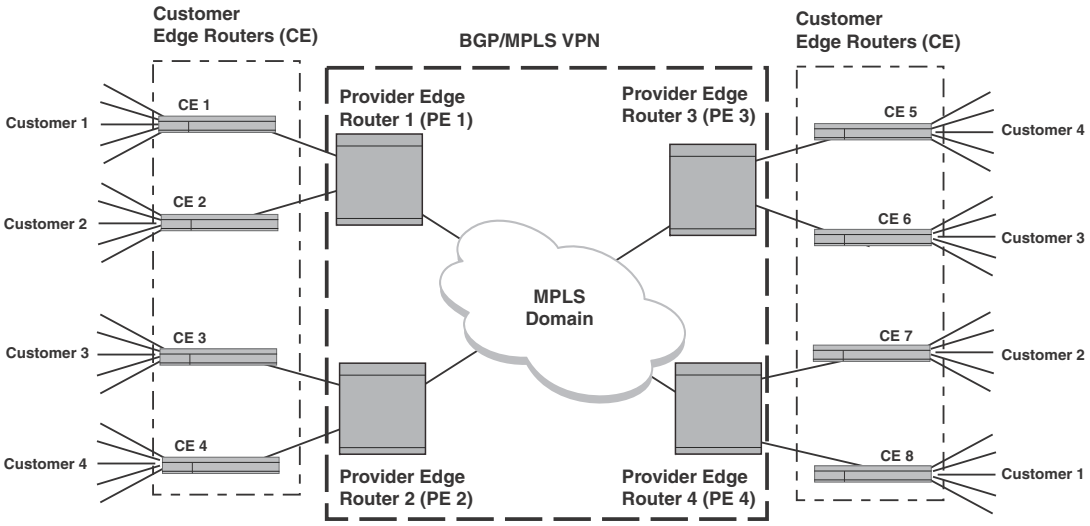
What is a BGP or MPLS VPN

MPLS provides scalable and efficient switching over an indeterminate group of devices along a predetermined Labeled Switch Path (LSP). Using MPLS, LSPs can be set statically or determined dynamically by the ISPs to provide traffic engineering features. BGP or MPLS VPNs build on this infrastructure to provide virtual-circuit connectionless service between remote sites. Using a common MPLS-domain, multiple Virtual Private Networks (VPNs) can be configured across a service-provider MPLS core network. Each VPN provides a secure data path that allows IP packetized traffic to share the infrastructure while being effectively segregated from other VPNs that are using the same MPLS Domain.

In Figure 202 four separate customers (1-4) each have remote sites. Each customer is connected to a network at a remote site through the MPLS domain while being completely segregated and secure from traffic between other sites. For instance, CE 1 and CE 8 belong to Customer 1. CE 1 is connected to the BGP or MPLS VPN network through PE 1 and CE 8 through PE 4. Using the service

provider's BGP or MPLS VPN service, traffic can be forwarded between CE1 and CE8 at the same time that Customers 2 through 4 use VPNs that operate over the same network infrastructure. Different customers can even use the same IP addresses without conflicting with other customers networks or creating any routing problems.

FIGURE 202 BGP or MPLS VPN network



IETF RFC and Internet Draft support

The implementation of BGP or MPLS VPNs supports the following IETF RFCs and Internet Drafts:

BGP or MPLS VPNs

RFC 4364: BGP or MPLS IP VPNs
RFC 4577: OSPF as the PE or CE Protocol in BGP or MPLS IP VPNs
RFC 4576: Using LSA Options Bit to Prevent Looping in BGP or MPLS IP VPNs (DN Bit)

BGP

RFC 1771 – A Border Gateway Protocol 4 (BGP-4)
RFC 1997 – BGP Communities Attribute
RFC 2283 – Multiprotocol Extensions for BGP-4
RFC 2842 – Capabilities Advertisement with BGP-4
RFC 2858 – Multiprotocol Extensions for BGP-4
RFC 3107 – Carrying Label Information in BGP-4

Draft standards

draft-ietf-idr-route-filter-11
draft-ietf-idr-bgp-ext-communities-07

MIB support

RFC 4382 – MPLS or BGP Layer 3 Virtual Private Network (VPN) Management Information Base.

BGP or MPLS VPN components and what they do

This section describes each of the following components, which make up a BGP or MPLS VPN (refer to Figure 203):

- Customer Edge device (CE)
- Provider Edge device (PE)
- Virtual Routing and Forwarding table (VRF)
- Provider MPLS Domain

The Customer Edge device (CE) – The CE provides connectivity with a customer's network and a Provider Edge device (PE). It can advertise routes available from the customer's network using RIP, OSPF or EBGP. Alternately, the CE can create a static default route to a PE. Outbound packets from a customer's network are forwarded from the CE to the PE, and inbound packets are forwarded from the PE to the CE attached to the customer's network.

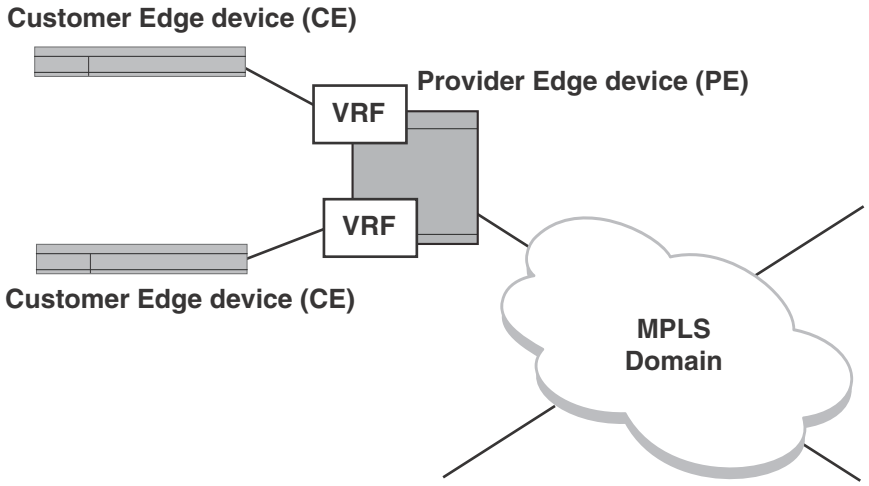
The Provider Edge device (PE) – In a BGP or MPLS VPN, the central component is the PE. The PE provides connectivity with the CE and with the MPLS Domain. On one side of the PE, routing information is exchanged with the CE using either static routes, RIP, OSPF, or EBGP. On the other side, IBGP is used with BGP multiprotocol extensions to communicate with all of the other PEs that

are connected to networks in the same VPN and available to the customer's network. When a CE sends packets to a PE to forward across an MPLS Domain, that PE functions as an MPLS ingress Label Edge device (LER) and the PE on the other end of the Domain functions as an MPLS egress LER.

Virtual Routing and Forwarding table (VRF) – The PE maintains a Virtual Routing and Forwarding table (VRF) for each customer that is attached to it through a CE. The VRF contains routes between the PE and the CE and Label Switched Paths (LSPs) across the MPLS domain for each PE that is a member of the customer's VPN. VRFs are defined on interfaces of the PEs.

Provider MPLS Domain – The Provider MPLS domain is composed of Provider (P) devices. An MPLS domain can traverse more than one service provider's MPLS network. The P devices do not store any VPN information; they just switch traffic from the ingress PE device along the LSP to the egress PE device.

FIGURE 203 BGP or MPLS VPN components



BGP or MPLS VPN operation

The purpose of a BGP or MPLS VPN is to forward packets between remote sites of a customer's network through a service provider's MPLS infrastructure. The section titled "BGP or MPLS VPN components and what they do" on page 1600 describes the network components required to perform that task. The following sections describe how those components work together to create this service:

- "Creating routes in a BGP or MPLS VPN"
- "Routing a packet through a BGP or MPLS VPN"

Creating routes in a BGP or MPLS VPN

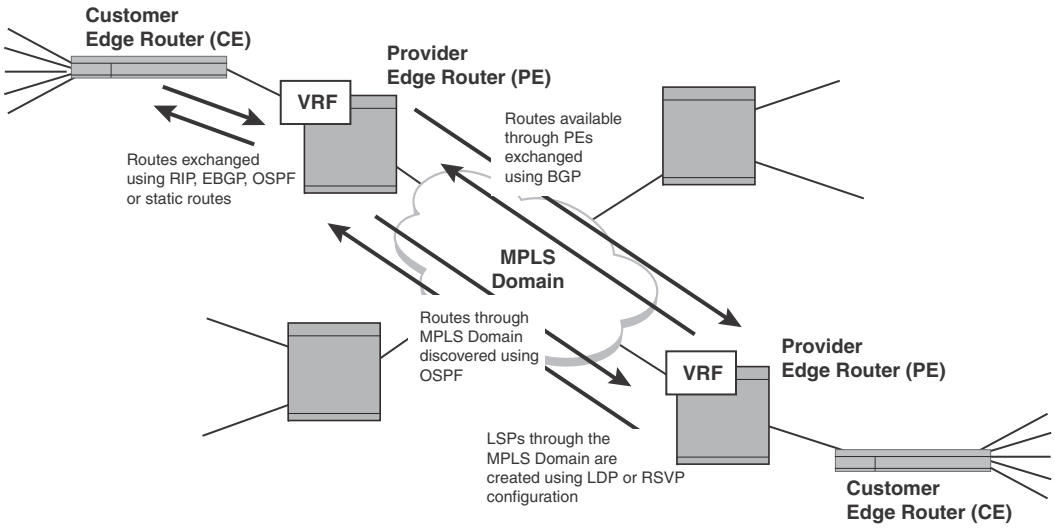
A CE device maintains the connection to the customer's network and is configured within that network to share access to its available network prefixes and to receive packets from other VPN-connected networks. That CE is connected to a PE through an interface that is configured for a specified VRF for connection to the BGP or MPLS VPN. This connection places the CE in the BGP or MPLS VPN. Routes that are available through the CE are then made available to the PE using RIP, OSPF, EBGP or a static route. These routes are then stored in the VRF where they are associated with the VPN. The route from the CE to the PE is kept in the CE's routing table.

The PE device is connected to the MPLS Domain through one or more interfaces. The PE must advertise the routes that it has available in it's VRF tables across the MPLS Domain to its PE peers. Available routes in the VRF are prepended with a Route Distinguisher (RD) and advertised across the MPLS Domain using IBGP. The PEs can either be configured for IBGP as either full mesh or with a route reflector to allow greater scalability. Routes that are advertised from other PEs in the VPN are received at the PE and collected in the VRF table. This procedure establishes which other PEs are in the VPN and what networks are available through them.

OSPF is used a the Interior Gateway Protocol (IGP) within the service provider's MPLS Domain to provide connectivity. OSPF also populates the traffic engineering (TE) used by RSVP-TE.

Labeled Switch Paths (LSPs) are then created using Label Distribution Protocol (LDP), Resource Reservation Protocol (RSVP) configurations in the MPLS Domain. Using this protocol, the PE obtains an LSP required to switch traffic to the other PEs. The network is now populated with all of the routes required to forward packets between the customer's networks.

FIGURE 204 BGP or MPLS VPN route discovery



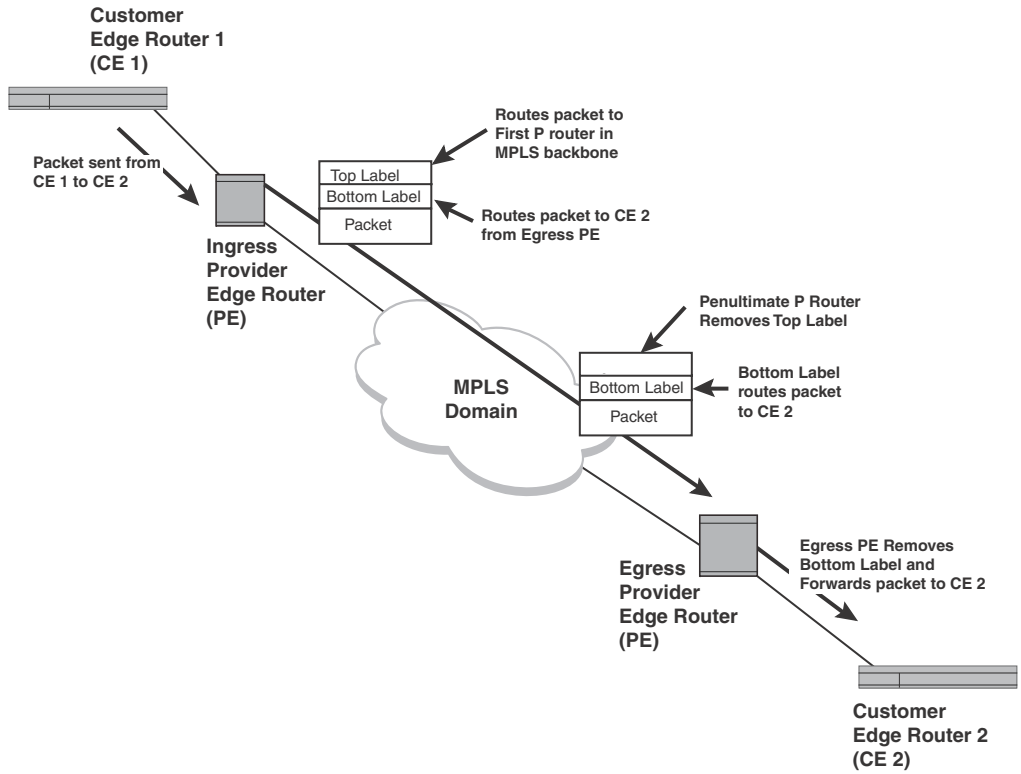
Routing a packet through a BGP or MPLS VPN

This section and the diagram in Figure 205 describe how a packet is forwarded through a BGP or MPLS VPN.

When a packet is forwarded from a CE to a PE, a bottom label is attached to the packet by the PE that is associated with the final destination. This label is obtained from the egress PE as part of the route discovery conducted by IBGP. Then, the top label which is obtained by the LSP connecting to the egress PE is added to the packet. The packet is then forwarded through the MPLS Domain and

is switched using the top label. At the penultimate device in the LSP, the top label is removed and the packet is forwarded to the egress PE. The egress PE uses the inner label to identify the CE to which the packet must be forwarded. The egress PE removes the inner label and forwards the packet to the correct CE.

FIGURE 205 Routing a packet through a BGP or MPLS VPN



Configuring BGP VPNs on a PE

To configure a BGP VPN on a Provider Edge device (PE) you must perform the configuration steps listed below.

1. "Defining a VRF routing instance"
2. "Configuring MPLS forwarding"
3. "Assigning a Route Distinguisher to a VRF"
4. 36, "Configuring BGP or MPLS VPNs"
5. "Defining automatic route filtering"
6. "Assigning a VRF routing instance to an interface"
7. "Assigning a VRF routing instance to a LAG interface"
8. "Setting up cooperative route filtering"
9. "Importing and exporting route maps"
10. "Defining an extended community for use with a route map"

11. "Creating a VPNv4 route reflector"
12. "Configuring BGP VRF load sharing"
13. "Configuring autonomous system number override"
14. "Configuring a PE to allow routes with its AS number"
15. "Setting up LSPs per VRF"
16. "Configuring OSPF sham links"
17. "Configuring OSPF on a PE device to redistribute BGP-VPNv4 routes"
18. "Generating traps for VRFs"

Defining a VRF routing instance

A single PE can contain one or more VRFs. Each of these VRFs must be defined separately on a PE. A PE will distribute routes and route packets to other members of the same VRF but not to other VRFs. The VRF name can be any string that you want to define it as.

To define the VRF routing instance VPN1 on a PE, enter the following command.

```
NetIron(config)# ip vrf VPN1
NetIron(config-vrf-vpn1)# exit-vrf
NetIron(config)#
```

Syntax: **[no] ip vrf** <*vrf_name*> **[max-routes** <*num*>**]**

Configures a VRF table on the device with the name **vrf_name** and puts the device in config-vrf mode.

The <*vrf_name*> parameter specifies a name for the VRF being created.

The **max-routes** parameter can be used to set the maximum number of routes (the <*num*> variable) that the VRF will accept. The default value for <*num*> is 5120. The acceptable range is from 128 to 262143.

Syntax: [no] exit-vrf

The **exit-vrf** command moves you out of the VRF configuration mode for the VRF you are configuring.

Configuring MPLS forwarding

A unique MPLS label is allocated for each VRF. This is called the per-VRF label. By default, this label is used as part of the BGP VPNv4 route when exchanging routes with a remote PE peer. When the per-VRF label is used, When the **label-switched** option in the **mpls-forwarding** command (within the IP VRF mode) is selected, a unique MPLS label is allocated for each BGP VPNv4 route. The following example enables mpls-forwarding for the VRF named VPN1.

```
NetIron(config)# ip vrf VPN1
NetIron(config-vrf-vpn1)# mpls-forwarding label-switched
NetIron(config-vrf-vpn1)# exit-vrf
NetIron(config)#
```

Syntax: [no] mpls-forwarding label-switched

When **mpls-forwarding** is set to **label-switched,** a unique MPLS label is allocated for each BGP VPNv4 route advertised to the remote PE peer. The forwarding behavior remains unchanged.

Assigning a Route Distinguisher to a VRF

Each instance of a VRF must have a unique Route Distinguisher (RD) assigned to it. The RD is prepended on any address being routed or advertised. The RD can be defined as either ASN-relative or IP address-relative. Since the RD is unique to an instance of a VRF, it allows the same IP address to be used in different VPNs without creating any conflict.

To assign a Route Distinguisher (RD) for a VRF based on the AS number 3 and the arbitrary identification number 6, enter the following command.

```
NetIron(config-vrf)# rd 3:6
```

Syntax: [no] rd <*route_distinguisher*>

The route_distinguisher variable specifies a route distinguisher for a VRF that gives a route associated with the VRF a unique identity. The RD is prepended on the address being advertised. The RD allows the same IP address to be used in different VPNs without creating any conflicts. It can also be used with the **route-target** command to constrain distribution of routes to or from a VPN. The route_distinguisher parameter can be either ASN-relative or IP address-relative as described:

ASN-relative – Composed of the local ASN number followed by a ":" and a unique arbitrary number. For example: 3:6.

IP address-relative – Composed of the local IP address followed by a ":" and a unique arbitrary number.

Defining IPv4 or IPv6 address families of a VRF

Each address family configuration level allows you to access commands that apply to that particular address family only.

To define IPv4 or IPv6 address families of a VRF, enter the following command.It will allow each address family to have its own max-route value.

```
NetIron(config)#vrf VPN1
NetIron(config-vrf-vpn1)#address-family ipv4 max-route 4544
NetIron(config-vrf-vpn1-ipv4)#exit-address-family
NetIron(config-vrf-vpn1)#exit-vrf
NetIron(config)#
```

Syntax: [**no**]**address-family**<ipv4/ipv6> [max-route <num>]

The max-route parameter can be used to set the maximum number of routes (the <*num*> variable) that the VRF will accept. The default value for <*num*> is 5120. The acceptable range is from 128 to 262143..

For IPv6 address family, the max-route acceptable range is 64 to 16384, with 128 as the default value.

Syntax: exit-address-family

The **exit-address-family** command moves you out of the ipv4 or ipv6 address family of a VRF you are configuring.

Defining automatic route filtering

Each VRF is configured with import and export route targets. The export route target sets an extended community attribute number that is appended to all routes that are exported from the VRF. The import route target value sets a filter that determines the routes that will be accepted into the VRF. Any route with a value in its import route-target contained in its extended attributes field matching the value in the VRF's import route target will be accepted. Otherwise the route will be rejected. This process is referred to as automatic route filtering.

To define an import route target of 3:6 and an export route target of 3:8 for a VPN, enter the following commands.

```
NetIron(config-vrf)# route-target import 3:6
NetIron(config-vrf)# route-target export 3:8
```

Syntax: [no] route-target [import | export | both] <*route-target*>

This command associates a route target specified by the route-target variable with a specified VRF for control on routes.

The **import** parameter specifies that routes with route-target extended community attributes matching the specified route-target variable can be imported into the VRF where this command is configured.

The **export** parameter specifies the route-target extended community attributes that are attached to routes export from the specified VRF.

The **both** parameter specifies that both the import and export values apply to the specified route-target variable for the VRF where this command is configured. This is the default state. It applies if no specific value for this parameter is set.

The <*route-target*> variable specifies a target VRF extended community. Like a route distinguisher, it is either AS-relative or IP address-relative.

Assigning a VRF routing instance to an interface

Once a VRF routing instance is defined, it must be assigned to one or more virtual or physical interfaces on a PE.

To assign the VRF named VPN1 to Ethernet interface 1/1, enter the following commands.

```
NetIron(config)# interface ethernet 1/1
NetIron(config-if-e10000-1/1)# ip vrf forwarding VPN1
```

Syntax: [no] ip vrf forwarding <*vrf-name*>

The <*vrf-name*> variable is the name of the VPN that the interface is being assigned to.

Assigning a VRF routing instance to a LAG interface

A VRF routing instance can be assigned to a dynamic LAG interface. To assign a VRF routing instance to a LAG the following rules must be observed:

- The dynamic LAG must be configured before assigning any of its ports to a non-default VRF routing instance.

- Before deployment of the dynamic LAG all members of the LAG must be in the default VRF routing instance.
- After the LAG is deployed, the primary port can be assigned to a non-default VRF routing instance.
- Once the dynamic LAG is deployed, all ports are in the LACP_BLOCK state until the LACP protocol can negotiate with the other end. Once the negotiation with the other end is completed, all the LAP ports are set to the FORWARD state.
- When the Dynamic LAG is undeployed, the primary port will stay in the VRF that it was assigned to but all secondary ports will move back to the default VRF.

The following configuration creates a dynamic LAG named “red” and assigns port 1/1 as the primary port and port 1/2 as a secondary port. The LAG is deployed and the primary port (1/1) is assigned to the VRF routing instance named “VPN1”. All ports in the LAG named “red” are then assigned to the VRF routing instance named “VPN1”.

```
NetIron(config)# lag red dynamic
NetIron(config-lag-red)# ports ethernet 1/1 to 1/2
NetIron(config-lag-red)# primary port 1/1
NetIron(config-lag-red)# ports ethernet 1/2
NetIron(config-lag-red)# deploy
NetIron(config-lag-red)# exit
NetIron(config)# interface ethernet 1/1
NetIron(config-if-e10000-1/1)# ip vrf forwarding VPN1
```

If the dynamic LAG named “red” is undeployed as shown in the following, port 1/1 will remain in the VRF routing instance named “VPN1” but port 1/2 will be returned to the default VRF.

```
NetIron(config)# lag red dynamic
NetIron(config-lag-red)# no deploy
```

Setting up cooperative route filtering

Automatic route filtering in VRFs is provided through the **route-target** import command. By placing this command in the VRF configuration, routes can be filtered from being imported into a given VRF. Routes with extended community route targets matching the VRF’s import route-targets are permitted into a VRF. Otherwise, the routes are rejected.

The cooperative route filtering feature requires that you set a send command on the device that is sending the ORF, and a receive command on the device that is installing the ORF. To configure the sending device, use the following command in the VPNv4 address family.

```
NetIron(config-bgp-vpnv4u)# neighbor 3.3.3.1 capability orf extended-community
send-vrf-filter
```

Syntax: [no] neighbor <*neighbor_IPaddress*> **capability orf extended-community send-vrf-filter**

To configure the peering device use the following command in the VPNv4 address family.

```
NetIron(config-bgp-vpnv4u)# neighbor 3.3.3.2 capability orf extended-community
receive
```

Syntax: [no] neighbor <*neighbor_IPaddress*> **capability orf extended-community receive**

Importing and exporting route maps

Route-maps configured using the **route-map** command can be applied to a VRF to provide filtering of VPNv4 routes between PEs in a BGP or MPLS VPN. When a route-map is applied to a VRF, only VPNv4 routes are filtered. Other routes such as static routes, connected routes, OSPF VRF routes, or BGP CE side routes are not affected. Because the route map is applied to the VRF, it filters traffic to all connected PEs. This is in contrast to applying a route-map using the BGP neighbor. In that case, the route map applies to routes imported from or exported to the neighbor that is specified.

Route maps applied to a VRF can coexist with route maps that are applied to a BGP neighbor. You can filter routes from being imported into a VRF using the import and export route commands. This allows you to accept or deny the routes for one VRF without affecting the routes that are imported or exported from other VRFs. To do this, you must define a route-map import or export command.

To configure a VRF to apply the import route map ImportOne, use the following command at the VPNv4 prompt.

```
NetIron(config)# ip vrf vrfone
NetIron(config-ip-vrf-vrfone)# import map ImportOne
NetIron(config-ip-vrf-vrfone)# exit-vrf
NetIron(config)#
```

Syntax: [no] import map <*map-name*>

The map-name parameter is the name of the route map that you want to apply to the VRF.

To configure a VRF to apply the export route map ExportOne, use the following command at the VPNv4 prompt.

```
NetIron(config)# ip vrf vrfone
NetIron(config-ip-vrf-vrfone)# export map ExportOne
NetIron(config-ip-vrf-vrfone)# exit-vrf
NetIron(config)#
```

Syntax: [no] export map <*map-name*>

The **map-name** parameter is the name of the route map that you want to apply to the VRF.

Defining an extended community for use with a route map

Routes can be filtered in or out of a PE by the use of an IP extended community to identify them. In this situation, a route is identified by its extended community variable. It is entered as a route target in an IP extended community list and then matched in a route-map command. This route map is then applied from the PE that is defining the route to be filtered to the PE where the route filter is to be implemented by using a **neighbor** <*ip_address*> [**route-map**] command. If a VRF exists on the neighbor that exports the route-target being blocked, all routes from that VRF are blocked from being sent to the PE where the filter is defined.

To define the IP extended community list 20 to define route target RT 100:6 to be denied, enter the following command.

```
NetIron(config)# ip extcommunity-list 20 deny rt 100:6
```

Syntax: [no] ip extcommunity-list <*num*> **route-map [permit] [deny] [rt** <*route ID*>**] [soo** <*route ID*>**]**

The <*num*> variable is the extended community list number.

The **permit | deny** parameter indicates that action the device takes if the match is true.

The rt <*route ID*> variable specifies the route target that is applied to filtering. The <*route ID*> has the format of either ASN:nn or IP-address:nn. If four-byte ASNs have been enabled or if four-byte IP addresses are used, the user-purposed *nn* value can be a maximum of two bytes instead of our bytes.

The soo <*route ID*> variable specifies the site of origin. The <*route ID*> has the format of either ASN:nn or IP-address:nn. If four-byte ASNs have been enabled or if four-byte IP addresses are used, the user-purposed *nn* value can be a maximum of two bytes instead of our bytes.

Creating a VPNv4 route reflector

PE devices in a BGP or MPLS VPN share routes between each other using IBGP. This can be accomplished using a full mesh configuration or a route reflector can be used to simplify a networks topology and improve scalability. While the general concepts are the same for using Route Reflectors in a normal IBGP network as in an BGP or MPLS VPN, there are some differences. In addition, there are special conditions that apply when a route reflector is configured for normal IPv4 BGP traffic (IPv4) and for BGP or MPLS VPN traffic (VPNv4). The differences and special considerations are described in the following:

Special considerations when configuring a route reflector for both IPv4 and VPNv4:

- A VPNv4 route does not need to be installed in any VRF before being reflected.
- Route reflector configurations for IPv4 and VPNv4 are separated in different address family configurations.
- For a VPNv4 route installed to a VRF, the reflected VPNv4 route still carries the original RD and PA.
- If there is a route reflector configuration change, a warning message is displayed that requests the user to clear the neighbor session.

Specific commands for VPNv4 – There are VPNv4 specific commands that must be configured to configure a route reflector for a BGP or MPLS VPN under address family VPNv4. A route reflector can be configured on a PE for IPv4 and VPNv4 or for either exclusively. If you are configuring a route reflector for a BGP or MPLS VPN, you must configure it specifically using the VPNv4 specific commands.

To create a VPNv4 route reflector with a client at the IP address 11.11.11.2, enter the following commands at the vpnv4 level of BGP Config level.

```
NetIron(config-bgp-vpnv4u)# neighbor 11.11.11.2 route-reflector-client
```

Syntax: [no] neighbor <*IPaddress*> **route-reflector-client**

The <*IPaddress*> variable is the IP address of the PE device that you want to define the route reflector client.

A route reflector can be setup with local import filtering to filter out VPNv4 routes matched by an extended community list. This requires that you create an extended community list for the routes you want to filter and set the following command.

```
NetIron(config-bgp)# address-family vpnv4 unicast
NetIron(config-bgp-vpnv4u)# rr-group 1
```

Syntax: [no] rr-group <*group-num*>

The <*group-num*> variable refers to an extended community list number from 1 to 99 that specifies the routes that you want to filter.

Configuring BGP VRF load sharing

The default for each VRF is to maintain only the lowest-cost route in its routing table for each VPN that it is connected to. If a lower-cost route is discovered, it will replace the route that is currently in the table. If another route of equal cost is discovered, it will be rejected. The PowerConnect however is able to perform load sharing over multiple routes to the same destination. In order to make this feature operational, you must increase the number of path entries allowed in a VRF's routing table.

Configuring BGP VRF load sharing requires two different CLI commands that work in relationship with each other. These are the global **ip load-sharing** command and the BGP VRF specific **maximum-path** command. The value set for ip load-sharing provides a maximum number that the maximum-path value for a specific route can be set to. The **maximum-path** command has a maximum value of 8. If the ip load-sharing value is set to 4 or greater, the maximum-path value for a specific BGP VRF can be set to a value of from 1 to 4. The default is 1. If the ip load-sharing value is set to less than 4, the maximum-path value for a specific BGP VRF can only be set to the global ip load-sharing value or less.

To set the **maximum-path** value to 4, enter the following commands at the VPNv4 level of the BGP configuration level.

```
NetIron(config-bgp)# maximum-paths 4
```

Syntax: [no] maximum-paths <*num*>

The <*num*> variable is the maximum number of routes that can be maintained for a VRF. The default value is 1. The maximum value is 4. The value cannot exceed the value set for the device by the **ip load-sharing** command.

ECMP forwarding for IP VPN

ECMP hardware forwarding is now supported for IP VPN packets when an outgoing interface is configured as a physical port and a VE interface. If multiple routes are using ECMP to route to a destination, then hardware ECMP is automatically enabled. ECMP load sharing for IP over MPLS is supported for 2-8 tunnels. For more information on configuring ECMP load sharing for IP VPN, refer to "Configuring BGP VRF load sharing" on page 1610.

ECMP hardware forwarding is supported only in static CAM mode. ECMP hardware forwarding is not supported for dynamic mode. Hitless upgrade for ECMP hardware forwarding is not supported.

When configuring ECMP hardware forwarding, all outgoing paths must configured in the same VRF. A hash value is computed for a packet when it is received by XPP. XPP will use the hash value to select a PRAM that is used to forward the packet to its destination. An ECMP PRAM block consists of 8 PRAMs. The hash value for each outgoing packet on a Customer Edge device interface is calculated based on the source MAC address, destination MAC address, VLAN ID, source IP address, destination IP address, IP protocol field, TCP or UDP source port, and TCP or UDP destination port.

The hash value for each incoming packet on the route target is calculated based on the source MAC address, destination MAC address, VLAN ID, source IP address, destination IP address, IP protocol field, TCP or UDP source port, TCP or UDP destination port, and a VC label for an MPLS packet.

Configuring autonomous system number override

There are some situations where a customer will want to connect to a service provider's BGP or MPLS VPN network using the same AS number at more than one site. This can create a problem because it is the default BGP procedure to reject routes from the same AS. One solution to this problem is to configure a PE router to override the AS_PATH attribute of its BGP neighbor. This is accomplished by configuring the **neighbor** <*ip_address*> **as-override** command on the PE. When this is enabled, the PE device determines when the AS_PATH attribute in a route intended for a neighbor CE contains the same AS number as the CE. When this is determined, the PE device substitutes its own AS number for the CE's in the AS_PATH attribute. The CE is then able to receive the route. The following additional conditions apply when this feature is in effect:

- In a situation where the AS_PATH attribute contains more than one occurrence of the CE's AS number in the initial sequence, the PE device will replace all those occurrences with its own AS number.
- The PE device will add its own AS number to the AS_PATH attribute just as it would normally.

The following command configures the PE device to replace its attached CE's AS number with its own AS number. BGP neighbor at IP address 33.33.36.2 the configuration of PE 2 required to enable Autonomous System number override for the BGP neighbor CE 2.

To configure a PE device to replace its attached CE's AS number with its own AS number, enter the following commands at the VRF level of the BGP Config level.

```
NetIron(config-bgp-vpnv4u)# neighbor 33.33.36.2 as-override
```

Syntax: [no] neighbor <*IPaddress*> **as-override**

The <*IPaddress*> variable is the IP address of the CE whose AS number is being replaced with the PE's AS number.

Configuring a PE to allow routes with its AS number

BGP rejects routes that contain its own AS number within its AS_PATH attribute to prevent routing loops. In an MPLS or VPN hub and spoke topology this can stop legitimate routes from being accepted. The **allowas-in** command fixes this problem by allowing you to set a parameter that disables the AS_PATH check function for routes learned from a specified location.

To configure a PE to disable the AS_PATH check function for routes sent to it by its BGP neighbor (a CE device with the IP address 33.33.36.2) for a maximum limit of 3 occurrences of the route, enter the following command at the BGP VRF configuration level.

```
NetIron(config-bgp-ipv4u-vrf)# neighbor 33.33.36.2 allowas-in 3
```

Syntax: [no] neighbor <*IPaddress*> **allowas-in** <*asn_limit*>

The <*IPaddress*> is the IP address of the neighbor CE device from which the PE device can accept routes that have the same AS number.

The asn_limit value prevents loops by limiting the number of occurrences that the PE's AS number can be accepted in routes that are received from the specified device.

Setting up LSPs per VRF

IBGP is used between PEs to determine routes that are available between VRFs. These routes are linked to a Label Switched Path (LSP) that has been defined separately either as a static path or using LDP or RSVP. The LSP is used to tunnel through the MPLS Domain to the destination PE. Under most circumstances, the default route between two PEs will be chosen by IBGP between the VRFs with the PE's loopback address as the next hop. If there is a single loopback on the PE, the same LSP tunnel will be the only path used between any VRF defined on a PE and VRFs on other specified PEs.

More than one LSP can be configured between PEs however, where each LSP is associated with a different Loopback address on the PE. In this case, any loopback address on a PE can be assigned as the nexthop address for a specific or multiple VRFs. This allows you to assign some VRFs on a PE to one LSP and other VRFs to a different LSP. Through this method, traffic from different VRFs can be assigned to LSPs that provide different qualities of service. This feature can also be employed to provide for load-balancing across the MPLS domain.

To configure a PE device to use different LSPs, a BGP next hop must be configured for a VRF as the following example illustrates.

```
NetIron(config)# ip vrf blue
NetIron(config-ip-vrf-blue)# bgp next-hop loopback 2
NetIron(config-ip-vrf-blue)# exit-vrf
NetIron(config)#
```

Syntax: [no] bgp next-hop <*loopback-interface*>

The <*loopback-interface*> variable is the number of the loopback interface that you will be assigning to the VRF as a BGP next hop. The loopback address becomes the defined VRF's nexthop for its VPNv4 routes that are sourced by this device only when:

- The loopback interface exists and has an IP address set.
- The loopback interface has an IP a subnet mask of /32
- The loopback interface is in the default VRF.

If these conditions are not met, the default nexthop is used.

For a detailed example of this feature refer to "Setting an LSP for each VRF on a PE" on page 1709

Configuring OSPF sham links

OSPF can be used to propagate links between a Customer Edge device (CE) and a Provider Edge device (PE). Normal operation of this type of network assumes that the only connections between CEs pass through the provider network. However, if other links or routes between the CEs exist within the same area, problems can arise due to the OSPF preference for Intra-area links over Inter-area links.

Problems can be avoided by creating a virtual intra-area OSPF link between two PEs. This virtual link is called a sham link. If the OSPF instances exist in the same area, a sham link causes OSPF to treat the route through the service provider network as an intra-area link instead of an inter-area link.

NOTE
If no backdoor link exists, no purpose exists for creating a sham link.

A cost is assigned to the sham link to help the OSPF network determine when to route over the sham link and when to route over the backdoor link. Because this virtual link (sham-link) appears as an intra-area link, the OSPF areas in which each of the PEs reside must be the same.

To configure an OSPF sham link, use the command for creating a sham link on both the local device and the remote PE device. Before attempting to create a sham link, note the following important information:

- For sham links to work, OSPF cannot be configured on the loopback interface in the applicable area.
- The redistribution of BGP to OSPF must be configured.
- A BGP VPN4 route to the loopback address must exist in both of the pertinent VRFs' routing tables.
- After the BGP VPN4 route exists in the VRF IP route table, the hello (and other) packet exchanges can go through for sham links even if the backdoor CE link does not exist.

The first example that follows illustrates the command for creating an OSPF sham link between PE devices. The command shows the command entry on one device with a source IP address of 2.2.2.1 and destination address of 2.2.2.2. The second example shows the complete configuration sequence (from both PE devices) and shows the command for viewing the sham link. (Refer to "Displaying OSPF sham links" on page 1681 for the display contents.)

Use this command in the OSPF VRF configuration level.

```
NetIron(config-ospf-router)# area 1 sham-link 2.2.2.1 2.2.2.2 cost 10
```

Syntax: **[no] area** <*area_id*> **sham-link** <*source_address*> <*destination_address*> **cost** <*cost_value*>

Possible values:

The area_id variable is the ID number of the OSPF area assigned to the sham ink being defined in this command.

The source_address variable is the IP address of the source PE device.

The destination_address variable is the IP address of the destination PE device.

The cost_value variable sets the OSPF cost for sending packets over the sham link. This parameter can be a numeric value in the range 1 – 65535.

The following illustrates the configuration that takes place first on PE1 and then on PE2:

Sham link configuration on PE1

```
router ospf vrf CustomerA
area 1
area 1 sham-link 172.31.255.1 172.31.255.2 cost 1
redistribution bgp

interface loopback 2
ip vrf forwarding CustomerA
ip address 172.31.255.1/32
!
```

```
NetIron@Router1#sh ip route vrf CustomerA 172.31.255.2
Type Codes - B:BGP D:Connected I:ISIS O:OSPF R:RIP S:Static; Cost - Dist/Metric
ISIS Codes - L1:Level-1 L2:Level-2
OSPF Codes - i:Inter Area 1:External Type 1 2:External Type 2 s:Sham Link
Destination Gateway Port Cost Type Uptime
1 172.31.255.2/32 172.30.255.48 lsp PE1-PE2 200/0 B 10m3s
```

Sham link configuration on PE2

```
router ospf vrf CustomerA
area 1
area 1 sham-link 172.31.255.2 172.31.255.1 cost 1
redistribution bgp

interface loopback 2
ip vrf forwarding CustomerA
ip address 172.31.255.2/32
!
NetIron@Router2#show ip route vrf CustomerA 172.31.255.1

Type Codes - B:BGP D:Connected I:ISIS S:Static R:RIP O:OSPF; Cost - Dist/Metric
Destination Gateway Port Cost Type
1 172.31.255.1/32 172.30.255.32 lsp PE2-PE1 200/0 B
```

Configuring OSPF on a PE device to redistribute BGP-VPNv4 routes

To allow OSPF route exchange between a specified VRF on a PE device and its associated CE device, OSPF must be configured to redistribute BGP routes from the local AS as described in the following steps:

- "Defining an OSPF instance in a VRF"
- "Creating an OSPF area in an OSPF VRF instance"
- "Creating a domain identifier in an OSPF VRF instance"
- "Assigning a domain tag in an OSPF VRF instance"

Defining an OSPF instance in a VRF

To define an OSPF instance in VRF VPN1, enter the following command at the OSPF Config level.

```
NetIron(config)# router ospf vrf VPN1
```

Syntax: [no] router ospf vrf <*vrf_name*>

The <*vrf_name*> value specifies the name of the VRF that you are creating an instance of OSPF in.

Creating an OSPF area in an OSPF VRF instance

To create OSPF area 1 in OSPF VRF instance VPN1, enter the following command in the OSPF VRF Instance Config level.

```
NetIron(config-ospf-router)# area 1
```

Syntax: [no] area <*area_id*>

The <*area-id*> value is the number of the OSPF area instance being created.

Creating a domain identifier in an OSPF VRF instance

To create OSPF domain identifier 0.0.0.100 in OSPF VRF instance VPN1, enter the following command in the OSPF VRF Instance Config level.

```
NetIron(config-ospf-router)# domain-id 0.0.0.100
```

Syntax: [no] domain-id <*domain_identifier*>

The <*domain_identifier*> value specifies an four-byte quantity.

Assigning a domain tag in an OSPF VRF instance

To assign OSPF domain tag 1200 in OSPF VRF instance VPN1, enter the following command in the OSPF VRF Instance Config level.

```
NetIron(config-ospf-router)# domain-tag 1200
```

Syntax: [no] domain-tag <*domain_tag*>

The <*domain_tag*> parameter specifies an arbitrary four-byte quantity. It is added in tag fields of Type-5 and Type-7 LSAs generated by a PE device for redistributed BGP-VPNv4 routes.

If not specified, the domain-tag value is calculated from the autonomous system number of the MPLS Domain.

Adding a static ARP entry for a VRF

To configure a static ARP entry to a VRF enter the following command at the global configuration level.

```
NetIron(config)# arp vrf green <num> <ip-addr> <mac-addr> ethernet <portnum>
```

Syntax: [no] arp vrf <*vrf-name*> <*num*> <*ip-addr*> <*mac-addr*> **ethernet** <*portnum*>

The <*vrf-name*> parameter specifies the VRF you are configuring a static ARP entry for.

The <*num*> parameter specifies the entry number. You can specify a number from 1 up to the maximum number of static entries allowed on the device. You can allocate more memory to increase this amount. To do so, enter the system-max ip-static-arp <*num*> command at the global CONFIG level of the CLI.

NOTE
This has be deprecated as of release 3.6.

The <*ip-addr*> command specifies the IP address of the device that has the MAC address of the entry.

The <*mac-addr*> parameter specifies the MAC address of the entry.

The ethernet <*portnum*> command specifies the port number attached to the device that has the MAC address of the entry.

To clear the ARP entries for a specified VRF, enter the following command.

```
NetIron# clear arp vrf blue
```

Syntax: clear arp vrf <*vrf-name*>

The <*vrf-name*> parameter specifies the VRF you want to clear all ARP entries for.

Configuring IP TTL to MPLS TTL propagation in an IPVPN

The **vrf-propagate-ttl** and **label-propagate-ttl** commands have been added which configure the device to propagate TTL values in an IPVPN between the IP TTL value and the MPLS TTL value as described in Table 272.

TABLE 272 MPLS TTL propagation behavior with IPVPNs on the PowerConnect B-MLXe.

With vrf-propagate-ttl and label-propagate-ttl configured	Without vrf-propagate-ttl and label-propagate-ttl configured (default)
• At the ingress device, the IP TTL value -1 is copied to both the tunnel label and the VC label. • At the transit device, the tunnel label is decremented by 1. • At the PHP device the Tunnel label TTL is set to the VC label and the tunnel label is popped. • At the egress device, the IP TTL value is set to min (VC label TTL, IP TTL) and the VC label is popped. The IP TTL value is then decremented by 1 if it is being forwarded out of the device.	• At the ingress device, both the tunnel TTL value and the VC label TTL value are set to 255 • At the transit device, the tunnel label is decremented by 1. • At the PHP device the Tunnel label TTL is popped without changing the VC label's TTL. • At the egress device, the VC label is popped without copying the TTL value to the IP packet. The IP TTL value is then decremented by 1 if it is being forwarded out of the device.

To configure a PowerConnect B-MLXe to propagate the IP TTL values to and from the MPLS TTL values in an IPVPN, enter **vrf-propagate-ttl** and **label-propagate-ttl** commands as shown in the following.

```
NetIron(config)# router mpls
NetIron#(config-mpls)# policy
NetIron#(config-mpls-policy)# vrf-propagate-ttl
NetIron#(config-mpls-policy)# label-propagate-ttl
```

To return the condition to the default off state if the **label-propagate-ttl** command has been previously configured, enter a command such as the following.

```
NetIron(config)# router mpls
NetIron#(config-mpls)# policy
NetIron#(config-mpls-policy)# no vrf-propagate-ttl
```

Syntax: [no] vrf-propagate-ttl

Using the **no** option returns the condition to the default off state if the **vrf-propagate-ttl** command has been previously configured.

Syntax: [no] label-propagate-ttl

Using the **no** option returns the condition to the default off state if the **label-propagate-ttl** command has been previously configured.

Configuring a static route within the VRF context

To configure a static route entry in a VRF, enter the following command.

```
NetIron#(config) ip vrf blue
NetIron#(config-vrf-blue) ip route 192.0.0.0 255.0.0.0 195.1.1.1
```

Syntax: [no] ip route <*dest-ip-addr*>/<*mask-bits*> <*next-hop-ip-addr*> [<*metric*>]

The <*dest-ip-addr*> is the route's destination. The <*dest-mask*> is the network mask for the route's destination IP address. Alternatively, you can specify the network mask information by entering a forward slash followed by the number of bits in the network mask. For example, you can enter 192.0.0.0 255.255.255.0 as 192.0.0.0/.24. To configure a default route, enter 0.0.0.0 for <*dest-ip-addr*> and 0.0.0.0 for <*dest-mask*> (or 0 for the <*mask-bits*> if you specify the address in CIDR format). Specify the IP address of the default gateway using the <*next-hop-ipaddr*> parameter.

The <*next-hop-ip-addr*> is the IP address of the next-hop device (gateway) for the route.

The <*metric*> parameter specifies the cost of the route and can be a number from 1 – 16. The default is 1.

NOTE
Note that the **ip route** command is executed at the "config-vrf" configuration level.

Configuring an IP Static interface route across VRFs

You can configure an IP Static interface route from one VRF to an IP interface in a different VRF. This is described in "Configuring an IP Static interface route across VRFs" on page 1617.

Configuring a backup Virtual Router for VRF using VRRPE

With this release, you can use the Virtual Router Redundancy Protocol Extended (VRRPE) to provide a redundant connection to a VRF instance in a BGP or MPLS VPN. This is accomplished by assigning the VRRPE interface to a port that is also assigned to the VRF.

Configuration of VRRPE support for a VRF must be accomplished in the order described below.

1. Enable an interface
2. Enable VRF forwarding on the interface
3. Configure an IP address on the interface
4. Enable VRRPE on the interface and set the VRID
5. Configure the IP address for the Virtual Router
6. Activate the virtual interface

DANGER
You must configure a VRF on an interface before configuring a Virtual Router (VRRPE) on it. If you enable the Virtual Router before you enable the VRF, the Virtual Router configuration will be deleted.

Configuration example

The following example configures a backup virtual device using VRRPE for VRF "blue" on an Ethernet interface.

```
NetIron(config)# interface ethernet 3/1
NetIron(config-if-3/1)# ip vrf forwarding blue
NetIron(config-if-3/1)# ip address 1.2.3.1/8
NetIron(config-if-3/1)# ip vrrp-extended vrid 1
NetIron(config-if-3/1-vrid-1)# backup
NetIron(config-if-3/1-vrid-1)# ip-address 1.2.3.10
NetIron(config-if-3/1-vrid-1)# activate
```

Ping and Traceroute for layer-3 VPNs

The Ping and Traceroute utilities have been enhanced in release 02.1.00 to help with management of Layer-3 VPNs:

Ping VRF

A VRF option has been added to the **ping** command. To use this option, enter the following command.

```
PE1# ping vrf blue 10.10.10.10
```

Syntax: ping vrf <*vrf-name*> <*ip-address*>

The <*vrf-name*> is the name of the VRF that you want to send a ping packet to.

The <*ip-address*> is the ip address containing the VRF tp which you want to send a ping packet .

Traceroute VRF

A VRF option has been added to the **traceroute** command. To use this option, enter the following command.

```
PE1# traceroute vrf blue 10.10.10.10
```

Syntax: traceroute vrf <*vrf-name*> <*ip-address*>

The <*vrf-name*> is the name of the VRF that you want to conduct a traceroute to.

The <*ip-address*> is the ip address containing the VRF to which you want to conduct a traceroute.

Generating traps for VRFs

You can enable and disable SNMP traps for VRFs. VRF traps are enabled by default.

To enable VRF traps after they have been disabled, enter the following command.

```
NetIron(config)# snmp-server enable traps vrf
```

Syntax: [no] snmp-server enable traps vrf

Use the **no** form of the command to disable VRF traps.

Displaying BGP or MPLS VPNv4 information

You can display the following information about a BGP or MPLS VPN configuration on the device:

- "Displaying VPNv4 route information"
- "Displaying VPNv4 route information for a specified IP address"
- "Displaying VPNv4 attribute entries information"
- "Displaying VPNv4 dampened paths information"
- "Displaying VPNv4 filtered routes information"
- "Displaying VPNv4 Flap statistics information"
- "Displaying VPNv4 route distinguisher information"
- "Displaying VPNv4 neighbor information"
- "Displaying advertised routes for a specified VPNv4 neighbor"
- "Displaying attribute entries for a specified VPNv4 neighbor"
- "Displaying Flap statistics for a specified VPNv4 neighbor by IP address"
- "Displaying received ORFs information for a specified VPNv4 neighbor"
- "Displaying a specified neighbor VPNv4 routes"
- "Displaying routes summary for a specified VPNv4 neighbor"
- "Displaying summary route information"
- "Displaying the VPNv4 route table"
- "Displaying BGP VPNv4 MPLS tag information"

Displaying VPNv4 route information

You can display route information about VPNv4 routes by entering the following command at any level of the CLI.

```
NetIron# show ip bgp vpnv4
Total number of BGP VPNv4 Routes: 285
Status codes: s suppressed, d damped, h history, * valid, > best, i internal
Origin codes: i - IGP, e - EGP, ? - incomplete
    Network            Next Hop        Metric LocPrf Weight Path
Route Distinguisher: 1:1
*i  10.80.1.1/32       2.2.2.2         100    0      206 311 i
*i  10.80.1.2/32       2.2.2.2         100    0      206 311 i
*i  10.80.1.3/32       2.2.2.2         100    0      206 311 i
*i  10.80.1.4/32       2.2.2.2         100    0      206 311 i
*i  10.80.1.5/32       2.2.2.2         100    0      206 311 i
*i  10.80.1.6/32       2.2.2.2         100    0      206 311 i
*i  10.80.1.7/32       2.2.2.2         100    0      206 311 i
*i  10.80.1.8/32       2.2.2.2         100    0      206 311 i
*i  10.80.1.9/32       2.2.2.2         100    0      206 311 i
*i  10.80.1.10/32      2.2.2.2         100    0      206 311 i
*i  10.80.1.11/32      2.2.2.2         100    0      206 311 i
*i  10.80.1.12/32      2.2.2.2         100    0      206 311 i
*i  10.80.1.13/32      2.2.2.2         100    0      206 311 i
*i  10.80.1.14/32      2.2.2.2         100    0      206 311 i
*i  10.80.1.15/32      2.2.2.2         100    0      206 311 i
*i  10.80.1.16/32      2.2.2.2         100    0      206 311 i
*i  10.80.1.17/32      2.2.2.2         100    0      206 311 i
*i  10.80.1.18/32      2.2.2.2         100    0      206 311 i

This display shows the following information.

TABLE 273 BGP4 summary information

This field...	Displays...
Total number of BGP VPNv4 Routes:	The number of BGP VPNv4 routes.
Status or Status Codes	The route's status, which can be one or more of the following: • A – AGGREGATE. The route is an aggregate route for multiple networks. • B – BEST. BGP4 has determined that this is the optimal route to the destination. **NOTE:** If the "b" is shown in lowercase, the software was not able to install the route in the IP route table. • b – NOT-INSTALLED-BEST. The routes received from the neighbor are the best BGP4 routes to their destinations, but were nonetheless not installed in the IP route table because the received better routes from other sources (such as OSPF, RIP, or static IP routes). • C – CONFED_EBGP. The route was learned from a neighbor in the same confederation and AS, but in a different sub-AS within the confederation. • D – DAMPED. This route has been dampened (by the route dampening feature), and is currently unusable. • H – HISTORY. Route dampening is configured for this route, and the route has a history of flapping and is unreachable now. • I – INTERNAL. The route was learned through BGP4. • L – LOCAL. The route originated on this device. • M – MULTIPATH. BGP4 load sharing is enabled and this route was selected as one of the best ones to the destination. The best route among the multiple paths also is marked with "B". **NOTE:** If the "m" is shown in lowercase, the software was not able to install the route in the IP route table. • S – SUPPRESSED. This route was suppressed during aggregation and thus is not advertised to neighbors. **NOTE:** This field appears only if you enter the **route** option.
Origin code	A character the display uses to indicate the route's origin. The origin code appears to the right of the AS path (Path field). The origin codes are described in the command's output.
Route Distinguisher	A unique ID that is prepended on any address being routed or advertised from a VRF. The RD can be defined as either ASN-relative or IP address-relative as described: • ASN-relative - Composed of the local ASN number followed by a ":" and a unique arbitrary number. For example: 3:6 • IP address-relative - Composed of the local IP address followed by a ":" and a unique arbitrary number.
Network	IP address or mask of the destination network of the route.
Next Hop	The next-hop device for reaching the network from this device.
Metric	The value of the route's MED attribute. If the route does not have a metric, this field is blank.
LocPrf	The degree of preference for this route relative to other routes in the local AS. When the BGP4 algorithm compares route on the basis of local preference, the route with the higher local preference is chosen. The preference can have a value from 0-4294967295

TABLE 273 BGP4 summary information (Continued)

This field...	Displays...
Weight	The value that this route associates with routes from a specific neighbor. For example, if the device receives routes to the same destination from two BGP4 neighbors, the device prefers the route from the neighbor with the larger weight.
Path	The routes AS path.

To clear the VPNv4 routing table, you must enter the following commands.

```
NetIron# clear ip bgp vpnv4 neighbor all soft out
NetIron# clear ip bgp vpnv4 neighbor all soft in
```

Syntax: clear ip bgp vpnv4

The **dampening** parameter clears route flap dampening information.

The **flap-statistics** parameter clears route flap statistics.

The **neighbor** parameter clears BGP neighbors.

Displaying VPNv4 route information for a specified IP address

To display only the routes to a specified network, enter a command such as the following at any level of the CLI.

```
NetIron# show ip bgp vpnv4 10.2.2.0/24
Route Distinguisher: 2:1
Number of BGP Routes matching display condition : 1
Status codes: s suppressed, d damped, h history, * valid, > best, i internal
Origin codes: i - IGP, e - EGP, ? - incomplete
    Network          Next Hop      Metric LocPrf Weight Path
*i  10.2.2.0/24        4.4.4.4        1      100     0       ?
```

Syntax: show ip bgp vpnv4 <*ip-addr*>

The <*address*> <*mask*> parameter specifies a particular route. If you also use the optional **longer-prefixes** parameter, then all statistics for routes that match the specified route or have a longer prefix than the specified route are displayed. For example, if you specify **209.157.0.0 longer**, then all routes with the prefix 209.157 or that have a longer prefix (such as 209.157.22) are displayed.

The **Number of BGP Routes** matching display conditions field in this display is described in Table 274 below. For information about all other fields in this display, refer to Table 273.

TABLE 274 Route flap dampening statistics

This field...	Displays...
Number of BGP Routes matching display conditions	The number of routes to the network specified as a parameter in the **show ip bgp vpnv4** <*ip-addr*> command.

Displaying VPNv4 attribute entries information

The route-attribute entries table lists the sets of BGP VPNv4 attributes stored in the device memory. Each set of attributes is unique and can be associated with one or more routes. In fact, the router typically has fewer route attribute entries than routes. To display the route-attribute entries table at any level of the CLI.

```
NetIron# show ip bgp vpn attribute-entries
        Total number of BGP Attribute Entries: 55
1       Next Hop  :0.0.0.0            Metric   :0               Origin:IGP
        Originator:0.0.0.0            Cluster List:None
        Aggregator:AS Number :0      Router-ID:0.0.0.0          Atomic:None
        Local Pref:100               Communities:Internet
        Extended Community: RT 600:1
        AS Path   :310
        Address: 0x24644060  Hash:45 (0x0100036e) Reference Counts: 0:0:30
2       Next Hop  :0.0.0.0            Metric   :0               Origin:IGP
        Originator:0.0.0.0            Cluster List:None
        Aggregator:AS Number :0      Router-ID:0.0.0.0          Atomic:None
        Local Pref:100               Communities:Internet
        Extended Community: RT 600:1
        AS Path   :311
        Address: 0x24645f48  Hash:47 (0x01000370) Reference Counts: 0:0:30
3       Next Hop  :2.2.2.2            Metric   :0               Origin:IGP
        Originator:0.0.0.0            Cluster List:None
        Aggregator:AS Number :0      Router-ID:0.0.0.0          Atomic:None
        Local Pref:100               Communities:Internet
        Extended Community: RT 100:1 RT 200:1
        AS Path   :206 311
        Address: 0x24645538  Hash:276 (0x0100087a) Reference Counts: 30:0:0
```

This display shows the following information.

TABLE 275 BGP VPNv4 attribute entries

This field...	Displays...
Total number of BGP Attribute Entries	The number of routes contained in the BGP4 route table for this device.
Next Hop	The IP address of the next hop device for routes that have this set of attributes.
Metric	The cost of the routes that have this set of attributes.
Origin	The source of the route information. The origin can be one of the following: • EGP – The routes with this set of attributes came to BGP through EGP. • IGP – The routes with this set of attributes came to BGP through IGP. • INCOMPLETE – The routes came from an origin other than one of the above. For example, they may have been redistributed from OSPF or RIP. When BGP4 compares multiple routes to a destination to select the best route, IGP is preferred over EGP and both are preferred over INCOMPLETE.
Originator	The originator of the route in a route reflector environment.
Cluster List	The route-reflector clusters through which this set of attributes has passed.

TABLE 275 BGP VPNv4 attribute entries (Continued)

This field...	Displays...
Aggregator	Aggregator information: • **AS Number** shows the AS in which the network information in the attribute set was aggregated. This value applies only to aggregated routes and is otherwise 0. **Router-ID** shows the device that originated this aggregator
Atomic	Whether the network information in this set of attributes has been aggregated and this aggregation has resulted in information loss. • TRUE – Indicates information loss has occurred • FALSE – Indicates no information loss has occurred **NOTE:** Information loss under these circumstances is a normal part of BGP4 and does not indicate an error.
Local Pref	The degree of preference for routes that use this set of attributes relative to other routes in the local AS.
Communities	The communities that routes with this set of attributes are in.
Extended Community	The extended community attributes.
AS Path	The ASs through which routes with this set of attributes have passed. The local AS is shown in parentheses.
Address	This is an internal value used for debugging purposes only.
Hash	This is an internal value used for debugging purposes only.
Reference Counts	This is an internal value used for debugging purposes only.

Displaying VPNv4 dampened paths information

To view BGP VPNv4 paths suppressed due to dampening, enter the following command.

```
NetIron# show ip bgp vpnv4 dampened-paths
```

Displaying VPNv4 filtered routes information

To view BGP VPNv4 filtered paths information, enter the following command.

```
NetIron# show ip bgp vpnv4 filtered-routes
```

Displaying VPNv4 Flap statistics information

To display route flap statistics for all routes, enter the following command at any level of the CLI.

```
NetIron# show ip bgp vpnv4 flap-statistics ?
```

Syntax: **show ip bgp vpnv4 flap-statistics [regular-expression** <*regular-expression*> **|** <*address*> <*mask*>
[longer-prefixes] | neighbor <*ip-addr*> **| filter-list** <*num*>**...]**

The <*address*> <*mask*> parameter specifies a particular route. If you also use the optional **longer-prefixes** parameter, then all statistics for routes that match the specified route or have a longer prefix than the specified route are displayed. For example, if you specify **209.157.0.0 longer**, then all routes with the prefix 209.157 or that have a longer prefix (such as 209.157.22) are displayed.

The **as-path-filter** <*num*> parameter specifies one or more filters. Only the routes that have been dampened and that match the specified filter or filters are displayed.

The **neighbor** <*ip-addr*> parameter displays route flap dampening statistics only for routes learned from the specified neighbor. You also can display route flap statistics for routes learned from a neighbor by entering the following command: **show ip bgp neighbor** <*ip-addr*> **flap-statistics**.

The **regular-expression** <*regular-expression*> parameter is a regular expression. The regular expressions are the same ones supported for BGP4 AS-path filters.

This display shows the following information.

TABLE 276 Route flap dampening statistics

This field...	Displays...
Total number of flapping routes	The total number of routes in the device's BGP4 route table that have changed state and thus have been marked as flapping routes.

You also can display all the dampened routes by entering the following command: **show ip bgp dampened-paths**.

Displaying VPNv4 route distinguisher information

In order to view the BGP VPNv4 information for routes that contain a specific route distinguisher, enter the following command.

```
NetIron# show ip bgp vpnv4 rd 5:1 detail
Total number of BGP Routes: 34
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED
1       Prefix: 10.6.1.0/24,  Status: I,  Age: 16h9m21s
         NEXT_HOP: 4.4.4.4,  Learned from Peer: 4.4.4.4 (1)
         Out-Label: 500000
          LOCAL_PREF: 100,  MED: 2,  ORIGIN: incomplete,  Weight: 0
           AS_PATH:
            Extended Community: RT 300:1 RT 100:2 RT 100:3
2       Prefix: 10.40.1.1/32,  Status: I,  Age: 16h9m21s
        NEXT_HOP: 4.4.4.4,  Learned from Peer: 4.4.4.4 (1)
         Out-Label: 500000
          LOCAL_PREF: 100,  MED: 2,  ORIGIN: incomplete,  Weight: 0
           AS_PATH:
            Extended Community: RT 300:1 RT 100:2 RT 100:3
3       Prefix: 10.40.1.2/32,  Status: I,  Age: 16h9m21s
         NEXT_HOP: 4.4.4.4,  Learned from Peer: 4.4.4.4 (1)
         Out-Label: 500000
          LOCAL_PREF: 100,  MED: 2,  ORIGIN: incomplete,  Weight: 0
           AS_PATH:
            Extended Community: RT 300:1 RT 100:2 RT 100:3
```

TABLE 277 BGP VPNv4 route distinguisher entries

This field...	Displays...
Total number of BGP Routes	The number of routes contained in the BGP4 route table that contain the specified RD.
Prefix	The network address and prefix.
Age	The last time an update occurred.
Learned from Peer	The IP address of the neighbor that sent this route.
Out-Label	MPLS label associated with this device.
MED	The route's metric. If the route does not have a metric, this field is blank.
AS Path	The route's AS path.
Extended Community	Extended community attributes associated with this device.

Displaying VPNv4 neighbor information

To view BGP4 configuration information and statistics for VPNv4 neighbors, enter the following command.

```
NetIron# show ip bgp vpnv4 neighbors
    Total number of BGP Neighbors: 2
1   IP Address: 2.2.2.2, AS: 1 (IBGP), RouterID: 2.2.2.2, VRF: default
    State: ESTABLISHED, Time: 14h47m39s, KeepAliveTime: 60, HoldTime: 180
       KeepAliveTimer Expire in 21 seconds, HoldTimer Expire in 141 seconds
       UpdateSource: Loopback 1
       RefreshCapability: Received
    Messages:    Open    Update  KeepAlive Notification Refresh-Req
       Sent    : 1       40      887       0            0
       Received: 1       35      887       0            0
    Last Update Time: NLRI       Withdraw          NLRI       Withdraw
                  Tx: ---        ---           Rx: ---        ---
    Last Connection Reset Reason:Unknown
    Notification Sent:     Unspecified
    Notification Received: Unspecified
    Neighbor NLRI Negotiation:
      Peer Negotiated IPV4  unicast  capability
      Peer Negotiated VPNv4 unicast  capability
      Peer configured for IPV4 unicast  Routes
      Peer configured for VPNv4 unicast  Routes
    TCP Connection state: ESTABLISHED
    TTL check: 0, value: 0, rcvd: 64
       Byte Sent:   29202, Received: 28108
       Local host:  3.3.3.3, Local  Port: 179
       Remote host: 2.2.2.2, Remote Port: 8079
       ISentSeq:    7683960  SendNext:    7713163  TotUnAck:          0
       TotSent:       29203  ReTrans:           0  UnAckSeq:    7713163
       IRcvSeq:   256457831  RcvNext:   256485940  SendWnd:       65000
       TotalRcv:      28109  DupliRcv:          0  RcvWnd:        65000
       SendQue:           0  RcvQue:            0  CngstWnd:       1479
```

This example shows how to display information for VPNv4 neighbors. None of the other display options are used; thus, all of the information is displayed for all neighbors. The number in the far left column indicates the neighbor for which information is displayed. When you list information for multiple neighbors, this number makes the display easier to read.

The TCP statistics at the end of the display show status for the TCP session with the neighbor. Most of the fields show information stored in theTransmission Control Block (TCB) for the TCP session between the device and a neighbor. These fields are described in detail in section *3.2 of RFC 793*, "*Transmission Control Protocol Functional Specification*".

Syntax: **show ip bgp vpnv4 neighbors** [*<ip-addr>* **[advertised-routes [detail** [*<ip-addr>*[*/<mask-bits>*]]]] **|**
[attribute-entries [detail]] | [flap-statistics] | [last-packet-with-error] | [received extended-community] | [received prefix-filter] | [routes [best] | [detail [best] | [not-installed-best] | [unreachable]] |
[rib-out-routes [*<ip-addr>*/*<mask-bits>* **|** *<ip-addr> <net-mask>* **| detail]] |**
[routes-summary]]

The *<vrf-name>* parameter specifies the VRF whose neighbor you want to display information about.

The *<ip-addr>* option lets you narrow the scope of the command to a specific neighbor. The display is the same as that for the command without this option except that it is limited to only the neighbor specified.

The **advertised-routes** option displays only the routes that the device has advertised to the neighbor during the current BGP4 neighbor session.

The **attribute-entries** option shows the attribute-entries associated with routes received from the neighbor.

The **flap-statistics** option shows the route flap statistics for routes received from or sent to the neighbor.

The **last-packet-with-error** option displays the last packet from the neighbor that contained an error. The packet's contents are displayed in decoded (human-readable) format.

The **received extended-community** option displays the received extended community Outbound Route Filters (ORFs) received from this neighbor.

The **received prefix-filter** option shows the Outbound Route Filters (ORFs) received from the neighbor. This option applies to cooperative route filtering.

The **routes** option lists the routes received in UPDATE messages from the neighbor. You can specify the following additional options:

- **best** – Displays the routes received from the neighbor that the device selected as the best routes to their destinations.
- **not-installed-best** – Displays the routes received from the neighbor that are the best BGP4 routes to their destinations, but were nonetheless not installed in the IP route table because the device received better routes from other sources (such as OSPF, RIP, or static IP routes).
- **unreachable** – Displays the routes that are unreachable because the device does not have a valid RIP, OSPF, or static route to the next hop.
- **detail** – Displays detailed information for the specified routes. You can refine your information request by also specifying one of the options above (**best**, **not-installed-best**, or **unreachable**).

The **rib-out-routes** option lists the route information base (RIB) for outbound routes. You can display all the routes or specify a network address.

The **routes-summary** option displays a summary of the following information:

- Number of routes received from the neighbor
- Number of routes accepted by this device from the neighbor

- Number of routes this device filtered out of the UPDATES received from the neighbor and did not accept
- Number of routes advertised to the neighbor
- Number of attribute entries associated with routes received from or advertised to the neighbor

This display shows the following information.

TABLE 278 BGP4 neighbor information

This field...	Displays...
IP Address	The IP address of the neighbor.
AS	The AS the neighbor is in.
EBGP or IBGP	Whether the neighbor session is an IBGP session, an EBGP session, or a confederation EBGP session: • EBGP – The neighbor is in another AS. • EBGP_Confed – The neighbor is a member of another sub-AS in the same confederation. • IBGP – The neighbor is in the same AS.
RouterID	The neighbor's ID.
Description	The description you gave the neighbor when you configured it on the device.
State	The state of the session with the neighbor. The states are from the perspective of this device of the session, not the perspective of the neighbor. The state values are based on the BGP4 state machine values described in RFC 1771 and can be one of the following for each device: • IDLE – The BGP4 process is waiting to be started. Usually, enabling BGP4 or establishing a neighbor session starts the BGP4 process. • A minus sign (-) indicates that the session has gone down and the software is clearing or removing routes. • ADMND – The neighbor has been administratively shut down. • A minus sign (-) indicates that the session has gone down and the software is clearing or removing routes. • CONNECT – BGP4 is waiting for the connection process for the TCP neighbor session to be completed. • ACTIVE – BGP4 is waiting for a TCP connection from the neighbor. **NOTE:** If the state frequently changes between CONNECT and ACTIVE, there may be a problem with the TCP connection. • OPEN SENT – BGP4 is waiting for an Open message from the neighbor. • OPEN CONFIRM – BGP4 has received an OPEN message from the neighbor and is now waiting for either a KEEPALIVE or NOTIFICATION message. If the device receives a KEEPALIVE message from the neighbor, the state changes to Established. If the message is a NOTIFICATION, the state changes to Idle. • ESTABLISHED – BGP4 is ready to exchange UPDATE messages with the neighbor. • If there is more BGP data in the TCP receiver queue, a plus sign (+) is also displayed. **NOTE:** If you display information for the neighbor using the **show ip bgp neighbor** <*ip-addr*> command, the TCP receiver queue value will be greater than 0.
Time	The amount of time this session has been in its current state.

TABLE 278 BGP4 neighbor information (Continued)

This field...	Displays...
KeepAliveTime	The keep alive time, which specifies how often this device sends keep alive messages to the neighbor.
HoldTime	The hold time, which specifies how many seconds the device will wait for a KEEPALIVE or UPDATE message from a BGP4 neighbor before deciding that the neighbor is dead.
PeerGroup	The name of the peer group the neighbor is in, if applicable.
Multihop-EBGP	Whether this option is enabled for the neighbor.
RouteReflectorClient	Whether this option is enabled for the neighbor.
SendCommunity	Whether this option is enabled for the neighbor.
NextHopSelf	Whether this option is enabled for the neighbor.
DefaultOriginate	Whether this option is enabled for the neighbor.
MaximumPrefixLimit	Lists the maximum number of prefixes the device will accept from this neighbor.
RemovePrivateAs	Whether this option is enabled for the neighbor.
RefreshCapability	Whether this device has received confirmation from the neighbor that the neighbor supports the dynamic refresh capability.
CooperativeFilteringCapability	Whether the neighbor is enabled for cooperative route filtering.
Distribute-list	Lists the distribute list parameters, if configured.
Filter-list	Lists the filter list parameters, if configured.
Prefix-list	Lists the prefix list parameters, if configured.
Route-map	Lists the route map parameters, if configured.
Messages Sent	The number of messages this device has sent to the neighbor. The display shows statistics for the following message types: • Open • Update • KeepAlive • Notification • Refresh-Req
Messages Received	The number of messages this device has received from the neighbor. The message types are the same as for the Message Sent field.
Last Update Time	Lists the last time updates were sent and received for the following: • NLRIs • Withdraws

TABLE 278 BGP4 neighbor information (Continued)

This field...	Displays...

Last Connection Reset Reason	The reason the previous session with this neighbor ended. The reason can be one of the following:
	• Reasons described in the BGP specifications:
	  • Message Header Error
	  • Connection Not Synchronized
	  • Bad Message Length
	  • Bad Message Type
	  • OPEN Message Error
	  • Unsupported Version Number
	  • Bad Peer AS Number
	  • Bad BGP Identifier
	  • Unsupported Optional Parameter
	  • Authentication Failure
	  • Unacceptable Hold Time
	  • Unsupported Capability
	  • UPDATE Message Error
	  • Malformed Attribute List
	  • Unrecognized Well-known Attribute
	  • Missing Well-known Attribute
	  • Attribute Flags Error
	  • Attribute Length Error
	  • Invalid ORIGIN Attribute
	  • Invalid NEXT_HOP Attribute
	  • Optional Attribute Error
	  • Invalid Network Field
	  • Malformed AS_PATH
	  • Hold Timer Expired
	  • Finite State Machine Error
	  • Rcv Notification

Last Connection Reset Reason (cont.)	• Reasons specific to the implementation:
	  • Reset All Peer Sessions
	  • User Reset Peer Session
	  • Port State Down
	  • Peer Removed
	  • Peer Shutdown
	  • Peer AS Number Change
	  • Peer AS Confederation Change
	  • TCP Connection KeepAlive Timeout
	  • TCP Connection Closed by Remote
	  • TCP Data Stream Error Detected

TABLE 278 BGP4 neighbor information (Continued)

This field...	Displays...

Notification Sent	If the device receives a NOTIFICATION message from the neighbor, the message contains an error code corresponding to one of the following errors. Some errors have subcodes that clarify the reason for the error. Where applicable, the subcode messages are listed underneath the error code messages.
	• Message Header Error:
	  • Connection Not Synchronized
	  • Bad Message Length
	  • Bad Message Type
	  • Unspecified
	• Open Message Error:
	  • Unsupported Version
	  • Bad Peer As
	  • Bad BGP Identifier
	  • Unsupported Optional Parameter
	  • Authentication Failure
	  • Unacceptable Hold Time
	  • Unspecified
	• Update Message Error:
	  • Malformed Attribute List
	  • Unrecognized Attribute
	  • Missing Attribute
	  • Attribute Flag Error
	  • Attribute Length Error
	  • Invalid Origin Attribute
	  • Invalid NextHop Attribute
	  • Optional Attribute Error
	  • Invalid Network Field
	  • Malformed AS Path
	  • Unspecified
	• Hold Timer Expired
	• Finite State Machine Error
	• Cease
	• Unspecified

Notification Received	See above.

TABLE 278 BGP4 neighbor information (Continued)

This field...	Displays...
TCP Connection state	The state of the connection with the neighbor. The connection can have one of the following states: • LISTEN – Waiting for a connection request. • SYN-SENT – Waiting for a matching connection request after having sent a connection request. • SYN-RECEIVED – Waiting for a confirming connection request acknowledgment after having both received and sent a connection request. • ESTABLISHED – Data can be sent and received over the connection. This is the normal operational state of the connection. • FIN-WAIT-1 – Waiting for a connection termination request from the remote TCP, or an acknowledgment of the connection termination request previously sent. • FIN-WAIT-2 – Waiting for a connection termination request from the remote TCP. • CLOSE-WAIT – Waiting for a connection termination request from the local user. • CLOSING – Waiting for a connection termination request acknowledgment from the remote TCP. • LAST-ACK – Waiting for an acknowledgment of the connection termination request previously sent to the remote TCP (which includes an acknowledgment of its connection termination request). • TIME-WAIT – Waiting for enough time to pass to be sure the remote TCP received the acknowledgment of its connection termination request. • CLOSED – There is no connection state.
Byte Sent	The number of bytes sent.
Byte Received	The number of bytes received.
Local host	The IP address of the device.
Local port	The TCP port the device is using for the BGP4 TCP session with the neighbor.
Remote host	The IP address of the neighbor.
Remote port	The TCP port the neighbor is using for the BGP4 TCP session with the device.
SentSeq	The initial send sequence number for the session.
SendNext	The next sequence number to be sent.
TotUnAck	The number of sequence numbers sent by the device that have not been acknowledged by the neighbor.
TotSent	The number of sequence numbers sent to the neighbor.
ReTrans	The number of sequence numbers that the device retransmitted because they were not acknowledged.
UnAckSeq	The current acknowledged sequence number.
IRcvSeq	The initial receive sequence number for the session.
RcvNext	The next sequence number expected from the neighbor.
SendWnd	The size of the send window.

TABLE 278 BGP4 neighbor information (Continued)

This field...	Displays...
TotalRcv	The number of sequence numbers received from the neighbor.
DupliRcv	The number of duplicate sequence numbers received from the neighbor.
RcvWnd	The size of the receive window.
SendQue	The number of sequence numbers in the send queue.
RcvQue	The number of sequence numbers in the receive queue.
CngstWnd	The number of times the window has changed.

Displaying advertised routes for a specified VPNv4 neighbor

To display the routes the device has advertised to a specific VPNv4 neighbor, enter a command such as the following at any level of the CLI.

```
NetIron# show ip bgp vpnv4 neighbors 2.2.2.2 advertised-routes
     There are 231 routes advertised to neighbor 2.2.2.2
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST E:EBGP I:IBGP L:LOCAL
       Prefix             Next Hop        Metric     LocPrf     Weight Status
1      10.100.100.30/32   0.0.0.0                    100        0      BE
         AS_PATH: 310
2      10.100.100.29/32   0.0.0.0                    100        0      BE
         AS_PATH: 310
3      10.100.100.28/32   0.0.0.0                    100        0      BE
         AS_PATH: 310
4      10.100.100.27/32   0.0.0.0                    100        0      BE
         AS_PATH: 310
5      10.100.100.26/32   0.0.0.0                    100        0      BE
         AS_PATH: 310
6      10.100.100.25/32   0.0.0.0                    100        0      BE
         AS_PATH: 310
7      10.100.100.24/32   0.0.0.0                    100        0      BE
         AS_PATH: 310
8      10.100.100.23/32   0.0.0.0                    100        0      BE
         AS_PATH: 310
```

Syntax: show ip bgp vpnv4 neighbor <*ip-addr*> **advertised-routes** [<*ip-addr*>/<*prefix*>]

For information about the fields in this display, refer to Table 273 on page 1621.

Displaying attribute entries for a specified VPNv4 neighbor

The neighbor attribute entries table lists the sets of BGP4 attributes stored in device memory. Each set of attributes is unique and can be associated with one or more routes. In fact, the device typically has fewer route attribute entries than routes. To display the route-attribute entries table for a specified VPNv4 neighbor, enter the following command.

```
NetIron# show ip bgp vpnv4 neighbors 2.2.2.2 attribute-entries
        Total number of BGP Attribute Entries: 35
1       Next Hop  :0.0.0.0            Metric   :0              Origin:IGP
        Originator:0.0.0.0            Cluster List:None
        Aggregator:AS Number :0      Router-ID:0.0.0.0         Atomic:None
        Local Pref:100               Communities:Internet
        Extended Community: RT 600:1
        AS Path   :310
        Address: 0x247194b0  Hash:45 (0x0100036e) Reference Counts: 0:0:30
2       Next Hop  :0.0.0.0            Metric   :0              Origin:IGP
        Originator:0.0.0.0            Cluster List:None
        Aggregator:AS Number :0      Router-ID:0.0.0.0         Atomic:None
        Local Pref:100               Communities:Internet
        Extended Community: RT 600:1
        AS Path   :311
        Address: 0x2471a480  Hash:47 (0x01000370) Reference Counts: 0:0:30
```

Syntax: show ip bgp vpnv4 neighbors <*IPaddress*> **attribute-entries**

The <*IPaddress*> variable is the IP address of the neighbor whose attribute entries you want to display.

This display shows the following information.

TABLE 279 BGP4 route-attribute entries information

This field...	Displays...
Total number of BGP Attribute Entries	The number attribute entries in the BGP4 route table for this device.
Next Hop	The IP address of the next hop device for routes with this set of attributes.
Metric	The cost of the routes that have this set of attributes.
Origin	The source of the route information. The origin can be one of the following: • EGP – The routes with this set of attributes came to BGP through EGP. • IGP – The routes with this set of attributes came to BGP through IGP. • INCOMPLETE – The routes came from an origin other than one of the above. For example, they may have been redistributed from OSPF or RIP. When BGP4 compares multiple routes to a destination to select the best route, IGP is preferred over EGP and both are preferred over INCOMPLETE.
Originator	The originator of the route in a route reflector environment.
Cluster List	The route-reflector clusters through which this set of attributes has passed.
Aggregator	Aggregator information: • **AS Number** shows the AS in which the network information in the attribute set was aggregated. This value applies only to aggregated routes and is otherwise 0. • **Router-ID** shows the device that originated this aggregator.
Router ID	

TABLE 279 BGP4 route-attribute entries information (Continued)

This field...	Displays...
Atomic	Whether the network information in this set of attributes has been aggregated and this aggregation has resulted in information loss: • TRUE – Indicates information loss has occurred • FALSE – Indicates no information loss has occurred **NOTE:** Information loss under these circumstances is a normal part of BGP4 and does not indicate an error.
Local Pref	The degree of preference for routes that use this set of attributes relative to other routes in the local AS.
Communities	The communities that routes with this set of attributes are in.
Extended Community	The extended community attributes of the device.
AS Path	The ASs through which routes with this set of attributes have passed. The local AS is shown in parentheses.
Address	This field is for internal Dell debugging purposes only.
Hash	This field is for internal Dell debugging purposes only.
Reference Counts	This field is for internal Dell debugging purposes only.

Displaying Flap statistics for a specified VPNv4 neighbor by IP address

To display flap-statistics for routes learned from the specified VRF neighbor, enter the following command at any level of the CLI.

```
R3-2547(config)#show ip bgp vpnv4 neighbors 2.2.2.2 flap-statistics
Total number of flapping routes: 0
```

Syntax: show ip bgp vpnv4 <*vrf-name*> **neighbor** <*ip-addr*> **flap-statistics**

The <*vrf-name*> parameter specifies the VPNv4 neighbor you want to display flap-statistics for.

The <*address*> <*mask*> parameter specifies a particular route. If you also use the optional **longer-prefixes** parameter, then all statistics for routes that match the specified route or have a longer prefix than the specified route are displayed. For example, if you specify **209.157.0.0 longer**, then all routes with the prefix 209.157 or that have a longer prefix (such as 209.157.22) are displayed.

This display shows the following information.

TABLE 280 Route flap dampening statistics

This field...	Displays...
Total number of flapping routes	The total number of routes in the device's BGP4 route table that have changed state and thus have been marked as flapping routes.

Displaying received ORFs information for a specified VPNv4 neighbor

To view BGP4 configuration information and statistics for a specified VPNv4 neighbor, enter the following command.

```
NetIron# show ip bgp vpn neighbors 2.2.2.2 received extended-community
Extended-community ORF capability was not negotiated
 No Prefix filter ORF received from neighbor 2.2.2.2!
```

Displaying a specified neighbor VPNv4 routes

To view the route table for a specified neighbor, enter the following command.

```
NetIron#show ip bgp vpnv4 neighbors 10.10.2.3 routes
       There are 30 accepted routes from neighbor 10.10.2.3
Searching for matching routes, use ^C to quit...
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED F:FILTERED
       Prefix             Next Hop        Metric     LocPrf     Weight Status

         AS_PATH: 310
6      10.100.100.6/32    10.10.2.3                  100        0      BE
         AS_PATH: 310
7      10.100.100.7/32    10.10.2.3                  100        0      BE
         AS_PATH: 310
8      10.100.100.8/32    10.10.2.3                  100        0      BE
         AS_PATH: 310
9      10.100.100.9/32    10.10.2.3                  100        0      BE
         AS_PATH: 310
```

Syntax: show ip bgp vpnv4 neighbors <*ip-addr*> **routes**

For information about the fields in this display, refer to Table 273 on page 1621.

Displaying the best routes

To display the routes received from a specific neighbor that are the “best” routes to their destinations, enter a command such as the following at any level of the CLI.

```
NetIron# show ip bgp vpnv4 neighbor 192.168.4.211 routes best
```

Syntax: show ip bgp vpnv4 neighbor <*ip-addr*> **routes best**

For information about the fields in this display, refer to Table 273 on page 1621.

Displaying the best routes that were nonetheless not installed in the IP route table

To display the BGP4 routes received from a specific neighbor that are the "best" routes to their destinations but are not installed in the device's IP route table, enter a command such as the following at any level of the CLI.

```
NetIron# show ip bgp vpnv4 neighbor 192.168.4.211 routes not-installed-best
```

Each of the displayed routes is a valid path to its destination, but the device received another path from a different source (such as OSPF, RIP, or a static route) that has a lower administrative distance. The device always selects the path with the lowest administrative distance to install in the IP route table.

Syntax: show ip bgp vpnv4 neighbor <*ip-addr*> **routes not-installed-best**

For information about the fields in this display, refer to Table 273 on page 1621.

Displaying the routes whose destinations are unreachable

To display BGP4 routes whose destinations are unreachable using any of the BGP4 paths in the BGP4 route table, enter a command such as the following at any level of the CLI.

```
NetIron# show ip bgp vpnv4 neighbor 192.168.4.211 routes unreachable
```

Syntax: show ip bgp vpnv4 neighbor <*ip-addr*> **routes unreachable**

For information about the fields in this display, refer to Table 273 on page 1621.

Displaying the Adj-RIB-Out for a VRF neighbor

To display the device's current BGP4 Routing Information Base (Adj-RIB-Out) for a specific VRF neighbor and a specific destination network, enter a command such as the following at any level of the CLI.

```
NetIron#show ip bgp vpnv4 neighbor 10.10.2.3 rib-out-routes
       There are 154 RIB_out routes for neighbor 10.10.2.3
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST E:EBGP I:IBGP L:LOCAL
       Prefix             Next Hop        Metric     LocPrf     Weight Status
1      10.100.101.30/32   10.10.3.3                  100        0      BE
         AS_PATH: 311
2      10.100.101.29/32   10.10.3.3                  100        0      BE
         AS_PATH: 311
3      10.100.101.28/32   10.10.3.3                  100        0      BE
         AS_PATH: 311
4      10.100.101.27/32   10.10.3.3                  100        0      BE
         AS_PATH: 311
5      10.100.101.26/32   10.10.3.3                  100        0      BE
         AS_PATH: 311
6      10.100.101.25/32   10.10.3.3                  100        0      BE
         AS_PATH: 311
7      10.100.101.24/32   10.10.3.3                  100        0      BE
         AS_PATH: 311
8      10.100.101.23/32   10.10.3.3                  100        0      BE
         AS_PATH: 311
9      10.100.101.22/32   10.10.3.3                  100        0      BE
         AS_PATH: 311
10     10.100.101.21/32   10.10.3.3                  100        0      BE
         AS_PATH: 311
```

The Adj-RIB-Out contains the routes that the device either has most recently sent to the VRF neighbor or is about to send to the neighbor.

Syntax: show ip bgp vpnv4 neighbor <*ip-addr*> **rib-out-routes** [<*ip-addr*>/<*prefix*>]

For information about the fields in this display, refer to Table 273 on page 1621

Displaying routes summary for a specified VPNv4 neighbor

To view the route table for a specified VPNv4 neighbor, enter the following command.

```
NetIron#show ip bgp vpnv4 neighbor 10.10.2.3 routes-summary
1   IP Address: 10.10.2.3
Routes Accepted/Installed:30,  Filtered/Kept:0,  Filtered:0
   Routes Selected as BEST Routes:30
      BEST Routes not Installed in IP Forwarding Table:0
   Unreachable Routes (no IGP Route for NEXTHOP):0
   History Routes:0
NLRIs Received in Update Message:30,  Withdraws:0 (0),  Replacements:0
   NLRIs Discarded due to
      Maximum Prefix Limit:0, AS Loop:0
      Invalid Nexthop:0, Invalid Nexthop Address:0.0.0.0
      Duplicated Originator_ID:0, Cluster_ID:0
Routes Advertised:154,  To be Sent:0,  To be Withdrawn:0
NLRIs Sent in Update Message:154,  Withdraws:0,  Replacements:0
Peer Out of Memory Count for:
   Receiving Update Messages:0, Accepting Routes(NLRI):0
   Attributes:0, Outbound Routes(RIB-out):0 Outbound Routes Holder:0
```

This display shows the following information.

TABLE 281 BGP4 route summary information for a VPNv4 neighbor

This field...	Displays...
Routes Accepted or Installed	How many routes the has received from the neighbor during the current BGP4 session: • Filtered – Indicates how many of the received routes the device filtered and did not accept. • Filtered or kept – Indicates how many of the received routes the device did not accept or install because they were denied by filters.
Routes Selected as BEST Routes	The number of routes that the device selected as the best routes to their destinations.
BEST Routes not Installed in IP Forwarding Table	The number of routes received from the neighbor that are the best BGP4 routes to their destinations, but were nonetheless not installed in the IP route table because the device received better routes from other sources (such as OSPF, RIP, or static IP routes).
Unreachable Routes	The number of routes received from the neighbor that are unreachable because the device does not have a valid RIP, OSPF, or static route to the next hop.
History Routes	The number of routes that are down but are being retained for route flap dampening purposes.
NLRIs Received in Update Message	The number of routes received in Network Layer Reachability (NLRI) format in UPDATE messages: • Withdraws – The number of withdrawn routes the device has received. • Replacements – The number of replacement routes the device has received.
NLRIs Discarded due to	Indicates the number of times the device discarded an NLRI for the neighbor due to the following reasons: • Maximum Prefix Limit – The configured maximum prefix amount had been reached. • AS Loop – An AS loop occurred. An AS loop occurs when the BGP4 AS-path attribute contains the local AS number. • Invalid Nexthop – The next hop value was not acceptable. • Duplicated Originator_ID – The originator ID was the same as the local device ID. • Cluster_ID – The cluster list contained the local cluster ID, or contained the local device ID (see above) if the cluster ID is not configured.
Routes Advertised	The number of routes the device has advertised to this neighbor: • To be Sent – The number of routes the device has queued to send to this neighbor. • To be Withdrawn – The number of NLRIs for withdrawing routes the device has queued up to send to this neighbor in UPDATE messages.

TABLE 281 BGP4 route summary information for a VPNv4 neighbor (Continued)

This field...	Displays...
NLRIs Sent in Update Message	The number of NLRIs for new routes the has sent to this neighbor in UPDATE messages: • Withdraws – The number of routes the device has sent to the neighbor to withdraw. • Replacements – The number of routes the device has sent to the neighbor to replace routes the neighbor already has.
Peer Out of Memory Count for	Statistics for the times the device has run out of BGP4 memory for the neighbor during the current BGP4 session: • Receiving Update Messages – The number of times UPDATE messages were discarded because there was no memory for attribute entries. • Accepting Routes(NLRI) – The number of NLRIs discarded because there was no memory for NLRI entries. This count is not included in the Receiving Update Messages count. • Attributes – The number of times there was no memory for BGP4 attribute entries. • Outbound Routes (RIB-out) – The number of times there was no memory to place a "best" route into the neighbor's route information base (Adj-RIB-Out) for routes to be advertised.

Displaying summary route information

To display summary statistics for all the VPNv4 routes in the device's BGP route table, enter a command such as the following at any level of the CLI.

```
NetIron# show ip bgp vpnv4 routes summary
  Total number of BGP routes (NLRIs) Installed     : 184
  Distinct BGP destination networks                : 184
  Filtered bgp routes for soft reconfig            : 0
  Routes originated by this router                 : 4
  Routes selected as BEST routes                   : 184
  BEST routes not installed in IP forwarding table : 0
  Unreachable routes (no IGP route for NEXTHOP)    : 0
  IBGP routes selected as best routes              : 90
  EBGP routes selected as best routes              : 90
```

Syntax: show ip bgp vpnv4 routes summary

This display shows the following information.

TABLE 282 BGP VPNv4 summary route information

This field...	Displays...
Total number of BGP VPNv4 routes (NLRIs) Installed	The number of BGP VPNv4 routes the device has installed in the BGP route table.
Distinct BGP VPNv4 destination networks	The number of destination networks the installed routes represent. The BGP route table can have multiple routes to the same network.
Filtered BGP VPNv4 routes for soft reconfig	The number of route updates received from soft-reconfigured neighbors or peer groups that have been filtered out but retained.
Routes originated by this device	The number of VPNv4 routes in the BGP route table that this device originated.

TABLE 282 BGP VPNv4 summary route information (Continued)

This field...	Displays...
Routes selected as BEST routes	The number of VPNv4 routes in the BGP route table that this device has selected as the best routes to the destinations.
BEST routes not installed in IP forwarding table	The number of BGP VPNv4 routes that are the best BGP VPNv4 routes to their destinations but were not installed in the IP route table because the device received better routes from other sources.
Unreachable routes (no IGP route for NEXTHOP)	The number of routes in the BGP route table whose destinations are unreachable because the next hop is unreachable.
IBGP routes selected as best routes	The number of "best" routes in the BGP VPNv4 route table that are IBGP routes.
EBGP routes selected as best routes	The number of "best" routes in the BGP VPNv4 route table that are EBGP routes.

Displaying the VPNv4 route table

If you want to view all the VPNv4 routes in a network, you can display the BGP VPNv4 table using the following method.

To view the BGP VPNv4 route table, enter the following command.

```
NetIron# show ip bgp vpnv4 routes
Total number of BGP Routes: 288
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED
       Prefix             Next Hop        Metric     LocPrf     Weight Status
Route Distinguisher: 4:1
1      10.6.1.0/24        2.2.2.2         3          100        0      I
         AS_PATH:
2      10.8.1.0/24        2.2.2.2         2          100        0      I
         AS_PATH:

5      10.40.1.3/32       2.2.2.2         4          100        0      I
         AS_PATH:
```

Syntax: **show ip bgp vpnv4 routes** [<*ip-addr*>] | <*num*> | [**age** <*secs*>] | [**as-path-access-list** <*num*>] |
[**as-path-filter** <*num, num,...*>] |[**best**] | [**cidr-only**] | [**community** <*num*> | **no-export** | **no-advertise** | **internet** | **local-as**] | [**community-access-list** <*num*>] | **community-filter** <*num*> | **community-reg-expression** <*regular-expression*>
| **detail** | **local** | **neighbor** <*ip-addr*> [**next-hop** <*ip-addr*>] | [**no-best**] | [**not-installed-best**] | [**prefix-list** <*string*>] | [**regular-expression** <*regular-expression*>] | [**route-map** <*map-name*>] | [**summary**] | [**unreachable**]

The <*ip-addr*> option displays routes for a specific network.

The <*num*> option specifies the table entry with which you want the display to start. For example, if you want to list entries beginning with table entry 100, specify 100.

The **age** <*secs*> parameter displays only the routes that have been received or updated more recently than the number of seconds you specify.

The **as-path-access-list** <*num*> parameter filters the display using the specified AS-path ACL.

The **best** parameter displays the routes received from the neighbor that the device selected as the best routes to their destinations.

The **cidr-only** option lists only the routes whose network masks do not match their class network length.

The **community** option lets you display routes for a specific community. You can specify **local-as**, **no-export**,
no-advertise, **internet**, or a private community number. You can specify the community number as either two five-digit integer values of up to 1– 65535, separated by a colon (for example, 12345:6789) or a single long integer value.

The **community-access-list** <*num*> parameter filters the display using the specified community ACL.

The **community-filter** option lets you display routes that match a specific community filter.

The **community regular-expression** <*regular-expression*> option filters the display based on a specified community regular expression.

The **local** option ....

The **neighbor** <*ip-addr*> option displays the number of accepted routes from the specified BGP neighbor.

The **detail** option lets you display more details about the routes. You can refine your request by also specifying one of the other display options after the **detail** keyword.

The **next-hop** <*ip-addr*> option displays the routes for a given next-hop IP address.

The **no-best** option displays the routes for which none of the routes to a given prefix were selected as the best route.

The **not-installed-best** option displays the routes received from the neighbor that are the best BGP4 routes to their destinations, but were nonetheless not installed in the IP route table because the device received better routes from other sources (such as OSPF, RIP, or static IP routes).

The **prefix-list** <*string*> parameter filters the display using the specified IP prefix list.

The **regular-expression** <*regular-expression*> option filters the display based on a regular expression.

The **route-map** <*map-name*> parameter filters the display using the specified route map. The software displays only the routes that match the match statements in the route map. The software disregards the route map's set statements.

The **summary** option displays summary information for the routes.

The **unreachable** option displays the routes that are unreachable because the device does not have a valid RIP, OSPF, or static route to the next hop.

For information about the fields in this display, refer to Table 273 on page 1621. The fields in this display also appear in the **show ip bgp vpnv4** display.

Displaying the best VPNv4 routes

To display all the VPNv4 routes in the BGP VPNv4 route table for the router that are the best routes to their destinations, enter a command such as the following at any level of the CLI.

```
NetIron(config-bgp-router)# show ip bgp vpnv4 routes best
Total number of BGP Routes: 28
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED F:FILTERED
       Prefix             Next Hop        Metric     LocPrf     Weight Status
Route Distinguisher: 4:1
1      3.0.0.0/8          192.168.4.106              100        0      BE
         AS_PATH: 65001 4355 701 80
2      4.0.0.0/8          192.168.4.106              100        0      BE
         AS_PATH: 65001 4355 1
3      4.60.212.0/22      192.168.4.106              100        0      BE
         AS_PATH: 65001 4355 701 1 189
4      6.0.0.0/8          192.168.4.106              100        0      BE
         AS_PATH: 65001 4355 3356 7170 1455
5      9.2.0.0/16         192.168.4.106              100        0      BE
         AS_PATH: 65001 4355 701
```

Syntax: show ip bgp vpnv4 routes best

For information about the fields in this display, refer to Table 273 on page 1621.

Displaying best VPNv4 routes that are not in the IP route table

When the router has multiple routes to a destination, the router selects the route with the lowest administrative distance as the best route, and installs that route in the IP route table.

To display the BGP4 routes that are the “best” routes to their destinations but are not installed in the device’s IP route table, enter a command such as the following at any level of the CLI.

```
NetIron(config-bgp-router)# show ip bgp vpnv4 routes not-installed-best
Searching for matching routes, use ^C to quit...
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED F:FILTERED
Route Distinguisher: 4:1
       Prefix             Next Hop        Metric     LocPrf     Weight Status
1      3.0.0.0/8          192.168.4.106              100        0      BE
       AS_PATH: 65001 4355 701 80
```

Each of the displayed routes is a valid path to its destination, but the router received another path from a different source that has a lower administrative distance. The router always selects the path with the lowest administrative distance to install in the IP route table.

Syntax: show ip bgp vpnv4 routes not-installed-best

For information about the fields in this display, refer to Table 273 on page 1621.

NOTE
To display the routes that the router has selected as the best routes and installed in the IP route table, display the IP route table using the **show ip route** command.

Displaying VPNv4 routes with unreachable destinations

To display BGP VPNv4 routes whose destinations are unreachable using any of the paths in the BGP route table, enter a command such as the following at any level of the CLI.

```
NetIron(config-bgp-router)# show ip bgp vpnv4 routes unreachable
Searching for matching routes, use ^C to quit...
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED F:FILTERED
Route Distinguisher: 4:1
       Prefix             Next Hop        Metric     LocPrf     Weight Status
1      3.0.0.0/8          192.168.4.106              100        0      BE
       AS_PATH: 65001 4355 701 80
```

Syntax: show ip bgp vpnv4 routes unreachable

For information about the fields in this display, refer to Table 273 on page 1621.

Displaying information for a specific VPNv4 route

To display BGP VPNv4 route information by specifying an IP address within the network, enter a command such as the following at any level of the CLI.

```
NetIron# show ip bgp vpnv4 routes 10.8.1.0/24
Route Distinguisher: 4:1
Number of BGP Routes matching display condition : 1
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED F:FILTERED
       Prefix             Next Hop        Metric     LocPrf     Weight Status
1      10.8.1.0/24        2.2.2.2         2          100        0      I
         AS_PATH:
Route Distinguisher: 5:1
Number of BGP Routes matching display condition : 1
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED F:FILTERED
       Prefix             Next Hop        Metric     LocPrf     Weight Status
1      10.8.1.0/24        4.4.4.4         3          100        0      I
         AS_PATH:
```

Syntax: show ip bgp vpnv4 routes <*ip-addr*>/<*prefix*> **[longer-prefixes] |** <*ip-addr*>

For information about the fields in this display, refer to Table 273 on page 1621 and Table 283.

Displaying VPNv4 route details

Here is an example of the information displayed when you use the **detail** option. In this example, the information for one route is shown.

```
NetIron# show ip bgp vpnv4 routes detail
Total number of BGP Routes: 288
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED
Route Distinguisher: 4:1
1     Prefix: 10.6.1.0/24,  Status: I,  Age: 15h36m10s
      NEXT_HOP: 2.2.2.2,  Learned from Peer: 2.2.2.2 (1)
      Out-Label: 500000
        LOCAL_PREF: 100,  MED: 3,  ORIGIN: incomplete,  Weight: 0
        AS_PATH:
        Extended Community: RT 300:1 OSPF DOMAIN ID:0.0.0.0 OSPF RT 0:1:0 OSPF RO
ID:0.0.0.0
```

For information about the fields in this display, refer to Table 273 on page 1621 and Table 283.

TABLE 283 BGP VPNv4 route information

This field...	Displays...
Prefix	The network address and prefix.
Age	The last time an update occurred.
Learned from Peer	The IP address of the neighbor that sent this route.
Local_Pref	The degree of preference for this route relative to other routes in the local AS. When the BGP4 algorithm compares routes on the basis of local preferences, the route with the higher local preference is chosen. The preference can have a value from 0 – 4294967295.
MED	The route's metric. If the route does not have a metric, this field is blank.
Origin	The source of the route information. The origin can be one of the following: • EGP – The routes with this set of attributes came to BGP through EGP. • IGP – The routes with this set of attributes came to BGP through IGP. • INCOMPLETE – The routes came from an origin other than one of the above. For example, they may have been redistributed from OSPF or RIP. When BGP4 compares multiple routes to a destination to select the best route, IGP is preferred over EGP and both are preferred over INCOMPLETE.
Atomic	Whether network information in this route has been aggregated and this aggregation has resulted in information loss. **NOTE:** Information loss under these circumstances is a normal part of BGP4 and does not indicate an error.
Aggregation ID	The router that originated this aggregator.
Aggregation AS	The AS in which the network information was aggregated. This value applies only to aggregated routes and is otherwise 0.
Originator	The originator of the route in a route reflector environment.
Cluster List	The route-reflector clusters through which this route has passed.
Learned From	The IP address of the neighbor from which the router learned the route.
Admin Distance	The administrative distance of the route.
Adj_RIB_out	The number of neighbors to which the route has been or will be advertised. This is the number of times the route has been selected as the best route and placed in the Adj-RIB-Out (outbound queue) for a BGP4 neighbor.
Communities	The communities the route is in.
Extended Community	The routers extended community attributes.

Displaying BGP VPNv4 MPLS tag information

To display the MPLS **in-label** and **out-label** tags in the VPNv4 routes, enter a command such as the following at any level of the CLI.

```
NetIron# show ip bgp vpnv4 tags
    Network            Next Hop        In-Label Out-Label
Route Distinguisher: 1:1
    10.80.1.1/32       2.2.2.2         -        500003
    10.80.1.2/32       2.2.2.2         -        500003
    10.80.1.3/32       2.2.2.2         -        500003
    10.80.1.4/32       2.2.2.2         -        500003
    10.80.1.5/32       2.2.2.2         -        500003
    10.80.1.6/32       2.2.2.2         -        500003
    10.80.1.7/32       2.2.2.2         -        500003
    10.80.1.8/32       2.2.2.2         -        500003
```

The **In-Label** and **Out-Label** fields in this display are described in Table 284 below. For information about all other fields in this display, refer to Table 273 on page 1621.

TABLE 284 Route flap dampening statistics

This field...	Displays...
In-Label	Local assigned MPLS label value.
Out-Label	Learned MPLS label value

Displaying BGP or MPLS VRF information

You can display the following information about a BGP or MPLS VRF configuration on the device:

- "Displaying VRF route information"
- "Displaying VRF route information for a specified IP address"
- "Displaying attribute entries information for a specified VRF"
- "Displaying dampened paths information for a specified VRF"
- "Displaying filtered routes information for a specified VRF"
- "Displaying Flap statistics information for a specified VRF"
- "Displaying BGP neighbor information for a specified VRF"
- "Displaying advertised routes for a specified VRF neighbor"
- "Displaying neighbor attribute entries for a specified VRF"
- "Displaying flap statistics for a specified VRF neighbor by IP address"
- "Displaying received ORF information for a specified VRF neighbor"
- "Displaying received routes for a specified VRF neighbor"
- "Displaying a specified VRF neighbor routes"
- "Displaying VPNv4 routes summary for a specified VRF neighbor"
- "Displaying summary route information for a specified VRF"
- "Displaying a VRF's BGP4 route table"

Displaying VRF route information

You can display information about BGP routes that are contained within a specified VRF route table by entering a command such as the following at any level of the CLI.

```
NetIron# show ip bgp vrf red
Total number of BGP Routes: 285
Status codes: s suppressed, d damped, h history, * valid, > best, i internal
Origin codes: i - IGP, e - EGP, ? - incomplete
    Network            Next Hop RD     Metric LocPrf Weight Path
*i  10.80.1.1/32       2.2.2.2  1:1    100    0      206 311 i
*i  10.80.1.2/32       2.2.2.2  1:1    100    0      206 311 i
*i  10.80.1.3/32       2.2.2.2  1:1    100    0      206 311 i
*i  10.80.1.4/32       2.2.2.2  1:1    100    0      206 311 i
*i  10.80.1.5/32       2.2.2.2  1:1    100    0      206 311 i
--More--, next page: Space, next line: Return key, quit: Control-c
```

This display shows the following information.

TABLE 285 BGP4 summary information

This field...	Displays...
Total number of BGP Routes:	The number of BGP routes.
Status or Status Codes	The route's status, which can be one or more of the following: • A – AGGREGATE. The route is an aggregate route for multiple networks. • B – BEST. BGP4 has determined that this is the optimal route to the destination. **NOTE:** If the "b" is shown in lowercase, the software was not able to install the route in the IP route table. • b – NOT-INSTALLED-BEST. The routes received from the neighbor are the best BGP4 routes to their destinations, but were nonetheless not installed in the IP route table because the router received better routes from other sources (such as OSPF, RIP, or static IP routes). • C – CONFED_EBGP. The route was learned from a neighbor in the same confederation and AS, but in a different sub-AS within the confederation. • D – DAMPED. This route has been dampened (by the route dampening feature), and is currently unusable. • H – HISTORY. Route dampening is configured for this route, and the route has a history of flapping and is unreachable now. • I – INTERNAL. The route was learned through BGP4. • L – LOCAL. The route originated on this router. • M – MULTIPATH. BGP4 load sharing is enabled and this route was selected as one of the best ones to the destination. The best route among the multiple paths also is marked with "B". **NOTE:** If the "m" is shown in lowercase, the software was not able to install the route in the IP route table. • S – SUPPRESSED. This route was suppressed during aggregation and thus is not advertised to neighbors. **NOTE:** This field appears only if you enter the **route** option.
Origin code	A character the display uses to indicate the route's origin. The origin code appears to the right of the AS path (Path field). The origin codes are described in the command's output.

TABLE 285 BGP4 summary information (Continued)

This field...	Displays...
RD	The Route Distinguisher. A unique ID that is prepended on any address being routed or advertised from a VRF. The RD can be defined as either ASN-relative or IP address-relative as described: • ASN-relative - Composed of the local ASN number followed by a ":" and a unique arbitrary number. For example: 3:6 • IP address-relative - Composed of the local IP address followed by a ":" and a unique arbitrary number.
Network	IP address or mask of the destination network of the route.
Next Hop	The next-hop router for reaching the network from this router.
Metric	The value of the route's MED attribute. If the route does not have a metric, this field is blank.
LocPrf	The degree of preference for this route relative to other routes in the local AS. When the BGP4 algorithm compares route on the basis of local preference, the route with the higher local preference is chosen. The preference can have a value from 0-4294967295
Weight	The value that this route associates with routes from a specific neighbor. For example, if the router receives routes to the same destination from two BGP4 neighbors, the router prefers the route from the neighbor with the larger weight.
Path	The routes AS path.

To clear the route table for a specific BGP VRF, enter the following command.

```
NetIron# clear ip bgp vrf green
```

Syntax: **clear ip bgp vrf** <*vrf-name*> **[dampening | flap-statistics | local | neighbor | routes | traffic]**

The **dampening** parameter clears route flap dampening statistics.

The **flap-statistics** parameter clears route flap statistics.

The **local** parameter clears local information.

The **neighbor** parameter clears the BGP neighbor.

The **routes** parameter clears the BGP routes.

The **traffic** parameter clears BGP traffic counters.

Displaying VRF route information for a specified IP address

To display only the routes to a specified network, enter a command such as the following at any level of the CLI.

```
NetIron# show ip bgp vrf green 10.2.2.0/24
Route Distinguisher: 2:1
Number of BGP Routes matching display condition : 1
Status codes: s suppressed, d damped, h history, * valid, > best, i internal
Origin codes: i - IGP, e - EGP, ? - incomplete
    Network          Next Hop      Metric LocPrf Weight Path
*i  10.2.2.0/24        4.4.4.4        1      100     0       ?
       Route is advertised to 2 peers:
        4.4.4.4(1)             2.2.2.2(1)
```

Syntax: show ip bgp vrf <*vrf-name*> <*ip-addr*>

The <*address*> <*mask*> parameter specifies a particular route. If you also use the optional **longer-prefixes** parameter, then all statistics for routes that match the specified route or have a longer prefix than the specified route are displayed. For example, if you specify **209.157.0.0 longer**, then all routes with the prefix 209.157 or that have a longer prefix (such as 209.157.22) are displayed.

The **Number of BGP Routes** matching display conditions field in this display is described in Table 286 below. For information about all other fields in this display, refer to Table 285.

TABLE 286 VRF route information

This field...	Displays...
Number of BGP Routes matching display conditions	The number of routes to the network specified as a parameter in the **show ip bgp vpnv4** <*ip-addr*> command.

Displaying attribute entries information for a specified VRF

The route-attribute entries table lists the sets of BGP attributes stored in the router's memory. Each set of attributes is unique and can be associated with one or more routes. In fact, the router typically has fewer route attribute entries than routes. To display the route-attribute entries table at any level of the CLI.

```
NetIron# show ip bgp vrf green attribute-entries
        Total number of BGP Attribute Entries: 26
1       Next Hop  :192.168.201.2      Metric   :1              Origin:INCOMP
        Originator:0.0.0.0            Cluster List:None
        Aggregator:AS Number :0      Router-ID:0.0.0.0         Atomic:None
        Local Pref:100               Communities:Internet
        AS Path   :
        Address: 0x247017ec  Hash:279 (0x03000000) Reference Counts: 1:0:0
2       Next Hop  :192.168.201.2      Metric   :2              Origin:INCOMP
        Originator:0.0.0.0            Cluster List:None
        Aggregator:AS Number :0      Router-ID:0.0.0.0         Atomic:None
        Local Pref:100               Communities:Internet
        AS Path   :
        Address: 0x247016d8  Hash:280 (0x03000000) Reference Counts: 1:0:0
3       Next Hop  :192.168.201.2      Metric   :3              Origin:INCOMP
        Originator:0.0.0.0            Cluster List:None
        Aggregator:AS Number :0      Router-ID:0.0.0.0         Atomic:None
        Local Pref:100               Communities:Internet
        AS Path   :
        Address: 0x24701900  Hash:281 (0x03000000) Reference Count
```

This display shows the following information.

TABLE 287 BGP VPNv4 attribute entries

This field...	Displays...
Total number of BGP Attribute Entries	The number of routes contained in this router's BGP4 route table.
Next Hop	The IP address of the next hop router for routes that have this set of attributes.
Metric	The cost of the routes that have this set of attributes.
Origin	The source of the route information. The origin can be one of the following: • EGP – The routes with this set of attributes came to BGP through EGP. • IGP – The routes with this set of attributes came to BGP through IGP. • INCOMPLETE – The routes came from an origin other than one of the above. For example, they may have been redistributed from OSPF or RIP. When BGP4 compares multiple routes to a destination to select the best route, IGP is preferred over EGP and both are preferred over INCOMPLETE.
Originator	The originator of the route in a route reflector environment.
Cluster List	The route-reflector clusters through which this set of attributes has passed.
Aggregator	Aggregator information: • **AS Number** shows the AS in which the network information in the attribute set was aggregated. This value applies only to aggregated routes and is otherwise 0. **Router-ID** shows the router that originated this aggregator
Atomic	Whether the network information in this set of attributes has been aggregated and this aggregation has resulted in information loss: • TRUE – Indicates information loss has occurred • FALSE – Indicates no information loss has occurred **NOTE:** Information loss under these circumstances is a normal part of BGP4 and does not indicate an error.
Local Pref	The degree of preference for routes that use this set of attributes relative to other routes in the local AS.
Communities	The communities that routes with this set of attributes are in.
AS Path	The ASs through which routes with this set of attributes have passed. The local AS is shown in parentheses.
Address	This field is used for internal Dell debugging purposes only.
Hash	This field is used for internal Dell debugging purposes only.
Reference Counts	This field is used for internal Dell debugging purposes only.

Displaying dampened paths information for a specified VRF

To view BGP VPNv4 paths suppressed due to dampening for a specified VRF, enter the following command.

```
NetIron# show ip bgp vrf green dampened-paths
```

Displaying filtered routes information for a specified VRF

To view BGP VPNv4 filtered paths information for a specified VRF, enter the following command.

```
NetIron# show ip bgp vrf green filtered-routes
```

Displaying Flap statistics information for a specified VRF

To display flap statistics for a specified VRF, enter the following command at any level of the CLI.

```
NetIron# show ip bgp vrf green flap-statistics
```

Syntax: **show ip bgp flap-statistics [regular-expression** <*regular-expression*> **|** <*address*> <*mask*> **[longer-prefixes] | neighbor** <*ip-addr*> **| filter-list** <*num*>**...]**

The <*address*> <*mask*> parameter specifies a particular route. If you also use the optional **longer-prefixes** parameter, then all statistics for routes that match the specified route or have a longer prefix than the specified route are displayed. For example, if you specify **209.157.0.0 longer**, then all routes with the prefix 209.157 or that have a longer prefix (such as 209.157.22) are displayed.

The **as-path-filter** <*num*> parameter specifies one or more filters. Only the routes that have been dampened and that match the specified filter or filters are displayed.

The **neighbor** <*ip-addr*> parameter displays route flap dampening statistics only for routes learned from the specified neighbor. You also can display route flap statistics for routes learned from a neighbor by entering the following command: **show ip bgp neighbor** <*ip-addr*> **flap-statistics**.

The **regular-expression** <*regular-expression*> parameter is a regular expression. The regular expressions are the same ones supported for BGP4 AS-path filters.

This display shows the following information.

TABLE 288 Route flap dampening statistics

This field...	Displays...
Total number of flapping routes	The total number of routes in the device's BGP4 route table that have changed state and thus have been marked as flapping routes.

You also can display all the dampened routes by entering the following command: **show ip bgp dampened-paths**.

Displaying BGP neighbor information for a specified VRF

To view BGP4 configuration information and statistics for a specified VRF's neighbors, enter the following command.

```
NetIron# show ip bgp vrf black neighbor
    Total number of BGP Neighbors: 3
1   IP Address: 10.10.2.3, AS: 206 (EBGP), RouterID: 10.10.2.3, VRF: black
    State: ESTABLISHED, Time: 14h31m51s, KeepAliveTime: 60, HoldTime: 180
       KeepAliveTimer Expire in 4 seconds, HoldTimer Expire in 135 seconds
    Messages:    Open    Update  KeepAlive Notification Refresh-Req
       Sent    : 1       4       871       0            0
       Received: 1       1       873       0            0
    Last Update Time: NLRI       Withdraw          NLRI       Withdraw
                  Tx: ---        ---           Rx: ---        ---
    Last Connection Reset Reason:Unknown
    Notification Sent:     Unspecified
    Notification Received: Unspecified
    Neighbor NLRI Negotiation:
      Peer Negotiated IPV4  unicast  capability
      Peer configured for IPV4 unicast  Routes
    TCP Connection state: ESTABLISHED
    TTL check: 0, value: 0, rcvd: 64
       Byte Sent:   17543, Received: 16814
       Local host:  10.10.2.1, Local  Port: 8135
       Remote host: 10.10.2.3, Remote Port: 179
       ISentSeq:    3301937  SendNext:    3319481  TotUnAck:          0
       TotSent:       17544  ReTrans:           0  UnAckSeq:    3319481
       IRcvSeq:   466270178  RcvNext:   466286993  SendWnd:        6432
       TotalRcv:      16815  DupliRcv:        285  RcvWnd:        65000
       SendQue:           0  RcvQue:            0  CngstWnd:       1456
```

This example shows how to display information for a specific VRF's neighbor. None of the other display options are used; thus, all of the information is displayed for the neighbor. The number in the far left column indicates the neighbor for which information is displayed. When you list information for multiple neighbors, this number makes the display easier to read.

The TCP statistics at the end of the display show status for the TCP session with the neighbor. Most of the fields show information stored in the device's Transmission Control Block (TCB) for the TCP session between the router and its neighbor. These fields are described in detail in section *3.2 of RFC 793*, "*Transmission Control Protocol Functional Specification*".

Syntax: **show ip bgp vrf** <*vrf-name*> **neighbors** [<*ip-addr*> **[advertised-routes [detail** [<*ip-addr*>[/<*mask-bits*>]]]] **|**
[attribute-entries [detail]] | [flap-statistics] | [last-packet-with-error] | [received prefix-filter] |
[received-routes] | [routes [best] | [detail [best] | [not-installed-best] | [unreachable]] |
[rib-out-routes [<*ip-addr*>/<*mask-bits*> **|** <*ip-addr*> <*net-mask*> **| detail]] |**
[routes-summary]]

The <*vrf-name*> parameter specifies the VRF whose neighbor you want to display information about.

The <*ip-addr*> option lets you narrow the scope of the command to a specific neighbor. The display is the same as that for the command without this option except that it is limited to only the neighbor specified.

The **advertised-routes** option displays only the routes that the router has advertised to the neighbor during the current BGP4 neighbor session.

The **attribute-entries** option shows the attribute-entries associated with routes received from the neighbor.

The **flap-statistics** option shows the route flap statistics for routes received from or sent to the neighbor.

The **last-packet-with-error** option displays the last packet from the neighbor that contained an error. The packet's contents are displayed in decoded (human-readable) format.

The **received extended-community** option

The **received prefix-filter** option shows the Outbound Route Filters (ORFs) received from the neighbor. This option applies to cooperative route filtering.

The **received-routes** option lists all the route information received in route updates from the neighbor since the soft reconfiguration feature was enabled.

The **routes** option lists the routes received in UPDATE messages from the neighbor. You can specify the following additional options:

- **best** – Displays the routes received from the neighbor that the router selected as the best routes to their destinations.
- **not-installed-best** – Displays the routes received from the neighbor that are the best BGP4 routes to their destinations, but were nonetheless not installed in the IP route table because the router received better routes from other sources (such as OSPF, RIP, or static IP routes).
- **unreachable** – Displays the routes that are unreachable because the router does not have a valid RIP, OSPF, or static route to the next hop.
- **detail** – Displays detailed information for the specified routes. You can refine your information request by also specifying one of the options above (best, not-installed-best, or unreachable).

The **rib-out-routes** option lists the route information base (RIB) for outbound routes. You can display all the routes or specify a network address.

The **routes-summary** option displays a summary of the following information:

- Number of routes received from the neighbor
- Number of routes accepted by this router from the neighbor
- Number of routes this router filtered out of the UPDATES received from the neighbor and did not accept
- Number of routes advertised to the neighbor
- Number of attribute entries associated with routes received from or advertised to the neighbor.

This display shows the following information.

TABLE 289 BGP4 neighbor information

This field...	Displays...
IP Address	The IP address of the neighbor.
AS	The AS the neighbor is in.

TABLE 289 BGP4 neighbor information (Continued)

This field...	Displays...
EBGP or IBGP	Whether the neighbor session is an IBGP session, an EBGP session, or a confederation EBGP session: • EBGP – The neighbor is in another AS. • EBGP_Confed – The neighbor is a member of another sub-AS in the same confederation. • IBGP – The neighbor is in the same AS.
RouterID	The neighbor's router ID.
Description	The description you gave the neighbor when you configured it on the router.

State	The state of the router's session with the neighbor. The states are from this router's perspective of the session, not the neighbor's perspective. The state values are based on the BGP4 state machine values described in RFC 1771 and can be one of the following for each router:
	• IDLE – The BGP4 process is waiting to be started. Usually, enabling BGP4 or establishing a neighbor session starts the BGP4 process.
	  • A minus sign (-) indicates that the session has gone down and the software is clearing or removing routes.
	• ADMND – The neighbor has been administratively shut down.
	  • A minus sign (-) indicates that the session has gone down and the software is clearing or removing routes.
	• CONNECT – BGP4 is waiting for the connection process for the TCP neighbor session to be completed.
	• ACTIVE – BGP4 is waiting for a TCP connection from the neighbor.
	NOTE: If the state frequently changes between CONNECT and ACTIVE, there may be a problem with the TCP connection.
	• OPEN SENT – BGP4 is waiting for an Open message from the neighbor.
	• OPEN CONFIRM – BGP4 has received an OPEN message from the neighbor and is now waiting for either a KEEPALIVE or NOTIFICATION message. If the router receives a KEEPALIVE message from the neighbor, the state changes to Established. If the message is a NOTIFICATION, the state changes to Idle.
	• ESTABLISHED – BGP4 is ready to exchange UPDATE messages with the neighbor.
	  • If there is more BGP data in the TCP receiver queue, a plus sign (+) is also displayed.
	NOTE: If you display information for the neighbor using the **show ip bgp neighbor** *<ip-addr>* command, the TCP receiver queue value will be greater than 0.

Time	The amount of time this session has been in its current state.
KeepAliveTime	The keep alive time, which specifies how often this router sends keep alive messages to the neighbor.
HoldTime	The hold time, which specifies how many seconds the router will wait for a KEEPALIVE or UPDATE message from a BGP4 neighbor before deciding that the neighbor is dead.
PeerGroup	The name of the peer group the neighbor is in, if applicable.
Multihop-EBGP	Whether this option is enabled for the neighbor.
RouteReflectorClient	Whether this option is enabled for the neighbor.
SendCommunity	Whether this option is enabled for the neighbor.
NextHopSelf	Whether this option is enabled for the neighbor.
DefaultOriginate	Whether this option is enabled for the neighbor.

TABLE 289 BGP4 neighbor information (Continued)

This field...	Displays...
MaximumPrefixLimit	Lists the maximum number of prefixes the router will accept from this neighbor.
RemovePrivateAs	Whether this option is enabled for the neighbor.
RefreshCapability	Whether this router has received confirmation from the neighbor that the neighbor supports the dynamic refresh capability.
CooperativeFilteringCapability	Whether the neighbor is enabled for cooperative route filtering.
Distribute-list	Lists the distribute list parameters, if configured.
Filter-list	Lists the filter list parameters, if configured.
Prefix-list	Lists the prefix list parameters, if configured.
Route-map	Lists the route map parameters, if configured.
Messages Sent	The number of messages this router has sent to the neighbor. The display shows statistics for the following message types: • Open • Update • KeepAlive • Notification • Refresh-Req
Messages Received	The number of messages this router has received from the neighbor. The message types are the same as for the Message Sent field.
Last Update Time	Lists the last time updates were sent and received for the following: • NLRIs • Withdraws

TABLE 289 BGP4 neighbor information (Continued)

This field...	Displays...

Last Connection Reset Reason	The reason the previous session with this neighbor ended. The reason can be one of the following:
	• Reasons described in the BGP specifications:
	  • Message Header Error
	  • Connection Not Synchronized
	  • Bad Message Length
	  • Bad Message Type
	  • OPEN Message Error
	  • Unsupported Version Number
	  • Bad Peer AS Number
	  • Bad BGP Identifier
	  • Unsupported Optional Parameter
	  • Authentication Failure
	  • Unacceptable Hold Time
	  • Unsupported Capability
	  • UPDATE Message Error
	  • Malformed Attribute List
	  • Unrecognized Well-known Attribute
	  • Missing Well-known Attribute
	  • Attribute Flags Error
	  • Attribute Length Error
	  • Invalid ORIGIN Attribute
	  • Invalid NEXT_HOP Attribute
	  • Optional Attribute Error
	  • Invalid Network Field
	  • Malformed AS_PATH
	  • Hold Timer Expired
	  • Finite State Machine Error
	  • Rcv Notification

Last Connection Reset Reason (cont.)	• Reasons specific to the implementation:
	  • Reset All Peer Sessions
	  • User Reset Peer Session
	  • Port State Down
	  • Peer Removed
	  • Peer Shutdown
	  • Peer AS Number Change
	  • Peer AS Confederation Change
	  • TCP Connection KeepAlive Timeout
	  • TCP Connection Closed by Remote
	  • TCP Data Stream Error Detected

TABLE 289 BGP4 neighbor information (Continued)

This field...	Displays...

Notification Sent	If the router receives a NOTIFICATION message from the neighbor, the message contains an error code corresponding to one of the following errors. Some errors have subcodes that clarify the reason for the error. Where applicable, the subcode messages are listed underneath the error code messages.
	• Message Header Error:
	  • Connection Not Synchronized
	  • Bad Message Length
	  • Bad Message Type
	  • Unspecified
	• Open Message Error:
	  • Unsupported Version
	  • Bad Peer As
	  • Bad BGP Identifier
	  • Unsupported Optional Parameter
	  • Authentication Failure
	  • Unacceptable Hold Time
	  • Unspecified
	• Update Message Error:
	  • Malformed Attribute List
	  • Unrecognized Attribute
	  • Missing Attribute
	  • Attribute Flag Error
	  • Attribute Length Error
	  • Invalid Origin Attribute
	  • Invalid NextHop Attribute
	  • Optional Attribute Error
	  • Invalid Network Field
	  • Malformed AS Path
	  • Unspecified
	• Hold Timer Expired
	• Finite State Machine Error
	• Cease
	• Unspecified

Notification Received	See above.

TABLE 289 BGP4 neighbor information (Continued)

This field...	Displays...
TCP Connection state	The state of the connection with the neighbor. The connection can have one of the following states: • LISTEN – Waiting for a connection request. • SYN-SENT – Waiting for a matching connection request after having sent a connection request. • SYN-RECEIVED – Waiting for a confirming connection request acknowledgment after having both received and sent a connection request. • ESTABLISHED – Data can be sent and received over the connection. This is the normal operational state of the connection. • FIN-WAIT-1 – Waiting for a connection termination request from the remote TCP, or an acknowledgment of the connection termination request previously sent. • FIN-WAIT-2 – Waiting for a connection termination request from the remote TCP. • CLOSE-WAIT – Waiting for a connection termination request from the local user. • CLOSING – Waiting for a connection termination request acknowledgment from the remote TCP. • LAST-ACK – Waiting for an acknowledgment of the connection termination request previously sent to the remote TCP (which includes an acknowledgment of its connection termination request). • TIME-WAIT – Waiting for enough time to pass to be sure the remote TCP received the acknowledgment of its connection termination request. • CLOSED – There is no connection state.
Byte Sent	The number of bytes sent.
Byte Received	The number of bytes received.
Local host	The IP address of the router.
Local port	The TCP port the router is using for the BGP4 TCP session with the neighbor.
Remote host	The IP address of the neighbor.
Remote port	The TCP port the neighbor is using for the BGP4 TCP session with the router.
ISentSeq	The initial send sequence number for the session.
SendNext	The next sequence number to be sent.
TotUnAck	The number of sequence numbers sent by the router that have not been acknowledged by the neighbor.
TotSent	The number of sequence numbers sent to the neighbor.
ReTrans	The number of sequence numbers that the router retransmitted because they were not acknowledged.
UnAckSeq	The current acknowledged sequence number.
IRcvSeq	The initial receive sequence number for the session.
RcvNext	The next sequence number expected from the neighbor.
SendWnd	The size of the send window.
TotalRcv	The number of sequence numbers received from the neighbor.
DupliRcv	The number of duplicate sequence numbers received from the neighbor.
RcvWnd	The size of the receive window.

TABLE 289 BGP4 neighbor information (Continued)

This field...	Displays...
SendQue	The number of sequence numbers in the send queue.
RcvQue	The number of sequence numbers in the receive queue.
CngstWnd	The number of times the window has changed.

Displaying advertised routes for a specified VRF neighbor

To display the routes the router has advertised to a specific VRF's neighbor, enter a command such as the following at any level of the CLI.

```
R3-2547#show ip bgp vrf black neighbor 10.10.2.3 advertised-routes
       There are 154 routes advertised to neighbor 10.10.2.3
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST E:EBGP I:IBGP L:LOCAL
       Prefix             Next Hop        Metric     LocPrf     Weight Status
1      10.100.101.30/32   10.10.3.3                             0      BE
         AS_PATH: 311
2      10.100.101.29/32   10.10.3.3                             0      BE
         AS_PATH: 311
3      10.100.101.28/32   10.10.3.3                             0      BE
         AS_PATH: 311
4      10.100.101.27/32   10.10.3.3                             0      BE
         AS_PATH: 311
5      10.100.101.26/32   10.10.3.3                             0      BE
         AS_PATH: 311
6      10.100.101.25/32   10.10.3.3                             0      BE
         AS_PATH: 311
7      10.100.101.24/32   10.10.3.3                             0      BE
         AS_PATH: 311
8      10.100.101.23/32   10.10.3.3                             0      BE
         AS_PATH: 311
9      10.100.101.22/32   10.10.3.3                             0      BE
         AS_PATH: 311
10     10.100.101.21/32   10.10.3.3                             0      BE
         AS_PATH: 311
```

Syntax: show ip bgp vrf <*vrf-name*> **neighbor** <*ip-addr*> **advertised-routes** [<*ip-addr*>/<*prefix*>]

For information about the fields in this display, refer to Table 273 on page 1621.

Displaying neighbor attribute entries for a specified VRF

The neighbor attribute entries table lists the sets of BGP4 attributes stored in the router's memory. Each set of attributes is unique and can be associated with one or more routes. In fact, the router typically has fewer route attribute entries than routes. To display the route-attribute entries table for a specified VRF, enter the following command.

```
NetIron#show ip bgp vrf black neighbor 10.10.2.3 attribute-entries
        Total number of BGP Attribute Entries: 2
1       Next Hop  :10.10.2.3          Metric   :0              Origin:IGP
        Originator:0.0.0.0            Cluster List:None
        Aggregator:AS Number :0      Router-ID:0.0.0.0         Atomic:None
        Local Pref:100               Communities:Internet
        AS Path   :310
        Address: 0x2470139c  Hash:223 (0x0100036e) Reference Counts: 30:0:60

        Originator:0.0.0.0            Cluster List:None
        Aggregator:AS Number :0      Router-ID:0.0.0.0         Atomic:None
        Local Pref:100               Communities:Internet
        Extended Community: RT 600:1 OSPF DOMAIN ID:0.0.0.0 OSPF RT 0:5:1 OSPF RO
ID:0.0.0.0
        AS Path   :
        Address: 0x24702310  Hash:992 (0x03000000) Reference Counts: 0:0:90
```

Syntax: show ip bgp <*vrf-name*> **attribute-entries**

This display shows the following information.

TABLE 290 BGP4 route-attribute entries information

This field...	Displays...
Total number of BGP Attribute Entries	The number of routes contained in this router's BGP4 route table.
Next Hop	The IP address of the next hop router for routes that have this set of attributes.
Metric	The cost of the routes that have this set of attributes.
Origin	The source of the route information. The origin can be one of the following: • EGP – The routes with this set of attributes came to BGP through EGP. • IGP – The routes with this set of attributes came to BGP through IGP. • INCOMPLETE – The routes came from an origin other than one of the above. For example, they may have been redistributed from OSPF or RIP. When BGP4 compares multiple routes to a destination to select the best route, IGP is preferred over EGP and both are preferred over INCOMPLETE.
Originator	The originator of the route in a route reflector environment.
Cluster List	The route-reflector clusters through which this set of attributes has passed.
Aggregator	Aggregator information: • **AS Number** shows the AS in which the network information in the attribute set was aggregated. This value applies only to aggregated routes and is otherwise 0. • **Router-ID** shows the router that originated this aggregator.
Atomic	Whether the network information in this set of attributes has been aggregated and this aggregation has resulted in information loss: • TRUE – Indicates information loss has occurred • FALSE – Indicates no information loss has occurred **NOTE:** Information loss under these circumstances is a normal part of BGP4 and does not indicate an error.

TABLE 290 BGP4 route-attribute entries information (Continued)

This field...	Displays...
Local Pref	The degree of preference for routes that use this set of attributes relative to other routes in the local AS.
Communities	The communities that routes with this set of attributes are in.
Extended Community	The VRF's extended community attibutes.
AS Path	The ASs through which routes with this set of attributes have passed. The local AS is shown in parentheses.

Displaying flap statistics for a specified VRF neighbor by IP address

To display flap-statistics for routes learned from the specified VRF neighbor, enter the following command at any level of the CLI.

```
R3-2547#show ip bgp vrf black neighbor 10.10.2.3 flap-statistics
Total number of flapping routes: 0
```

Syntax: show ip bgp vrf <*vrf-name*> **neighbor** <*ip-addr*> **flap-statistics**

The <*vrf-name*> parameter specifies the VRF whose neighbor you want to display flap-statistics for.

The <*address*> <*mask*> parameter specifies a particular route. If you also use the optional **longer-prefixes** parameter, then all statistics for routes that match the specified route or have a longer prefix than the specified route are displayed. For example, if you specify **209.157.0.0 longer**, then all routes with the prefix 209.157 or that have a longer prefix (such as 209.157.22) are displayed.

This display shows the following information.

TABLE 291 Route flap dampening statistics

This field...	Displays...
Total number of flapping routes	The total number of routes in the device's BGP4 route table that have changed state and thus have been marked as flapping routes.

Displaying received ORF information for a specified VRF neighbor

To view BGP4 VPNv4 configuration information and statistics for a specified VRF's neighbor, enter the following command.

```
NetIron #show ip bgp vrf black neighbor 10.10.2.3 received extended-community
Extended-community ORF capability was not negotiated

NetIron#show ip bgp vrf black neighbor 10.10.2.3 received prefix-filter
 No Prefix filter ORF received from neighbor 10.10.2.3!
```

Displaying received routes for a specified VRF neighbor

To view the BGP4 VPNv4 configuration and statistics for specified VRF's neighbor, enter the following command.

```
NetIron#show ip bgp vrf black neighbor 10.10.2.3 received-routes
Inbound soft reconfiguration not enabled for neighbor 10.10.2.3
```

Displaying a specified VRF neighbor routes

To view the route table for a specified VRF's neighbor, enter the following command.

```
NetIron#show ip bgp vrf black neighbor 10.10.2.3 routes
       There are 30 accepted routes from neighbor 10.10.2.3
Searching for matching routes, use ^C to quit...

```

Syntax: show ip bgp vrf <*vrf-name*> neighbor <*ip-addr*> routes

For information about the fields in this display, refer to Table 285 on page 1647.

Displaying the best routes

To display the routes received from a specific neighbor that are the "best" routes to their destinations, enter a command such as the following at any level of the CLI.

```
NetIron# show ip bgp vrf black neighbor 192.168.4.211 routes best
```

Syntax: show ip bgp vrf <*vrf-name*> **neighbor** <*ip-addr*> **routes best**

For information about the fields in this display, refer to Table 285 on page 1647.

Displaying the best routes that were nonetheless not installed in the IP route table

To display the BGP4 routes received from a specific neighbor that are the "best" routes to their destinations but are not installed in the router's IP route table, enter a command such as the following at any level of the CLI.

```
NetIron# show ip bgp vrf black neighbor 192.168.4.211 routes not-installed-best
```

Each of the displayed routes is a valid path to its destination, but the router received another path from a different source (such as OSPF, RIP, or a static route) that has a lower administrative distance. The router always selects the path with the lowest administrative distance to install in the IP route table.

Syntax: show ip bgp vrf <*vrf-name*> **neighbor** <*ip-addr*> **routes not-installed-best**

For information about the fields in this display, refer to Table 285 on page 1647.

Displaying the routes whose destinations are unreachable

To display BGP4 routes whose destinations are unreachable using any of the BGP4 paths in the BGP4 route table, enter a command such as the following at any level of the CLI.

```
NetIron# show ip bgp vrf black neighbor 192.168.4.211 routes unreachable
```

Syntax: show ip bgp vrf <*vrf-name*> **neighbor** <*ip-addr*> **routes unreachable**

For information about the fields in this display, refer to Table 285 on page 1647.

Displaying the Adj-RIB-Out for a VRF neighbor

To display the router's current BGP4 Routing Information Base (Adj-RIB-Out) for a specific VRF neighbor and a specific destination network, enter a command such as the following at any level of the CLI.

```
NetIron#show ip bgp vrf black neighbor 10.10.2.3 rib-out-routes
       There are 154 RIB_out routes for neighbor 10.10.2.3
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST E:EBGP I:IBGP L:LOCAL
       Prefix             Next Hop        Metric     LocPrf     Weight Status
1      10.100.101.30/32   10.10.3.3                  100        0      BE

   NLRIs Discarded due to
      Maximum Prefix Limit:0, AS Loop:0
      Invalid Nexthop:0, Invalid Nexthop Address:0.0.0.0
      Duplicated Originator_ID:0, Cluster_ID:0
Routes Advertised:154,  To be Sent:0,  To be Withdrawn:0
NLRIs Sent in Update Message:154,  Withdraws:0,  Replacements:0
Peer Out of Memory Count for:
   Receiving Update Messages:0, Accepting Routes(NLRI):0
   Attributes:0, Outbound Routes(RIB-out):0 Outbound Routes Holder:0
```

This display shows the following information.

TABLE 292 BGP4 route summary information for a VRF neighbor

This field...	Displays...
Routes Received	How many routes the router has received from the neighbor during the current BGP4 session. • Accepted or Installed – Indicates how many of the received routes the router accepted and installed in the BGP4 route table. • Filtered – Indicates how many of the received routes the device did not accept or install because they were denied by filters on the router.
Routes Selected as BEST Routes	The number of routes that the router selected as the best routes to their destinations.
BEST Routes not Installed in IP Forwarding Table	The number of routes received from the neighbor that are the best BGP4 routes to their destinations, but were nonetheless not installed in the IP route table because the router received better routes from other sources (such as OSPF, RIP, or static IP routes).
Unreachable Routes	The number of routes received from the neighbor that are unreachable because the router does not have a valid RIP, OSPF, or static route to the next hop.
History Routes	The number of routes that are down but are being retained for route flap dampening purposes.
NLRIs Received in Update Message	The number of routes received in Network Layer Reachability (NLRI) format in UPDATE messages. • Withdraws – The number of withdrawn routes the router has received. • Replacements – The number of replacement routes the router has received.
NLRIs Discarded due to	Indicates the number of times the router discarded an NLRI for the neighbor due to the following reasons: • Maximum Prefix Limit – The router's configured maximum prefix amount had been reached. • AS Loop – An AS loop occurred. An AS loop occurs when the BGP4 AS-path attribute contains the local AS number. • Invalid Nexthop – The next hop value was not acceptable. • Duplicated Originator_ID – The originator ID was the same as the local router ID. • Cluster_ID – The cluster list contained the local cluster ID, or contained the local router ID (see above) if the cluster ID is not configured.
Routes Advertised	The number of routes the router has advertised to this neighbor: • To be Sent – The number of routes the router has queued to send to this neighbor. • To be Withdrawn – The number of NLRIs for withdrawing routes the router has queued up to send to this neighbor in UPDATE messages.

TABLE 292 BGP4 route summary information for a VRF neighbor (Continued)

This field...	Displays...
NLRIs Sent in Update Message	The number of NLRIs for new routes the router has sent to this neighbor in UPDATE messages: • Withdraws – The number of routes the router has sent to the neighbor to withdraw. • Replacements – The number of routes the router has sent to the neighbor to replace routes the neighbor already has.
Peer Out of Memory Count for	Statistics for the times the router has run out of BGP4 memory for the neighbor during the current BGP4 session: • Receiving Update Messages – The number of times UPDATE messages were discarded because there was no memory for attribute entries. • Accepting Routes(NLRI) – The number of NLRIs discarded because there was no memory for NLRI entries. This count is not included in the Receiving Update Messages count. • Attributes – The number of times there was no memory for BGP4 attribute entries. • Outbound Routes (RIB-out) – The number of times there was no memory to place a "best" route into the neighbor's route information base (Adj-RIB-Out) for routes to be advertised.

Displaying summary route information for a specified VRF

To display summary statistics for all the VPNv4 routes in the device's BGP route table for a specified VRF, enter a command such as the following at any level of the CLI.

```
NetIron# show ip bgp vrf black routes summary
  Total number of BGP routes (NLRIs) Installed     : 184
  Distinct BGP destination networks                : 184
  Filtered bgp routes for soft reconfig            : 0
  Routes originated by this router                 : 4
  Routes selected as BEST routes                   : 184
  BEST routes not installed in IP forwarding table : 0
  Unreachable routes (no IGP route for NEXTHOP)    : 0
  IBGP routes selected as best routes              : 90
  EBGP routes selected as best routes              : 90
```

Syntax: show ip bgp vrf <*vrf-name*> **routes summary**

This display shows the following information.

TABLE 293 BGP VPNv4 summary route information

This field...	Displays...
Total number of BGP VPNv4 routes (NLRIs) Installed	The number of BGP VPNv4 routes the router has installed in the BGP route table.
Distinct BGP VPNv4 destination networks	The number of destination networks the installed routes represent. The BGP route table can have multiple routes to the same network.
Filtered BGP VPNv4 routes for soft reconfig	The number of route updates received from soft-reconfigured neighbors or peer groups that have been filtered out but retained.

TABLE 293 BGP VPNv4 summary route information (Continued)

This field...	Displays...
Routes originated by this router	The number of VPNv4 routes in the BGP route table that this router originated.
Routes selected as BEST routes	The number of VPNv4 routes in the BGP route table that this router has selected as the best routes to the destinations.
BEST routes not installed in IP forwarding table	The number of BGP VPNv4 routes that are the best BGP VPNv4 routes to their destinations but were not installed in the IP route table because the router received better routes from other sources.
Unreachable routes (no IGP route for NEXTHOP)	The number of routes in the BGP route table whose destinations are unreachable because the next hop is unreachable.
IBGP routes selected as best routes	The number of "best" routes in the BGP VPNv4 route table that are IBGP routes.
EBGP routes selected as best routes	The number of "best" routes in the BGP VPNv4 route table that are EBGP routes.

Displaying a VRF's BGP4 route table

If you want to view all the routes BGP routes in a VRF, you can display the VRF's BGP route table using the following method.

To view a VRF's BGP4 route table, enter the following command.

```
NetIron# show ip bgp vrf black routes
Total number of BGP Routes: 184
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED
       Prefix              Next Hop        Metric     LocPrf     Weight Status
1      7.7.7.7/32          0.0.0.0         0          100        32768  BL
         AS_PATH:
2      10.10.2.0/24        0.0.0.0         0          100        32768  BL
         AS_PATH:
3      10.10.3.0/24        0.0.0.0         0          100        32768  BL
         AS_PATH:
4      10.10.4.0/24        0.0.0.0         0          100        32768  BL
         AS_PATH:
5      10.100.100.1/32     10.10.2.3                  100        0      BE
         AS_PATH: 310
6      10.100.100.2/32     10.10.2.3                  100        0      BE
         AS_PATH: 310
7      10.100.100.3/32     10.10.2.3                  100        0      BE

         AS_PATH: 310
9      10.100.100.5/32     10.10.2.3                  100        0      BE
         AS_PATH: 310
10     10.100.100.6/32     10.10.2.3                  100        0      BE
```

Syntax: **show ip bgp vrf** <*vrf-name*> **routes** [<*ip-addr*>] | <*num*> | [**age** <*secs*>] | [**as-path-access-list** <*num*>] | [**as-path-filter** <*num, num,...*>] |[**best**] | [**cidr-only**] | [**community** <*num*> | **no-export** | **no-advertise** | **internet** | **local-as**] | [**community-access-list** <*num*>] | **community-filter** <*num*> | **community-reg-expression** <*regular-expression*>

| detail | local | neighbor <*ip-addr*> **[next-hop** <*ip-addr*>**] | [no-best] | [not-installed-best] | [prefix-list** <*string*>**] | [regular-expression** <*regular-expression*>**] | [route-map** <*map-name*>**] | [summary] | [unreachable]**

The <*vrf-name*> parameter specifies the VRF whose neighbor you want to display information about.

The <*ip-addr*> option displays routes for a specific network.

The <*num*> option specifies the table entry with which you want the display to start. For example, if you want to list entries beginning with table entry 100, specify 100.

The **age** <*secs*> parameter displays only the routes that have been received or updated more recently than the number of seconds you specify.

The **as-path-access-list** <*num*> parameter filters the display using the specified AS-path ACL.

The **best** parameter displays the routes received from the neighbor that the router selected as the best routes to their destinations.

The **cidr-only** option lists only the routes whose network masks do not match their class network length.

The **community** option lets you display routes for a specific community. You can specify **local-as**, **no-export**, **no-advertise**, **internet**, or a private community number. You can specify the community number as either two five-digit integer values of up to 1– 65535, separated by a colon (for example, 12345:6789) or a single long integer value.

The **community-access-list** <*num*> parameter filters the display using the specified community ACL.

The **community-filter** option lets you display routes that match a specific community filter.

The c**ommunity regular-expression** <*regular-expression*> option filters the display based on a specified community regular expression.

The **local** option ....

The **neighbor** <*ip-addr*> option displays the number of accepted routes from the specified BGP neighbor.

The **detail** option lets you display more details about the routes. You can refine your request by also specifying one of the other display options after the **detail** keyword.

The **next-hop** <*ip-addr*> option displays the routes for a given next-hop IP address.

The **no-best** option displays the routes for which none of the routes to a given prefix were selected as the best route.

The **not-installed-best** option displays the routes received from the neighbor that are the best BGP4 routes to their destinations, but were nonetheless not installed in the IP route table because the router received better routes from other sources (such as OSPF, RIP, or static IP routes).

The **prefix-list** <*string*> parameter filters the display using the specified IP prefix list.

The **regular-expression** <*regular-expression*> option filters the display based on a regular expression.

The **route-map** <*map-name*> parameter filters the display using the specified route map. The software displays only the routes that match the match statements in the route map. The software disregards the route map's set statements.

The **summary** option displays summary information for the routes.

The **unreachable** option displays the routes that are unreachable because the router does not have a valid RIP, OSPF, or static route to the next hop.

For information about the fields in this display, refer to Table 273 on page 1621. The fields in this display also appear in the **show ip bgp vpnv4** display.

Displaying the best BGP4 routes

To display all the BGP4 routes in the device's BGP4 route table that are the best routes to their destinations, enter a command such as the following at any level of the CLI.

```
NetIron#show ip bgp vrf black routes best
Searching for matching routes, use ^C to quit...
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED

```

Syntax: show ip bgp vrf <*vrf-name*> **routes best**

For information about the fields in this display, refer to Table 285 on page 1647.

Displaying best BGP4 routes that are not in the IP route table

When the router has multiple routes to a destination, the router selects the route with the lowest administrative distance as the best route, and installs that route in the IP route table.

To display the BGP4 routes for a specified VRF that are the "best" routes to their destinations but are not installed in the device's IP route table, enter a command such as the following at any level of the CLI.

```
NetIron# show ip bgp vrf black routes not-installed-best
Searching for matching routes, use ^C to quit...
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED F:FILTERED

1      3.0.0.0/8          192.168.4.106              100        0      BE
       AS_PATH: 65001 4355 701 80
```

Each of the displayed routes is a valid path to its destination, but the router received another path from a different source that has a lower administrative distance. The router always selects the path with the lowest administrative distance to install in the IP route table.

Syntax: show ip bgp vrf <*vrf-name*> **routes not-installed-best**

For information about the fields in this display, refer to Table 285 on page 1647.

NOTE
To display the routes that the router has selected as the best routes and installed in the IP route table, display the IP route table using the **show ip route** command.

Displaying BGP4 routes whose destinations are unreachable

To display BGP routes for a specified VRF whose destinations are unreachable using any of the paths in the BGP route table, enter a command such as the following at any level of the CLI.

```
NetIron# show ip bgp vrf black routes unreachable
Searching for matching routes, use ^C to quit...
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED F:FILTERED
Route Distinguisher: 4:1
       Prefix             Next Hop        Metric     LocPrf     Weight Status
1      3.0.0.0/8          192.168.4.106              100        0      BE
       AS_PATH: 65001 4355 701 80
```

Syntax: show ip bgp vrf black routes unreachable

For information about the fields in this display, refer to Table 285 on page 1647.

Displaying information for a specific route

To display BGP VPNv4 route information for a specified VRF by specifying an IP address within the network, enter a command such as the following at any level of the CLI.

```
NetIron# show ip bgp vrf black routes 10.8.1.0/24
Route Distinguisher: 4:1
Number of BGP Routes matching display condition : 1
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED F:FILTERED
       Prefix             Next Hop        Metric     LocPrf     Weight Status
1      10.8.1.0/24        2.2.2.2         2          100        0      I
         AS_PATH:
Route Distinguisher: 5:1
Number of BGP Routes matching display condition : 1
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED F:FILTERED
       Prefix             Next Hop        Metric     LocPrf     Weight Status
1      10.8.1.0/24        4.4.4.4         3          100        0      I
         AS_PATH:
```

Syntax: show ip bgp vrf black routes <*ip-addr*>/<*prefix*> **[longer-prefixes] |** <*ip-addr*>

For information about the fields in this display, refer to Table 285 on page 1647 and Table 283 on page 1645.

Displaying route details

Here is an example of the information displayed when you use the **detail** option. In this example, the information for one route is shown.

```
NetIron# show ip bgp vrf black routes detail
Total number of BGP Routes: 288
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED
Route Distinguisher: 4:1
1     Prefix: 10.6.1.0/24,  Status: I,  Age: 15h36m10s
      NEXT_HOP: 2.2.2.2,  Learned from Peer: 2.2.2.2 (1)
      Out-Label: 500000
        LOCAL_PREF: 100,  MED: 3,  ORIGIN: incomplete,  Weight: 0
        AS_PATH:
        Extended Community: RT 300:1 OSPF DOMAIN ID:0.0.0.0 OSPF RT 0:1:0 OSPF RO
ID:0.0.0.0
```

For information about the fields in this display, refer to Table 285 on page 1647 and Table 294.

TABLE 294 BGP VPNv4 route information

This field...	Displays...
Prefix	The network address and prefix.
Age	The last time an update occurred.
Learned from Peer	The IP address of the neighbor that sent this route.
Local_Pref	The degree of preference for this route relative to other routes in the local AS. When the BGP4 algorithm compares routes on the basis of local preferences, the route with the higher local preference is chosen. The preference can have a value from 0 – 4294967295.
MED	The route's metric. If the route has no metric, this field is blank.
Origin	The source of the route information. The origin can be one of the following: • EGP – The routes with this set of attributes came to BGP through EGP. • IGP – The routes with this set of attributes came to BGP through IGP. • INCOMPLETE – The routes came from an origin other than one of the above. For example, they may have been redistributed from OSPF or RIP. When BGP4 compares multiple routes to a destination to select the best route, IGP is preferred over EGP and both are preferred over INCOMPLETE.
Atomic	Whether network information in this route has been aggregated and this aggregation has resulted in information loss. **NOTE:** Information loss under these circumstances is a normal part of BGP4 and does not indicate an error.
Aggregation ID	The router that originated this aggregator.
Aggregation AS	The AS in which the network information was aggregated. This value applies only to aggregated routes and is otherwise 0.
Originator	The originator of the route in a route reflector environment.
Cluster List	The route-reflector clusters through which this route has passed.
Learned From	The IP address of the neighbor from which the router learned the route.
Admin Distance	The administrative distance of the route.

TABLE 294 BGP VPNv4 route information (Continued)

This field...	Displays...
Adj_RIB_out	The number of neighbors to which the route has been or will be advertised. This is the number of times the route has been selected as the best route and placed in the Adj-RIB-Out (outbound queue) for a BGP4 neighbor.
Communities	The communities the route is in.
Extended Community	The extended communities the route is in.

Displaying additional BGP or MPLS VPN information

You can display the following additional information about a BGP or MPLS configuration on the device:

- "Displaying IP network information for a VRF"
- "Displaying the IP route table for a specified VRF"
- "Displaying ARP VRF information"
- "Displaying OSPF information for a VRF"
- "Displaying OSPF area information for a VRF"
- "Displaying OSPF ABR and ASBR information for a VRF"
- "Displaying general OSPF configuration information for a VRF"
- "Displaying OSPF external link state information for a VRF"
- "Displaying OSPF interface information"
- "Displaying OSPF neighbor information for a VRF"
- "Displaying the routes that have been redistributed into OSPF"
- "Displaying OSPF route information for a VRF"
- "Displaying OSPF sham links"
- "Displaying OSPF trap status for a VRF"
- "Displaying OSPF virtual links for a VRF"
- "Displaying OSPF virtual neighbor information for a VRF"
- "Displaying IP extcommunity list information"
- "Displaying the IP static route table for a VRF"
- "Displaying the static ARP table for a VRF"
- "Displaying TCP connections for a VRF"
- "Displaying MPLS statistics for a VRF"

Displaying VRF information

To display IP Information for a specified VRF, enter the following command at any level of the CLI.

```
NetIron# show ip vrf green
VRF green, default RD 4:1, Table ID 2
Label: 500000,  Label-Switched Mode: OFF
Max Routes: 64000
  Interfaces:
    e6/3 lo4 lo5 lo6
  Export VPN route-target communities:
    RT:300:1
  Import VPN route-target communities:
    RT:300:1
  No import route-map
  Export route-map: export1
```

Syntax: show ip vrf <*vrf-name*>

The <*vrf-name*> parameter specifies the VRF that you want to display IP information for.

TABLE 295 Output from the show IP VRF command

This field...	Displays...
VRF Name	The name of the VRF.
Default RD	The default route distinguisher for the VRF.
Table ID	The table ID for the VRF.
Label	Display the unique VRF label that has been assigned to the specified VRF.
Label Switched Mode	Displays if Label Switched Mode is ON or OFF.
Max routes	The maximum number of routes that can be configured on this VRF.
Interfaces	The interface from this router that are configured within this VRF.
Export VPN route-target communities:	The export route-targets that are configured for this VRF.
Import VPN route-target communities	The import route-targets that are configured for this VRF.
Import route-map	The name of the import route-map if any that is configured for this VRF.
Export route-map	The name of the export route-map if a route-map has been configured for this VRF.

Displaying IP network information for a VRF

To display IP network information for a specified VRF, use the following command at any level of the CLI.

```
NetIron# show ip network vrf green
Total IP and IPVPN Cache Entry Usage on LPs:
 Module        Host    Network       Free      Total
      2          26          0     204774     204800
      5          28        240     204532     204800
```

Syntax: show ip network vrf <*vrf-name*>

This display shows the following information.

TABLE 296 BGP VPNv4 summary route information

This field...	Displays...
Module	The slot number of the module.
Host	The number of host cache entries.
Network	The number of network cache entries
Free	The number of cache entries that are unused.
Total	The total number of cache entries used and unused.

Displaying the IP route table for a specified VRF

To display the IP routes for a specified VRF, enter the following command at any CLI level.

```
NetIron#show ip route vrf green
Total number of IP routes: 99
 Type Codes - B:BGP  D:Connected  S:Static  R:RIP  O:OSPF;   Cost - Dist/Metric
        Destination        Gateway         Port        Cost       Type
1       10.5.1.0/24        192.168.201.2   eth 6/3     110/2      O
2       10.6.1.0/24        4.4.4.4         lsp toR4    200/0      B
3       10.8.1.0/24        2.2.2.2         lsp toR2    200/0      B
4       10.30.1.1/32       192.168.201.2   eth 6/3     110/3      O1
5       10.30.1.2/32       192.168.201.2   eth 6/3     110/3      O1
6       10.30.1.3/32       192.168.201.2   eth 6/3     110/3      O1
7       10.30.1.4/32       192.168.201.2   eth 6/3     110/3      O1
8       10.30.1.5/32       192.168.201.2   eth 6/3     110/3      O1
9       10.30.1.6/32       192.168.201.2   eth 6/3     110/3      O1
10      10.30.1.7/32       192.168.201.2   eth 6/3     110/3      O1
11      10.30.1.8/32       192.168.201.2   eth 6/3     110/3      O1
```

Syntax: show ip route vrf <*vrf-name*>

The <*vrf-name*> parameter specifies the VRF that you want to display IP routes for.

The following table lists the information displayed by the **show ip route vrf** command.

TABLE 297 CLI display of IP route table

This field...	Displays...
Total number of IP routes	The total number of IP routes that are in the specified VRP routing table.
Destination	The destination network of the route.
NetMask	The network mask of the destination address.
Gateway	The next-hop router.
Port	The port through which this router sends packets to reach the route's destination.

TABLE 297 CLI display of IP route table (Continued)

This field...	Displays...
Cost	The route's cost.

Type	The route type, which can be one of the following:
	• B – The route was learned from BGP.
	• D – The destination is directly connected to this router.
	• R – The route was learned from RIP.
	• S – The route is a static route.
	• * – The route is a candidate default route.
	• O – The route is an OSPF route. Unless you use the **ospf** option to display the route table, "O" is used for all OSPF routes. If you do use the **ospf** option, the following type codes are used:
	  • O – OSPF intra area route (within the same area).
	  • IA – The route is an OSPF inter area route (a route that passes from one area into another).
	  • E1 – The route is an OSPF external type 1 route.
	  • E2 – The route is an OSPF external type 2 route.

Displaying ARP VRF information

To display the ARP information for a specified VRF, enter the following command.

```
NetIron#show arp vrf green
Total number of ARP entries: 9
Entries in VRF green:
      IP Address          MAC Address         Type        Age      Port
1     192.168.201.2       00e0.52cf.e840      Dynamic     0         6/3
```

Syntax: show arp vrf <*vrf-name*> **[number] [ip-address] [ethernet** <*slot/port*>**] [mac-address** <*mac-addr*>**]**

The <*vrf-name*> parameter specifies the VRF that you want to display arp entries for.

To clear the ARP table.

```
NetIron# clear arp vrf green
```

Syntax: clear arp vrf <*vrf-name*>

Displaying OSPF information for a VRF

To display the OSPF Information for a specified VRF, enter the following command at any CLI level.

```
NetIron#show ip ospf vrf green
OSPF Version Number           Version 2
Router Id                     192.168.201.1
Domain Id                     2.2.2.2
Domain Tag                    2.2.2.2
ASBR Status                   Yes
ABR Status                    Yes        (1)
Redistribute Ext Routes from  BGP
External LSA Counter          96
Originate New LSA Counter     1738
Rx New LSA Counter            173
External LSA Limit            14447047
Database Overflow Interval    0
Database Overflow State :     NOT OVERFLOWED
RFC 1583 Compatibility :        Enabled
```

Syntax: show ip ospf vrf <*vrf-name*> **[area** [<*area-id*> **|** <*area-ipaddress*>**]] [border-routers** <*router-id*>**] [config] [database [database-summary | external-link-state [advertise** <*number*>**] | extensive | link-state-id** <*id-number*> **|router-id** <*advertising-router-id*> **| sequence-number** <*HEX*>**] [link-state [advertise** <*number*>**] | sabre <**

The <*vrf-name*> parameter specifies the VRF that you want to display OSPF information for.

Displaying OSPF area information for a VRF

To display OSPF Area Information for a specified VRF, enter the following command at any level of the CLI.

```
NetIron#show ip ospf vrf green area
Indx Area            Type   Cost       SPFR       ABR   ASBR  LSA   Chksum(Hex)
1    0               normal 0          6          0     0     6     00039ba2
2    1               normal 0          6          0     2     6     0003af4b
```

Syntax: show ip ospf vrf <*vrf-name*> **area** [<*area-id*>] **|** [<*ip-address*>]

The <*vrf-name*> parameter specifies the VRF that you want to the OSPF area information for.

The <*area-id*> parameter shows information for the specified area.

The <*ip-address*> parameter displays the entry that corresponds to the IP address you enter.

Displaying OSPF ABR and ASBR information for a VRF

To display OSPF ABR and ABSR Information for a specified VRF, enter the following command at any level of the CLI.

```
NetIron#show ip ospf vrf green border-routers
      router ID       router type next hop router outgoing interface Area
1     1.2.10.2        ASBR        192.168.201.2   6/3                1
1     10.5.1.3        ASBR        192.168.201.2   6/3                1
```

Syntax: show ip ospf vrf <*vrf-name*> **border-routers** <*router-id*>

The <*vrf-name*> parameter specifies the VRF that you want to display OSPF ABR and ABSR information for.

The < *router-id*> parameter specifies the display of OSPF ABR and ABSR information for the router with the specified router ID.

Displaying general OSPF configuration information for a VRF

To display OSPF ABR and ABSR Information for a specified VRF, enter the following command at any level of the CLI.

```
NetIron#show ip ospf vrf green config
Router OSPF: Enabled
Redistribution: Enabled
Default OSPF Metric: 10
OSPF Auto-cost Reference Bandwidth: Disabled

OSPF Redistribution Metric: Type2

OSPF External LSA Limit: 14447047

OSPF Database Overflow Interval: 0

RFC 1583 Compatibility: Enabled

Router id: 192.168.201.1
Interface State Change Trap:                      Enabled
Virtual Interface State Change Trap:              Enabled

Virtual Neighbor State Change Trap:               Enabled
Interface Configuration Error Trap:               Enabled
Virtual Interface Configuration Error Trap:       Enabled
Interface Authentication Failure Trap:            Enabled
Virtual Interface Authentication Failure Trap:    Enabled
Interface Receive Bad Packet Trap:                Enabled
Virtual Interface Receive Bad Packet Trap:        Enabled
Interface Retransmit Packet Trap:                 Disabled
Virtual Interface Retransmit Packet Trap:         Disabled
Originate LSA Trap:                               Disabled
Originate MaxAge LSA Trap:                        Disabled
Link State Database Overflow Trap:                Disabled
Link State Database Approaching Overflow Trap:    Disabled

OSPF Area currently defined:
Area-ID          Area-Type Cost
0                normal    0
1                normal    0
```

Syntax: show ip ospf vrf <*vrf-name*> **config**

The <*vrf-name*> parameter specifies the VRF that you want to display general OSPF configuration information for.

Displaying OSPF external link state information for a VRF

To display OSPF External Link State Information for a specified VRF, enter the following command at any level of the CLI.

```
NetIron#show ip ospf vrf green database external-link-state
Index Aging  LS ID           Router          Netmask  Metric    Flag
1     491    10.30.1.6       10.5.1.3        ffffffff 00000001  0000
2     1005   10.40.1.30      192.168.201.1   ffffffff 8000000a  0000
3     765    10.60.1.10      192.168.201.1   ffffffff 8000000a  0000
4     1005   10.40.1.9       192.168.201.1   ffffffff 8000000a  0000
5     491    10.30.1.19      10.5.1.3        ffffffff 00000001  0000
6     765    10.60.1.23      192.168.201.1   ffffffff 8000000a  0000
7     1005   10.40.1.22      192.168.201.1   ffffffff 8000000a  0000
8     765    10.60.1.2       192.168.201.1   ffffffff 8000000a  0000
9     1005   10.40.1.1       192.168.201.1   ffffffff 8000000a  0000
10    491    10.30.1.11      10.5.1.3        ffffffff 00000001  0000
11    765    10.60.1.15      192.168.201.1   ffffffff 8000000a  0000
12    1005   10.40.1.14      192.168.201.1   ffffffff 8000000a  0000
13    491    10.30.1.24      10.5.1.3        ffffffff 00000001  0000
14    491    10.30.1.3       10.5.1.3        ffffffff 00000001  0000
```

Syntax: **show ip ospf vrf** <*vrf-name*> **database external-link-state [advertise** <*num*>**] | [extensive] | [link-state-id** <*ip-addr*>**] | [router-id** <*ip-addr*>**] | [sequence-number** <*num (Hex)* >**] | [status** <*num*>**]**

The <*vrf-name*> parameter specifies the VRF that you want to display OSPF external link state information for.

The advertise <*num*> parameter displays the data in the specified LSA packet. The <*num*> parameter identifies the LSA packet by its position in the router's External LSA table. To determine an LSA packet's position in the table, enter the **show ip ospf vrf** <*vrf-name*> **external-link-state** command to display the table.

The extensive option displays the data in the LSAs in decrypted format.

The link-state-id <*ip-addr*> parameter displays the External LSAs for the LSA source specified by <*IP-addr*>.

The router-id <*ip-addr*> parameter shows the External LSAs for the specified OSPF router.

The status <*num*> option shows status information.

The sequence-number <*num (Hex)*> parameter displays the External LSA entries for the specified hexadecimal LSA sequence number.

Displaying OSPF link state information for a VRF

To display OSPF Link State Information for a specified VRF, enter the following command at any level of the CLI.

```
NetIron#show ip ospf vrf green database link-state
Index Area ID         Type LS ID           Adv Rtr         Seq(Hex) Age  Cksum

```

Syntax: **show ip ospf vrf** <*vrf-name*> **database link-state [advertise** <*num*>**] | [asbr] | [extensive] | [link-state-id** <*ip-addr*>**] |[network] | [nssa] | [opaque-area] | [router] | [router-id** <*ip-addr*>**] | [sequence-number** <*num (Hex)*>**] | [status** <*num*>**] | [summary]**

The <*vrf-name*> parameter specifies the VRF that you want to display OSPF link state information for.

The advertise <*num*> parameter displays the hexadecimal data in the specified LSA packet. The <*num*> parameter identifies the LSA packet by its position in the router's External LSA table. To determine an LSA packet's position in the table, enter the **show ip ospf vrf** <*vrf-name*> **external-link-state** command to display the table.

The asbr option shows ASBR information.

The extensive option displays the LSAs in decrypted format.

The link-state-id <*ip-addr*> parameter displays the External LSAs for the LSA source specified by <*IP-addr*>.

The network option shows network information.

The nssa option shows network information.

The opaque-area option shows information for opaque areas.

The router-id <*ip-addr*> parameter shows the External LSAs for the specified OSPF router.

The sequence-number <*num (Hex)*> parameter displays the External LSA entries for the specified hexadecimal LSA sequence number.

The status <*num*> option shows status information.

The summary option shows summary information.

Displaying OSPF interface information

To display OSPF interface information for a specified VRF, enter the following command at any CLI level.

```
NetIron# show ip ospf vrf green interface
ethernet 6/3,OSPF enabled
     IP Address 192.168.201.1, Area 1
     OSPF state DR, Pri 1, Cost 1, Options 2, Type broadcast Events 3
     Timers(sec): Transit 1, Retrans 5, Hello 10, Dead 40
     DR:  Router ID 192.168.201.1     Interface Address 192.168.201.1
     BDR: Router ID 1.2.10.2          Interface Address 192.168.201.2
     Neighbor Count = 1, Adjacent Neighbor Count= 1
     Neighbor:         192.168.201.2
     Authentication-Key:None
     MD5 Authentication: Key None, Key-Id None, Auth-change-wait-time 300
```

Syntax: show ip ospf vrf <*vrf-name*> **interface** [<*ip-addr*>]

The <*vrf-name*> parameter specifies the VRF that you want to display OSPF interface information for.

The <*ip-addr*> parameter displays the OSPF interface information for the specified IP address.

Displaying OSPF neighbor information for a VRF

To display OSPF neighbor information for a specified VRF, enter the following command at any CLI level.

```
NetIron# show ip ospf vrf green neighbor

Port  Address         Pri State      Neigh Address   Neigh ID        Ev Opt Cnt
6/3   192.168.201.1   1   FULL/BDR   192.168.201.2   1.2.10.2        6  2   0
```

Syntax: show ip ospf vrf <*vrf-name*> **neighbor [router-id** <*ip-addr*>**] | [**<*num*>**] | [detail]**

The <*vrf-name*> parameter specifies the VRF that you want to display OSPF neighbor information for.

The router-id <*ip-addr*> parameter displays only the neighbor entries for the specified router.

The <*num*> parameter displays only the entry in the specified index position in the neighbor table. For example, if you enter "1", only the first entry in the table is displayed.

The detail parameter displays detailed information about the neighbor routers.

Displaying the routes that have been redistributed into OSPF

You can display the routes that have been redistributed into OSPF for a VRF. To display the redistributed routes, enter the following command at any level of the CLI.

```
NetIron# show ip ospf vrf green redistribute route
  10.6.1.0 255.255.255.0 bgp
  10.8.1.0 255.255.255.0 bgp
  10.40.1.1 255.255.255.255 bgp
  10.40.1.2 255.255.255.255 bgp
```

In this example, four routes have been redistributed from BGP routes

Syntax: show ip ospf vrf <*vrf-name*> **redistribute route**

The <*vrf-name*> parameter specifies the VRF that you want to display routes redistributed into OSPF for.

Displaying OSPF route information for a VRF

To display the OSPF route information for a specified VRF, enter the following command at any level of the CLI.

```
NetIron# show ip ospf vrf green routes
OSPF Area 0x00000001 ASBR Routes 2:
      Destination     Mask            Path_Cost Type2_Cost Path_Type
      1.2.10.2        255.255.255.255 1         0          Intra
      Adv_Router      Link_State      Dest_Type State      Tag       Flags
      1.2.10.2        1.2.10.2        Asbr      Valid      0          0000
      Paths Out_Port  Next_Hop        Type      State
      1     6/3       192.168.201.2   OSPF      00 00
```

In this example, four routes have been redistributed from BGP routes

Syntax: show ip ospf vrf <*vrf-name*> **routes** [<*ip-addr*>]

The <*vrf-name*> parameter specifies the VRF that you want to display OSPF routes for.

The <*ip-addr*> parameter specifies a destination IP address. If you use this parameter, only the route entries for that destination are shown.

Displaying OSPF sham links

To display the OSPF sham links information for a VRF, enter the **show ip ospf vrf** <*vrf-name*> **sham-links** command at any level of the CLI, as in the following example.

```
NetIron# show ip ospf vrf CustomerA sham-links
Sham Link in OSPF instance CustomerA to 10.1.1.2 is UP, Established over lsp(LDP)
 Area 1 source address 10.1.1.1
   Link cost 1 Transmit Delay is 1 sec, State ptpt
   Timer intervals configured, Hello 10, Dead 40, Wait 40, Retransmit 5
   Adjacency State UP, number of interface events 417
```

Syntax: show ip ospf vrf <*vrf-name*> **sham-links**

The <*vrf-name*> variable identifies the VRF for which you want to display OSPF sham links information.

Displaying OSPF trap status for a VRF

To display the state (enabled or disabled) of the OSPF traps for a specified VRF, enter the following command at any CLI level.

```
NetIron# R3-2547#show ip ospf vrf green trap
Interface State Change Trap:                      Enabled
Virtual Interface State Change Trap:              Enabled
Neighbor State Change Trap:                       Enabled
Virtual Neighbor State Change Trap:               Enabled
Interface Configuration Error Trap:               Enabled
Virtual Interface Configuration Error Trap:       Enabled
Interface Authentication Failure Trap:            Enabled
Virtual Interface Authentication Failure Trap:    Enabled
Interface Receive Bad Packet Trap:                Enabled
Virtual Interface Receive Bad Packet Trap:        Enabled
Interface Retransmit Packet Trap:                 Disabled
Virtual Interface Retransmit Packet Trap:         Disabled
Originate LSA Trap:                               Disabled
Originate MaxAge LSA Trap:                        Disabled
Link State Database Overflow Trap:                Disabled
Link State Database Approaching Overflow Trap:    Disabled
```

Syntax: show ip ospf vrf <*vrf-name*> **trap**

The <*vrf-name*> parameter specifies the VRF that you want to display OSPF trap status for.

Displaying OSPF virtual links for a VRF

To display the OSPF virtual links information for a specified VRF, enter the following command at any level of the CLI.

```
NetIron# show ip ospf vrf green virtual-links
No ospf virtual-link entries available
```

Syntax: show ip ospf vrf <*vrf-name*> **virtual-link** [<*num*>]

The <*vrf-name*> parameter specifies the VRF that you want to display OSPF virtual links information for.

The <*num*> parameter displays the table beginning at the specified entry number.

Displaying OSPF virtual neighbor information for a VRF

To display the OSPF virtual neighbor information for a specified VRF, enter the following command at any level of the CLI.

```
NetIron# R3-2547#show ip ospf vrf green virtual-neighbor
```

Syntax: show ip ospf vrf <*vrf-name*> **virtual-neighbor** [<*num*>]

The <*vrf-name*> parameter specifies the VRF that you want to display OSPF virtual neighbor information for.

The <*num*> parameter displays the table beginning at the specified entry number.

Displaying IP extcommunity list information

To display the IP Extcommunity information, enter the following command at any level of the CLI.

```
NetIron#show ip extcommunity-list
ip extcommunity access list 20:
  permit RT 100:1
```

Syntax: show ip extcommunity-list

For information about the fields, refer to the following.

TABLE 298 Output of show IP extcommunity list

This field...	Displays...
ip extcommunity access list	The contents of all extended community lists on the router.

Displaying the IP static route table for a VRF

To display the IP static route table for a VRF, enter the following command at any level of the CLI.

```
NetIron # show ip static route vrf green
IP Static Routing Table - entries:
    IP Prefix         Next Hop      Interface     Dis/Met/Tag   Name
    10.22.66.0/24     10.22.66.0    -             1/1/0         green
```

Syntax: show ip static route vrf <*vrf-name*>

The <*vrf-name*> parameter specifies the VRF that you want to display the static route table for.

Show run displays the entire name of the static IP route. The **show ip static route** command displays an asterisk (*) after the first twelve characters if the assigned name is thirteen characters or more. The **show ipv6 static route** command displays an asterisk after the first two characters if the assigned name is three characters or more.

Displaying the static ARP table for a VRF

To display the static ARP table for a VRF, enter the following command at any level of the CLI.

```
NetIron# show ip static-arp vrf green
Static ARP table size: 2048, configurable from 2048 to 4096
  Index   IP Address          MAC Address         Port
    1      207.95.6.111       0800.093b.d210       1/1
    3      207.95.6.123       0800.093b.d211       1/1
```

Syntax: show ip static-arp vrf <*vrf-name*>

The <*vrf-name*> parameter specifies the VRF that you want to display the static ARP table for.

To clear the static ARP table in a VRF, enter the following command.

```
PE1# clear arp vrf blue
```

Syntax: clear arp vrf <*vrf-name*>

Displaying TCP connections for a VRF

The **show ip tcp vrf connections** command displays information about each TCP connection on the VRF, including the local IP address, local port number, remote IP address, remote port number and the state of the connection. For example.

```
NetIron# show ip tcp vrf green connections
Local IP address:port <-> Remote IP address:port TCP state    (hdl itc cln pdn)
0.0.0.0:179 <-> 0.0.0.0:0 LISTEN (000100bf: 13, 0, 0)
Total 1 TCP connections
```

Syntax: show ip tcp vrf <*vrf-name*> **connections**

The <*vrf-name*> parameter specifies the VRF that you want to display TCP connections for.

Displaying MPLS statistics for a VRF

To display MPLS statistics on a per-interface basis for a specified VRF, enter the following command at any level of the CLI.

```
NetIron# show mpls statistics vrf green
VRF Name       In-Port(s)     Endpt Out-Pkt     Tnl Out-Pkt
green          e3/1           0                 0
               e3/2           0                 0
               e3/3           0                 0
               e3/4           0                 0
               e6/1           0                 0
               e6/2           4367535952        0
               e6/3           0                 4366414365
               e6/4           0                 0
```

Syntax: show mpls statistics vrf <*vrf-name*>

The <*vrf-name*> parameter specifies the VRF that you want to display MPLS statistics for.

For information about the fields in this display, refer the following.

TABLE 299 Output from the show MPLS statistics VRF command

This field...	Displays...
VRF Name	The name of the VRF MPLS statistics are being collected for.
In-Ports	The port where the traffic is received.
Endpt Out-Pkt	The number of packets transmitted out of local endpoints.
Tnl Out-Pkt	The number of packets transmitted out of lsp tunnels.

To clear the MPLS statistics counters.

```
NetIron# clear mpls statistics
```

Syntax: clear mpls statistics [label | tunnel | vpls | vrf]

The **label** parameter clears in-label statistics.

The **tunnel** parameter clears MPLS tunnel statistics.

The **vpls** parameter clears VPLS statistics.

The **vrf** parameter clears vrf statistics.

Displaying IP route information for a VRF

Display IP route Information for a specified VRF by entering the following command.

```
NetIron#show ip route vrf yellow
Total number of IP routes: 2
 Type Codes - B:BGP  D:Connected  S:Static  R:RIP  O:OSPF;   Cost - Dist/Metric
        Destination        Gateway         Port        Cost       Type
1       8.8.8.8/32         DIRECT          loopback 1  0/0        D
2       9.9.9.8/32         20.0.0.1        lsp to1     200/0      B
```

Syntax: show ip route vrf <*vrf-name*> [<*num*>] | [<*ip-addr*>] | **[bgp]** | **[connected]** |**[isis]** | **[ospf]** | **[rip]** | **[static]** | **[tags]**

The <*vrf-name*> parameter specifies the VRF that you want to display IP route information for.

Displaying RIP information for a VRF

To display RIP Information for a specified VRF, enter the following command at any level of the CLI.

```
NetIron#show ip rip vrf black
RIP Summary
  Default port 520
      Administrative distance is 120
      Updates every 30 seconds, expire after 180
      Holddown lasts 180 seconds, garbage collect after 120
      Last broadcast  27, Next Update 29
      Need trigger update  0, Next trigger broadcast 3
      Minimum update  interval 25, Max update Interval 5
      Split horizon is on; poison reverse is off
      Import metric 1
      Prefix List, Inbound : Not set
      Prefix List, Outbound : Not set
      Route-map, Inbound : Not set
```

Syntax: show ip rip vrf <*vrf-name*> **[interface [ethernet** <*slot/port*>**]] | [route** <*ipaddress*>**]**

The <*vrf-name*> parameter specifies the VRF that you want to display IP route information for.

To clear all RIP routes from a specified VRF, enter the following command.

```
PE1# clear ip rip routes vrf blue
```

Syntax: clear ip rip routes vrf <*vrf-name*>

To clear all local RIP routes from a specified VRF, enter the following command.

```
PE1# clear ip rip local routes vrf blue
```

Syntax: clear ip rip local routes vrf <*vrf-name*>

BGP or MPLS VPN sample configurations

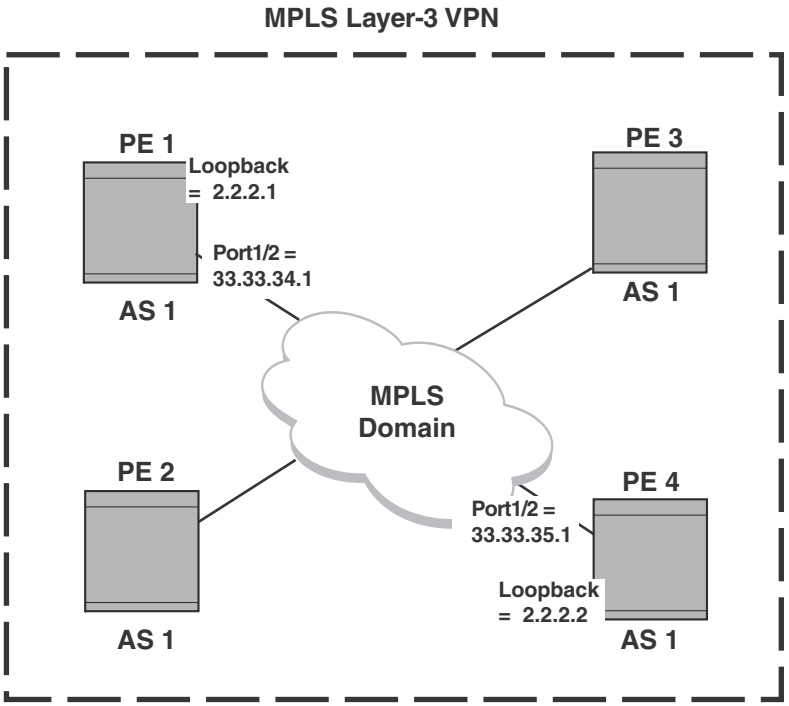
This section presents examples of typical MPLS configurations. The following sample configurations are presented:

- "Basic configuration example for IBGP on the PEs"
- "EBGP for route exchange"
- "Static routes for route exchange"
- "RIP for route exchange"
- "OSPF for route exchange"
- "Cooperative route filtering"
- "Using an IP extcommunity variable with route map"
- "Autonomous system number override"
- "Setting an LSP for each VRF on a PE"
- "OSPF sham links"

Basic configuration example for IBGP on the PEs

PE routers use IBGP to exchange VRF routes. As in all BGP configurations, this is accomplished by configuring BGP neighbors where you want to exchange routes. If the neighbors are configured in the same AS, it will be an IBGP configuration. In addition, since MPLS LSPs are made between router loopback addresses, the [update-source loopback] parameters must be used. The example in Figure 206 shows two PE routers (PE 1 and PE 4) that are configured as BGP neighbors.

FIGURE 206 IBGP example



To configure IBGP on a Provider Edge router (PE) of a BGP or MPLS VPN network, you must perform the configuration steps listed beolw.

1. "Assigning an AS number to a PE"
2. "Assigning a loopback interface"
3. "Configuring an IBGP neighbor on a PE"

Assigning an AS number to a PE

In the IBGP configuration used in a BGP or MPLS VPN, all PEs are configured with the same AS number. To assign the local AS number 1 to the PE 1 router as shown in Figure 206, enter the following commands.

```
PE1(config)#router bgp
PE1(config-bgp)# local-as 1
```

Assigning a loopback interface

A loopback interface is used as the termination for address for BGP sessions. This allows BGP to stay up even when the outbound interface is down as long as an alternate path is available. To install the loopback interface on PE 1 as shown in Figure 206, enter the following commands.

```
PE1(config)#interface loopback 1
PE1(config-lbif-1)# ip address 2.2.2.1/32
```

Configuring an IBGP neighbor on a PE

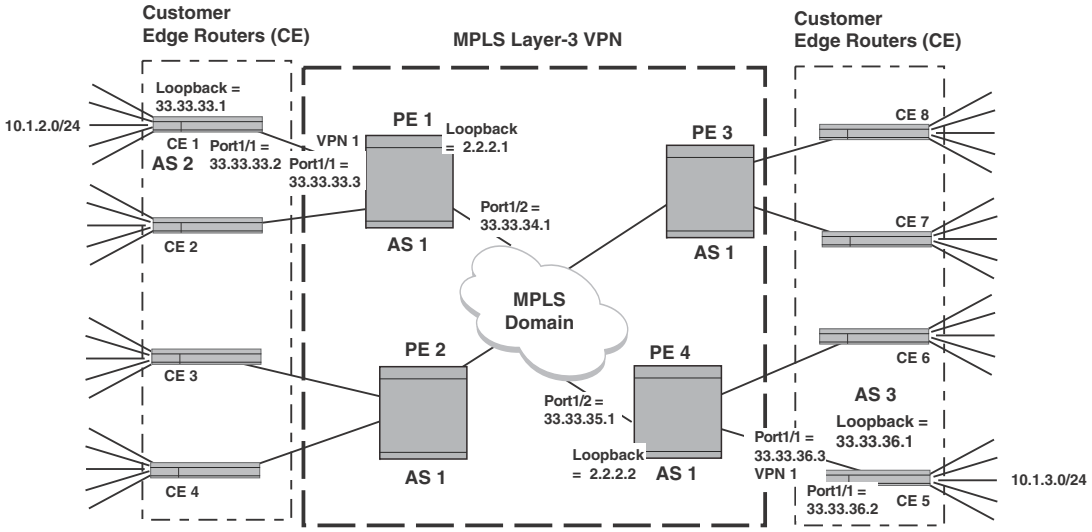
Other PEs that you want to exchange IBGP routes with must be configured as BGP neighbors. In addition, the neighbor must be set to enable the BGP to update the loopback address. To assign an IBGP neighbor with the IP address 33.33.35.1, a remote AS number of 1, and an update-source to loopback 1 of the PE 1 router shown in Figure 206, enter the following commands.

```
PE1(config-bgp)# neighbor 2.2.2.2 remote-as 1
PE1(config-bgp)# neighbor 2.2.2.2 update-source loopback 1
PE1(config-bgp)# address-family vpnv4 unicast
PE1(config-bgp-vpnv4u)# neighbor 2.2.2.2 activate
```

EBGP for route exchange

EBGP can be used to exchange routes for CE routers to PE routers. In this situation, a BGP neighbor must be configured on CE and PE routers. In the example shown in Figure 207, the CE 1 router is configured to exchange routes with the PE 1 router and the CE 5 router is configured to exchange routes with the PE 4 router.

FIGURE 207 EBGP to CE network example



To configure EBGP to exchange routes between PE routers and CE routers, you must perform the configuration steps listed below.

1. "Configuring EBGP on a CE router".
2. "Configuring EBGP on a PE router".

Configuring EBGP on a CE router

To allow route exchange between a CE router and its associated PE router, BGP must be enabled on the CE router and the associated PE router must be configured as a BGP neighbor. To enable BGP on CE 1 and assign PE 1 as a BGP neighbor in the network shown in Figure 207, enter the following commands.

```
CE1(config)# router bgp
CE1(config-bgp)# local-as 2
CE1(config-bgp)# neighbor 33.33.33.3 remote-as 1
```

Configuring EBGP on a PE router

To allow route exchange between a VRF on a PE router and its associated CE router, BGP must be enabled on the appropriate VRF of the PE router and the associated CE router must be configured as a BGP neighbor. To assign CE 1 as a BGP neighbor to the VRF VPN1 on PE 1 in the network shown in Figure 207, enter the following commands.

```
PE1(config-bgp)# address-family ipv4 unicast vrf VPN1
PE1(config-bgp-ipv4u-vrf)# neighbor 33.33.33.2 remote-as 2
```

EBGP to CE network example

In the example shown in Figure 207, the network is configured to use EBGP to forward routes between the networks attached to the CE routers and the PE routers. IBGP is used to forward routes between the PE routers and an LSP tunnel is configured across the MPLS Domain. Figure 207 contains all of the network addresses and AS numbers required to perform this configuration. The configurations are shown for only the CE 1, CE 5, PE 1 and PE 5 routers, which demonstrates what is required to make VPN1 work. The configurations for VPN2, VPN3, and VPN 4 would essentially be the same.

CE 1 configuration

This configuration example describes what is required to operate the CE 1 router in Figure 207. In this example, a static route is configured between the external network (10.1.2.0/24) and the loopback interface. EBGP is configured between CE 1 and PE 1, and the static route is redistributed through this connection.

```
CE1(config)# ip route 10.1.2.0/24 33.33.33.1
CE1(config)# router bgp
CE1(config-bgp)# local-as 2
CE1(config-bgp)# neighbor 33.33.33.3 remote-as 1
CE1(config-bgp)# redistribute static
CE1(config-bgp)# exit

CE1(config)# interface ethernet 1/1
CE1(config-if-e10000-1/1)# ip address 33.33.33.2/24
CE1(config-if-e10000-1/1)# exit
```

CE 5 configuration

This configuration example describes what is required to operate the CE 5 router in Figure 207. In this example, a static route is configured between the external network (10.1.3.0/24) and the loopback interface. EBGP is configured between CE 5 and PE 4, and the static route is redistributed through this connection.

```
CE5(config)#interface loopback 1
CE5(config-lbif-1)# ip address 33.33.36.1/32
CE5(config-lbif-1)# exit

CE5(config)# ip route 10.1.3.0/24 33.33.36.1
CE5(config)# router bgp
CE5(config)# local-as 3
CE5(config-bgp)# neighbor 33.33.36.3 remote-as 1
CE5(config-bgp)# redistribute static
CE5(config-bgp)# exit

CE5(config)#interface ethernet 1/1
CE5(config-if-e10000-1/1)# ip address 33.33.36.2/24
CE5(config-if-e10000-1/1)# exit
```

PE 1 configuration

This configuration example describes what is required to operate the PE 1 router in Figure 207. In this example, the VRF VPN1 is created with a unique route descriptor consisting of the BGP AS number (1) and a random other number (2), and route targets are set for import and export. The VRF (VPN1) is defined on the interface that connects to CE 1. EBGP is configured between VPN1 and CE 1. IBGP with extended community attributes is configured between PE 1 and PE 4.

The OSPF area is specified as 0 and MPLS is set up for OSPF traffic engineering. In addition, MPLS is configured with a signalled LSP named “tunnel1” to PE 4.

```
PE1(config)#interface loopback 1
PE1(config-lbif-1)# ip address 2.2.2.1/32
PE1(config-lbif-1)# ip ospf area 0
PE1(config-lbif-1)# exit

PE1(config)#ip vrf VPN1
PE1(config-ip-vrf-vpn1)#rd 1:1
PE1(config-ip-vrf-vpn1)#route-target export 100:1
PE1(config-ip-vrf-vpn1)#route-target import 100:2
PE1(config-ip-vrf-vpn1)# exit-vrf

PE1(config)# router bgp
PE1(config-bgp)# local-as 1
PE1(config-bgp)# neighbor 2.2.2.2 remote-as 1

PE1(config-mpls-lsp-tunnel1)# to 2.2.2.2
PE1(config-mpls-lsp-tunnel1)# enable
PE1(config-mpls-lsp-tunnel1)# exit

PE1(config)#interface ethernet 1/1
PE1(config-if-e10000-1/1)# ip vrf forwarding VPN1
PE1(config-if-e10000-1/1)# ip address 33.33.33.3/24
```

PE 4 configuration

This configuration example describes what is required to operate the PE 2 router in Figure 207. In this example, the VRF VPN1 is created with a unique route descriptor consisting of the BGP AS number (1) and a random other number (2), and route targets are set for import and export. The VRF (VPN1) is defined on the interface that connects to CE 5. EBGP is configured between VPN1 and CE 5. IBGP with extended community attributes is configured between PE 4 and PE 1.

The OSPF area is specified as 0 and MPLS is set up for OSPF traffic engineering. In addition, MPLS is configured with a signalled LSP named “tunnel1” to PE 1.

```
PE4(config)#interface loopback 1
PE4(config-lbif-1)# ip address 2.2.2.2/32
PE4(config-lbif-1)# ip ospf area 0
PE4(config-lbif-1)# exit

PE4(config)#ip vrf VPN1
PE4(config-vrf-vpn1)#rd 1:2
PE4(config-vrf-vpn1)#route-target export 100:1

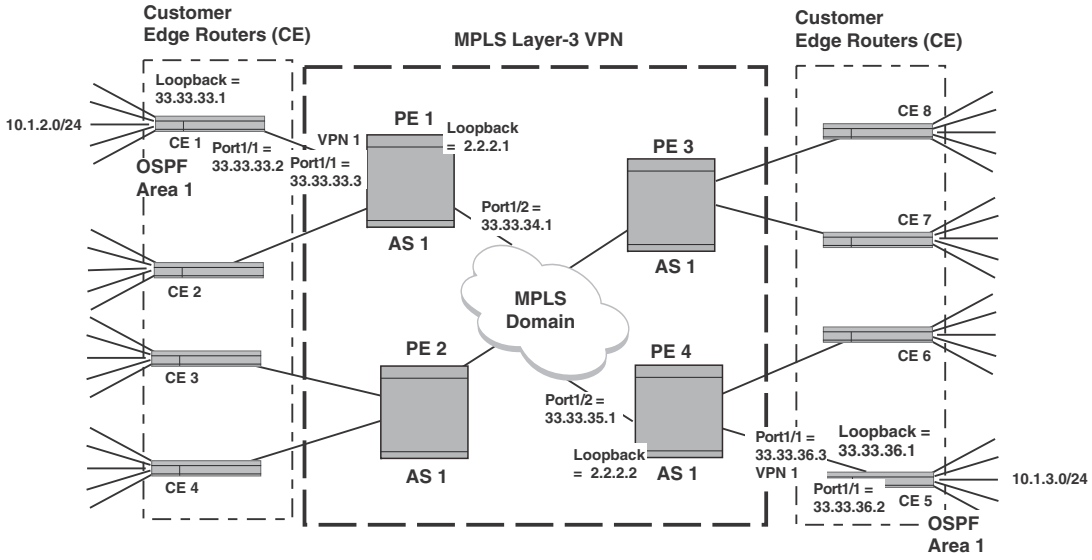
```

Static routes for route exchange

Static routes can be used to exchange routes between CE routers and PE routers. In this situation, a default static route must be configured on a CE router to its associated PE router. A static route must be configured between the PE router and the network (or networks) that the PE wants to advertise as available through a VRF.

FIGURE 208 Static route to CE network example



To configure static routes to exchange routes between PE routers and CE routers, you must perform the configuration steps listed below.

1. "Configuring a static default route on a CE router"
2. "Configuring a static default route on a PE router"

Configuring a static default route on a CE router

To allow route exchange between a CE router and its associated PE router, a static default route must be created to the interface on the associated PE router where the VPN is enabled. In Figure 208, the PE 1 router has the VRF "VPN1" enabled on port 1/1, which has the IP address 33.33.33.3. To create a default static route from CE 1 to this interface on PE 1, enter the following command.

```
CE1(config)# ip route 0.0.0.0 33.33.33.3
```

Configuring a static default route on a PE router

To allow route exchange between a PE router and its associated CE router, a static route must be created to the route that you want to provide access to with a next hop consisting of the IP address of the interface that is connected to the VRF. In Figure 208, the IP address of the connected port on the CE router is 33.33.33.2, and the address on the CE that will be provided access from the PE's VRF is 10.1.2.0/24. To create a static route from PE 1 to CE 1, enter the following command.

```
PE1(config)# ip route vrf VPN1 10.1.2.0/24 33.33.33.2
```

Static route to CE example

In this example, the network shown in Figure 208 is configured for a default static route to forward routes between the networks attached to the CE routers and the PE routers. IBGP is used to forward routes between the PE routers and an LSP tunnel is configured across the MPLS domain. Figure 208 contains all of the network addresses and AS numbers required to perform this configuration. The configurations are shown for only the CE 1, CE 5, PE 1 and PE 5 routers which demonstrates what is required to make VPN1 work. The configurations for VPN2, VPN3, and VPN 4 would essentially be the same.

CE 1 configuration

This configuration example describes what is required to operate the CE 1 router in Figure 208. In this example, a default static route is configured between the CE 1 router and the attached interface of PE 1.

```
CE1(config)# ip route 0.0.0.0/0 33.33.33.3
CE1(config)#interface ethernet 1/1
CE1(config-if-e10000-1/1)# ip address 33.33.33.2
```

CE 5 configuration

This configuration example describes what is required to operate the CE 5 router in Figure 208. In this example, a default static route is configured between the CE 5 router and the attached interface of PE 4.

```
CE5(config)# ip route 0.0.0.0/0 33.33.36.3
CE5(config)#interface ethernet 1/1
CE5(config-if-e10000-1/1)# ip address 33.33.34.2
```

PE 1 configuration

This configuration example describes what is required to operate the PE 1 router in Figure 208. In this example, the VRF VPN1 is created with a unique route descriptor consisting of the BGP AS number (1) and a random other number (2), and route targets are set for import and export. The VRF (VPN1) is defined on the interface that connects to CE 1. A static route is configured between this router and the network connected to CE 1. IBGP with extended community attributes is configured between PE 1 and PE 4.

The OSPF area is specified as 0 and MPLS is set up for OSPF traffic engineering. In addition, MPLS is configured with a signaled LSP named “tunnel1” to PE 4.

```
PE1(config)#interface loopback 1
PE1(config-lbif-1)# ip address 2.2.2.1/24
PE1(config-lbif-1)# ip ospf area 0
PE1(config-lbif-1)# exit

PE1(config)#ip vrf VPN1
PE1(config-vrf-vpn1)# rd 1:1
PE1(config-vrf-vpn1)# route-target export 100:1
PE1(config-vrf-vpn1)# route-target import 100:2
PE1(config-vrf-vpn1)# exit-vrf

PE1(config)# ip route vrf VPN1 10.1.2.0/24 33.33.33.2
PE1(config)# router bgp
PE1(config-bgp)# local-as 1
```

```
PE1(config-bgp)# neighbor 2.2.2.2 remote-as 1
PE1(config-bgp)# neighbor 2.2.2.2 update-source loopback 1
PE1(config-bgp)# address-family vpnv4 unicast
PE1(config-bgp-vpnv4u)# neighbor 2.2.2.2 activate
PE1(config-bgp)# address-family ipv4 unicast vrf VPN1
PE1(config-bgp-ipv4u-vrf)# redistribute static
PE1(config-bgp-ipv4u-vrf)# exit

PE1(config)# router ospf
PE1(config-ospf-router)# area 0
PE1(config-ospf-router)# exit

PE1(config)# interface ethernet 1/2
PE1(config-if-e10000-1/2)# ip address 33.33.34.1/24
PE1(config-if-e10000-1/2)# ip ospf area 0
PE1(config-if-e10000-1/2)# exit

PE1(config)# router mpls
PE1(config-mpls)# policy
PE1(config-mpls-policy)# traffic-engineering ospf
PE1(config-mpls)# mpls-interface eth 1/2
PE1(config-mpls)# lsp tunnel1
PE1(config-mpls-lsp-tunnel1)# to 2.2.2.2
PE1(config-mpls-lsp-tunnel1)# enable
PE1(config-mpls-lsp-tunnel1)# exit

PE1(config)#interface ethernet 1/1
PE1(config-if-e10000-1/1)# ip vrf forwarding VPN1
PE1(config-if-e10000-1/1)# ip address 33.33.33.3/24
PE1(config-if-e10000-1/1)#
```

PE 4 configuration

This configuration example describes what is required to operate the PE 4 router in Figure 208. In this example, the VRF VPN1 is created with a unique route descriptor consisting of the BGP AS number (1) and a random other number (2), and route targets are set for import and export. The VRF (VPN1) is defined on the interface that connects to CE 5. A static route is configured between this router and the network connected to CE 5.

IBGP with extended community attributes is configured between PE 1 and PE 4. The OSPF area is specified as 0 and MPLS is set up for OSPF traffic engineering. In addition, MPLS is configured with a signalled LSP named “tunnel1” to PE 1.

```
PE4(config)#interface loopback 1
PE4(config-lbif-1)# ip address 2.2.2.2/32
PE4(config-lbif-1)# ip ospf area 0
PE4(config-lbif-1)# exit

PE4(config)#ip vrf VPN1
PE4(config-vrf-vpn1)# rd 1:2
PE4(config-vrf-vpn1)# route-target export 100:1
PE4(config-vrf-vpn1)# route-target import 100:2
PE4(config-vrf-vpn1)# exit-vrf

PE4(config)# ip route vrf VPN1 10.1.2.0/24 33.33.36.2
PE4(config)# router bgp
PE4(config-bgp)# local-as 1
PE4(config-bgp)# neighbor 2.2.2.1 remote-as 1
PE4(config-bgp)# neighbor 2.2.2.1 update-source loopback 1
```

```
PE4(config-bgp)# address-family vpnv4 unicast
PE4(config-bgp-vpnv4u)# neighbor 2.2.2.1 activate
PE4(config-bgp)# address-family ipv4 unicast vrf VPN1
PE4(config-bgp-ipv4u-vrf)# redistribute static
PE4(config-bgp-ipv4u-vrf)# exit

PE4(config)# router ospf
PE4(config-ospf-router)# area 0
PE4(config-ospf-router)# exit

PE4(config)#interface ethernet 1/2
PE4(config-if-e10000-1/2)# ip address 33.33.35.1/24
PE4(config-if-e10000-1/2)# ip ospf area 0
PE4(config-if-e10000-1/2)# exit

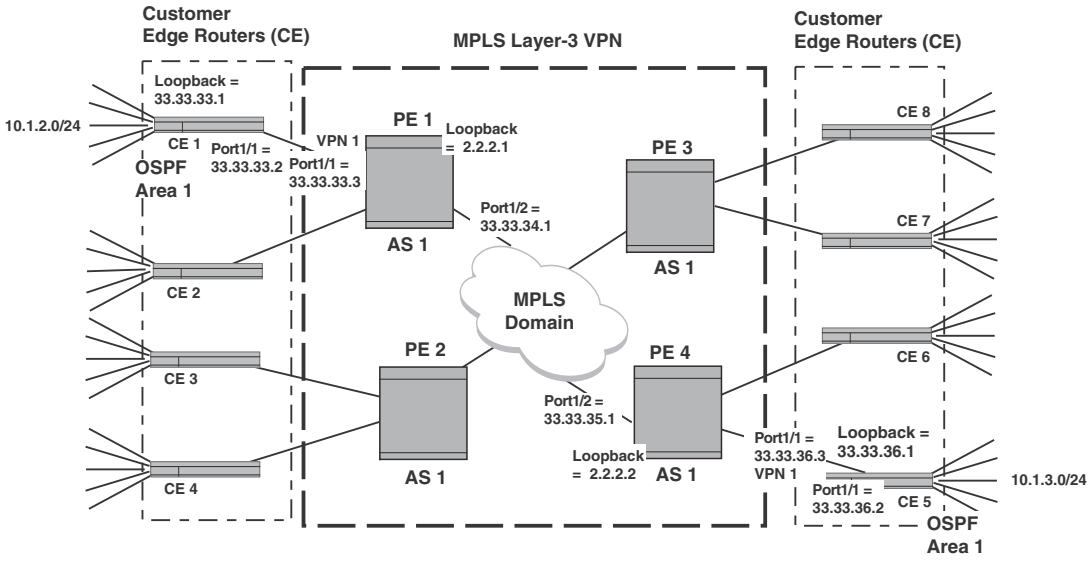
PE4(config)# router mpls
PE4(config-mpls)# policy
PE4(config-mpls-policy)# traffic-engineering ospf
PE4(config-mpls)# mpls-interface eth 1/2
PE4(config-mpls)# lsp tunnel1
PE4(config-mpls-lsp-tunnel1)# to 2.2.2.1
PE4(config-mpls-lsp-tunnel1)# enable
PE4(config-mpls-lsp-tunnel1)# exit

PE4(config)# interface ethernet 1/1
PE4(config-if-e10000-1/1)# ip vrf forwarding VPN1
PE4(config-if-e10000-1/1)# ip address 33.33.36.3/24
PE4(config-if-e10000-1/1)# exit
```

RIP for route exchange

RIP can be used to exchange routes between CE routers and PE routers. In this situation, RIP must be enabled on the CE router and enabled on the interface that is connected to the interface of the PE that is associated with the VRF that you want to advertise RIP routes on. On the PE router, the VRF must be enabled to redistribute RIP routes, and RIP must be enabled for the VRF and configured to redistribute routes from BGP in the VRF. Figure 209 provides an example of a network where RIP is used to exchange routes between CE routers and PE routers.

FIGURE 209 RIP to CE network example



To configure RIP to exchange routes between PE routers and CE routers, you must perform the configuration steps listed below.

1. "Configuring RIP on the CE router"
2. "Enabling RIP on the CE router' interface"
3. "Configuring the VRF on the PE router to redistribute RIP routes"
4. "Configuring RIP on the PE router to redistribute BGP-VPNv4 routes"
5. "Enabling RIP on the PE router interface"

Configuring RIP on the CE router

To allow RIP route exchange between a CE router and its associated PE router, RIP must be enabled on the CE router. To configure RIP on the CE 1 router in Figure 209 and enable it to redistribute static routes through RIP, enter the following commands.

```
CE1(config)# router rip
CE1(config-rip-router)# redistribute static
```

Enabling RIP on the CE router' interface

To allow RIP route exchange between a CE router and its associated PE router, RIP must be enabled on the interface that connects to the VRF-enabled interface of its associated PE router. To configure RIP on the interface of the CE 1 router in Figure 209 that is connected to the VRF VPN1 associated interface on PE 1, enter the following commands.

```
CE1(config)#interface ethernet 1/1
CE1(config-if-e10000-1/1)# ip rip v2-only
CE1(config-if-e10000-1/1)# ip address 33.33.33.2
```

Configuring the VRF on the PE router to redistribute RIP routes

To allow RIP route exchange between a specified VRF on a PE router and its associated CE router, the VRF must be enabled redistribute RIP routes. To enable the VRF VPN1 on PE 1 router in Figure 209 to redistribute RIP routes, enter the following commands.

```
PE1(config-bgp)# address-family ipv4 unicast vrf VPN1
PE1(config-bgp-ipv4u-vrf)# redistribute rip
```

Configuring RIP on the PE router to redistribute BGP-VPNv4 routes

To allow RIP route exchange between a specified VRF on a PE router and its associated CE router, RIP must be configured to redistribute BGP routes from the local AS. To enable RIP on PE 1 in Figure 209 and configure it to redistribute BGP-VPNv4 routes into RIP, enter the following commands.

```
PE1(config)# router rip vrf VPN1
PE1(config-rip-router)# redistribute bgp
```

Enabling RIP on the PE router interface

To allow RIP route exchange between a PE router and its associated CE router, RIP must be enabled on the PE's interface that is associated with the VRF and connected to the PE router. To configure RIP on the interface of the PE 1 router that is associated with VRF VPN1 in Figure 209 to CE 1, enter the following commands.

```
PE1(config)#interface ethernet 1/1
PE1(config-if-e10000-1/1)# ip vrf forwarding VPN1
PE1(config-if-e10000-1/1)# ip address 33.33.33.3/24
PE1(config-if-e10000-1/1)# ip rip v2-only
```

RIP to CE example

In this example, the network shown in Figure 209 is configured for RIP to forward routes between the networks attached to the CE routers and the PE routers. IBGP is used to forward routes between the PE routers and an LSP tunnel is configured across the MPLS Domain. Figure 209 contains all of the network addresses and AS numbers required to perform this configuration. The configurations are shown for only the CE 1, CE 5, PE 1 and PE 5 routers, which demonstrates what is required to make VPN1 work. The configurations for VPN2, VPN3, and VPN 4 would essentially be the same.

CE 1 configuration

This configuration example describes what is required to operate the CE 1 router in Figure 209. In this example, a static route is configured between the external network (10.1.2.0/24) and the loopback interface. RIP is configured to redistribute static routes between the CE 1 router and the attached interface of PE 1.

```
CE1(config)#interface loopback 1
CE1(config-lbif-1)# ip address 33.33.33.1/32
CE1(config-lbif-1)# exit

CE1(config)# ip route 10.1.2.0/24 33.33.33.1
CE1(config)# router rip
CE1(config-lbif-1)# redistribute static
CE1(config-lbif-1)# exit
```

```
CE1(config)# interface ethernet 1/1
CE1(config-if-e10000-1/1)# ip rip v2-only
CE1(config-if-e10000-1/1)# ip address 33.33.33.2
CE1(config-if-e10000-1/1)# exit
```

CE 5 configuration

This configuration example describes what is required to operate the CE 5 router in Figure 209. In this example, a static route is configured between the external network (10.1.3.0/24) and the loopback interface. RIP is configured to redistribute static routes between the CE 5 router and the attached interface of PE 4.

```
CE5(config)#interface loopback 1
CE5(config-lbif-1)# ip address 33.33.36.1/32
CE5(config-lbif-1)# exit

CE5(config)# ip route 10.1.3.0/24 33.33.36.1
CE5(config)# router rip
CE5(config-rip-router)# redistribute static
CE5(config-rip-router)# exit

CE5(config)#interface ethernet 1/1
CE5(config-if-e10000-1/1)# ip rip v2-only
CE5(config-if-e10000-1/1)# ip address 33.33.36.2
CE5(config-if-e10000-1/1)# exit
```

PE 1 configuration

This configuration example describes what is required to operate the PE 1 router in Figure 209. In this example, the VRF VPN1 is created with a unique route descriptor consisting of the BGP AS number (1) and a random other number (2), and route targets are set for import and export. The VRF (VPN1) is defined on the interface that connects to CE 1. RIP is configured on the VRF named VPN1 to exchange routes with CE 1 and to redistribute routes from across the MPLS Domain.

IBGP with extended community attributes is configured between PE 1 and PE 4. The OSPF area is specified as 0 and MPLS is set up for OSPF traffic engineering. In addition, MPLS is configured with a signalled LSP named “tunnel1” to PE 1.

```
PE1(config)#interface loopback 1
PE1(config-lbif-1)# ip address 2.2.2.1/32
PE1(config-lbif-1)# ip ospf area 0
PE1(config-lbif-1)# exit

PE1(config)#ip vrf VPN1
PE1(config-vrf-vpn1)# rd 1:1
PE1(config-vrf-vpn1)# route-target export 100:1
PE1(config-vrf-vpn1)# route-target import 100:2
PE1(config-vrf-vpn1)# exit-vrf

PE1(config)# router bgp
PE1(config-bgp)# local-as 1
PE1(config-bgp)# neighbor 2.2.2.2 remote-as 1
PE1(config-bgp)# neighbor 2.2.2.2 update-source loopback 1
PE1(config-bgp)# address-family vpnv4 unicast
PE1(config-bgp-vpnv4u)# neighbor 2.2.2.2 activate
PE1(config-bgp)# address-family ipv4 unicast vrf VPN1
PE1(config-bgp-ipv4u-vrf)# redistribute rip
PE1(config-bgp-ipv4u-vrf)# exit
```

```
PE1(config)# router rip vrf VPN1
PE1(config-rip-router)# redistribute bgp
PE1(config-rip-router)# exit

PE1(config)# router ospf
PE1(config-ospf-router)# area 0
PE1(config-ospf-router)#

PE1(config)#interface ethernet 1/2
PE1(config-if-e10000-1/2)# ip address 33.33.34.1/24
PE1(config-if-e10000-1/2)# ip ospf area 0
PE1(config-if-e10000-1/2)# exit

PE1(config)# router mpls
PE1(config-mpls)# policy
PE1(config-mpls-policy)# traffic-engineering ospf
PE1(config-mpls)# mpls-interface eth 1/2
PE1(config-mpls)# lsp tunnel1
PE1(config-mpls-lsp-tunnel1)# to 2.2.2.2
PE1(config-mpls-lsp-tunnel1)# enable
PE1(config-mpls-lsp-tunnel1)# exit

PE1(config)#interface ethernet 1/1
PE1(config-if-e10000-1/1)# ip vrf forwarding VPN1
PE1(config-if-e10000-1/1)# ip address 33.33.33.3/24
PE1(config-if-e10000-1/1)# ip rip v2-only
PE1(config-if-e10000-1/1)# exit
```

PE 4 configuration

This configuration example describes what is required to operate the PE 4 router in Figure 209. In this example, the VRF VPN1 is created with a unique route descriptor consisting of the BGP AS number (1) and a random other number (2), and route targets are set for import and export. The VRF (VPN1) is defined on the interface that connects to CE 5. RIP is configured on the VRF named VPN1 to exchange routes with CE 1 and to redistribute routes from across the MPLS Domain.

IBGP with extended community attributes is configured between PE 4 and PE 1. The OSPF area is specified as 0, and MPLS is set up for OSPF traffic engineering. In addition, MPLS is configured with a signaled LSP named “tunnel1” to PE 1.

```
PE4(config)# interface loopback 1
PE4(config-lbif-1)# ip address 2.2.2.2/24
PE4(config-lbif-1)# ip ospf area 0
PE4(config-lbif-1)# exit

PE4(config)#ip vrf VPN1
PE4(config-vrf-vpn1)# rd 1:2
PE4(config-vrf-vpn1)# route-target export 100:1
PE4(config-vrf-vpn1)# route-target import 100:2
PE4(config-vrf-vpn1)# exit-vrf

PE4(config)# router bgp
PE4(config-bgp)# local-as 1
PE4(config-bgp)# neighbor 2.2.2.1 remote-as 1
PE4(config-bgp)# neighbor 2.2.2.1 update-source loopback 1
PE4(config-bgp)# address-family vpnv4 unicast
PE4(config-bgp-vpnv4u)# neighbor 2.2.2.1 activate
PE4(config-bgp)# address-family ipv4 unicast vrf VPN1
PE4(config-bgp-ipv4u-vrf)# redistribute rip
PE4(config-bgp-ipv4u-vrf)# exit
```

```
PE4(config)# router rip vrf VPN1
PE4(config-rip-router)# redistribute bgp
PE4(config-rip-router)# exit

PE4(config)# router ospf
PE4(config-ospf-router)# area 0
PE4(config-ospf-router)# exit

PE4(config)#interface ethernet 1/2
PE4(config-if-e10000-1/2)# ip address 33.33.35.1/24
PE4(config-if-e10000-1/2)# ip ospf area 0
PE4(config-if-e10000-1/2)# exit

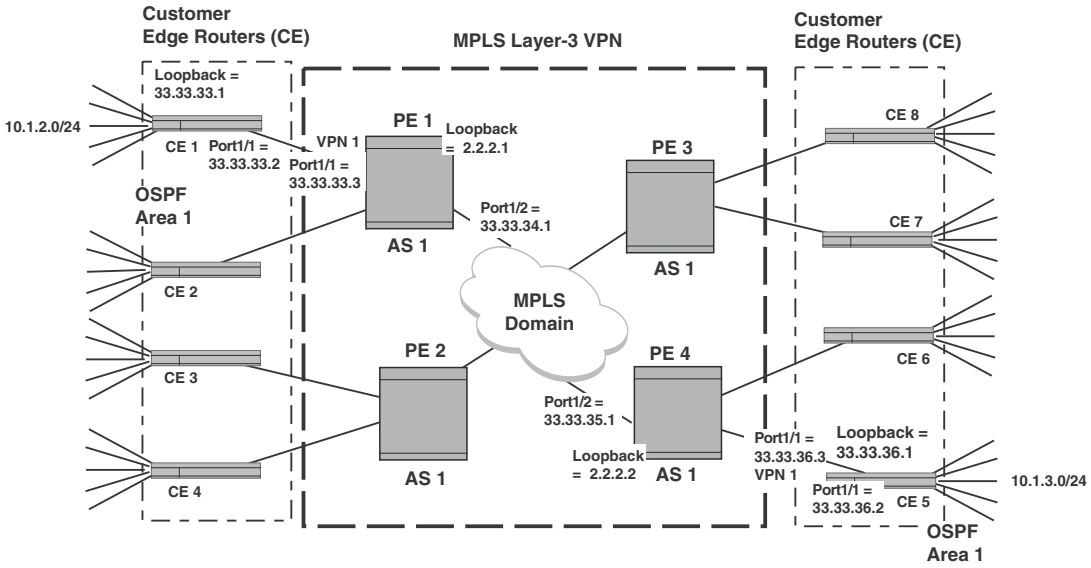
PE4(config)# router mpls
PE4(config-mpls)# policy
PE4(config-mpls-policy)# traffic-engineering ospf
PE4(config-mpls)# mpls-interface eth 1/2
PE4(config-mpls)# lsp tunnel1
PE4(config-mpls-lsp-tunnel1)# to 2.2.2.1
PE4(config-mpls-lsp-tunnel1)# enable
PE4(config-mpls-lsp-tunnel1)# exit

PE4(config)#interface ethernet 1/1
PE4(config-if-e10000-1/1)# ip vrf forwarding VPN1
PE4(config-if-e10000-1/1)# ip address 33.33.36.3/24
PE4(config-if-e10000-1/1)# ip rip v2-only
PE4(config-if-e10000-1/1)# exit
```

OSPF for route exchange

OSPF can be used to exchange routes between CE routers and PE routers. In this situation, OSPF must be enabled on the CE router with a local area and enabled on the interface that is connected to the interface of the PE that is associated with the VRF that you want to advertise OSPF routes on. On the PE router, the VRF must be enabled in BGP to redistribute OSPF routes, and OSPF must be enabled for the VRF and configured to redistribute routes from BGP-VPNv4. Figure 210 provides an example of a network where OSPF is used to exchange routes between CE routers and PE routers.

FIGURE 210 OSPF to CE network example



To configure OSPF to exchange routes between PE routers and CE routers, you must perform the configuration steps listed below.

1. "Configuring OSPF on the CE router".
2. "Enabling OSPF on the CE router interface".
3. "Configuring the VRF on the PE router to redistribute OSPF routes".
4. "Configuring OSPF on the PE router to redistribute BGP-VPNv4 routes".
5. "Enabling OSPF on the PE router interface".

Configuring OSPF on the CE router

To allow OSPF route exchange between a CE router and its associated PE router, OSPF must be enabled on the CE router. To configure OSPF on the CE 1 router for local area 1 in Figure 210 and enable it to redistribute static routes through OSPF, enter the following commands.

```
CE1(config)# router ospf
CE1(config-ospf-router)# area 1
CE1(config-ospf-router)# redistribute static
```

Enabling OSPF on the CE router interface

To allow OSPF route exchange between a CE router and its associated PE router, OSPF must be enabled on the interface that connects to the VRF-enabled interface of its associated PE router. To configure OSPF on the interface of the CE 1 router in Figure 210 that is connected to the VRF VPN1 associated interface on PE 1, enter the following commands.

```
CE1(config)#interface ethernet 1/1
CE1(config-if-e10000-1/1)# ip ospf area 1
CE1(config-if-e10000-1/1)# ip address 33.33.33.2
```

Configuring the VRF on the PE router to redistribute OSPF routes

To allow OSPF route exchange between a specified VRF on a PE router and its associated CE router, the VRF must be enabled to redistribute OSPF routes. To enable the VRF VPN1 on PE 1 router in Figure 210 to redistribute OSPF routes, enter the following commands.

```
PE1(config-bgp)# address-family ipv4 unicast vrf VPN1
PE1(config-bgp-ipv4u-vrf)# redistribute ospf match internal
PE1(config-bgp-ipv4u-vrf)# redistribute ospf match external1
PE1(config-bgp-ipv4u-vrf)# redistribute ospf match external2
```

Configuring OSPF on the PE router to redistribute BGP-VPNv4 routes

To allow OSPF route exchange between a specified VRF on a PE router and its associated CE router, OSPF must be configured to redistribute BGP routes from the local AS. To enable OSPF on PE 1 in Figure 210 and configure it to redistribute BGP-VPNv4 routes into OSPF, enter the following commands.

```
PE1(config)# router ospf vrf VPN1
PE1(config-ospf-router)# domain-id 0.0.0.100
PE1(config-ospf-router)# domain-tag 1200
PE1(config-ospf-router)# area 1
PE1(config-ospf-router)# redistribute bgp
```

Enabling OSPF on the PE router interface

To allow OSPF route exchange between a PE router and its associated CE router, OSPF must be enabled on the PE's interface that is associated with the VRF and connected to the PE router. To configure OSPF on the interface of the PE 1 router that is associated with VRF VPN1 in Figure 210 to CE 1, enter the following commands.

```
PE1(config)#interface ethernet 1/1
PE1(config-if-e10000-1/1)# ip vrf forwarding VPN1
PE1(config-if-e10000-1/1)# ip address 33.33.33.3/24
PE1(config-if-e10000-1/1)# ip ospf area 1
```

OSPF to CE example

In this example, the network shown in Figure 210 is configured for OSPF to forward routes between the networks attached to the CE routers and the PE routers. IBGP is used to forward routes between the PE routers and an LSP tunnel is configured across the MPLS Domain. Figure 210 contains all of the network addresses and AS numbers required to perform this configuration. The configurations are shown for only the CE 1, CE 5, PE 1 and PE 5 routers, which demonstrates what is required to make VPN1 work. The configurations for VPN2, VPN3, and VPN 4 would essentially be the same.

CE 1 configuration

This configuration example describes what is required to operate the CE 1 router in Figure 210. In this example, a static route is configured between the external network (10.1.2.0/24) and the loopback interface. OSPF is configured to redistribute static routes between the CE 1 router and the attached interface of PE 1.

```
CE1(config)#interface loopback 1
CE1(config-lbif-1)# ip address 33.33.33.1/32
CE1(config-lbif-1)# exit

CE1(config)# ip route 10.1.2.0/24 33.33.33.1
CE1(config)# router ospf
CE1(config-ospf-router)# area 1
CE1(config-ospf-router)# redistribute static
CE1(config-ospf-router)# exit

CE1(config)#interface ethernet 1/1
CE1(config-if-e10000-1/1)# ip address 33.33.33.2
CE1(config-if-e10000-1/1)# ip ospf area 1
CE1(config-if-e10000-1/1)# exit
```

CE 5 configuration

This configuration example describes what is required to operate the CE 5 router in Figure 210. In this example, a static route is configured between the external network (10.1.3.0/24) and the loopback interface. OSPF is configured to redistribute static routes between the CE 5 router and the attached interface of PE 4.

```
CE5(config)#interface loopback 1
CE5(config-lbif-1)# ip address 33.33.36.1/32
CE5(config-lbif-1)# exit

CE5(config)# ip route 10.1.3.0/24 33.33.36.1
CE5(config)# router ospf
CE5(config-ospf-router)# area 1
CE5(config-ospf-router)# redistribution static
CE5(config-ospf-router)# exit

CE5(config)#interface ethernet 1/1
CE5(config-if-e10000-1/1)# ip address 33.33.36.2
CE5(config-if-e10000-1/1)# ip ospf area 1
CE5(config-if-e10000-1/1)# exit
```

PE 1 configuration

This configuration example describes what is required to operate the PE 1 router in Figure 210. In this example, the VRF VPN1 is created with a unique route descriptor consisting of the BGP AS number (1) and a random other number (2), and route targets are set for import and export. The VRF (VPN1) is defined on the interface that connects to CE 1. OSPF is configured on the VRF named VPN1 to exchange routes with CE 1 and to redistribute routes from across the MPLS Domain.

IBGP with extended community attributes is configured between PE 1 and PE 4. The OSPF area is specified as 0 and MPLS is set up for OSPF traffic engineering. In addition, MPLS is configured with a signalled LSP named “tunnel1” to PE 1.

```
PE1(config)#interface loopback 1
PE1(config-lbif-1)# ip address 2.2.2.1/24
PE1(config-lbif-1)# ip ospf area 0
PE1(config-lbif-1)# exit

PE1(config)#ip vrf VPN1
PE1(config-vrf-vpn1)# rd 1:1
PE1(config-vrf-vpn1)# route-target export 100:1
PE1(config-vrf-vpn1)# route-target import 100:2
```

```
PE1(config-vrf-vpn1)# exit-vrf

PE1(config)# router bgp
PE1(config-bgp)# local-as 1
PE1(config-bgp)# neighbor 2.2.2.2 remote-as 1
PE1(config-bgp)# neighbor 2.2.2.2 update-source loopback 1
PE1(config-bgp)# address-family vpnv4 unicast
PE1(config-bgp-vpnv4u)# neighbor 2.2.2.2 activate
PE1(config-bgp)# address-family ipv4 unicast vrf VPN1
PE1(config-bgp-ipv4u-vrf)# redistribute ospf
PE1(config-bgp-ipv4u-vrf)# exit

PE1(config)# router ospf vrf VPN1
PE1(config-ospf-router)# domain-id 0.0.0.100
PE1(config-ospf-router)# domain-tag 0.0.0.100
PE1(config-ospf-router)# area 1
PE1(config-ospf-router)# redistribute bgp
PE1(config-ospf-router)# exit

PE1(config)# router ospf
PE1(config-ospf-router)# area 0
PE1(config-ospf-router)# exit

PE1(config)#interface ethernet 1/2
PE1(config-if-e10000-1/2)# ip address 33.33.34.1/24
PE1(config-if-e10000-1/2)# ip ospf area 0
PE1(config-if-e10000-1/2)# exit

PE1(config)# router mpls
PE1(config-mpls)# policy
PE1(config-mpls-policy)# traffic-engineering ospf
PE1(config-mpls)# mpls-interface eth 1/2
PE1(config-mpls)# lsp tunnel1
PE1(config-mpls-lsp-tunnel1)# to 2.2.2.2
PE1(config-mpls-lsp-tunnel1)# enable
PE1(config-if-e10000-1/2)# exit

PE1(config)#interface ethernet 1/1
PE1(config-if-e10000-1/1)# ip vrf forwarding VPN1
PE1(config-if-e10000-1/1)# ip address 33.33.33.3/24
PE1(config-if-e10000-1/1)# ip ospf area 1
PE1(config-if-e10000-1/1)# exit
```

PE 4 configuration

This configuration example describes what is required to operate the PE 4 router in Figure 210. In this example, the VRF VPN1 is created with a unique route descriptor consisting of the BGP AS number (1) and a random other number (2), and route targets are set for import and export. The VRF (VPN1) is defined on the interface that connects to CE 5. OSPF is configured on the VRF named VPN1 to exchange routes with CE 5 and to redistribute routes from across the MPLS Domain.

```
PE4(config)#interface loopback 1
PE4(config-lbif-1)# ip address 2.2.2.2/32
PE1(config-lbif-1)# ip ospf area 1
PE1(config-lbif-1)# exit

PE4(config)#ip vrf VPN1
PE4(config-vrf-vpn1)# rd 2:1
```

```
PE4(config-vrf-vpn1)# route-target export 100:1
PE4(config-vrf-vpn1)# route-target import 100:2
PE4(config-vrf-vpn1)# exit-vrf

PE4(config)# router bgp
PE4(config-bgp)# local-as 1
PE4(config-bgp)# neighbor 2.2.2.1 remote-as 1
PE4(config-bgp)# neighbor 2.2.2.1 update-source loopback 1
PE4(config-bgp)# address-family vpnv4 unicast
PE4(config-bgp-vpnv4u)# neighbor 2.2.2.1 activate
PE4(config-bgp)# address-family ipv4 unicast vrf VPN1
PE4(config-bgp-ipv4u-vrf)# redistribute ospf
PE4(config-bgp-ipv4u-vrf)# exit

PE4(config)# router ospf vrf VPN1
PE4(config-ospf-router)# domain-id 0.0.0.100
PE4(config-ospf-router)# domain-tag 0.0.0.100
PE4(config-ospf-router)# area 1
PE4(config-ospf-router)# redistribute bgp
PE4(config-ospf-router)# exit

PE4(config)# router ospf
PE4(config-ospf-router)# area 0
PE4(config-ospf-router)# exit

PE4(config)#interface ethernet 1/2
PE4(config-if-e10000-1/2)# ip ospf area 0
PE4(config-if-e10000-1/2)# ip address 33.33.35.1/24
PE4(config-if-e10000-1/2)#exit

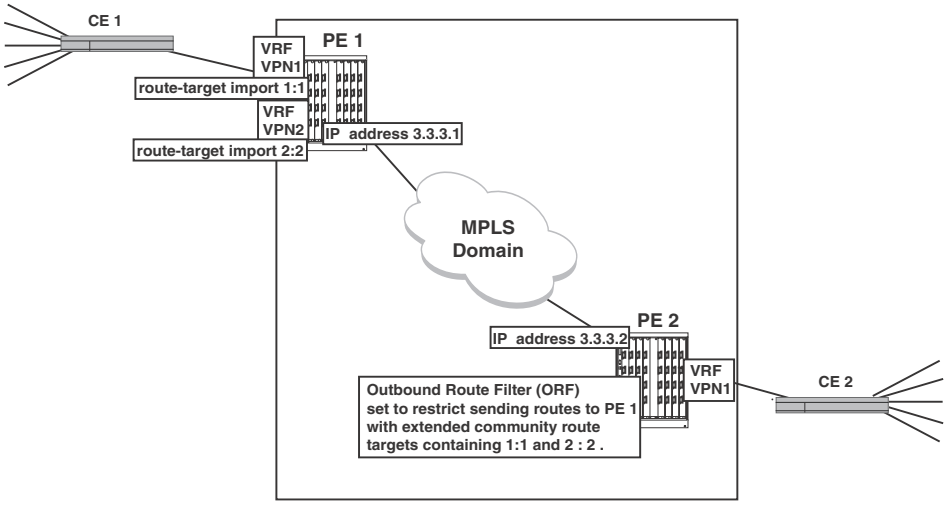
PE4(config)# router mpls
PE4(config-mpls)# policy
PE4(config-mpls-policy)# traffic-engineering ospf
PE4(config-mpls)# mpls-interface eth 1/2
PE4(config-mpls)# lsp tunnel1
PE4(config-mpls-lsp-tunnel1)# to 2.2.2.1
PE4(config-mpls-lsp-tunnel1)# enable
PE4(config-mpls-lsp-tunnel1)# exit

PE4(config)# interface ethernet 1/1
PE4(config-if-e10000-1/1)# ip vrf forwarding VPN1
PE4(config-if-e10000-1/1)# ip address 33.33.36.3/24
PE4(config-if-e10000-1/1)# ip ospf area 1
PE4(config-if-e10000-1/1)# exit
```

Cooperative route filtering

The ***cooperative route filtering*** feature allows you to move the filtering function of a route-target import filter to a peer. In this situation, an Outbound Route Filter (ORF) is derived from the contents of all of the ***route-target import*** commands of BGP configured VRFs on a PE and shared with a peer PE. This ORF is then used to exclude any routes that are blocked by that ORF from being sent by the peer PE to the PE with the ***route-target import*** commands that the ORF was derived from. For example, in Figure 211 the routes that are admitted into VPN1 and VPN2 have route targets of 1:1 and 2:2. You can use the cooperative route filtering feature to send an ORF that is derived from the route-target import commands on PE 1 to PE 2 to only accept these routes.

FIGURE 211 Cooperative route filtering example



The following example shows the commands required to configure VRF VPN1 on PE 1 in Figure 211 with an import route-target of 1:1 and VRF VPN2 on PE 1 with an import route-target import of 2:2.

```
PE1(config)#ip vrf VPN1
PE1(config-ip-vrf-VPN1)# route-target import 1:1
PE1(config-ip-vrf-VPN1)#exit-vrf

PE1(config)#ip vrf VPN2
PE1(config-ip-vrf-VPN2)# route-target import 2:2
PE1(config-ip-vrf-VPN2)#exit-vrf
```

The following commands configure PE 1 to send the filter derived from the import route-target commands in VPN1 and VPN2 to PE 2.

```
PE1(config-bgp)# address-family vpnv4 unicast
PE1(config-bgp-vpnv4u)# neighbor 3.3.3.2 capability orf extended-community
send-vrf-filter
```

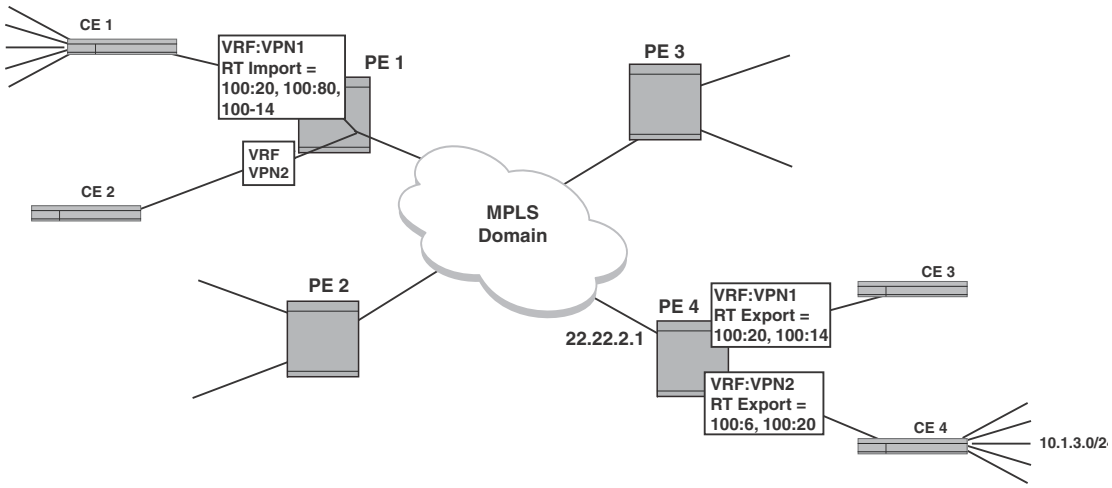
The following commands configure PE 2 to receive the filter derived from the import route-target commands in VPN1 and VPN2 on PE 1.

```
PE2(config-bgp)# address-family vpnv4 unicast
PE2(config-bgp-ivpnv4u)# neighbor 3.3.3.1 capability orf extended-community
receive
```

Using an IP extcommunity variable with route map

In Figure 212, the VRF named “VPN1” on PE 1 is set to import routes with RT 100:14, 100:20 and 100:80. The VRF named “VPN1” on PE 4 is configured to export routes with RT 100:20 and 100:14. The VRF named “VPN2” on PE 4 is configured to export routes with RT 100:6 and 100:20. A route-map is configured from a BGP neighbor command on PE 1 to not install all routes from PE 4 with RT 100:6. This will block all routes from VPN2 being sent to PE 1.

FIGURE 212 IP Extcommunity and route-map usage



The following example shows the configuration commands required on the PE 1 router for the example shown in Figure 212. In this example, the route-map ExcludeRoute has a **match extcommunity** value that references the extcommunity 20. The **extended community list 20** command specifies that routes with RT 100:6 are to be denied. The **neighbor route-map** command exports the ExcludeRoute route-map to the BGP neighbor PE 4. Consequently, PE 4 will block the export or route-target 100:6 to PE 1. This will block all routes from VPN2 on PE 4 from being sent to PE 1.

```
PE1(config)# router bgp
PE1(config-bgp)# local-as 100
PE1(config-bgp)# neighbor 22.22.2.1 remote-as 100
PE1(config-bgp)# address-family vpnv4 unicast
PE1(config-bgp-vpnv4u)# neighbor 22.22.2.1 activate
PE1(config-bgp-vpnv4u)# neighbor 22.22.2.1 route-map in ExcludeRoute
PE1(config-bgp-vpnv4u)# neighbor 22.22.2.1 send-community extended
PE1(config-bgp-vpnv4u)# exit

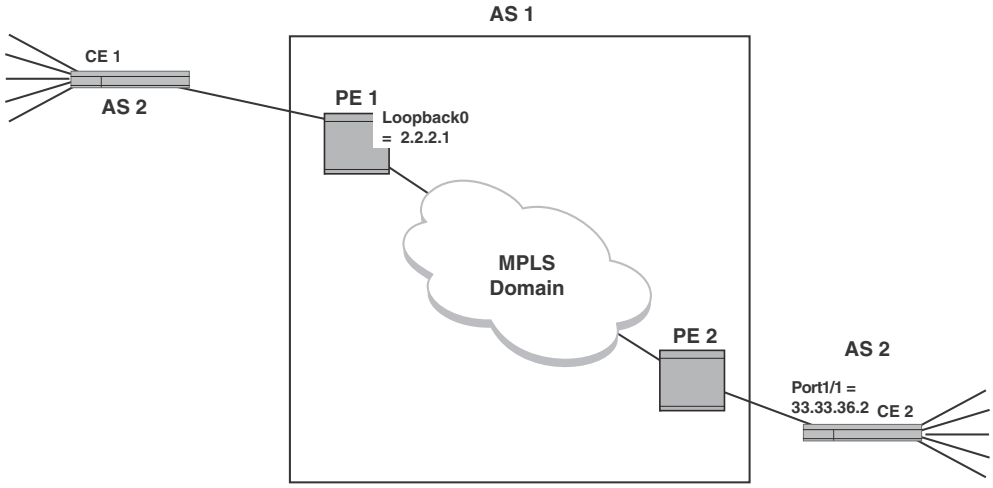
PE1(config)# route-map ExcludeRoute permit 10
PE1(config-routemap ExcludeRoute)# match extcommunity 20
PE1(config-routemap ExcludeRoute)# exit

PE1(config)#ip extcommunity-list 20 deny RT 100:6
PE1(config)#ip vrf VPN1
PE1(config-ip-vrf-vpn1)#rd 1:1
PE1(config-ip-vrf-vpn1)#route-target import 100:20
PE1(config-ip-vrf-vpn1)#route-target import 100:80
PE1(config-ip-vrf-vpn1)#route-target import 100:14
PE1(config-ip-vrf-vpn1)#exit-vrf
```

Autonomous system number override

In the example shown in Figure 213 the service providers network is in AS1 and the customer wants both of his CE routers at different sites to use AS 2. When a route is sent from CE 1 to CE 2, it will contain an AS_PATH attribute containing AS 2. When CE 2 sees that the AS_PATH attribute contains its own AS number, it will reject the route.

FIGURE 213 AS number override example



One solution to this problem is to configure PE 2 to override the AS_PATH attribute that contains AS 2. When this is enabled, the PE router determines when the AS_PATH attribute in a route intended for a neighbor CE contains the same AS number as the CE. When this is determined, the PE router substitutes its own AS number for the CE's in the AS_PATH attribute. The CE is then able to receive the route. The following addition conditions apply when this feature is in effect:

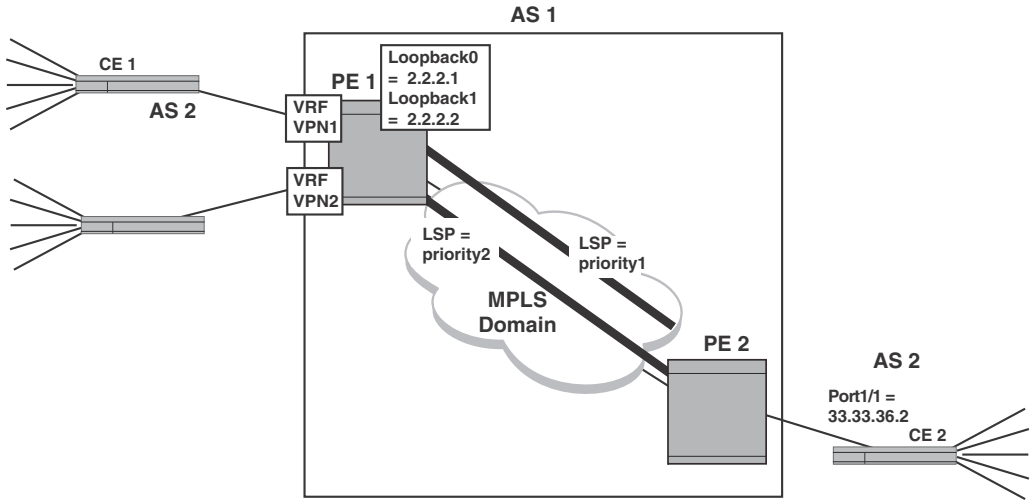
The following example describes the configuration of PE 2 required to enable Autonomous System number override for the BGP neighbor CE 2.

```
PE2(config)# router bgp
PE2(config-bgp)# local-as 1
PE2(config-bgp)# neighbor 2.2.2.1 remote-as 1
PE2(config-bgp)# neighbor 2.2.2.1 update-source loopback0
PE2(config-bgp)# address-family ipv4 unicast vrf VPN1
PE2(config-bgp-ipv4u-vrf)# neighbor 33.33.36.2 remote-as 2
PE2(config-bgp-ipv4u-vrf)# neighbor 33.33.36.2 as-override
```

Setting an LSP for each VRF on a PE

Figure 214 provides an example of assigning a different LSP for each VRF on a PE. In this example, PE 1 contains two VRFs: VPN1 and VPN2. It also contains two loopback interfaces with the following IP addresses: Loopback 0 = 2.2.2.1 and Loopback 2 = 2.2.2.2. Nexthop addresses for VPN1 and VPN2 can be created separately to Loopback 0 and Loopback 1. Then, different LSPs are assigned to each of the Loopback addresses.

FIGURE 214 Support per-VRF BGP nexthop



The following configuration example shows the elements in the PE 2 configuration required to make this example operate.

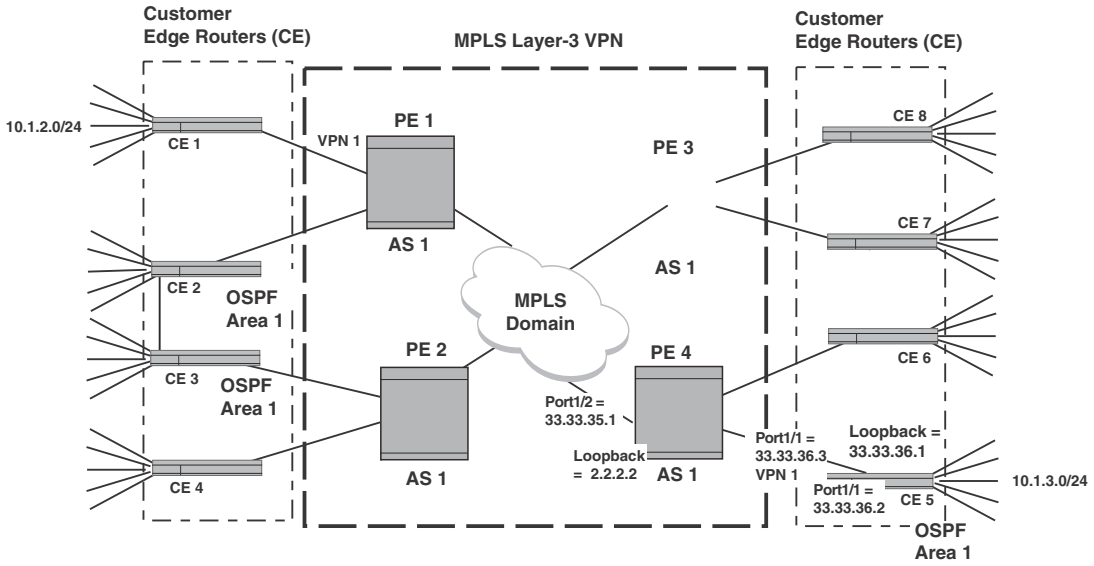
```
PE2(config)# ip vrf VPN1
PE2(config-ip-vrf-vpn1)# bgp next-hop loopback 0
PE2(config-ip-vrf-vpn1)#exit-vrf
PE2(config)# ip vrf VPN2
PE2(config-ip-vrf-vpn2)# bgp next-hop loopback 1
PE2(config-ip-vrf-vpn2)# exit-vrf

PE2(config)# router mpls
PE2(config-mpls)# mpls-interface ethe 1/1
PE2(config-mpls)# lsp priority1
PE2(config-mpls-lsp-priority1)# to 2.2.2.2
PE2(config-mpls-lsp-priority1)# primary-path prim-path1
PE2(config-mpls-lsp-priority1)# secondary-path sec-path1
PE2(config-mpls-lsp-priority1)# enable
PE2(config-mpls)# lsp priority2
PE2(config-mpls-lsp-priority2)# to 2.2.2.1
PE2(config-mpls-lsp-priority2)# primary prim-path2
PE2(config-mpls-lsp-priority2)# secondary sec-path2
PE2(config-mpls-lsp-priority2)# enable
```

OSPF sham links

In the example shown in Figure 215, CE 2 and CE 3 are both in OSPF Area 1 and connect to the same service provider network through different PEs. An additional backdoor connection is configured between them over another network. OSPF recognizes the backdoor connection as an Intra-area connection and the connection through the service provider network as an Inter-network connection. Because OSPF favors Intra-area routes over Inter-network routes, most traffic between CE 2 and CE 3 travels across the backdoor link. If this is the preferred link in the network, the configuration is as it should be. However, if you prefer traffic between the two networks to be routed across the service provider network, this configuration can causes problems.

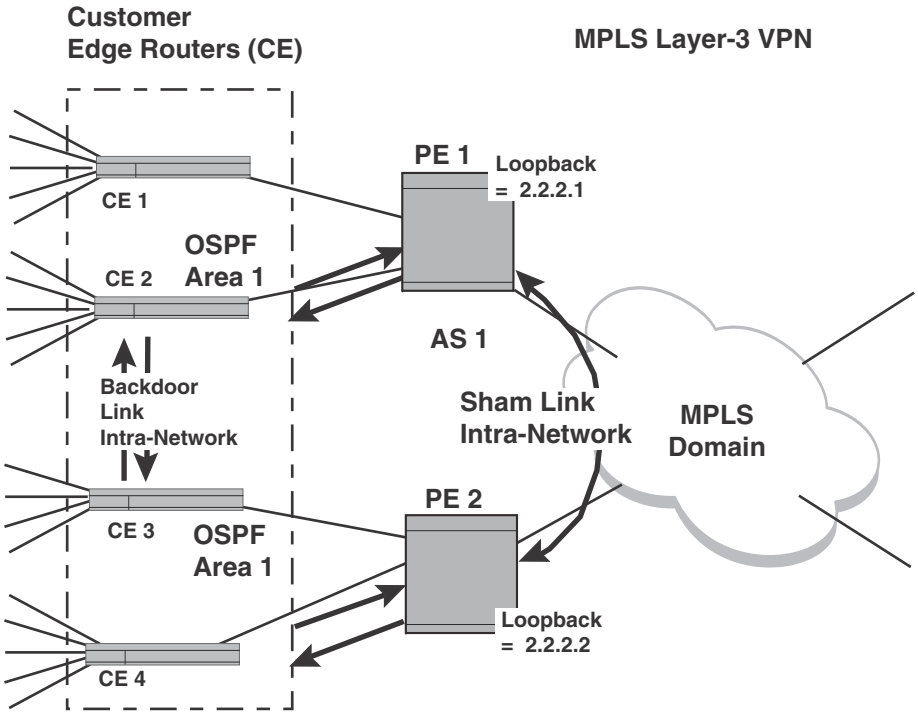
FIGURE 215 BGP or MPLS VPN with OSPF backdoor link



Problems can be avoided by creating a virtual intra-area OSPF link between two PEs. This virtual link is called a sham link. A sham link directs OSPF to treat the route through the service provider network as an intra-area link. A cost is assigned to the sham link to help the OSPF network determine when to route over the sham link route and when to use the backdoor link. Because this virtual link (sham-link) is an intra-area link, the OSPF areas in which each of the PEs reside must be the same.

NOTE
For sham links to work, OSPF cannot be configured on the loopback interface in the applicable area.

FIGURE 216 BGP or MPLS VPN with OSPF including Sham link and backdoor link



This configuration example describes the additional configuration required to create a sham link between PE 1 and PE 2 in the example shown in Figure 216. In this example, the VRF VPN1 is added to the loopback interface configuration, and a sham link with a cost of 10 is created between the loopback interfaces on PE 1 and PE 2.

After this configuration is implemented, routes between CE 2 and CE 3 over the service provider network will be preferred to the backdoor link that exists between these CEs.

PE 1 configuration

```
PE1(config)#interface loopback 1
PE1(config-lbif-1)#ip vrf forwarding VPN1
PE1(config-lbif-1)# ip address 2.2.2.1/24
PE1(config)#ip vrf VPN1
PE1(config)# router ospf vrf VLAN1
PE1(config-ospf-router)# area 1 sham-link 2.2.2.1 2.2.2.2 cost 10
PE1(config-ospf-router)# redistribution bgp
```

PE 2 configuration

```
PE2(config)#interface loopback 1
PE2(config-lbif-1)#ip vrf forwarding VPN1
PE2(config-lbif-1)# ip address 2.2.2.2/24
PE2(config)#ip vrf VPN1
PE2(config)# router ospf vrf VLAN1
PE2(config-ospf-router)# area 1 sham-link 2.2.2.2 2.2.2.1 cost 10
PE2(config-ospf-router)# redistribution bgp
```

IPv6 Addressing 37

IPv6 addressing overview

PowerConnect B-MLXe supports the following IPv6 Addressing features:

- IPv6 Addressing
- IPv6 Address Unicast
- IPv6 Address Multicast
- IPv6 Address Anycast
- IPv6 Stateless auto-configuration
- IPv6 Address in the Configuration

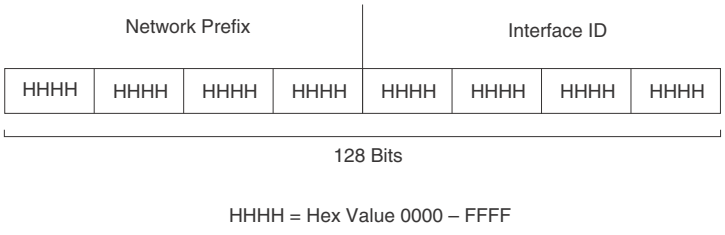
This chapter includes overview information about the following topics:

- IPv6 addressing.
- The IPv6 stateless auto-configuration feature, which enables a host on a local link to automatically configure its interfaces with new and globally unique IPv6 addresses associated with its location.

A limitation of IPv4 is its 32-bit addressing format, which is unable to satisfy potential increases in the number of users, geographical needs, and emerging applications. To address this limitation, IPv6 introduces a new 128-bit addressing format.

An IPv6 address is composed of 8 fields of 16-bit hexadecimal values separated by colons (:). Figure 217 shows the IPv6 address format.

FIGURE 217 IPv6 address format



As shown in Figure 217, HHHH is a 16-bit hexadecimal value, while H is a 4-bit hexadecimal value. The following is an example of an IPv6 address:

2001:0000:0000:0200:002D:D0FF:FE48:4672

Note that the sample IPv6 address includes hexadecimal fields of zeros. To make the address less cumbersome, you can do the following:

- Omit the leading zeros; for example, 2001:0:0:200:2D:D0FF:FE48:4672.

- Compress the successive groups of zeros at the beginning, middle, or end of an IPv6 address to two colons (::) once per address; for example, 2001::200:2D:D0FF:FE48:4672.

When specifying an IPv6 address in a command syntax, keep the following in mind:

- You can use the two colons (::) once in the address to represent the longest successive hexadecimal fields of zeros.
- The hexadecimal letters in the IPv6 addresses are not case-sensitive.

As shown in Figure 217, the IPv6 network prefix is composed of the left-most bits of the address. As with an IPv4 address, you can specify the IPv6 prefix using the <*prefix*> or <*prefix-length*> format, where the following applies:

The <*prefix*> parameter is specified as 16-bit hexadecimal values separated by a colon.

The <*prefix-length*> parameter is specified as a decimal value that indicates the left-most bits of the IPv6 address.

The following is an example of an IPv6 prefix:

2001:FF08:49EA:D088::/64

IPv6 address types

As with IPv4 addresses, you can assign multiple IPv6 addresses to a router interface. Table 300 presents the three major types of IPv6 addresses that you can assign to a router interface.

A major difference between IPv4 and IPv6 addresses is that IPv6 addresses support ***scope***, which describes the topology in which the address may be used as a unique identifier for an interface or set of interfaces.

Unicast and multicast addresses support scoping as follows:

- **Unicast addresses support two types of scope:** global scope and local scope. In turn, local scope supports site-local addresses and link-local addresses. Table 300 describes global, site-local, and link-local addresses and the topologies in which they are used.
- Multicast addresses support a scope field, which Table 300 describes.

TABLE 300 IPv6 address types

Address type	Description	Address structure
Unicast	An address for a single interface. A packet sent to a unicast address is delivered to the interface identified by the address.	Depends on the type of the unicast address: • Aggregatable global address — An address equivalent to a global or public IPv4 address. The address structure is as follows: a fixed prefix of 2000::/3 (001), a 45-bit global routing prefix, a 16-bit subnet ID, and a 64-bit interface ID. • Site-local address — An address used within a site or intranet. (This address is similar to a private IPv4 address.) A site consists of multiple network links. The address structure is as follows: a fixed prefix of FEC0::/10 (1111 1110 11), a 16-bit subnet ID, and a 64-bit interface ID. • Link-local address — An address used between directly connected nodes on a single network link. The address structure is as follows: a fixed prefix of FE80::/10 (1111 1110 10) and a 64-bit interface ID. • IPv4-compatible address — An address used in IPv6 transition mechanisms that tunnel IPv6 packets dynamically over IPv4 infrastructures. The address embeds an IPv4 address in the low-order 32 bits and the high-order 96 bits are zeros. The address structure is as follows: 0:0:0:0:0:0:A.B.C.D. • Loopback address — An address (0:0:0:0:0:0:0:1 or ::1) that a router can use to send an IPv6 packet to itself. You cannot assign a loopback address to a physical interface. • Unspecified address — An address (0:0:0:0:0:0:0:0 or ::) that a node can use until you configure an IPv6 address for it.
Multicast	An address for a set of interfaces belonging to different nodes. Sending a packet to a multicast address results in the delivery of the packet to all interfaces in the set.	A multicast address has a fixed prefix of FF00::/8 (1111 1111). The next 4 bits define the address as a permanent or temporary address. The next 4 bits define the scope of the address (node, link, site, organization, global).
Anycast	An address for a set of interfaces belonging to different nodes. Sending a packet to an anycast address results in the delivery of the packet to the closest interface identified by the address.	An anycast address looks similar to a unicast address, because it is allocated from the unicast address space. If you assign a unicast address to multiple interfaces, it is an anycast address. An interface assigned an anycast address must be configured to recognize the address as an anycast address. An anycast address can be assigned to a router only. An anycast address must not be used as the source address of an IPv6 packet.

A router automatically configures a link-local unicast address for an interface by using the prefix of FE80::/10 (1111 1110 10) and a 64-bit interface ID. The 128-bit IPv6 address is then subjected to duplicate address detection to ensure that the address is unique on the link. If desired, you can override this automatically configured address by explicitly configuring an address. For more information about explicitly configuring this address, refer to "Configuring IPv6 on each interface" on page 1718.

IPv6 stateless auto-configuration

Dell devices use the IPv6 stateless auto-configuration feature to enable a host on a local link to automatically configure its interfaces with new and globally unique IPv6 addresses associated with its location. The automatic configuration of a host interface is performed without the use of a server, such as a Dynamic Host Configuration Protocol (DHCP) server, or manual configuration.

The automatic configuration of a host interface works in the following way: a router on a local link periodically sends router advertisement messages containing network-type information, such as the 64-bit prefix of the local link and the default route, to all nodes on the link. When a host on the link receives the message, it takes the local link prefix from the message and appends a 64-bit interface ID, thereby automatically configuring its interface. (The 64-bit interface ID is derived from the MAC address of the host's NIC.) The 128-bit IPv6 address is then subjected to duplicate address detection to ensure that the address is unique on the link.

The duplicate address detection feature verifies that a unicast IPv6 address is unique before it is assigned to a host interface by the stateless auto configuration feature. Duplicate address detection uses neighbor solicitation messages to verify that a unicast IPv6 address is unique. For more information about duplicate address detection, refer to "Setting neighbor solicitation parameters for duplicate address detection" on page 1735.

NOTE
For the stateless auto configuration feature to work properly, the advertised prefix length in router advertisement messages must always be 64 bits. For more information about the router advertisement message, refer to "Router advertisement and solicitation messages" on page 1734.

The IPv6 stateless auto-configuration feature can also automatically reconfigure a host's interfaces if you change the ISP for the host's network. (The host's interfaces must be renumbered with the IPv6 prefix of the new ISP.)

The renumbering occurs in the following way: a router on a local link periodically sends advertisements updated with the prefix of the new ISP to all nodes on the link. (The advertisements still contain the prefix of the old ISP.) A host can use the addresses created from the new prefix and the existing addresses created from the old prefix on the link. When you are ready for the host to use the new addresses only, you can configure the lifetime parameters appropriately using the **ipv6 nd prefix-advertisement** command. During this transition, the old prefix is removed from the router advertisements. At this point, only addresses that contain the new prefix are used on the link. For more information about configuring the lifetime parameters, refer to "Controlling prefixes advertised in IPv6 router advertisement messages" on page 1737.

Configuring Basic IPv6 Connectivity 38

PowerConnect B-MLXe supports the following Basic IPv6 Connectivity features.

- IPv6 Routing
- IPv6 Anycast Addresses
- IPv6 Host Support
- Restricting SNMP Access to an IPv6 Node
- IPv6 Domain Name Server (DNS) Resolver
- ECMP Load Sharing for IPv6
- IPv6 ICMP
- DHCPv6
- IPv6 Neighbor Discovery
- IPv6 Source Routing Security
- IPv6 MTU
- Static Neighbor Entries
- Limiting the Number of Hops an IPv6 Packet Can Traverse
- QoS for IPv6 Traffic
- DNS Queries of IPv4 and IPv6 DNS Servers
- Displaying IPv6 Traffic Statistics
- Displaying the IPv6 Route Table

This chapter explains how to get a PowerConnect router up and running with IPv6. To configure basic IPv6 connectivity, you must do the following:

- Enable IPv6 routing globally.
- Configure an IPv6 address or explicitly enable IPv6 on each router interface over which you plan to forward IPv6 traffic.
- Configure IPv4 and IPv6 protocol stacks. (This step is mandatory only if you want a router interface to send and receive both IPv4 and IPv6 traffic.)

The following configuration tasks are optional:

- Configure IPv6 Domain Name Server (DNS) resolver.
- Configure equal-cost mulitpath (ECMP) routing Load Sharing for IPv6.
- Configure IPv6 Internet Control Message Protocol (ICMP).
- Configure the IPv6 neighbor discovery feature.
- Change the IPv6 maximum transmission unit (MTU).
- Configure static neighbor entries.
- Limit the hop count of an IPv6 packet.

- Configure Quality of Service (QoS) for IPv6 traffic.

Enabling IPv6 routing

By default, IPv6 routing is enabled. If forwarding of IPv6 traffic globally on the device has been disabled, you can enable it by entering the following command.

```
NetIron(config)# ipv6 unicast-routing
```

Syntax: [no] ipv6 unicast-routing

To disable the forwarding of IPv6 traffic globally on the device, enter the **no** form of this command.

NOTE
IPv6 routing is enabled by default and therefore does not appear in the configuration.

Configuring IPv6 on each interface

To forward IPv6 traffic on an interface, the interface must have an IPv6 address, or IPv6 must be explicitly enabled. By default, an IPv6 address is not configured on an interface.

If you choose to configure a global or site-local IPv6 address for an interface, IPv6 is also enabled on the interface. Further, when you configure a global or site-local IPv6 address, you must decide on one of the following in the low-order 64 bits:

- A manually configured interface ID.
- An automatically computed EUI-64 interface ID.

If you prefer to assign a link-local IPv6 address to the interface, you must explicitly enable IPv6, which causes a link-local address to be automatically computed for the interface. If preferred, you can override the automatically configured link-local address with an address that you manually configure.

This section provides the following information:

- Configuring a global or site-local address with a manually configured or automatically computed interface ID for an interface.
- Automatically or manually configuring a link-local address for an interface.
- Configuring IPv6 anycast addresses

Configuring a global or site-local IPv6 address

Configuring a global or site-local IPv6 address on an interface does the following:

- Automatically configures an interface ID (a link-local address), if specified.
- Enables IPv6 on that interface.

Additionally, the configured interface automatically joins the following required multicast groups for that link:

- Solicited-node multicast group FF02:0:0:0:0:1:FF00::/104 for each unicast address assigned to the interface.

- All-nodes link-local multicast group FF02::1
- All-routers link-local multicast group FF02::2

The neighbor discovery feature sends messages to these multicast groups. For more information, refer to "Configuring IPv6 neighbor discovery" on page 1733.

Configuring a global or site-local IPv6 address with a manually configured interface ID

To configure a global or site-local IPv6 address, including a manually configured interface ID, for an interface, enter commands such as the following.

```
NetIron(config)# interface ethernet 3/1
NetIron(config-if-e100-3/1)# ipv6 address 2001:200:12D:1300:240:D0FF:
FE48:4672/64
```

These commands configure the global prefix 2001:200:12d:1300::/64 and the interface ID::240:D0FF:FE48:4672, and enable IPv6 on Ethernet interface 3/1.

Syntax: ipv6 address <*ipv6-prefix*>/<*prefix-length*>

You must specify the <*ipv6-prefix*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

You must specify the <*prefix-length*> parameter as a decimal value. A slash mark (/) must follow the <*ipv6-prefix*> parameter and precede the <*prefix-length*> parameter.

Configuring a global or site-local IPv6 address with an automatically computed EUI-64 interface ID

To configure a global or site-local IPv6 address with an automatically computed EUI-64 interface ID in the low-order 64-bits, enter commands such as the following.

```
NetIron(config)# interface ethernet 3/1
NetIron(config-if-e100-3/1)# ipv6 address 2001:200:12D:1300::/64 eui-64
```

These commands configure the global prefix 2001:200:12d:1300::/64 and an interface ID, and enable IPv6 on Ethernet interface 3/1.

Syntax: [**no**] **ipv6 address** <*ipv6-prefix*>/<*prefix-length*> **eui-64**

You must specify the <*ipv6-prefix*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

You must specify the <*prefix-length*> parameter as a decimal value. A slash mark (/) must follow the <*ipv6-prefix*> parameter and precede the <*prefix-length*> parameter.

The **eui-64** keyword configures the global or site-local address with an EUI-64 interface ID in the low-order 64 bits.The interface ID is automatically constructed in IEEE EUI-64 format using the interface's MAC address.

Configuring a link-local IPv6 address

To explicitly enable IPv6 on an interface without configuring a global or site-local address for the interface, enter commands such as the following.

```
NetIron(config)# interface ethernet 3/1
NetIron(config-if-e100-3/1)# ipv6 enable
```

These commands enable IPv6 on Ethernet interface 3/1 and specify that the interface is assigned an automatically computed link-local address.

Syntax: [**no**] **ipv6 enable**

NOTE
When configuring VLANs that share a common tagged interface with a Virtual Ethernet (VE) interface, it is recommended that you override the automatically computed link-local address with a manually configured unique address for the interface. If the interface uses the automatically computed address, which in the case of VE interfaces is derived from a global MAC address, all VE interfaces will have the same MAC address.

To override a link-local address that is automatically computed for an interface with a manually configured address, enter commands such as the following.

```
NetIron(config)# interface ethernet 3/1
NetIron(config-if-e100-3/1)# ipv6 address FE80::240:D0FF:FE48:4672 link-local
```

These commands explicitly configure the link-local address FE80::240:D0FF:FE48:4672 for Ethernet interface 3/1.

Syntax: [**no**] **ipv6 address** <*ipv6-address*> **link-local**

You must specify the <*ipv6-address*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The **link-local** keyword indicates that the router interface should use the manually configured link-local address instead of the automatically computed link-local address.

Configuring IPv6 anycast addresses

In IPv6, an ***anycast*** address is an address for a set of interfaces that belong to different nodes. Sending a packet to an anycast address results in the delivery of the packet to the closest interface that has an anycast address.

An anycast address looks similar to a unicast address, because it is allocated from the unicast address space. If you assign an IPv6 unicast address to multiple interfaces, it is an anycast address. On the device, you configure an interface assigned an anycast address to recognize the address as an anycast address.

For example, the following commands configure an anycast address on interface 2/1.

```
NetIron(config)# int e 2/1
NetIron(config-if-e100-2/1)# ipv6 address 2002::6/64 anycast
```

Syntax: [**no**] **ipv6 address** <*ipv6-prefix*>|<*prefix-length*> [**anycast**]

IPv6 anycast addresses are described in detail in RFC 1884. See RFC 2461 for a description of how the IPv6 Neighbor Discovery mechanism handles anycast addresses.

Configuring the management port for an IPv6 automatic address configuration

You can configure the management port to automatically obtain an IPv6 address. The process is the same for all ports and is described in detail in the "Configuring a global or site-local IPv6 address with an automatically computed EUI-64 interface ID" on page 1719

IPv6 host support

You can configure the device to be an IPv6 host. An IPv6 host has interfaces with IPv6 addresses, but does not have IPv6 routing enabled.

This section lists supported and unsupported IPv6 host features.

IPv6 host supported features

The following IPv6 host features are supported:

- Automatic address configuration

NOTE
Automatic IPv6 address configuration is supported, however, automatic configuration of an IPv6 *global* address is supported only if there is an IPv6 router present on the network. Manual IPv6 address configuration is not supported.

- HTTP/HTTPS over IPv6
- IPv6 ping
- Telnet using an IPv6 address
- TFTP using an IPv6 address
- Trace route using an IPv6 address
- Name to IPv6 address resolution using IPv6 DNS Server
- IPv6 access lists
- IPv6 debugging
- SSH version 1 over IPv6
- SNMP over IPv6
- Logging (Syslog) over IPv6

IPv6 unsupported features

The following IPv6 features are not supported:

- IPv6 routing
- Tunneling
- MLD version 1 and version 2
- IP security

- IPv6 in boot PROM
- IPv6 address configuration using DHCP
- IPv6 TFTP using IPv6 link local address for a TFTP server
- IPv6 link local address is not supported for IPv6 DNS server
- TACACS, RADIUS, NTP over IPv6

Restricting SNMP access to an IPv6 node

You can restrict SNMP access to a specified IPv6 host. Enter a command such as the following.

```
NetIron(config)# snmp-client ipv6 2001:efff:89::23
```

Syntax: [no] snmp-client ipv6 <*ipv6-address*>

The <*ipv6-address*> must be in hexadecimal format using 16-bit values between colons, as documented in RFC 2373.

NOTE
You cannot use the following IPv6 addresses with the **snmp-client ipv6** <*ipv6-address*> command: :: (unspecified address), ff02::01 (all nodes address), and ff02:02 (all routers address)).

Specifying an IPv6 SNMP trap receiver

You can specify an IPv6 host to be a trap receiver so that all SNMP traps are sent to the same SNMP trap receiver or set of receivers, typically one or more host devices on the network. Enter a command such as the following.

```
NetIron(config)# snmp-server host ipv6 2001:efff:89::13
```

Syntax: [no] snmp-server host ipv6 <*ipv6-address*>

The <*ipv6-address*> must be in hexadecimal format using 16-bit values between colons, as documented in RFC 2373.

Restricting Telnet access by specifying an IPv6 ACL

You can specify an IPv6 ACL to restrict Telnet access to management functions on the device. Enter commands similar to the following.

```
(config)# ipv6 access-list acl1
(config-ipv6-access-list acl1)# deny ipv6 host 2000:2382::e0bb:2 any
(config-ipv6-access-list acl1)# deny ipv6 30ff:3782::ff89/128 any
(config-ipv6-access-list acl1)# permit ipv6 any any
(config-ipv6-access-list acl1)# exit
(config)# telnet access-group ipv6 acl1
```

This example configures and applies an IPv6 ACL named “acl1”, which denies Telnet access to the device from the specified IPv6 addresses, but allows access from any other IPv6 address.

```
(config)# ipv6 access-list acl2
(config-ipv6-access-list acl2)# permit ipv6 host 2000:2382::e0bb:2 any
(config-ipv6-access-list acl2)# deny ipv6 any any
(config-ipv6-access-list acl2)# exit
```

This example configures and applies an IPv6 ACL named “acl2”, which allows Telnet access to the device only from the specified IPv6 address, and denies access from any other IPv6 address.

Syntax: telnet access-group ipv6 <*ipv6-acl-name*>

The <*ipv6-acl-name*> is a valid IPv6 ACL.

Restricting SSH access by specifying an IPv6 ACL

You can configure an IPv6 ACL to restrict SSH access to management functions on the device. Enter commands such as the following.

```
(config)# ipv6 access-list acl1
(config-ipv6-access-list acl1)# deny ipv6 host 2000:2382::e0bb:2 any
(config-ipv6-access-list acl1)# deny ipv6 30ff:3782::ff89/128 any
(config-ipv6-access-list acl1)# permit ipv6 any any
(config-ipv6-access-list acl1)# exit
(config)# ssh access-group ipv6 acl1
```

This example configures and applies an IPv6 ACL named “acl1”, which denies SSH access to the device from the specified IPv6 addresses, but allows access from any other IPv6 address.

```
(config)# ipv6 access-list acl2
(config-ipv6-access-list acl2)# permit ipv6 host 2000:2382::e0bb:2 any
(config-ipv6-access-list acl2)# deny ipv6 any any
(config-ipv6-access-list acl2)# exit
(config)# ssh access-group ipv6 acl2
```

This example configures and applies an IPv6 ACL named “acl2”, which allows SSH access to the device only from the specified IPv6 address, and denies access from any other IPv6 address.

Syntax: [**no**] **ssh access-group ipv6** <*ipv6-acl-name*>

The <*ipv6-acl-name*> is a valid IPv6 ACL.

Restricting Web management access by specifying an IPv6 ACL

You can configure an IPv6 ACL to restrict Web management access to management functions on the device. Enter commands such as the following.

```
(config)# ipv6 access-list acl1
(config-ipv6-access-list acl1)# deny ipv6 host 2000:2382::e0bb:2 any
(config-ipv6-access-list acl1)# deny ipv6 30ff:3782::ff89/128 any
(config-ipv6-access-list acl1)# permit ipv6 any any
(config-ipv6-access-list acl1)# exit
(config)# web access-group ipv6 acl1
```

This example configures and applies an IPv6 ACL named “acl1”, which denies Web management access to the device from the specified IPv6 addresses, but allows access from any other IPv6 address.

```
(config)# ipv6 access-list acl2
(config-ipv6-access-list acl2)# permit ipv6 host 2000:2382::e0bb:2 any
(config-ipv6-access-list acl2)# deny ipv6 any any
(config-ipv6-access-list acl2)# exit
```

This example configures and applies an IPv6 ACL named “acl2”, which allows Web management access to the device only from the specified IPv6 address, and denies access from any other IPv6 address.

Syntax: **web access-group ipv6** <*ipv6-acl-name*>

The <*ipv6-acl-name*> variable is a valid IPv6 ACL.

Restricting SNMP access by specifying an IPv6 ACL

You can configure an IPv6 ACL to restrict Web management access to management functions on the device.

NOTE
The syntax for configuring ACLs for SNMP access differs from the syntax for controlling Telnet, SSH, and Web management access using ACLs.

```
NetIron(config)# ipv6 access-list aclro
NetIron(config-ipv6-access-list aclro)# deny ipv6 host 2000:2382::e0bb:2 any
NetIron(config-ipv6-access-list aclro)# deny ipv6 30ff:3782::ff89/128 any
NetIron(config-ipv6-access-list aclro)# permit ipv6 any any
NetIron(config-ipv6-access-list aclro)# exit
NetIron(config)# ipv6 access-list aclrw
NetIron(config-ipv6-access-list aclrw)# permit ipv6 host 2000:2382::e0bb:2 any
NetIron(config-ipv6-access-list aclrw)# deny ipv6 any any
NetIron(config-ipv6-access-list aclrw)# exit
NetIron(config)# snmp-server community public ro ipv6 aclro
NetIron(config)# snmp-server community private rw ipv6 aclrw
NetIron(config)# write memory
```

These commands configure IPv6 ACLs *aclro* and *aclrw*, then apply these ACLs to community strings. ACL *aclro* controls read-only access using the “public” community string. ACL *aclrw* controls read-write access using the “private” community string.

Syntax: [**no**] **snmp-server community** <*string*> {**ro** | **rw**} ipv6 <ipv6-acl-name>

The <*string*> specifies the SNMP community string you must enter for SNMP access.

The **ro** parameter indicates that the community string is for read-only (“get”) access. The **rw** parameter indicates the community string is for read-write (“set”) access.

The **ipv6** parameter indicates that you are applying an IPv6 access list.

The <*ipv6-acl-name*> variable specifies the IPv6 access list name.

NOTE
When **snmp-server community** is configured, all incoming SNMP packets are validated first by their community strings and then by their bound ACLs. Packets are permitted if no filters are configured for an ACL.

Restricting Web management access to your device to a specific IPv6 host

You can restrict Web management access to your device to a specific IPv6 host only. Enter commands such as the following.

```
NetIron(config)# web client ipv6 3000:2383:e0bb::2/128
```

Syntax: [**no**] **web client ipv6** <*ipv6-address*>

The <*ipv6-address*> must be in hexadecimal format using 16-bit values between colons, as documented in RFC 2373.

Specifying an IPv6 Syslog server

To specify an IPv6 Syslog server, enter a command such as the following.

```
NetIron(config)# log host ipv6 2000:2383:e0bb::4/128
```

Syntax: [no] log host ipv6 <*ipv6-address*> [<*udp-port-num*>]

The <*ipv6-address*> must be in hexadecimal using 16-bit values between colons, as documented in RFC 2373.

The <*udp-port-num*> optional parameter specifies the UDP application port used for the Syslog facility.

Viewing IPv6 SNMP server addresses

Many **show** commands display IPv6 addresses for IPv6 SNMP servers. This example shows output for the **show snmp server** command.

```
NetIron# show snmp server

      Contact:
     Location:
Community(ro): .....

Traps
              Warm/Cold start: Enable
                      Link up: Enable
                    Link down: Enable
               Authentication: Enable
     Locked address violation: Enable
         Power supply failure: Enable
                  Fan failure: Enable
           Temperature warning: Enable
                 STP new root: Enable
           STP topology change: Enable
                         vsrp: Enable

 Total Trap-Receiver Entries: 4

Trap-Receiver IP-Address                Port-Number Community

     1        192.147.201.100               162     .....

     2        4000::200                     162     .....

     3        192.147.202.100               162     .....

     4        3000::200                     162     .....
```

Disabling router advertisement and solicitation messages

Router advertisement and solicitation messages enable a device to discover other devices on the same link. By default, router advertisement and solicitation message generation is enabled. To disable this feature, configure an IPv6 access list that denies them. Enter commands such as the following.

```
NetIron(config)# ipv6 access-list rtradvert
NetIron(config)# deny icmp any any router-advertisement
NetIron(config)# deny icmp any any router-solicitation
NetIron(config)# permit ipv6 any any
```

Configuring IPv4 and IPv6 protocol stacks

If a device is deployed as an endpoint for an IPv6 over IPv4 tunnel, you must configure the device to support IPv4 and IPv6 protocol stacks. Each interface that sends and receives IPv4 and IPv6 traffic must be configured with an IPv4 address and an IPv6 address. You can also explicitly enable IPv6 using the **ipv6 enable** command. Refer to "Configuring a link-local IPv6 address" on page 1719.)

To configure an interface to support both IPv4 and IPv6 protocol stacks, enter commands such as the following.

```
NetIron(config)# ipv6 unicast-routing
NetIron(config)# interface ethernet 3/1
NetIron(config-if-e100-3/1)# ip address 192.168.1.1 255.255.255.0
NetIron(config-if-e100-3/1)# ipv6 address 2001:200:12d:1300::/64 eui-64
```

These commands globally enable IPv6 routing on the device, and configure an IPv4 address and an IPv6 address for Ethernet interface 3/1.

Syntax: [**no**] **ipv6 unicast-routing**

To disable IPv6 traffic globally on the router, enter the **no** form of this command.

Syntax: [**no**] **ip address** <*ip-address*> <*sub-net-mask*> [**secondary**]

You must specify the <*ip-address*> parameter using 8-bit values in dotted decimal notation.

You can specify the <*sub-net-mask*> parameter in either dotted decimal notation or as a decimal value preceded by a slash mark (/).

The **secondary** keyword specifies that the configured address is a secondary IPv4 address.

To remove the IPv4 address from the interface, enter the **no** form of this command.

Syntax: [**no**] **ipv6 address** <*ipv6-prefix*>/<*prefix-length*> [**eui-64**]

This syntax specifies a global or site-local IPv6 address. For information about configuring a link-local IPv6 address, refer to "Configuring a link-local IPv6 address" on page 1719.

You must specify the <*ipv6-prefix*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

You must specify the <*prefix-length*> parameter as a decimal value. A slash mark (/) must follow the <*ipv6-prefix*> parameter and precede the <*prefix-length*> parameter.

The **eui-64** keyword configures the global or site-local address with an EUI-64 interface ID in the low-order 64 bits. The interface ID is automatically constructed in IEEE EUI-64 format using the MAC address of the interface. If you do not specify the **eui-64** keyword, you must manually configure the 64-bit interface ID as well as the 64-bit network prefix. For more information about manually configuring an interface ID, refer to "Configuring a global or site-local IPv6 address" on page 1718.

Configuring IPv6 Domain Name Server (DNS) resolver

The Domain Name Server (DNS) resolver feature lets you use a host name to perform Telnet, ping, and traceroute commands. You can also define a DNS domain on a device to recognize all hosts within that domain. After you define a domain name, the device automatically appends the appropriate domain to the host and forwards it to the domain name server.

For example, if the domain "newyork.com" is defined on a device, and you want to initiate a ping to host "NYC01" on that domain, you only need to reference the host name instead of the host name and the domain name. For example, enter either of the following commands to initiate the ping.

```
NetIron# ping nyc01
NetIron# ping nyc01.newyork.com
```

Defining a DNS entry

You can define up to four DNS servers for each DNS entry. The first entry serves as the primary default address. If a query to the primary address is not resolved after three attempts, the next gateway address is queried (up to three times). This process continues for each defined gateway address until the query is resolved. The order in which the default gateway addresses are polled is the same as the order in which you enter them.

To define the domain name *newyork.com* on a device and then define four possible default DNS gateway addresses, using IPv4 addressing, enter the following commands.

```
NetIron(config)# ip dns domain-name newyork.com
NetIron(config)# ip dns server-address 209.157.22.199 205.96.7.15 208.95.7.25
201.98.7.15
```

Syntax: [**no**] **ip dns server-address** <*ip-addr*> [<*ip-addr*>] [<*ip-addr*>] [<*ip-addr*>]

In this example, the first IP address in the command becomes the primary gateway address and all others are secondary addresses. Because IP address 201.98.7.15 is the last address listed, it is also the last address consulted to resolve a query.

Defining an IPv6 DNS entry

IPv6 defines new DNS record types to resolve queries for domain names to IPv6 addresses, as well as IPv6 addresses to domain names. Devices running IPv6 software support AAAA DNS records, which are defined in RFC 1886.

AAAA DNS records are analogous to the A DNS records used with IPv4. A complete IPv6 address is stored in each record. AAAA records have a type value of 28.

To establish an IPv6 DNS entry for the device, enter the following command.

```
NetIron(config)# ipv6 dns domain-name companynet.com
```

Syntax: [**no**] **ipv6 dns domain-name** <*domain name*>

To define an IPv6 DNS server address, enter the following command.

```
NetIron(config)# ipv6 dns server-address 200::1
```

Syntax: [**no**] **ipv6 dns server-address** <*ipv6-addr*> [<*ipv6-addr*>] [<*ipv6-addr*>] [<*ipv6-addr*>]

For example, in a configuration where *ftp6.companynet.com* is a server with an IPv6 protocol stack, when a user pings *ftp6.companynet.com*, the device attempts to resolve the AAAA DNS record. In addition, if the DNS server does not have an IPv6 address, as long as it is able to resolve AAAA records, it can still respond to DNS queries.

DNS queries of IPv4 and IPv6 DNS servers

IPv4 and IPv6 DNS record queries search through IPv4 and IPv6 DNS servers as described here.

For IPv4 DNS record queries:

- Loop through all configured IPv4 DNS servers.
- If no IPv4 DNS servers are configured, then loop through all configured IPv6 DNS servers (if any).

For IPv6 DNS record queries:

- Loop through all configured IPv6 DNS servers.
- If no IPv6 DNS servers are configured, then loop through all configured IPv4 DNS servers (if any).

ECMP load sharing for IPv6

IPv6 ECMP load sharing is hardware-managed. If there is more than one path to a given destination, a hash is calculated based on the source MAC address, destination MAC address, source IPv6 address, destination IPv6 address, and TCP/UDP source port and destination port (if the packet is also a TCP and UDP packet). This hash is used to select one of the paths.

IPv6 options for load sharing are described in "Options for IP load sharing and LAGs" on page 734. Configuration of these parameters applies to IPv6 and IPv4 load sharing.

Disabling or re-enabling ECMP load sharing for IPv6

ECMP load sharing for IPv6 is enabled by default. To disable the feature, enter the following command.

```
NetIron(config)# no ipv6 load-sharing
```

To re-enable the feature after disabling it, enter the following command.

```
NetIron(config)# ipv6 load-sharing 4
```

Syntax: [**no**] **ipv6 load-sharing** [<*num*>]

The <*num*> parameter specifies the number of paths and can be from 2 – 8. When re-enabling IPv6 load sharing, you must specify a number of paths. If you do not, IPv6 load sharing will not be re-enabled.

Changing the maximum number of load sharing paths for IPv6

By default, IPv6 ECMP load sharing balances traffic across up to four equal paths. You can change the maximum number of paths to a value from 2 – 8.

To change the number of ECMP load sharing paths for IPv6, enter a command such as the following.

```
NetIron(config)# ipv6 load-sharing 8
```

Syntax: [no] ipv6 load-sharing [<*num*>]

The <*num*> parameter specifies the number of paths and can be from 2 – 8. The default is 4.

DHCP relay agent for IPv6

A client locates a DHCP server using a reserved, link-scoped multicast address. Direct communication between client and the server requires that they be attached by the same link. In some situations where ease-of-management, economy, and scalability are concerns, you can allow a DHCPv6 client to send a message to a DHCP server using a DHCPv6 relay agent. A DHCPv6 relay agent, which may reside on the client link, but is transparent to the client, relays messages between the client and the server.

When the relay agent receives a message, it creates a new relay-forward message, inserts the original DHCPv6 message, and sends the relay-forward message as the DHCP server.

Configuring DHCP for IPv6 relay agent

You can enable the DHCP for IPv6 relay agent function and specify the relay destination address (i.e. the DHCP server) on an interface by entering this command at the interface level.

```
NetIron(config)# interface ethernet 2/3
NetIron(config-if-e10000-2/3)#ipv6 dhcp-relay-dest 2001::2
```

Syntax: [no] ipv6 dhcp-relay-dest <*ipv6-address*>

Specify the <*ipv6-address*> as a destination address to which client messages are forwarded and which enables DHCP for IPv6 relay service on the interface. A maximum of 16 relay destination addresses may be entered.

Enabling support for network-based ECMP load sharing for IPv6

If network-based ECMP load sharing is configured, traffic is distributed across equal-cost paths based on the destination network address. Routes to each network are stored in CAM and accessed when a path to a network is required. Because multiple hosts are likely to reside on a network, this method uses fewer CAM entries than load sharing by host. When you configure network-based ECMP load sharing, you can choose either of the following CAM modes:

- **Dynamic mode** – In the dynamic mode, routes are entered into the CAM dynamically using a flow-based scheme, where routes are only added to the CAM as they are required. Once routes are added to the CAM, they can be aged-out when they are not in use. Because this mode conserves CAM, it is useful for situations where CAM resources are stressed or limited.
- **Static mode** – In the static mode, routes are entered into the CAM whenever they are discovered. Routes are not aged once routes are added to the CAM and can be aged-out when they are not in use.

IPv6 VPN CAM supports ECMP load sharing, which is created for IPv6 VPN routes.

Configuring the CAM mode to support network-based ECMP load sharing for IPv6

To configure the CAM mode to support network-based ECMP load sharing for IPv6, enter a command such as the following at the Global Configuration level.

```
NetIron(config)# cam-mode ipv6 dynamic
```

Syntax: [**no**] **cam-mode ipv6** [**dynamic** | **static** | **host**]

The **dynamic** parameter configures the device for network-based ECMP load sharing using the dynamic CAM mode.

The **static** parameter configures the device for network-based ECMP load sharing using the static CAM mode.

The **host** parameter configures the device for host-based ECMP load sharing using the dynamic CAM mode.

You must restart the device for this command to take effect.

Displaying ECMP load-sharing information for IPv6

To display the status of ECMP load sharing for IPv6, enter the following command.

```
NetIron# show ipv6
Global Settings
  unicast-routing enabled, ipv6 allowed to run, hop-limit 64
  reverse-path-check disabled
  urpf-exclude-default disabled
  session-logging-age 5
  No Inbound Access List Set
  No Outbound Access List Set
  Prefix-based IPv6 Load-sharing is Enabled, Number of load share paths: 4
  source-route disabled, forward-source-route disabled
Configured Static Routes: 66
Configured Static Mroutes: 66
RIP: enabled
OSPF (default VRF): enabled
BGP: enabled, 1 active neighbor(s) configured
```

Syntax: **show ipv6**

You can display the entries in the IPv6 forwarding cache by entering the **show ipv6 cache** command.

```
NetIron# show ipv6 cache
Total number of cache entries: 10
    IPv6 Address                        Next Hop                        Port
1   5000:2::2                           LOCAL                           tunnel 2
2   2000:4::106                         LOCAL                           ethe 2
3   2000:4::110                         DIRECT                          ethe 2
4   2002:c0a8:46a::1                    LOCAL                           ethe 2
5   fe80::2e0:52ff:fe99:9737            LOCAL                           ethe 2
6   fe80::ffff:ffff:feff:ffff           LOCAL                           loopback 2
7   fe80::c0a8:46a                      LOCAL                           tunnel 2
8   fe80::c0a8:46a                      LOCAL                           tunnel 6
9   2999::1                             LOCAL                           loopback 2
10  fe80::2e0:52ff:fe99:9700            LOCAL                           ethe 1
```

Syntax: **show ipv6 cache** [<*index-number*> | <*ipv6-prefix*>/<*prefix-length*> | <*ipv6-address*> | **ethernet** <*port*> | **ve** <*number*> | **tunnel** <*number*>]

Configuring IPv6 ICMP

ICMP for IPv6 provides error and informational messages. The stateless auto-configuration, neighbor discovery, and path MTU discovery features use ICMP messages.

This section explains how to configure the following IPv6 ICMP options:

- ICMP rate limiting
- ICMP redirects
- ICMP unreachable address or route messages

Configuring ICMP rate limiting

You can limit the rate at which IPv6 ICMP error messages are sent out on a network. For this rate-limiting implementation, IPv6 ICMP uses a token bucket algorithm.

The algorithm works using a *virtual bucket* that contains a number of tokens, where each token represents the ability to send one ICMP error message. Tokens are placed in the bucket at a specified interval until the maximum allowed number of tokens is reached. For each error message ICMP sends, a token is removed from the bucket. ICMP generates a series of error messages until the bucket is empty. When the bucket is empty, further error messages cannot be sent until a new token is placed in the bucket.

You can adjust the following elements related to the token bucket algorithm:

- The interval at which tokens are added to the bucket. The default is 100 milliseconds.
- The maximum number of tokens in the bucket. The default is 10 tokens.

For example, to adjust the interval to 1000 milliseconds and the number of tokens to 100 tokens, enter the following command.

```
NetIron(config)# ipv6 icmp error-interval 1000 100
```

Syntax: [**no**] **ipv6 icmp error-interval** <*interval*> [<*number-of-tokens*>]

The interval at which tokens are placed in the bucket has a range of 0 – 2147483647 milliseconds. The maximum number of tokens stored in the bucket has a range of 1 – 200.

NOTE
If you keep the default interval (100 milliseconds), output from the **show run** command does not show the setting of the **ipv6 icmp error-interval** command. In addition, if you configure the interval value to a number that does not evenly divide into 100000 (100 milliseconds), the system rounds the value up to the next higher value that does divide evenly. For example, if you specify an interval value of 150, the system rounds it to 200.

ICMP rate limiting is enabled by default. To disable ICMP rate limiting, set the interval to 0.

Disabling or re-enabling ICMP redirect messages

You can disable or re-enable a device to transmit ICMP redirect messages from an interface. By default, a device sends an ICMP redirect message to a neighboring host to inform it of a better first-hop device on a path to a destination. No further configuration is required to enable the sending of ICMP redirect messages. (For more information about how ICMP redirect messages are implemented for IPv6, refer to "Configuring IPv6 neighbor discovery" on page 1733.)

For example, to disable the ICMP redirect messages from Ethernet interface 3/1, enter the following commands.

```
NetIron(config)# interface ethernet 3/1
NetIron(config-if-e100-3/1)# no ipv6 redirects
```

Syntax: [no] ipv6 redirects

To re-enable the sending of ICMP redirect messages on Ethernet interface 3/1, enter the following commands.

```
NetIron(config)# interface ethernet 3/1
NetIron(config-if-e100-3/1)# ipv6 redirects
```

Use the **show ipv6 interface** <*interface*> <*port-number*> command to verify that the sending of ICMP redirect messages is enabled on a particular interface.

Disabling ICMP error messages for source-routed IPv6 packets

By default, ICMP error messages are transmitted to announce discarded IPv6 source-routed packets that were addressed to one of the IPv6 addresses of a device. By default, these packets are discarded in software, as described in "Software filtering of IPv6 source-routed packets" on page 1740.

You can disable or re-enable the sending of ICMP error messages for discarded, IPv6 source-routed packets by using the **ipv6 icmp source-route** command. Use the **no** form of this command to disable the transmission of these error messages. The following example illustrates the disabling operation.

```
NetIron(config)# no ipv6 icmp source-route
```

Syntax: [no] ipv6 icmp source-route

Enabling ICMP error messages for an unreachable address

By default, the ICMPv6 destination unreachable messages with the code for an unreachable address are not sent for a discarded IPv6 packet. You can enable the sending of these messages by using the **ipv6 icmp unreachable address** command. This command applies globally.

For example, to enable ICMPv6 error messages for unreachable address on the current device, enter the following command.

```
NetIron(config)# ipv6 icmp unreachable address
```

Syntax: [no] ipv6 icmp unreachable address

Use the **no** parameter in front of the **ipv6 icmp unreachable address** command to disable the sending of ICMPv6 destination unreachable messages with the code is address unreachable.

Enabling ICMP messages for an unreachable route

By default, the ICMPv6 destination unreachable messages with the code for an unreachable route are not sent for a discarded IPv6 packet. You can enable the sending of these messages by using the **ipv6 icmp unreachable route** command.

For example, to enable ICMPv6 error messages for unreachable route on the current device, enter the following command.

```
NetIron(config)# ipv6 icmp unreachable route
```

Syntax: [no] ipv6 icmp unreachable route

Use the **no** parameter in front of the **ipv6 icmp unreachable route** command to disable the sending of ICMPv6 destination unreachable messages with the code for destination unreachable.

Configuring IPv6 neighbor discovery

The neighbor discovery feature for IPv6 uses IPv6 ICMP messages to do the following:

- Determine the link-layer address of a neighbor on the same link.
- Verify that a neighbor is reachable.
- Track neighbor devices.

An IPv6 host is required to listen for and recognize the following addresses, which identify this host:

- Link-local address.
- Assigned unicast address.
- Loopback address.
- All-nodes multicast address.
- Solicited-node multicast address.
- Multicast address to all other groups to which it belongs.

You can adjust the following IPv6 neighbor discovery features:

- Neighbor solicitation messages for duplicate address detection.

- Router advertisement messages:
  - Interval between router advertisement messages.
  - Value that indicates a device is advertised as a default device (for use by all nodes on a given link).
  - Prefixes advertised in router advertisement messages.
  - Flags for host stateful autoconfiguration.
- The time that an IPv6 node considers a remote node reachable (for use by all nodes on a given link).

The memory is allocated for IPv4 and IPv6 separately. The maximum IPv4 ARP and IPv6 ND entries can be supported together.

Neighbor solicitation and advertisement messages

Neighbor solicitation and advertisement messages enable a node to determine the link-layer address of another node (neighbor) on the same link. (This function is similar to the function provided by the Address Resolution Protocol [ARP] in IPv4.) For example, node 1 on a link wants to determine the link-layer address of node 2 on the same link. To do so, node 1, the source node, multicasts a neighbor solicitation message. The neighbor solicitation message, which has a value of 135 in the Type field of the ICMP packet header, contains the following information:

- **Source address:** IPv6 address of node 1 interface that sends the message.
- **Destination address:** solicited-node multicast address (FF02:0:0:0:0:1:FF00::/104) that corresponds the IPv6 address of node 2.
- Link-layer address of node 1.
- A query for the link-layer address of node 2.

After receiving the neighbor solicitation message from node 1, node 2 replies by sending a neighbor advertisement message, which has a value of 136 in the Type field of the ICMP packet header. The neighbor solicitation message contains the following information:

- **Source address:** IPv6 address of the node 2 interface that sends the message.
- **Destination address:** IPv6 address of node 1.
- Link-layer address of node 2.

After node 1 receives the neighbor advertisement message from node 2, nodes 1 and 2 can now exchange packets on the link.

After the link-layer address of node 2 is determined, node 1 can send neighbor solicitation messages to node 2 to verify that it is reachable. Also, nodes 1, 2, or any other node on the same link can send a neighbor advertisement message to the all-nodes multicast address (FF02::1) if there is a change in their link-layer address.

Router advertisement and solicitation messages

Router advertisement and solicitation messages enable a node on a link to discover the devices on the same link.

Each configured interface on a link sends out a router advertisement message, which has a value of 134 in the Type field of the ICMP packet header, periodically to the all-nodes link-local multicast address (FF02::1).

A configured interface can also send a router advertisement message in response to a router solicitation message from a node on the same link. This message is sent to the unicast IPv6 address of the node that sent the router solicitation message.

At system startup, a host on a link sends a router solicitation message to the all-routers multicast address (FF01). Sending a router solicitation message, which has a value of 133 in the Type field of the ICMP packet header, enables the host to automatically configure its IPv6 address immediately instead of awaiting the next periodic router advertisement message.

Because a host at system startup typically does not have a unicast IPv6 address, the source address in the router solicitation message is usually the unspecified IPv6 address (0:0:0:0:0:0:0:0). If the host has a unicast IPv6 address, the source address is the unicast IPv6 address of the host interface sending the router solicitation message.

Entering the **ipv6 unicast-routing** command automatically enables the sending of router advertisement messages on all configured interfaces. You can configure several router advertisement message parameters. For information about disabling router advertisement messages and the router advertisement parameters you can configure, refer to "Configuring reachable time for remote IPv6 nodes" on page 1738 and "Setting IPv6 router advertisement parameters" on page 1736.

Neighbor redirect messages

After forwarding a packet, by default, a device can send a neighbor redirect message to a host to inform it of a better first-hop device. The host receiving the neighbor redirect message will then readdress the packet to the better device.

A device sends a neighbor redirect message only for unicast packets, only to the originating node, and to be processed by the node.

A neighbor redirect message has a value of 137 in the Type field of the ICMP packet header.

Setting neighbor solicitation parameters for duplicate address detection

Although the stateless autoconfiguration feature assigns the 64-bit interface ID portion of an IPv6 address using the MAC address of the host's NIC, duplicate MAC addresses can occur. Therefore, the duplicate address detection feature verifies that a unicast IPv6 address is unique before it is assigned to a host interface by the stateless autoconfiguration feature. Duplicate address detection verifies that a unicast IPv6 address is unique.

If duplicate address detection identifies a duplicate unicast IPv6 address, the address is not used. If the duplicate address is the link-local address of the host interface, the interface stops processing IPv6 packets.

You can configure the following neighbor solicitation message parameters that affect duplicate address detection while it verifies that a tentative unicast IPv6 address is unique:

- The number of consecutive neighbor solicitation messages that duplicate address detection sends on an interface. By default, duplicate address detection sends three neighbor solicitation messages without any follow-up messages.
- The interval in seconds at which duplicate address detection sends a neighbor solicitation message on an interface. By default, duplicate address detection sends a neighbor solicitation message every 1 second.

NOTE
For the interval at which duplicate address detection sends a neighbor solicitation message on an interface, the device uses seconds as the unit of measure instead of milliseconds.

For example, to change the number of neighbor solicitation messages sent on Ethernet interface 3/1 to two and the interval between the transmission of the two messages to 9 seconds, enter the following commands.

```
NetIron(config)# interface ethernet 3/1
NetIron(config-if-e100-3/1)# ipv6 nd dad attempt 2
NetIron(config-if-e100-3/1)# ipv6 nd ns-interval 9
```

Syntax: [no] ipv6 nd dad attempt <*number*>

Syntax: [no] ipv6 nd ns-interval <*number*>

For the number of neighbor solicitation messages, you can specify any number of attempts. Configuring a value of 0 disables duplicate address detection processing on the specified interface. To restore the number of messages to the default value, use the **no** form of this command.

For the interval between neighbor solicitation messages, you can specify any number of seconds. Not recommended for very short intervals in normal IPv6 operation. When a non-default value is configured, the configured time is both advertised and used by the device itself. To restore the default interval, use the **no** form of this command.

Setting IPv6 router advertisement parameters

You can adjust the following parameters for router advertisement messages:

- The interval (in seconds) at which an interface sends router advertisement messages. By default, an interface sends a router advertisement message every 200 seconds.
- The “router lifetime” value, which is included in router advertisements sent from a particular interface. The value (in seconds) indicates if the device is advertised as a default device on this interface. If you set the value of this parameter to 0, the device is not advertised as a default device on an interface. If you set this parameter to a value that is not 0, the device is advertised as a default device on this interface. By default, the device lifetime value included in device advertisement messages sent from an interface is 1800 seconds.

When adjusting these parameter settings, it is recommended that the interval between device advertisement transmission be less than or equal to the device lifetime value if the device is advertised as a default device. For example, to adjust the interval of device advertisements to 300 seconds and the device lifetime value to 1900 seconds on Ethernet interface 3/1, enter the following commands.

```
NetIron(config)# interface ethernet 3/1
NetIron(config-if-e100-3/1)# ipv6 nd ra-interval 300
NetIron(config-if-e100-3/1)# ipv6 nd ra-lifetime 1900
```

Syntax: [no] ipv6 nd ra-interval <*number*>

Syntax: [no] ipv6 nd ra-lifetime <*number*>

The <*number*> parameter in both commands indicates any numerical value. To restore the default interval or device lifetime value, use the **no** form of the respective command.

Controlling prefixes advertised in IPv6 router advertisement messages

By default, router advertisement messages include prefixes configured as addresses on interfaces using the **ipv6 address** command. You can use the **ipv6 nd prefix-advertisement** command to control exactly which prefixes are included in router advertisement messages. Along with which prefixes the router advertisement messages contain, you can also specify the following parameters:

- Valid lifetime — (Mandatory) The time interval (in seconds) in which the specified prefix is advertised as valid. The default is 2592000 seconds (30 days). When the timer expires, the prefix is no longer considered to be valid.
- Preferred lifetime — (Mandatory) The time interval (in seconds) in which the specified prefix is advertised as preferred. The default is 604800 seconds (7 days). When the timer expires, the prefix is no longer considered to be preferred.
- Onlink flag — (Optional) If this flag is set, the specified prefix is assigned to the link upon which it is advertised. Nodes sending traffic to addresses that contain the specified prefix consider the destination to be reachable on the local link.
- Autoconfiguration flag — (Optional) If this flag is set, the stateless auto configuration feature can use the specified prefix in the automatic configuration of 128-bit IPv6 addresses for hosts on the local link. For more information, refer to "IPv6 stateless auto-configuration" on page 1716.

For example, to advertise the prefix 2001:e077:a487:7365::/64 in router advertisement messages sent out on Ethernet interface 3/1 with a valid lifetime of 1000 seconds, a preferred lifetime of 800 seconds, and the Onlink and Autoconfig flags set, enter the following commands.

```
NetIron(config)# interface ethernet 3/1
NetIron(config-if-e100-3/1)# ipv6 nd prefix-advertisement
2001:e077:a487:7365::/64 1000 800 onlink autoconfig
```

Syntax: [no] ipv6 nd prefix-advertisement <*ipv6-prefix*>/<*prefix-length*> <*valid-lifetime*> <*preferred-lifetime*> [autoconfig] [onlink]

You must specify the <*ipv6-prefix*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

You must specify the <*prefix-length*> parameter as a decimal value. A slash mark (/) must follow the <*ipv6-prefix*> parameter and precede the <*prefix-length*> parameter.

The valid lifetime and preferred lifetime is a numerical value between 0 – 4294967295 seconds. The default valid lifetime is 2592000 seconds (30 days), while the default preferred lifetime is 604800 seconds (7 days).

To remove a prefix from the router advertisement messages sent from a particular interface, use the **no** form of this command.

Setting flags in IPv6 router advertisement messages

An IPv6 router advertisement message can include the following flags:

- **Managed Address Configuration** — This flag indicates to hosts on a local link if they should use the stateful autoconfiguration feature to get IPv6 addresses for their interfaces. If the flag is set, the hosts use stateful autoconfiguration to get addresses as well as non-IPv6-address information. If the flag is not set, the hosts do not use stateful autoconfiguration to get addresses and if the hosts can get non-IPv6-address information from stateful autoconfiguration is determined by the setting of the Other Stateful Configuration flag.
- **Other Stateful Configuration** — This flag indicates to hosts on a local link if they can get non-IPv6 address autoconfiguration information. If the flag is set, the hosts can use stateful autoconfiguration to get non-IPv6-address information.

NOTE
When determining if hosts can use stateful autoconfiguration to get non-IPv6-address information, a set Managed Address Configuration flag overrides an unset Other Stateful Configuration flag. In this situation, the hosts can obtain non address information. However, if the Managed Address Configuration flag is not set and the Other Stateful Configuration flag is set, then the setting of the Other Stateful Configuration flag is used.

By default, the Managed Address Configuration and Other Stateful Configuration flags are not set in router advertisement messages. For example, to set these flags in router advertisement messages sent from Ethernet interface 3/1, enter the following commands.

```
NetIron(config)# interface ethernet 3/1
NetIron(config-if-e100-3/1)# ipv6 nd managed-config-flag
NetIron(config-if-e100-3/1)# ipv6 nd other-config-flag
```

Syntax: [no] ipv6 nd managed-config-flag

Syntax: [no] ipv6 nd other-config-flag

To remove either flag from router advertisement messages sent on an interface, use the **no** form of the respective command.

Configuring reachable time for remote IPv6 nodes

You can configure the duration (in seconds) that a device considers a remote IPv6 node reachable. By default, an interface uses the value of 30 seconds.

The router advertisement messages sent by an interface include the amount of time specified by the **ipv6 nd reachable-time** command so that nodes on a link use the same reachable time duration. By default, the messages include a default value of 0.

NOTE
The device uses seconds, instead of milliseconds, for the interval at which it sends router advertisement messages.

It is not recommended to configure a short reachable time duration, because a short duration causes the IPv6 network devices to process the information at a greater frequency.

For example, to configure the reachable time of 40 seconds for Ethernet interface 3/1, enter the following commands.

```
NetIron(config)# interface ethernet 3/1
NetIron(config-if-e100-3/1)# ipv6 nd reachable-time 40
```

Syntax: [no] ipv6 nd reachable-time <*seconds*>

For the <*seconds*> parameter, you can specify any numerical value. To restore the default time, use the **no** form of this command.

IPv6 source routing security enhancements

The IPv6 specification (RFC 2460) specifies support for IPv6 source-routed packets using a type 0 Routing extension header, requiring device and host to process the type 0 routing extension header. However, this requirement may leave a network open to a DoS attack.

A security enhancement disables sending IPv6 source-routed packets to IPv6 devices either completely or selectively as described in the following sections. (This enhancement conforms to RFC 5095.)

Complete filtering of IPv6 source-routed packets

Dell devices are configured to drop all IPv6 source-routed packets in hardware and software as described:

- **Hardware** – IPv6 source-routed packets that contain a type 0 routing extension header immediately after the IPv6 header are dropped in hardware by default.
- **Software** – IPv6 source-routed packets addressed to any IPv6 address on a device (regardless of where the routing extension header is located) are dropped in software by default.

Details of hardware and software filtering of IPv6 source-routed packets is provided in the following.

Hardware filtering of IPv6 source-routed packets

All IPv6 source-routed packets that contain a type 0 routing extension header immediately after the IPv6 header are automatically dropped in hardware. This filtering is performed on both IPv6 packets that require forwarding and IPv6 packets addressed to one of the IPv6 addresses on the device without sending an ICMP error message. This filtering behavior is enabled by default. Consequently, if you want a the device to process IPv6 source-routed packets that contain a type 0 routing extension header immediately after the IPv6 header you must direct it to perform this action through use of the **ipv6 forward-source-route** command, as shown in the following.

```
NetIron(config)# ipv6 forward-source-route
```

Syntax: [no] ipv6 forward-source-route

The default condition is for source-routed packets to be dropped. If you enable forwarding using this command, you can return to the default state by using the **no** option in front of the command.

NOTE
Source routed, IPv6 packets where the type 0 routing extension header does not follow directly after the IPv6 header are not automatically dropped in hardware.

Software filtering of IPv6 source-routed packets

By default, all IPv6 source-routed packets addressed to any IPv6 address on a PowerConnect are dropped by software (regardless of where the Routing Extension Header resides). You can enable the forwarding of these packets by using the **ipv6 source-route** command, as the following example shows.

```
NetIron(config)# ipv6 source-route
```

Syntax: [no] ipv6 source-route

The default condition is to disallow the forwarding of source-routed packets to IPv6 addresses. If you enable forwarding by using this command, you can return to the default state by using the **no** option of the command.

The **ipv6 forward-source-route** command must be enabled for the **ipv6 source-route** command to operate.

By default, ICMP error messages are sent for packets dropped by software. You can use the **ipv6 icmp source-route** command to disable the generation of ICMPv6 parameter problem for software discarded IPv6 source-routed packets addressed to one of the IPv6 addresses of a device. This is described in "Disabling ICMP error messages for source-routed IPv6 packets" on page 1732.

Selective filtering of IPv6 source-routed packets using ACLs

You can selectively filter IPv6 source-routed packets using ACLs. This is accomplished by creating an IPv6 ACL that specifies a type 0 routing extension header. This is done using the **routing-header-type** option when configuring an IPv6 ACL as described in "Filtering packets based on routing header type" on page 1778. An example of an IPv6 ACL that selectively drops IPv6 source-routed packets is shown in the following.

```
NetIron(config)# ipv6 access-list deny-access1
NetIron(config-ipv6-access-list deny-access1)#deny ipv6 any any
routing-header-type 0
```

As with complete filtering, selective filtering can be done in both hardware and software as described:

- **Hardware** – Inbound and outbound IPv6 source-routed packets that contain a type 0 routing extension header immediately after the IPv6 header can be selectively dropped in hardware through use of an IPv6 ACL and bound to an interface using the **ipv6 traffic-filter** command.
- **Software** – Inbound IPv6 source-routed packets that contain a routing extension header anywhere in a packet can be selectively dropped in software using an IPv6 ACL and bound to interfaces using the **ipv6 access-class** command.

Details about how to configure selective hardware and software filtering of IPv6 source-routed packets are provided in the following.

Selective hardware filtering of IPv6 source-routed packets

Both inbound and outbound IPv6 source-routed packets that contain a type 0 routing extension header immediately after the IPv6 header can be selectively dropped in hardware using an IPv6 ACL. source-routed packets dropped in hardware are dropped without an ICMP error message being sent. To apply an IPv6 ACL with the **routing-header-type** option for hardware filtering, you must apply the IPv6 ACL to specific ports using the **ipv6 traffic-filter** command as shown in the following example.

```
NetIron(config)# interface ethernet 3/1
NetIron(config-if-e100-3/1)# ipv6 traffic-filter deny-access1 in
```

Additionally, you must also enable forwarding using the **ipv6 forward-source-route** command (as shown in the following) to allow any forwarding of IPv6 source-routed packets.

```
NetIron(config)# ipv6 forward-source-route
```

Selective software filtering of IPv6 source-routed packets

Inbound IPv6 source-routed packets that contain a routing extension header anywhere in a packet can be selectively dropped in software using an IPv6 ACL. source-routed packets dropped in software generate ICMP Destination Unreachable error messages.

NOTE
This filtering only applies to packets addressed to one of the IPv6 addresses of the device.

To apply an IPv6 ACL with the **routing-header-type** option for software filtering, you must apply the IPv6 ACL system wide using the **ipv6 access-class** command.

```
NetIron(config)# # ipv6 access-class deny-access1 in
```

Additionally, you must also enable forwarding using the **ipv6 forward-source-route** and **ipv6 source-route** commands (as shown in the following) to allow any forwarding of IPv6 source-routed packets.

```
NetIron(config)# ipv6 forward-source-route
NetIron(config)# ipv6 source-route
```

Complete and selective filtering combination and order of application

If the complete filtering of IPv6 source-routed packets is enabled (the default state) then selective filtering cannot be performed. Consequently, you must use the **ipv6 forward-source-route** and **ipv6 source-route** commands to allow IPv6 source-routed packets when you are selectively allowing some IPv6 source-routed packets.

The following configuration of complete hardware and software filtering can be used with selective filtering if the commands are configured in the correct order:

- When the **ipv6 forward-source-route** command is configured, IPv6 source-routed packets that contain a type 0 routing extension header immediately after the IPv6 header are not dropped by hardware.
- All IPv6 source-routed packets addressed to any IPv6 address on a PowerConnect (regardless of where the Routing Extension Header is located) are dropped by software. This is the default configuration.

When using the **ipv6 forward-source-route** and **ipv6 source-route** commands as described, the filtering is performed in the order described below.

1. Inbound filtering is performed on the receiving interface using an ACL applied using the **ipv6 traffic-filter** command. This filtering is performed using hardware.
2. Complete filtering for ipv6 source route. This filtering is performed by the CPU.
3. Selective filtering using an IPv6 ACL applied on a system-wide basis using the **ipv6 access-class** command.
4. Selective filtering by hardware using an IPv6 ACL bound to an interface for outbound traffic using the **ipv6 traffic-filter** command.

Configuration examples for complete and selective filtering of source routed packets

The following examples demonstrate how to use this feature for different purposes:

- Dropping all IPv6 Source Routed Packets on all Ports
- Dropping all IPv6 Source Routed Packets on a Specified Port
- Silently Dropping all IPv6 Source Routed Packets Addressed to IPv6 Addresses
- Dropping all IPv6 Source Routed Packets Addressed to IPv6 Addresses from a Specified Source
- Allowing IPv6 Source Routed Packets from a Specified Source on a Specified Interface

Each of these examples are described in detail in the following sections.

Dropping all IPv6 source-routed packets on all ports

By default, all IPv6 source-routed packets received on all device ports are dropped.

Dropping all IPv6 source-routed packets on a specified port

The following example shows a configuration that will drop all IPv6 source-routed packets received on port 1/1 of a device.

In this example, the IPv6 ACL is configured to drop any IPv6 packet with a type 0 routing header immediately after the IPv6 header.

```
NetIron(config)# ipv6 access-list deny-access1
NetIron(config-ipv6-access-list deny-access1)# deny any any ipv6
routing-header-type 0
NetIron(config-ipv6-access-list deny-access1# permit ipv6 any any
NetIron(config-ipv6-access-list deny-access1)# exit
```

The default is for the device to drop all IPv6 source-routed packets in hardware and software. Forwarding of these packets must be explicitly enabled using the **ipv6 forward-source-route** and **ipv6 source-route** commands as shown.

```
NetIron(config)# ipv6 forward-source-route
NetIron(config)# ipv6 source-route
```

The IPv6 ACL must then be bound to the interface it is intended to filter as shown in the following example for the Ethernet 1/1 interface.

```
NetIron(config)# interface ethernet 1/1
NetIron(config-if-e100-1/1)# ipv6 traffic-filter deny-access1 in
```

Silently dropping all IPv6 source-routed packets sent to IPv6 addresses

The following configuration drops all IPv6 source-routed packets addressed to the IPv6 addresses on a device without sending an ICMP error message.

ICMPv6 parameter problem error messages are sent for dropped IPv6 source-routed packets addressed to the IPv6 addresses on the device. To disable these messages, use the **no** option with the **ipv6 icmp source-route** command.

```
NetIron(config)# no ipv6 icmp source-route
```

By default, the device drops all IPv6 source-routed packets in hardware and software. Use the **ipv6 forward-source- route** command to enable the forwarding of IPv6 source-routed packets with a type 0 routing extension header immediately after the IPv6 header, as shown in this example.

```
NetIron(config)# ipv6 forward-source-route
```

Dropping all IPv6 source-routed packets to IPv6 addresses from a specified source

This configuration demonstrates how to drop all IPv6 source-routed packets sent from a specified IPv6 address.

In this example, IPv6 ACL is configured to deny IPv6 source-routed packets with a destination address of aa:bb::1, and permit any other IPv6 packets.

```
NetIron(config)# ipv6 access-list deny-access2
NetIron(config-ipv6-access-list deny-access2)# deny host aa:bb::1 any
routing-header-type 0
NetIron(config-ipv6-access-list deny-access2)# permit ipv6 any any
NetIron(config-ipv6-access-list deny-access2)# exit
```

The IPv6 ACL is then applied globally to the device for inbound traffic using the **ipv6 access-class** command as shown.

```
NetIron(config)#ipv6 access-class deny-access2 in
```

By default, the device drops all IPv6 source-routed packets in hardware and software. Use the **ipv6 forward-source- route** and ipv6 source-route commands to enable forwarding of IPv6 source-routed packets, as shown.

```
NetIron(config)# ipv6 forward-source-route
NetIron(config)# ipv6 source-route
```

Allowing IPv6 source-routed packets from a specified source on a specified interface

The following configuration allows IPv6 source-routed packets sent from a specified source and addressed to the IPv6 address on the device to be received on port 1/1. Source-routed packets received on all other ports are denied.

NOTE
This configuration only works when the routing header type 0 appears immediately after the IPv6 header.

The following IPv6 ACL is configured to permit IPv6 source route packets that have a source address of aa:bb::1, deny any IPv6 source route packets with any other source address, and permit all other IPv6 packets.

```
NetIron(config)# ipv6 access-list allow-access
NetIron(config-ipv6-access-list allow-access)# permit ipv6 host aa:bb::1 any
routing-header-type 0
NetIron(config-ipv6-access-list allow-access)# deny any any routing-header-type 0
NetIron(config-ipv6-access-list allow-access)# permit ipv6 any any
NetIron(config-ipv6-access-list allow-access)# exit
```

Because this example permits IPv6 source-routed packets on a single specified interface, they must be explicitly dropped on all other interfaces on the router. The following IPv6 ACL is configured drop all source-routed packets.

```
NetIron(config)# ipv6 access-list drop-access
NetIron(config-ipv6-access-list drop-access)# deny any any routing-header-type 0
NetIron(config-ipv6-access-list drop-access)# permit ipv6 any any
NetIron(config-ipv6-access-list drop-access)# exit
```

The IPv6 ACL “allow-access” is bound to interface 1/1 where the IPv6 source-routed packets are permitted.

```
NetIron(config)# interface ethernet 1/1
NetIron(config-if-e100-1/1)# ipv6 traffic-filter allow-access
NetIron(config-if-e100-1/1)#exit
```

The IPv6 ACL “drop-access” is bound to all other interfaces on the device to drop IPv6 source-routed packets. The next example shows the “drop-access” ACL being bound to interface 1/2.

```
NetIron(config)# interface ethernet 1/2
NetIron(config-if-e100-1/2)# ipv6 traffic-filter drop-access in
NetIron(config-if-e100-1/2)#exit
...
```

The IPv6 ACL “drop-access” must be bound to all other interfaces on the device.

By default, the device drops all IPv6 source-routed packets in hardware and software as described in “Complete filtering of IPv6 source-routed packets” on page 1739. Use the **ipv6 forward-source-route** and **ipv6 source-route** commands to enable forwarding of IPv6 source-routed packets.

```
NetIron(config)# ipv6 forward-source-route
NetIron(config)# ipv6 source-route
```

Changing the IPv6 MTU

The IPv6 MTU is the maximum length of an IPv6 packet that can be transmitted on a particular interface. If an IPv6 packet is longer than an MTU, the host that originated the packet breaks the packet into fragments and transmits the fragments in multiple packets that are shorter than the configured MTU. You can configure the MTU on individual interfaces. Per RFC 2460, the minimum IPv6 MTU for any interface is 1280 bytes.

To configure the MTU on interface 3/1 to 1280 bytes, enter the following commands.

```
NetIron(config)# interface ethernet 3/1
NetIron(config-if-e100-3/1)# ipv6 mtu 1280
```

Syntax: [**no**] **ipv6 mtu** <*bytes*>

You can specify between 1284 – (**default-max-frame-size** minus 18). If a non-default value is configured for an interface, router advertisements include an MTU option. The minimum values you can configure are: 1298 (**IP6_MIN_MTU** + 18) for Ethernet ports and 1284 (**IP6_MIN_MTU** + 4) for POS ports.

You can configure IPv6 MTU for to be greater than 1500 bytes, although the default remains at 1500 bytes.

At the global CLI level, the **ipv6 mtu** command has been deprecated and replaced by the **ipv6 global-mtu** command. For devices running release 04.1.00 or later, the old command syntax is no longer accepted except at system bootup.

To define IPv6 MTU globally, enter.

```
NetIron(config)#ipv6 global-mtu 1300
```

If the old command syntax is entered, the following error message is displayed.

```
NetIron(config)#ipv6 mtu 1500
ERROR - Command deprecated. Keyword mtu is replaced by global-mtu.
```

Syntax: [**no**] **ipv6 global-mtu** <*value*>

To define IPv6 MTU on an interface, enter.

```
NetIron(config-if-e1000-2/1)#ipv6 mtu
```

Syntax: ipv6 mtu <*value*>

NOTE
If the size of a jumbo packet received on a port is equal to the maximum frame size of - 18 (Layer 2 MAC header + CRC) and if this value is greater than the IPv4/IPv6 MTU of the outgoing port, it will be forwarded in the CPU.

How to determine the actual IPv6 MTU value

An IPv6 port can obtain an MTU value from any of the following sources:

- Default IP MTU setting
- Global MTU Setting
- Interface MTU Setting

An interface determines the actual MTU value through these processes.

1. If an IPv6 interface MTU value is configured, that value is used.
2. If an IPv6 interface MTU value is not configured and an IPv6 global MTU value is configured, the configured global MTU value is used.
3. If neither an IPv6 interface MTU value or an IPv6 global MTU value are configured, the default IPv6 MTU value of 1500 is used.

Configuring static neighbor entries

In some cases, a neighbor cannot be reached using neighbor discovery. In this situation, you can add a static entry to the IPv6 neighbor discovery cache, which causes a neighbor to be reachable at all times without using neighbor discovery. (A static entry in the IPv6 neighbor discovery cache functions like a static ARP entry in IPv4.)

For example, to add a static entry for a neighbor with the IPv6 address 3001:ffe0:2678:47b and link-layer address 0004.6a2b.8641 that is reachable through Ethernet interface 3/1, enter the following command.

```
NetIron(config)# ipv6 neighbor 3001:ffe0:2678:47b ethernet 3/1 0004.6a2b.8641
```

Syntax: [**no**] **ipv6 neighbor** <*ipv6-address*> **ethernet** <*port*> | **ve** <*ve-number*> [**ethernet** <*port*>] <*link-layer-address*>

The <*ipv6-address*> parameter specifies the address of the neighbor.

The **ethernet | ve** parameter specifies the interface through which to reach a neighbor. If you specify an Ethernet interface, you must also specify the port number. If you specify a VE, specify the VE number and then the Ethernet port numbers associated with the VE. The link-layer address is a 48-bit hardware address of the neighbor.

If you attempt to add an entry that already exists in the neighbor discovery cache, the software changes the already existing entry to a static entry.

To remove a static IPv6 entry from the IPv6 neighbor discovery cache, use the **no** form of this command.

Limiting the number of hops an IPv6 packet can traverse

By default, the maximum number of hops an IPv6 packet can traverse is 64. You can change this value to between 1 – 255 hops. For example, to change the maximum number of hops to 70, enter the following command.

```
NetIron(config)# ipv6 hop-limit 70
```

Syntax: [**no**] **ipv6 hop-limit** <*number*>

The number of hops can be from 1 – 255.

QoS for IPv6 traffic

Configuring QoS for IPv6 traffic is generally the same as it is for IPv4 traffic. The QoS policies you configure on the device apply to both incoming IPv6 and IPv4 traffic. ACLs can be used to perform QoS for IPv6 traffic for the following values as described in 21, “Access Control List”:

- dscp
- fragments
- priority-force
- priority-mapping
- source routing
- drop-precedence
- drop-precedence force

To enable QoS for IPv6 traffic, enter the following commands.

```
NetIron(config)# port-priority
NetIron(config)# write memory
NetIron(config)# end
NetIron# reload
```

Syntax: [**no**] **port-priority**

NOTE
You must save the configuration and reload the software to place the change into effect. This applies whether you are enabling QoS for IPv6 or IPv4 traffic.

The **port-priority** command globally enables QoS for IPv6 traffic on all interfaces. On Dell devices, when QoS is enabled with the **port-priority** command, the device inserts a value in the internal header based on a combination of the following information:

- 802.1p priority
- Interface priority (if configured)
- VLAN priority (if configured)
- The DSCP field in the Type of Service (ToS) header

For more information, refer to the 9, “Configuring Quality of Service for the NetIron MLX”.

Clearing global IPv6 information

You can clear the following global IPv6 information:

- Entries from the IPv6 cache.
- Entries from the IPv6 neighbor table.
- IPv6 routes from the IPv6 route table.
- IPv6 traffic statistics.
- IPv6 session flows

Clearing the IPv6 cache

You can remove all entries from the IPv6 cache or specify an entry based on the following:

- IPv6 prefix.
- IPv6 address.
- Interface type.

For example, to remove entries for IPv6 address 2000:e0ff::1, enter the following command at the Privileged EXEC level or any of the Config levels of the CLI.

```
NetIron# clear ipv6 cache 2000:e0ff::1
```

Syntax: **clear ipv6 cache** [<*ipv6-prefix*>/<*prefix-length*> | <*ipv6-address*> | **ethernet** <*port*> | **pos** <*number*> |**tunnel** <*number*> | **ve** <*number*>] [**vrf** <*vrf-name*>]

You must specify the <*ipv6-prefix*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the <*prefix-length*> parameter as a decimal value. A slash mark (/) must follow the <*ipv6-prefix*> parameter and precede the <*prefix-length*> parameter.

You must specify the <*ipv6-address*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The **ethernet** | **pos** | **tunnel** | **ve** parameter specifies the interfaces for which you can remove cache entries. If you specify an Ethernet interface, you must also specify the port number associated with the interface. If you specify a VE or tunnel interface, also specify the VE or tunnel number, respectively.

The <*vrf-name*> parameter specifies the VRF for which you want to clear the cache entry. If no vrf parameter is entered, the default VRF is used.

Clearing IPv6 neighbor information

You can remove all entries from the IPv6 neighbor table or specify an entry based on the following:

- IPv6 prefix.
- IPv6 address.
- Interface type.

For example, to remove entries for Ethernet interface 3/1, enter the following command at the Privileged EXEC level or any of the CONFIG levels of the CLI.

```
NetIron# clear ipv6 neighbor ethernet 3/1
```

Syntax: clear ipv6 neighbor [<*ipv6-prefix*>/<*prefix-length*> | <*ipv6-address*> | **ethernet** <*port*> | **ve** <*number*>]

You must specify the <*ipv6-prefix*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the <*prefix-length*> parameter as a decimal value. A slash mark (/) must follow the <*ipv6-prefix*> parameter and precede the <*prefix-length*> parameter.

You must specify the <*ipv6-address*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The **ethernet** | **ve** parameter specifies the interfaces for which you can remove cache entries. If you specify an Ethernet interface, you must also specify the port number associated with the interface. If you specify a VE, you must also specify the VE number.

Clearing IPv6 routes from the IPv6 route table

You can clear all IPv6 routes or only those routes associated with a particular IPv6 prefix from the IPv6 route table and reset the routes.

For example, to clear IPv6 routes associated with the prefix 2000:7838::/32, enter the following command at the Privileged EXEC level or any of the Config levels of the CLI.

```
NetIron# clear ipv6 route 2000:7838::/32
```

Syntax: clear ipv6 route [<*ipv6-prefix*>/<*prefix-length*>]

The <*ipv6-prefix*>/<*prefix-length*> parameter clears routes associated with a particular IPv6 prefix. You must specify the <*ipv6-prefix*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the <*prefix-length*> parameter as a decimal value. A slash mark (/) must follow the <*ipv6-prefix*> parameter and precede the <*prefix-length*> parameter.

Clearing IPv6 traffic statistics

To clear all IPv6 traffic statistics (reset all fields to zero), enter the following command at the Privileged EXEC level or any of the Config levels of the CLI.

```
NetIron(config)# clear ipv6 traffic
```

Syntax: clear ipv6 traffic

Deleting IPv6 session flows

To delete all flows from the IPv6 session cache, enter the following command.

```
NetIron# clear ipv6 flows
```

Syntax: clear ipv6 flows

Displaying global IPv6 information

You can display output for the following global IPv6 parameters:

- IPv6 cache.
- IPv6 interfaces.
- IPv6 neighbors.
- IPv6 route table.
- Local IPv6 routers.
- IPv6 TCP connections and the status of individual connections.
- IPv6 traffic statistics.
- IPv6 session flows

Displaying IPv6 cache information

The IPv6 cache contains an IPv6 host table with indices to the next hop gateway and the interface on which the route was learned.

To display IPv6 cache information, enter the following command at any CLI level.

```
NetIron# show ipv6 cache
Total number of cache entries: 10
    IPv6 Address                    Next Hop                    Port
1   5000:2::2                       LOCAL                       tunnel 2
2   2000:4::106                     LOCAL                       ethe 3/2
3   2000:4::110                     DIRECT                      ethe 3/2
4   2002:c0a8:46a::1                LOCAL                       ethe 3/2
5   fe80::2e0:52ff:fe99:9737        LOCAL                       ethe 3/2
6   fe80::ffff:ffff:feff:ffff       LOCAL                       loopback 2
7   fe80::c0a8:46a                  LOCAL                       tunnel 2
8   fe80::c0a8:46a                  LOCAL                       tunnel 6
9   2999::1                         LOCAL                       loopback 2
10  fe80::2e0:52ff:fe99:9700        LOCAL                       ethe 3/1
```

Syntax: show ipv6 cache [<*index-number*> | <*ipv6-prefix*>/<*prefix-length*> | <*ipv6-address*> | **ethernet** <*port*> | **pos** <*number*>| **ve** <*number*> | **tunnel** <*number*>][**vrf** <*vrf-name*>]

The <*index-number*> parameter restricts the display to the entry for the specified index number and subsequent entries.

The <*ipv6-prefix*>/<*prefix-length*> parameter restricts the display to the entries for the specified IPv6 prefix. You must specify the <*ipv6-prefix*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the <*prefix-length*> parameter as a decimal value. A slash mark (/) must follow the <*ipv6-prefix*> parameter and precede the <*prefix-length*> parameter.

The **ethernet | pos | ve | tunnel** parameter restricts the display to the entries for the specified interface. The <*ipv6-address*> parameter restricts the display to the entries for the specified IPv6 address. You must specify this parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The **vrf** <vrf-name> parameter specifies the VRF for which you want to display the cache entry. If a vrf parameter is not entered, then the default VRF is used.

If you specify an Ethernet interface, also specify the port number associated with the interface. If you specify a VE interface, you must also specify the VE number. If you specify a tunnel interface, you must also specify the tunnel number.

This display shows the following information.

TABLE 301 IPv6 cache information fields

This field...	Displays...
Total number of cache entries	The number of entries in the cache table.
IPv6 Address	The host IPv6 address.
Next Hop	The next hop, which can be one of the following: • Direct – The next hop is directly connected to the device. • Local – The next hop is originated on this device. • <*ipv6 address*> – The IPv6 address of the next hop.
Port	The port on which the entry was learned.

Displaying IPv6 interface information

To display IPv6 interface information, enter the following command at any CLI level.

```
NetIron# show ipv6 interface
Routing Protocols : R - RIP  O - OSPF I - ISIS
Interface      Status     Routing  Global Unicast Address
Ethernet 3/3   down/down  R
Ethernet 3/5   down/down
Ethernet 3/17  up/up               2017::c017:101/64
Ethernet 3/19  up/up               2019::c019:101/64
VE 4           down/down
VE 14          up/up               2024::c060:101/64
Loopback 1     up/up               ::1/128
Loopback 2     up/up               2005::303:303/128
Loopback 3     up/up
```

Syntax: show ipv6 interface [<*interface*> [<*port-number*> |<*number*>]]

The <*interface*> parameter displays detailed information for a specified interface. For the interface, you can specify the **Ethernet**, **loopback**, **tunnel**, or **VE** keywords. If you specify an Ethernet interface, you must also specify the port number associated with the interface. If you specify a loopback, tunnel, or VE interface, you must also specify the number associated with the interface.

This display shows the following information.

TABLE 302 General IPv6 interface information fields

This field...	Displays...
Routing protocols	A one-letter code that represents a routing protocol that can be enabled on an interface.
Interface	The interface type, and the port number or number of the interface.
Status	The status of the interface. The entry in the Status field will be either “up/up” or “down/down”.
Routing	The routing protocols enabled on the interface.
Global Unicast Address	The global unicast address of the interface.

Displaying IPv6 interface information for a specified interface

To display detailed information for a specific interface, enter a command such as the following at any CLI level.

```
NetIron# show ipv6 interface ethernet 3/1
Interface Ethernet 3/1 is up, line protocol is up
  IPv6 is enabled, link-local address is fe80::2e0:52ff:fe99:97
  Global unicast address(es):
  Joined group address(es):
    ff02::9
    ff02::1:ff99:9700
    ff02::2
    ff02::1
  MTU is 1500 bytes
  ICMP redirects are enabled
  ND DAD is enabled, number of DAD attempts: 3
  ND reachable time is 30 seconds
  ND advertised reachable time is 0 seconds
  ND retransmit interval is 1 seconds
  ND advertised retransmit interval is 0 seconds
  ND router advertisements are sent every 200 seconds
  ND router advertisements live for 1800 seconds
  No Inbound Access List Set
  No Outbound Access List Set
  RIP enabled
  RxPkts:  200  TxPkts:  200
  RxBytes: 12000 TxBytes: 12000
```

This display shows the following information.

TABLE 303 Detailed IPv6 interface information fields

This field...	Displays...
Interface/line protocol status	The status of interface and line protocol. If you have disabled the interface with the **disable** command, the status will be "administratively down". Otherwise, the status is either "up" or "down".
IPv6 status/link-local address	The status of IPv6. The status is either "enabled" or "disabled". Displays the link-local address, if one is configured for the interface.
Global unicast address(es)	Displays the global unicast addresses, if one or more are configured for the interface.
Joined group address(es)	The multicast addresses that a device interface listens for and recognizes.
MTU	The setting of the maximum transmission unit (MTU) configured for the IPv6 interface. The MTU is the maximum length an IPv6 packet can have to be transmitted on the interface. If an IPv6 packet is longer than an MTU, the host that originated the packet fragments the packet and transmits its contents in multiple packets that are shorter than the configured MTU.
ICMP	The setting of the ICMP redirect parameter for the interface.
ND	The setting of the various neighbor discovery parameters for the interface.
Access List	The inbound and outbound access lists applied to the interface.
Routing protocols	The routing protocols enabled on the interface.
RxPkts	The number of packets received at the specified port. This field supports IPv4 and IPv6 packet and byte counters.
TxPkts	The number of packets transmitted from the specified port. This field supports IPv4 and IPv6 packet and byte counters.
RxBytes	The number of bytes received at the specified port. This field supports IPv4 and IPv6 packet and byte counters.s
TxBytes	The number of bytes transmitted from the specified port. This field supports IPv4 and IPv6 packet and byte counters.

Displaying interface counters for all ports

Previous versions of the Multi-Service IronWare software support IPv4 and IPv6 packet and byte counters. The contents of these counters can be displayed for all ports on a device or per port. Output from the **show ipv6 interface ethernet** command includes packet and byte counter information on a per-port basis. Refer to "Displaying IPv6 interface information for a specified interface" on page 1751.

The default byte counters include the 20-byte per-packet Ethernet overhead. You can configure a device to exclude the 20-byte per-packet Ethernet overhead from byte accounting using the **vlan-counter exclude-overhead** command. Refer to "Extended VLAN counters for 8x10G modules" on page 265.

IPv4 and IPv6 commands display the interface counters for all ports on a router. The following example displays packet and byte counter information for all ports.

```
NetIron# show ipv6 interface counters
Interface      RxPkts     TxPkts     RxBytes     TxBytes
eth 3/3        200        200        850000      850000
eth 3/4        500        500        40000       40000
```

Syntax: show ipv6 interface counters

Table 304 describes the fields that display interface counter statistics.

TABLE 304 Interface counter display statistics

This field...	Displays...
Interface	The interface for which counter statistics are being displayed.
RxPkts	The number of packets received at the specified port.
TxPkts	The number of packets transmitted from the specified port.
RxBytes	The number of bytes received at the specified port.
TxBytes	The number of bytes transmitted from the specified port.

Clearing the interface counters

Use the following command to clear all interface counters on a router.

```
NetIron# clear ip interface counters
```

Syntax: clear ip interface counters

Use the following command to clear the interface counters for a specified port.

```
NetIron# clear ip interface ethernet 3/2
```

Syntax: clear ip interface ethernet <*port-number*>

The **port-number** variable specifies the slot and port number for which you want to clear the interface counters.

Displaying IPv6 neighbor information

You can display the IPv6 neighbor table, which contains an entry for each IPv6 neighbor with which the device exchanges IPv6 packets.

To display the IPv6 neighbor table, enter the following command at any CLI level.

```
NetIron(config)# show ipv6 neighbor
Total number of Neighbor entries: 3
    IPv6 Address                          LinkLayer-Addr State Age Port    IsR
1   2000:4::110                           00e0.5291.bb37 REACH 20  ethe 3/1  1
2   fe80::2e0:52ff:fe91:bb37              00e0.5291.bb37 DELAY 1   ethe 3/2  1
3   fe80::2e0:52ff:fe91:bb40              00e0.5291.bb40 STALE 5930 ethe 3/3  1
```

Syntax: show ipv6 neighbor [<*ipv6-prefix*>/<*prefix-length*> | <*ipv6-address*> | <*interface*> [<*port*> |<*number*>]]

The <*ipv6-prefix*>/<*prefix-length*> parameters restrict the display to the entries for the specified IPv6 prefix. You must specify the <*ipv6-prefix*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the <*prefix-length*> parameter as a decimal value. A slash mark (/) must follow the <*ipv6-prefix*> parameter and precede the <*prefix-length*> parameter.

The <*ipv6-address*> parameter restricts the display to the entries for the specified IPv6 address. You must specify this parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The <*interface*> parameter restricts the display to the entries for the specified router interface. For this parameter, you can specify the **Ethernet** or **VE** keywords. If you specify an Ethernet interface, you must also specify the port number associated with the interface. If you specify a VE interface, you must also specify the VE number.

This display shows the following information.

TABLE 305 IPv6 neighbor information fields

This field...	Displays...
Total number of neighbor entries	The total number of entries in the IPv6 neighbor table.
IPv6 Address	The 128-bit IPv6 address of the neighbor.
Link-Layer Address	The 48-bit interface ID of the neighbor.
State	The current state of the neighbor. Possible states are as follows: • INCOMPLETE – Address resolution of the entry is being performed. • REACH – The forward path to the neighbor is functioning properly. • STALE – This entry has remained unused for the maximum interval. While stale, no action takes place until a packet is sent. • DELAY – This entry has remained unused for the maximum interval, and a packet was sent before another interval elapsed. • PROBE – Neighbor solicitation are transmitted until a reachability confirmation is received.
Age	The number of seconds the entry has remained unused. If this value remains unused for the number of seconds specified by the **ipv6 nd reachable-time command** (the default is 30 seconds), the entry is removed from the table.
Port	The port on which the entry was learned.
IsR	Determines if the neighbor is a device or host: 0 – Indicates that the neighbor is a host. 1 – Indicates that the neighbor is a device.

Displaying the IPv6 route table

To display the IPv6 route table, enter the following command at any CLI level.

```
NetIron# show ipv6 route
IPv6 Routing Table - 6 entries:
Type Codes -  B:BGP C:Connected I:ISIS L:Local O:OSPF R:RIP S:Static
OSPF  Type:  i - Inter, 1 - External Type1, 2 - External Type2, e - External
Type IPv6 Prefix          Next Hop Router           Interface  Dis/Metric Uptime
C  2001::/64               ::                        eth 1/7     0/0       45m18s
C  2001:470:0:25::/64      ::                        loopback 1  0/0       1h0m
L  2001:470:0:25::1/128    ::                        loopback 1  0/0       13m18s
C  5000:2000::/64          ::                        eth 1/13    0/0       1h0m
O  8000:4000::1/128        fe80::202:17ff:fe6e:c41c  eth 1/13    110/1     2m42s
O1 9000::1/128             fe80::20c:dbff:fef4:7406  eth 1/7     110/2     13m18s
```

Syntax: **show ipv6 route** [<*ipv6-address*> | <*ipv6-prefix*>/<*prefix-length*> | **bgp** | **connect** | **ospf** | **rip** | **isis** | **static** | **summary**]

The <*ipv6-address*> parameter restricts the display to the entries for the specified IPv6 address. You must specify the <*ipv6-address*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The <*ipv6-prefix*>/<*prefix-length*> parameters restrict the display to the entries for the specified IPv6 prefix. You must specify the <*ipv6-prefix*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the <*prefix-length*> parameter as a decimal value. A slash mark (/) must follow the <*ipv6-prefix*> parameter and precede the <*prefix-length*> parameter.

The **bgp** keyword restricts the display to entries for BGP4+ routes.

The **connect** keyword restricts the display to entries for directly connected interface IPv6 routes.

The **isis** keyword restricts the display to entries for IPv6 IS-IS routes.

The **ospf** keyword restricts the display to entries for OSPFv3 routes.

The **rip** keyword restricts the display to entries for RIPng routes.

The **static** keyword restricts the display to entries for static IPv6 routes.

The **summary** keyword displays a summary of the prefixes and different route types.

The following table lists the information displayed by the **show ipv6 route** command.

TABLE 306 IPv6 route table fields

This field...	Displays...
Number of entries	The number of entries in the IPv6 route table.
Type	The route type, which can be one of the following: • B – The route is learned from BGP4+. • C – The destination is directly connected to the device. • I – The route is learned from IPv6 IS-IS. • L – The route is the host address of a loopback interface that is assigned an ipv6 address. • O – The route is learned from OSPFv3. • R – The route is learned from RIPng. • S – The route is a static route.
OSPF Type	• i – an internal route calculated by OSPF. • 1 – An OSPF type 1 external route. • 2 – An OSPF type 2 external route. • e – an external route calculated by OSPF.
IPv6 Prefix	The destination network of the route.
Next-Hop Router	The next-hop device.
Interface	The interface through which this device sends packets to reach the route destination.
Dis/Metric	The administrative distance and metric value of the route.

To display a summary of the IPv6 route table, enter the following command at any CLI level.

```
NetIron# show ipv6 route summary
IPv6 Routing Table - 7 entries:
  4 connected, 2 static, 0 RIP, 1 OSPF, 0 BGP
  Number of prefixes:
  /16: 1 /32: 1 /64: 3 /128: 2
```

Table 307 lists the information displayed by the **show ipv6 route summary** command.

TABLE 307 IPv6 route table summary fields

This field...	Displays...
Number of entries	The number of entries in the IPv6 route table.
Number of route types	The number of entries for each route type.
Number of prefixes	A summary of prefixes in the IPv6 route table, sorted by prefix length.

Displaying local IPv6 devices

The device can function as an IPv6 host, if you configure IPv6 addresses on the interfaces but do not enable IPv6 routing using the **ipv6 unicast-routing** command.

From the IPv6 host, you can display information about IPv6 devices to which the host is connected. The host learns about the devices through their router advertisement messages. To display information about the IPv6 devices connected to an IPv6 host, enter the following command at any CLI level.

```
NetIron# show ipv6 router
Router fe80::2e0:80ff:fe46:3431 on Ethernet 50, last update 0 min
Hops 64, Lifetime 1800 sec
Reachable time 0 msec, Retransmit time 0 msec
```

Syntax: show ipv6 router

If you configure your device to function as an IPv6 device (configure IPv6 addresses on the interfaces and enable IPv6 routing using the **ipv6 unicast-routing** command) and then enter the **show ipv6 router command**, you will receive the following output.

```
No IPv6 router in table
```

Meaningful output for this command is generated for devices configured to function as IPv6 hosts only.

This display shows the following information.

TABLE 308 IPv6 local router information fields

This field...	Displays...
Router <*ipv6 address*> on <*interface*> <*port*>	The IPv6 address for a particular interface.
Last update	The amount of elapsed time (in minutes) between the current and previous updates received from a device.
Hops	The default value that should be included in the Hop Count field of the IPv6 header for outgoing IPv6 packets. The hops value applies to the device for which you are displaying information and should be followed by IPv6 hosts attached to the device. A value of 0 indicates that the device leaves this field unspecified.
Lifetime	The amount of time (in seconds) that the device is useful as the default device.

TABLE 308 IPv6 local router information fields

This field...	Displays...
Reachable time	The amount of time (in milliseconds) that a device assumes a neighbor is reachable after receiving a reachability confirmation. The reachable time value applies to the device for which you are displaying information and should be followed by IPv6 hosts attached to the device. A value of 0 indicates that the device leaves this field unspecified.
Retransmit time	The amount of time (in milliseconds) between retransmissions of neighbor solicitation messages. The retransmit time value applies to the device for which you are displaying information and should be followed by IPv6 hosts attached to the device. A value of 0 indicates that the device leaves this field unspecified.

Displaying IPv6 TCP information

You can display the following IPv6 TCP information:

- General information about each TCP connection on the device, including the percentage of free memory for each of the internal TCP buffers.
- Detailed information about a specified TCP connection.

To display general information about each TCP connection on the device, enter the following command at any CLI level.

```
NetIron# show ipv6 tcp connections
Local IP address:port <-> Remote IP address:port TCP state
192.168.182.110:23 <->    192.168.8.186:4933     ESTABLISHED
192.168.182.110:8218 <->  192.168.182.106:179    ESTABLISHED
192.168.182.110:8039 <->  192.168.2.119:179      SYN-SENT
192.168.182.110:8159 <->  192.168.2.102:179      SYN-SENT
2000:4::110:179 <->       2000:4::106:8222       ESTABLISHED (1440)
Total 5 TCP connections

TCP MEMORY USAGE PERCENTAGE
FREE TCB = 98 percent
FREE TCP QUEUE BUFFER = 99 percent
FREE TCP SEND BUFFER = 97 percent
FREE TCP RECEIVE BUFFER = 100 percent
FREE TCP OUT OF SEQUENCE BUFFER = 100 percent
```

Syntax: show ipv6 tcp connections

This display shows the following information.

TABLE 309 General IPv6 TCP connection fields

This field...	Displays...
Local IP address:port	The IPv4 or IPv6 address and port number of the local interface over which the TCP connection occurs.
Remote IP address:port	The IPv4 or IPv6 address and port number of the remote interface over which the TCP connection occurs.

TABLE 309 General IPv6 TCP connection fields (Continued)

This field...	Displays...
TCP state	The state of the TCP connection. Possible states include the following: • LISTEN – Waiting for a connection request. • SYN-SENT – Waiting for a matching connection request after having sent a connection request. • SYN-RECEIVED – Waiting for a confirming connection request acknowledgment after having both received and sent a connection request. • ESTABLISHED – Data can be sent and received over the connection. This is the normal operational state. • FIN-WAIT-1 – Waiting for a connection termination request from the remote TCP, or an acknowledgment of the connection termination request previously sent. • FIN-WAIT-2 – Waiting for a connection termination request from the remote TCP. • CLOSE-WAIT – Waiting for a connection termination request from the local user. • CLOSING – Waiting for a connection termination request acknowledgment from the remote TCP. • LAST-ACK – Waiting for an acknowledgment of the connection termination request previously sent to the remote TCP (which includes an acknowledgment of its connection termination request). • TIME-WAIT – Waiting for enough time to pass to be sure the remote TCP received the acknowledgment of its connection termination request. • CLOSED – There is no connection state.
FREE TCB = <*percentage*>	The percentage of free TCP control block (TCB) space.
FREE TCB QUEUE BUFFER = <*percentage*>	The percentage of free TCB queue buffer space.
FREE TCB SEND BUFFER = <*percentage*>	The percentage of free TCB send buffer space.
FREE TCB RECEIVE BUFFER = <*percentage*>	The percentage of free TCB receive buffer space.
FREE TCB OUT OF SEQUENCE BUFFER = <*percentage*>	The percentage of free TCB out of sequence buffer space.

To display detailed information about a specified TCP connection, enter a command such as the following at any CLI level.

```
NetIron# show ipv6 tcp status 2000:4::110 179 2000:4::106 8222
TCP: TCB = 0x217fc300
TCP: 2000:4::110:179 <-> 2000:4::106:8222: state: ESTABLISHED Port: 1
  Send: initial sequence number = 242365900
  Send: first unacknowledged sequence number = 242434080
  Send: current send pointer = 242434080
  Send: next sequence number to send = 242434080
  Send: remote received window = 16384
  Send: total unacknowledged sequence number = 0
  Send: total used buffers 0
  Receive: initial incoming sequence number = 740437769
  Receive: expected incoming sequence number = 740507227
  Receive: received window = 16384
  Receive: bytes in receive queue = 0
  Receive: congestion window = 1459
```

Syntax: show ipv6 tcp status <*local-ip-address*> <*local-port-number*> <*remote-ip-address*> <*remote-port-number*>

The <*local-ip-address*> parameter can be the IPv4 or IPv6 address of the local interface over which the TCP connection is taking place.

The <*local-port-number*> parameter is the local port number over which a TCP connection is taking place.

The <*remote-ip-address*> parameter can be the IPv4 or IPv6 address of the remote interface over which the TCP connection is taking place.

The <*remote-port-number*> parameter is the local port number over which a TCP connection is taking place.

This display shows the following information.

TABLE 310 Specific IPv6 TCP connection fields

This field...	Displays...
TCB = <*location*>	The location of the TCB.
<*local-ip-address*> <*local-port-number*> <*remote-ip-address*> <*remote-port-number*> <*state*> <*port*>	This field provides a general summary of the following: • The local IPv4 or IPv6 address and port number. • The remote IPv4 or IPv6 address and port number. • The state of the TCP connection. For information on possible states, refer to Table 309 on page 1757. • The port numbers of the local interface.
Send: initial sequence number = <*number*>	The initial sequence number sent by the local device.
Send: first unacknowledged sequence number = <*number*>	The first unacknowledged sequence number sent by the local device.
Send: current send pointer = <*number*>	The current send pointer.
Send: next sequence number to send = <*number*>	The next sequence number sent by the local device.
Send: remote received window = <*number*>	The size of the remote received window.
Send: total unacknowledged sequence number = <*number*>	The total number of unacknowledged sequence numbers sent by the local device.
Send: total used buffers <*number*>	The total number of buffers used by the local device in setting up the TCP connection.

TABLE 310 Specific IPv6 TCP connection fields (Continued)

This field...	Displays...
Receive: initial incoming sequence number = <*number*>	The initial incoming sequence number received by the local device.
Receive: expected incoming sequence number = <*number*>	The incoming sequence number expected by the local device.
Receive: received window = <*number*>	The size of the local device receive window.
Receive: bytes in receive queue = <*number*>	The number of bytes in the local device receive queue.
Receive: congestion window = <*number*>	The size of the local device receive congestion window.

Displaying IPv6 traffic statistics

To display IPv6 traffic statistics, enter the following command at any CLI level.

```
NetIron# show ipv6 traffic
IP6 Statistics
  36947 received, 66818 sent, 0 forwarded, 36867 delivered, 0 rawout
  0 bad vers, 23 bad scope, 0 bad options, 0 too many hdr
  0 no route, 0 can't forward, 0 redirect sent, 0 source routed
  0 frag recv, 0 frag dropped, 0 frag timeout, 0 frag overflow
  0 reassembled, 0 fragmented, 0 ofragments, 0 can't frag
  0 too short, 0 too small, 11 not member
  0 no buffer, 66819 allocated, 21769 freed
  0 forward cache hit, 46 forward cache miss

```

Syntax: show ipv6 traffic

This display shows the following information.

TABLE 311 IPv6 traffic statistics fields

This field...	Displays...
IPv6 statistics	
received	The total number of IPv6 packets received by the device.
sent	The total number of IPv6 packets originated and sent by the device.
forwarded	The total number of IPv6 packets received by the router and forwarded to other devices.
delivered	The total number of IPv6 packets delivered to the upper layer protocol.
rawout	This information is used by Dell Technical Support.
bad vers	The number of IPv6 packets dropped by the device because the version number is not 6.
bad scope	The number of IPv6 packets dropped by the device because of a bad address scope.
bad options	The number of IPv6 packets dropped by the device because of bad options.
too many hdr	The number of IPv6 packets dropped by the device because the packets had too many headers.
no route	The number of IPv6 packets dropped by the device because there was no route.
can not forward	The number of IPv6 packets the device could not forward to another device.
redirect sent	This information is used by Dell Technical Support.
source routed	The number of IPv6 source-routed packets dropped.
frag recv	The number of fragments received by the device.
frag dropped	The number of fragments dropped by the device.
frag timeout	The number of fragment timeouts that occurred.
frag overflow	The number of fragment overflows that occurred.
reassembled	The number of fragmented IPv6 packets that the device reassembled.
fragmented	The number of IPv6 packets fragmented by the device to accommodate the MTU of this device or of another device.
ofragments	The number of output fragments generated by the device.
can not frag	The number of IPv6 packets the device could not fragment.
too short	The number of IPv6 packets dropped because they are too short.
too small	The number of IPv6 packets dropped because they do not have enough data.
not member	The number of IPv6 packets dropped because the recipient is not a member of a multicast group.
no buffer	The number of IPv6 packets dropped because there is no buffer available.
forward cache miss	The number of IPv6 packets received for which there is no corresponding cache entry.
ICMP6 statistics Some ICMP statistics apply to both Received and Sent, some apply to Received only, some apply to Sent only, and some apply to Sent Errors only.	
Applies to Received and Sent	

TABLE 311 IPv6 traffic statistics fields (Continued)

This field...	Displays...
dest unreach	The number of Destination Unreachable messages sent or received by the device.
pkt too big	The number of Packet Too Big messages sent or received by the device.
time exceeded	The number of Time Exceeded messages sent or received by the device.
param prob	The number of Parameter Problem messages sent or received by the device.
echo req	The number of Echo Request messages sent or received by the device.
echo reply	The number of Echo Reply messages sent or received by the device.
mem query	The number of Group Membership Query messages sent or received by the device.
mem report	The number of Membership Report messages sent or received by the device.
mem red	The number of Membership Reduction messages sent or received by the device.
router soli	The number of Router Solicitation messages sent or received by the device.
router adv	The number of Router Advertisement messages sent or received by the device.
nei soli	The number of Neighbor Solicitation messages sent or received by the device.
nei adv	The number of Router Advertisement messages sent or received by the device.
redirect	The number of redirect messages sent or received by the device.
Applies to Received Only	
bad code	The number of Bad Code messages received by the device.
too short	The number of Too Short messages received by the device.
bad checksum	The number of Bad Checksum messages received by the router.
bad len	The number of Bad Length messages received by the device.
nd toomany opt	The number of Neighbor Discovery Too Many Options messages received by the device.
badhopcount	The number of Bad Hop Count messages received by the device.
Applies to Sent Only	
error	The number of Error messages sent by the device.
can not send error	The number of times the device encountered errors in ICMP error messages.
too freq	The number of times the device has exceeded the frequency of sending error messages.
Applies to Sent Errors Only	
unreach no route	The number of Unreachable No Route errors sent by the device.
admin	The number of Admin errors sent by the device.
beyond scope	The number of Beyond Scope errors sent by the device.
address	The number of Address errors sent by the device.
no port	The number of No Port errors sent by the device.
pkt too big	The number of Packet Too Big errors sent by the device.

TABLE 311 IPv6 traffic statistics fields (Continued)

This field...	Displays...
source address policy	The number of ICMPv6 destination unreachable messages sent with code 5 because an IPv6 packet is dropped by an Access Control policy and the IPv6 source address of a packet matches the source address filtering policy.
reject route	The number of ICMPv6 destination unreachable messages sent code 6 because an IPv6 packet is dropped due to the destination address in the packet matching a route that has been configured to drop the packet.
time exceed transit	The number of Time Exceed Transit errors sent by the device.
time exceed reassembly	The number of Time Exceed Reassembly errors sent by the device.
param problem header	The number of Parameter Problem Header errors sent by the device.
nextheader	The number of Next Header errors sent by the device.
option	The number of Option errors sent by the device.
redirect	The number of Redirect errors sent by the device.
unknown	The number of Unknown errors sent by the device.
UDP statistics	
received	The number of UDP packets received by the device.
sent	The number of UDP packets sent by the device.
no port	The number of UDP packets dropped because the packet did not contain a valid UDP port number.
input errors	This information is used by Dell Technical Support.
TCP statistics	
active opens	The number of TCP connections opened by the device by sending a TCP SYN to another device.
passive opens	The number of TCP connections opened by the device in response to connection requests (TCP SYNs) received from other devices.
failed attempts	This information is used by Dell Technical Support.
active resets	The number of TCP connections the device reset by sending a TCP RESET message to the device at the other end of the connection.
passive resets	The number of TCP connections the device reset because the device at the other end of the connection sent a TCP RESET message.
input errors	This information is used by Dell Technical Support.
in segments	The number of TCP segments received by the device.
out segments	The number of TCP segments sent by the device.
retransmission	The number of segments that the device retransmitted because the retransmission timer for the segment had expired before the device at the other end of the connection had acknowledged receipt of the segment.

Displaying IPv6 session flows

To display the contents of an IPv6 session cache, enter the following command.

```
NetIron# show ipv6 flows
```

Syntax: **show ipv6 flows** [<*source-ipv6-prefix*/*prefix-length*> | **any** | **host** <*source-ipv6_address*> <*destination-ipv6-prefix*/*prefix-length*> | **any** | **host** <*destination-ipv6-address*>]

If you do not specify a source or destination, all IPv6 flows are displayed.

Enter a value for <*source-ipv6-prefix*>/<*prefix-length*> or <*destination-ipv6-prefix*>/<*prefix-length*> to specify a source or destination prefix and prefix length that a flow must match to be included in the display.

Enter **any** for source or destination if a flow can have any source or any destination to be included in the display.

The **host** <*source-ipv6-address*> and **host** <*destination-ipv6-address*> parameters allow you specify a source or destination host IPv6 address that a flow must match to be included in the display.

EXAMPLES:

To show all IPv6 flows, enter the following command.

```
NetIron# show ipv6 flows
```

To show all IPv6 flows with any IPv6 source and any IPv6 destination addresses, enter the following command.

```
NetIron# show ipv6 flows any any
```

To show all IPv6 flows that match the source prefix 4000::/16 and any destination address, enter the following command.

```
NetIron# show ipv6 flows 4000::/16 any
```

To show all IPv6 flows that have any source address but only a destination address of host 5020::30, enter the following command.

```
NetIron# show ipv6 flows any host 5020::30
```

To show all IPv6 flows that have the source address of host 4050::30 and the destination address of host 5020::30, enter the following command.

```
NetIron# show ipv6 flows host 4050::30 host 5020::30
```

This output is an example of what is displayed when you enter the **show ipv6 flows** command.

```
NetIron# show ipv6 flows
ipv6 flows count: 6
A:Ack D:Deny E:Estab F:Fin P:Psh Pe:Permit R:Rst U:urg Fr:Fragment
Sr:SRouted
SourceAddress                          DestinationAddress
  Protocol SrcPort/IcmpType DestPort/IcmpCode Dscp FlowLabel  Flags     Age
3001::3                                3020::160
 icmp      128             0                 0    0          Pe        4
3001::3                                3020::160
 tcp       telnet          3456              0    0          DAR       3
3001::3                                3020::160
 tcp       telnet          3456              0    0          DAS       3
3001::3                                3020::160
 icmp      129             0                 0    0          Pe        8
3001::3                                3020::160
 tcp       3456            telnet            0    0          DAR       9
3001::3                                3020::165
 icmp      128             0                 0    0          Pe        4
```

The first line (ipv6 flows count) shows the number of flows included on the display.

The next line defines the flags used in the display.

Information for each flow on the display appears on two lines in the following sequence:

- **Source Address** – Source address of the flow.
- **Destination Address** – Destination address of the flow.
- **Protocol** – Protocol in the flow.
- **SrcPort/IcmpType** – Either the source TCP or UDP port or the ICMP type of the flow.
- **DestPort or IcmpCode** – Either the destination TCP or UDP port or the ICMP code of the flow.
- **Dscp** – DSCP value in the flow.
- **FlowLabel** – Value in the flow label field of the IPv6 packet header.
- **Flags** – Status of the flow, which can be a combination of different flag types. For example, DAR means the flow was denied (D), acknowledged (A), and reset (R).
- **Age** – Age of the flow.

NOTE
The life of an idle flow is 50 seconds.

Chapter

Configuring an IPv6 Prefix List 39

PowerConnect B-MLXe supports the following IPv6 Prefix List features:

- IPv6 Prefix List
- Displaying Prefix List Information

Configuring an IPv6 prefix list

PowerConnect devices support IPv6 prefix lists, which you can use for basic traffic filtering. You can configure up to 100 IPv6 prefix lists.

An IPv6 prefix list is composed of one or more conditional statements that pose an action (permit or deny) if a packet matches a specified prefix. In prefix lists with multiple statements, you can specify a sequence number for each statement.The specified sequence number determines the order in which the statement appears in the prefix.

You can configure an IPv6 prefix list on a global basis, then use it as input to other commands or processes, such as route aggregation, route redistribution, route distribution, route maps, and so on. When a router interface sends or receives an IPv6 packet, it applies the statements within the IPv6 prefix list in their order of appearance to the packet. As soon as a match occurs, the router takes the specified action (permit or deny the packet) and stops further comparison for that packet.

You can use permit statements in the prefix list to specify the traffic that you want to send to the other feature. If you use deny statements, the traffic specified by the deny statements is not supplied to the other feature.

To configure an IPv6 prefix list and use it as input to the RIPng **distribute-list** command, enter commands such as the following.

```
NetIron(config)# ipv6 prefix-list routesfor2001 permit 2001::/16
NetIron(config)# ipv6 router rip
NetIron(config-ripng-router)# distribute-list prefix-list routesfor2001 out
ethernet 3/1
```

These commands permit the inclusion of routes with the IPv6 prefix 2001::/16 in RIPng routing updates sent from Ethernet interface 3/1.

Syntax: [**no**] **ipv6 prefix-list** <*name*> [**seq** <*sequence-number*>] **deny** <*ipv6-prefix*>/<*prefix-length*> | **permit** <*ipv6-prefix*>/<*prefix-length*> | **description** <*string*> [**ge** <*ge-value*>] [**le** <*le-value*>]

The <*name*> parameter specifies the prefix list name. You use this name when using the prefix list as input to command or route map.

The **seq** <*seq-number*> parameter is optional and specifies the IPv6 prefix list's sequence number. If you do not specify a sequence number, the software numbers them in increments of 5, beginning with prefix list entry 5. The router interprets the prefix list entries in numerical order, beginning with the lowest sequence number.

The **description** <*string*> parameter is a text string describing the prefix list.

The **deny** <*ipv6-prefix*>/<*prefix-length*> | **permit** <*ipv6-prefix*>/<*prefix-length*> parameters specify the action the router takes if a packet contains a route specified in this prefix list.

You must specify the <*ipv6-prefix*> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

You must specify the <*prefix-length*> parameter as a decimal value. A slash mark (/) must follow the <*ipv6-prefix*> parameter and precede the <*prefix-length*> parameter.

The prefix list matches only on the specified prefix/prefix length unless you use the **ge** <*prefix-length*> or **le** <*prefix-length*> parameters. (See below.)

You can specify a range of prefix lengths for prefixes that are more specific than <*ipv6-prefix*>/<*prefix-length*>.

- If you specify only **ge** <*ge-value*>, then the range is from <*ge-value*> to 128.
- If you specify only **le** <*le-value*>, then the range is from <*le-value*> to the <*prefix-length*> parameter.

The <*ge-value*> or <*le-value*> you specify must meet the following condition.

prefix-length < ge-value <= le-value <= 128

If you do not specify **ge** <*ge-value*> or **le** <*le-value*>, the prefix list matches only on the exact prefix you specify with the <*ipv6-prefix*>/<*prefix-length*> parameter.

To delete the prefix list entry, use the **no** form of this command.

Displaying prefix list information

To display the IPv6 prefix lists configured on a router, enter the following command at any level of the CLI.

```
NetIron(config)# show ipv6 prefix-lists
ipv6 prefix-list routesfor2001: 1 entries
     seq 5 permit 2001::/16
```

Syntax: show ipv6 prefix-lists [<*name*>]

The <*name*> parameter restricts the display to the specified prefix list. Specify the name of the prefix list that you want to display.

Chapter

Configuring an IPv6 Access Control List

40

PowerConnect B-MLXe supports the following IPv6 Access Control List features:

- IPv6 Access Control List
- Filtering IPv6 Packets Based on DSCP Values
- Filtering IPv6 Packets Based on Routing Header Type
- Applying an IPv6 ACL to a Router Interface
- Adding a Comment to an IPv6 ACL Entry
- ACL CAM sharing for Inbound IPv6 ACLs
- IPv6 Extended ACLs
- ACL CAM sharing
- IPv6 ACL Accounting
- IPv6 ACL Logging

Dell devices support IPv6 access control lists (ACLs), which you can use for traffic filtering. You can configure up to 100 IPv6 ACLs. For details on Layer 2 ACLs, refer to 20, “Layer 2 Access Control Lists”. For details on IPv4 ACLs, refer to 21, “Access Control List”.

An IPv6 ACL is composed of one or more conditional statements that identify an action (permit or deny) if a packet matches a specified source or destination prefix. There can be up to 1024 statements per device.

In ACLs with multiple statements, you can specify a priority for each statement.The specified priority determines the order in which the statement appears in the ACL.The last statement is an implicit deny statement for all packets that do not match the previous statements in the ACL.

You can configure an IPv6 ACL on a global basis, then apply it to the incoming or outgoing IPv6 packets on specified router interfaces. You can apply only one IPv6 ACL to incoming traffic for an interface and only one IPv6 ACL to outgoing traffic on an interface. When an interface sends or receives an IPv6 packet, it applies the statements within the ACL (in their order of occurrence in the ACL) to the packet. When a match occurs, the router takes the specified action (permits or denies the packet) and stops further comparison for that packet.

For dynamic LAG creation and deletion using IPv6 ACLs, before a LAG is formed, all ports which will be part of the LAG must have the same configuration. After the LAG is removed, all ACL bindings (if any) are propagated to all of the secondary ports.

IPv6 ACLs enable traffic filtering based on the following information:

- IPv6 protocol
- Source IPv6 address
- Destination IPv6 address
- ICMP message type (if the protocol is ICMP)
- Source TCP or UDP port (if the IPv6 protocol is TCP or UDP)
- Destination TCP or UDP port (if the IPv6 protocol is TCP or UDP)

The IPv6 protocol can be one of the following well-known names, or any IPv6 protocol number from 0 – 255:

- Authentication Header (AHP)
- Encapsulating Security Payload (ESP)
- Internet Control Message Protocol (ICMP)
- Internet Protocol Version 6 (IPv6)
- Stream Control Transmission Protocol (SCTP)
- Transmission Control Protocol (TCP)
- User Datagram Protocol (UDP)

For TCP and UDP, you also can specify a comparison operator and port name or number. For example, you can configure a policy to block Web access to a specific site by denying all TCP port 80 (HTTP) packets from a specified source IPv6 address to the IPv6 address of the site.

IPv6 ACLs also support the filtering of packets based on DSCP values.

NOTE
IPv6 ACLs are only applied to routed packets.This also includes mirror and deny-log actions.

Configuration considerations for IPv6 outbound ACLs on VPLS, VLL, and VLL-local endpoints

The following considerations apply to IPv6 outbound ACLs on VPLS, VLL, and VLL-local endpoints:

- Configure the port as a VPLS, VLL, or VLL-local endpoint and then bind the IPv6 outbound ACL to the port.
- Remove the IPv6 outbound ACL from a VPLS, VLL, or VLL-local endpoint before removing the port from the VPLS, VLL, or VLL-local instance or corresponding VLAN.
- Remove the IPv6 outbound ACL from a VPLS, VLL, or VLL-local endpoint before deleting the VPLS, VLL, or VLL-local instance or corresponding VLAN.
- If the VPLS, VLL, or VLL-local endpoint is a LAG port, you must first remove the IPv6 outbound ACL from the primary LAG port before deleting the LAG. This restriction is applicable even if you attempt to delete the lag using **force** keyword.
- If a VLL or VLL-local endpoint is a LAG port with an IPv6 outbound ACL, you must first remove the IPv6 outbound ACL from the primary LAG port before dynamically removing a port from the LAG.
- Ensure that no VPLS, VLL, or VLL-local endpoint exists with an IPv6 outbound ACL before entering the command: **no router mpls**.

This chapter contains the following sections:

Using IPv6 ACLs as input to other features

You can use an IPv6 ACL to provide input to other features such as route maps and distribution lists. When you use an ACL this way, permit statements in the ACL specify traffic that you want to send to the other feature. If you use deny statements, the traffic specified by the deny statements is not supplied to the other feature.

Configuring an IPv6 ACL

To configure an IPv6 ACL, you must perform the following tasks:

- Create the ACL.
- Apply the ACL to a router interface.

The following configuration tasks are optional:

- Control access to and from a router.

Example configurations

To configure an access list that blocks all Telnet traffic received on port 1/1 from IPv6 host 2000:2382:e0bb::2, enter the following commands.

```
NetIron(config)# ipv6 access-list fdry
NetIron(config-ipv6-access-list-fdry)# deny tcp host 2000:2382:e0bb::2 any eq
telnet
NetIron(config-ipv6-access-list-fdry)# permit ipv6 any any
NetIron(config-ipv6-access-list-fdry)# exit
NetIron(config)# int eth 1/1
NetIron(config-if-1/1)# ipv6 traffic-filter fdry in
NetIron(config)# write memory
```

Here is another example of how to configure an ACL and apply it to an interface.

```
NetIron(config)# ipv6 access-list netw
NetIron(config-ipv6-access-list-netw)# permit icmp 2000:2383:e0bb::/64
2001:3782::/64
NetIron(config-ipv6-access-list-netw)# deny ipv6 host 2000:2383:e0ac::2 host
2000:2383:e0aa:0::24
NetIron(config-ipv6-access-list-netw)# deny udp any any
NetIron(config-ipv6-access-list-netw)# permit ipv6 any any
```

The first condition permits ICMP traffic from hosts in the 2000:2383:e0bb::x network to hosts in the 2001:3782::x network.

The second condition denies all IPv6 traffic from host 2000:2383:e0ac::2 to host 2000:2383:e0aa:0::24.

The third condition denies all UDP traffic.

The fourth condition permits all packets that are not explicitly denied by the other entries. Without this entry, the ACL denies all incoming or outgoing IPv6 traffic on the ports to which the ACL is assigned.

The commands in the next example apply the ACL "netw" to the incoming and outgoing traffic on port 1/2 and to the incoming traffic on port 4/3.

```
NetIron(config)# int eth 1/2
NetIron(config-if-1/2)# ipv6 traffic-filter netw in
NetIron(config-if-1/2)# ipv6 traffic-filter netw out
NetIron(config-if-1/2)# exit
NetIron(config)# int eth 4/3
NetIron(config-if-4/3)# ipv6 traffic-filter netw in
NetIron(config)# write memory
```

Here is another example of an ACL.

```
NetIron(config)# ipv6 access-list rtr
NetIron(config-ipv6-access-list rtr)# deny tcp 2001:1570:21::/24
2001:1570:22::/24
NetIron(config-ipv6-access-list rtr)# deny udp any range 5 6 2001:1570:22::/24
NetIron(config-ipv6-access-list rtr)# permit ipv6 any any
NetIron(config-ipv6-access-list rtr)# write memory
```

The first condition in this ACL denies TCP traffic from the 2001:1570:21::x network to the 2001:1570:22::x network.

The second condition denies UDP packets from any source with source UDP ports in ranges 5 to 6 and with the 2001:1570:22::/24 network as a destination.

The third condition permits all packets containing source and destination addresses that are not explicitly denied by the first two conditions. Without this entry, the ACL would deny all incoming or outgoing IPv6 traffic on the ports to which you assign the ACL.

A **show running-config** command output resembles the following.

```
NetIron(config)# show running-config
ipv6 access-list rtr
deny tcp 2001:1570:21::/24 2001:1570:22::/24
 deny udp any range 5 6 2001:1570:22::/24
 permit ipv6 any any
```

A **show ipv6 access-list** command output resembles the following.

```
NetIron(config)# show ipv6 access-list rtr
ipv6 access-list rtr: 3 entries
 10: deny tcp 2001:1570:21::/24 2001:1570:22::/24
 20: deny udp any range 5 6 2001:1570:22::/24
 30: permit ipv6 any any
```

The following commands apply the ACL “rtr” to the incoming traffic on ports 2/1 and 2/2.

```
NetIron(config)# int eth 2/1
NetIron(config-if-2/1)# ipv6 traffic-filter rtr in
NetIron(config-if-2/1)# exit
NetIron(config)# int eth 2/2
NetIron(config-if-2/2)# ipv6 traffic-filter rtr in
NetIron(config)# write memory
```

Default and implicit IPv6 ACL action

The default action when no IPv6 ACLs are configured is to permit all IPv6 traffic. Once you configure an IPv6 ACL and apply it to an interface, the default action for that interface is to deny all IPv6 traffic that is not explicitly permitted on the interface. The following actions can be taken:

- To tightly control access, configure ACLs with permit entries for the access you want to permit. These ACLs implicitly deny all other access.
- To secure access in environments with many users, configure ACLs with explicit deny entries, then add an entry to permit all access to the end of each ACL. The router permits packets that are not denied by the deny entries.

Every IPv6 ACL has the following implicit conditions as the last match condition.

1. **permit icmp any any nd-na** – Allows ICMP neighbor discovery acknowledgement.
2. **permit icmp any any nd-ns** – Allows ICMP neighbor discovery solicitation.
3. **deny ipv6 any any** – Denies IPv6 traffic. You must enter a **permit ipv6 any any** as the last statement in the ACL to permit IPv6 traffic that was not denied by the previous statements.

The conditions are applied in the order shown above, with **deny ipv6 any any** as the last condition.

For example, to deny ICMP neighbor discovery acknowledgement, then permit any remaining IPv6 traffic, enter commands such as the following.

```
NetIron(config)# ipv6 access-list netw
NetIron(config-ipv6-access-list-netw)# permit icmp 2000:2383:e0bb::/64
2001:3782::/64
NetIron(config-ipv6-access-list-netw)# deny icmp any any nd-na
NetIron(config-ipv6-access-list-netw)# permit ipv6 any any
```

The first permit statement permits ICMP traffic from hosts in the 2000:2383:e0bb::x network to hosts in the 2001:3782::x network.

The deny statement denies ICMP neighbor discovery acknowledgement.

The last command permits all packets that are not explicitly denied by the other entries. Without this entry, the ACL denies all incoming or outgoing IPv6 traffic on the ports to which you assigned the ACL.

Furthermore, if you add the statement **deny icmp any any** in the access list, then all neighbor discovery messages will be denied. You must explicitly enter the **permit icmp any any nd-na** and **permit icmp any any nd-ns** statements just before the **deny icmp** statement if you want the ACLs to permit neighbor discovery as in this example.

```
NetIron(config)# ipv6 access-list netw
NetIron(config-ipv6-access-list-netw)# permit icmp 2000:2383:e0bb::/64
2001:3782::/64
NetIron(config-ipv6-access-list-netw)# permit icmp any any nd-na
NetIron(config-ipv6-access-list-netw)# permit icmp any any nd-ns
NetIron(config-ipv6-access-list-netw)# deny icmp any any
NetIron(config-ipv6-access-list-netw)# permit ipv6 any any
```

ACL syntax

The following syntax rules apply for IPv6 ACLs.

Syntax: [**no**] **ipv6 access-list** <*acl name*>

Syntax: [**no**] **permit** | **deny** <*protocol*>
<*ipv6-source-prefix/prefix-length*> | **any** | **host** <*source-ipv6_address*>
<*ipv6-destination-prefix/prefix-length*> | **any** | **host** <*ipv6-destination-address*>
[**ipv6-operator** [<*value*>]]

The **ipv6 access-list** <*acl name*> parameter enables the IPv6 configuration level and defines the name of the IPv6 ACL. The <*acl name*> can contain up to 199 characters and numbers, but cannot begin with a number and cannot contain any spaces or quotation marks.

The **permit** keyword indicates that the ACL will permit (forward) packets that match a policy in the access list.

The **deny** keyword indicates that the ACL will deny (drop) packets that match a policy in the access list.

The <*protocol*> parameter indicates the type of IPv6 packet that is being filtered. You can specify a well-known name for some protocols with numbers less than 255. For other protocols, you must enter the number. Enter "?" instead of a protocol to list the well-known names recognized by the CLI. IPv6 protocols include:

- **AHP** – Authentication Header
- **ESP** – Encapsulating Security Payload
- **IPv6** – Internet Protocol version 6
- **SCTP** – Stream Control Transmission Protocol

The <*ipv6-source-prefix*>/<*prefix-length*> and <*ipv6-destination-prefix*>/<*prefix-length*> parameters specify a source or destination prefix and prefix length that a packet must match for the specified deny or permit action to occur. You must specify the <*ipv6-source-prefix*> and <*ipv6-destination-prefix*> parameters in hexadecimal using 16-bit values between colons, as documented in RFC 2373. You must specify the <*prefix-length*> parameter as a decimal value. A slash mark (/) must follow the <*ipv6-prefix*> parameter and precede the <*prefix-length*> parameter.

The **any** keyword, when specified instead of the <*ipv6-source-prefix*>/<*prefix-length*> or <*ipv6-destination-prefix*>/<*prefix-length*> parameters, matches any IPv6 prefix and is equivalent to the IPv6 prefix ::/0.

The **host** <*ipv6-source-address*> and **host** <*ipv6-destination-address*> parameter lets you specify a host IPv6 address. When you use this parameter, you do not need to specify the prefix length. A prefix length of all128 is implied.

The **ipv6-operator** [<*value*>] parameter allows you to further filter the packets using one of these options:

- **dscp** – The policy applies to packets that match the traffic class value in the traffic class field of the IPv6 packet header. This operator allows you to filter traffic based on TOS or IP precedence. You can specify a value from 0 – 63.
- **fragments** – The policy applies to fragmented packets that contain a non-zero fragment offset.

NOTE
This option is supported only when the <*protocol*> parameter is IPv6. This option is not applicable to filtering based on source or destination port, TCP flags, and ICMP flags.

- **priority-force** – forces packet outgoing priority.

- **priority-mapping** – maps incoming packet priority.
- **routing** – applies only to IPv6 source-routed packets.
- **sequence** – The sequence parameter specifies where the conditional statement is to be added in the access list. You can add a conditional statement at particular place in an access list by specifying the entry number using the sequence keyword. You can specify a value from 1 – 4294967295.

NOTE
The following ACL features are not supported:

- ipv6-operator **flow-label**
- ipv6-operator **fragments** when any protocol other than IPv6 is specified. If you specify **tcp** or any other protocol instead of **ipv6**, the keyword **fragments** cannot be used.
- ipv6-operator **routing** when a protocol is specified. (Same limitation as for ipv6-operator **fragments)**

When creating ACLs, use the appropriate syntax described in the following sections for the protocol you are filtering.

For ICMP

Syntax: [**no**] **ipv6 access-list** <*acl name*>

Syntax: [**no**] **permit** | **deny icmp**
<*ipv6-source-prefix/prefix-length*> | **any** | **host** <*source-ipv6_address*>
<*ipv6-destination-prefix/prefix-length*> | **any** | **host** <*ipv6-destination-address*>
[**ipv6-operator** [<*value*>]]
[[<*icmp-type*>][<*icmp-code*>]] | [<*icmp-messge*>]

The icmp protocol indicates the you are filtering ICMP packets.

To specify an ICMP type, enter a value between 0–255 for the <*icmp-type*> parameter.

To specify an ICMP code, enter a value between 0–255 for the <*icmp-code*> parameter.

To specify an ICMP message, enter one of the following:

- beyond-scope
- destination-unreachable
- dscp
- echo-reply
- echo-request
- flow-label
- fragments
- header
- hop-limit
- mld-query
- mld-reduction
- mld-report
- nd-na

- nd-ns
- next-header
- no-admin
- no-route
- packet-too-big
- parameter-option
- parameter-problem
- port-unreachable
- reassembly-timeout
- renum-command
- renum-result
- renum-seq-number
- router-advertisement
- router-renumbering
- router-solicitation
- routing
- sequence
- time-exceeded
- unreachable

NOTE
If you do not specify a message type, the ACL applies to all ICMP message types.

For TCP

Syntax: [**no**] **ipv6 access-list** <*acl name*>

Syntax: [**no**] **permit** | **deny tcp**
<*ipv6-source-prefix/prefix-length*> | **any** | **host** <*source-ipv6_address*>
[<*tcp-udp-operator*> [<*source-port-number*>]]
<*ipv6-destination-prefix/prefix-length*> | **any** | **host** <*ipv6-destination-address*>
[[<*tcp-udp-operator*> [<*source-port-number*>]]
[**ipv6-operator** [<*value*>]] [**tcp-operator** [<*value*>]]

The tcp protocol indicates the you are filtering TCP packets.

The <*tcp-udp-operator*> parameter can be one of the following:

- **eq** – The policy applies to the TCP or UDP port name or number you enter after **eq**.
- **gt** – The policy applies to TCP or UDP port numbers greater than the port number, or the numeric equivalent of the port name you enter after **gt**. Enter "?" to list the port names.
- **lt** – The policy applies to TCP or UDP port numbers that are less than the port number or the numeric equivalent of the port name you enter after **lt**.
- **neq** – The policy applies to all TCP or UDP port numbers except the port number or port name you enter after **neq**.

- **range** – The policy applies to all TCP port numbers that are between the first TCP or UDP port name or number and the second one you enter following the **range** parameter. The range includes the port names or numbers you enter. For example, to apply the policy to all ports between and including 23 (Telnet) and 53 (DNS), enter the following: **range 23 53**. The first port number in the range must be lower than the last number in the range.

The <*source-port number*> and <*destination-port-number*> for the tcp-udp-operator are the numbers of the source and destination ports.

The **tcp-operator** [<*value*>] parameter specifies a comparison operator for the TCP port. This parameter applies only when you specify tcp as the protocol. You can enter one of the following operators:

- **established** – This operator applies only to TCP packets. If you use this operator, the policy applies to TCP packets that have the ACK (Acknowledgment) or RST (Reset) bits set on (set to "1") in the Control Bits field of the TCP packet header. The policy applies only to established TCP sessions, not to new sessions.
- **syn** – The policy applies to TCP packets with the SYN (Synchronize) bits set on (set to "1") in the Control Bits field of the TCP packet header.

For UDP

Syntax: [**no**] **ipv6 access-list** <*acl name*>

Syntax: [**no**] **permit** | **deny udp**
<*ipv6-source-prefix/prefix-length*> | **any** | **host** <*source-ipv6_address*>
[<*tcp-udp-operator*> [<*source port number*>]]
<*ipv6-destination-prefix/prefix-length*> | **any** | **host** <*ipv6-destination-address*>
[<*tcp-udp-operator*> [<*destination port number*>]]
[**ipv6-operator** [<*value*>]]

The udp protocol indicates the you are filtering UDP packets.

The <*tcp-udp-operator*> parameter can be one of the following:

- **eq** – The policy applies to the TCP or UDP port name or number you enter after **eq**.
- **gt** – The policy applies to TCP or UDP port numbers greater than the port number, or the numeric equivalent of the port name you enter after **gt**. Enter "?" to list the port names.
- **lt** – The policy applies to TCP or UDP port numbers that are less than the port number or the numeric equivalent of the port name you enter after **lt**.
- **neq** – The policy applies to all TCP or UDP port numbers except the port number or port name you enter after **neq**.
- **range** – The policy applies to all UDP port numbers that are between the first TCP or UDP port name or number and the second one you enter following the **range** parameter. The range includes the port names or numbers you enter. For example, to apply the policy to all ports between and including 23 (Telnet) and 53 (DNS), enter the following: **range 23 53**. The first port number in the range must be lower than the last number in the range.
- The <*source-port number*> and <*destination-port-number*> for the tcp-udp-operator are the numbers of the source and destination ports.

Filtering packets based on DSCP values

To filter packets based on DSCP values, enter commands such as the following.

```
NetIron(config)# ipv6 access-list netw
NetIron(config-ipv6-access-list netw) deny ipv6 any any dscp 3
```

Syntax: [**no**] **ipv6 access-list** <*name*>
deny | **permit**
<*ipv6-source-prefix*>/<*prefix-length*> | **any**
<*ipv6-destination-prefix*>/<*prefix-length*> | **any** [**sequence** <*number*>]
dscp <*dscp-value*>

Enter a value from 0 - 63 for the **dscp** <*dscp-value*> parameter to filter packets based on their DSCP value.

For more information on the syntax, refer to "ACL syntax" on page 1773.

Filtering packets based on routing header type

You can filter IPv6 packets based on their routing header type. This is of particular value when you want to filter IPv6 source-routed packets to prevent DoS attacks. These packets are type 0.

To filter IPv6 packets based on the routing header type, enter commands such as the following.

```
NetIron(config)# ipv6 access-list drop-source-routed
NetIron(config-ipv6-access-list drop-source-routed) deny ipv6 routing-header-type
0
```

Syntax: [**no**] **ipv6 access-list** <*name*>
deny | **permit**
routing-header-type <*type-value*>

Enter a value from 0 - 255 for the **routing-header-type** <*type-value*> parameter to filter packets based on their IPv6 header type value.

For more information on the syntax, refer to "ACL syntax" on page 1773.

NOTE
The **routing-header-type** option is separate and independent of the **routing** option. The **routing-header-type** and **routing** options are mutually exclusive and cannot be used in the same filter.

NOTE
For more information on configuring the **acl-mirror-port** command, refer to "ACL-based inbound mirroring" on page 148.

Extended IPv6 ACLs

Configuration considerations for extended IPv6 layer 4 ACL

The following configuration considerations apply to extended IPv6 L4 ACLs:

- There are two lookups available for ingress direction. In ingress direction, you can bind IPv6 layer 4 ACLs, IPv4 layer 4 ACLs, layer 2 ACLs, and layer 3 ACLs on the same port.
- The PowerConnect B-MLXe has one CAM lookup for inbound and outbound ACLs.
- Only one L2 or IPv6 lookup is allowed per port.
- There is only one lookup available for egress direction. When you bind outbound IPv6 L4 ACL to a port, the port does not allow L2, IPv4, or IPv6 ACL in that egress direction.
- Layer 4 ACLs filter incoming traffic based on IPv6 packet header fields. The following attributes can be added to the IPv6 packet header fields:
  - VLAN ID
  - Source IPv6 address (SIP) prefix
  - Destination IPv6 address (DIP) prefix
  - IP protocol (SPI matching is not supported for AHP or ESP
  - UDP or TCP source port
  - UDP or TCP destination port
  - TCP flags - established (RST or ACK)
  - TCP flags - SYN
  - ICMP type and code
  - DSCP value
  - IPv6 fragments
  - source routed packets
  - specific routing header type
- The following actions are available for the ingress ACL:
  - Permit
  - Deny
  - Copy-sflow
  - Drop-precedence
  - Drop-precedence-force
  - Priority-force
  - Mirror

The following actions are available for the egress ACL:

- Permit
- Deny

ACL syntax

The command syntax for the IPv6 ACLs is as follows.

Syntax: [**no**] **ipv6 access-list** <*acl name*>

Syntax: **permit** | **deny** <*protocol*>

<*ipv6-source-prefix/prefix-length*> | **any** | **host** <*source-ipv6_address*>

<*ipv6-destination-prefix/prefix-length*> | **any** | **host** <*ipv6-destination-address*>

[**ipv6-operator** [<*value*>]]If a port has an acl applied, the user must remove ACL bindings prior to creating or adding that port to a vlan or a ve interface.

[**copy-sflow**] | [**drop-precedence** <*dp-value*>] | [**drop-precedence-force** <*dp-value*>] | [**dscp** <*dscp-value*>] | [**mirror**] | [**priority-force** <*number*>] | [**sequence**]

The **ipv6 access-list** <*acl name*> parameter enables the IPv6 configuration level and defines the name of the IPv6 ACL. The <*acl name*> variable can contain up to 199 characters and numbers, but cannot begin with a number and cannot contain any spaces or quotation marks.

The **permit** keyword indicates that the ACL permits (forwards) packets that match a policy in the ACL.

The **deny** keyword indicates that the ACL denies (drops) packets that match a policy in the ACL.

The <*protocol*> parameter indicates the type of IPv6 packet you are filtering. You can specify a well-known name for some protocols with number lower than 255. For other protocols, you must enter the number. Enter "?" instead of a protocol to list the well-known names recognized by the CLI. IPv6 protocols include:

- **AHP** – Authentication Header
- **ESP** – Encapsulating Security Payload
- **IPv6** – Internet Protocol version 6
- **SCTP** – Stream Control Transmission Protocol

The <*ipv6-source-prefix*>/<*prefix-length*> and <*ipv6-destination-prefix*>/<*prefix-length*> parameters specify a source or destination prefix and prefix length that a packet must match for the specified deny or permit action to occur. You must specify the <*ipv6-source-prefix*> and <*ipv6-destination-prefix*> parameters in hexadecimal using 16-bit values between colons, as documented in RFC 2373. You must specify the <*prefix-length*> parameter as a decimal value. A slash (/) must follow the <*ipv6-prefix*> parameter and precede the <*prefix-length*> parameter.

The **any** keyword, when specified instead of the <*ipv6-source-prefix*>/<*prefix-length*> or <*ipv6-destination-prefix*>/<*prefix-length*> parameters, matches any IPv6 prefix and is equivalent to the IPv6 prefix::/0

The **host** <*ipv6-source-address*> and **host** <*ipv6-destination-address*> parameter lets you specify a host IPv6 address. When you use this parameter, you do not need to specify the prefix length. A prefix length of all 128 is implied.

The **ipv6-operator** [<*value*>] parameter allows you to further filter packets using one of the following options:

- **dscp** – Applies to packets that match the traffic class value in the traffic class field of the IPv6 packet header. Allows you to filter traffic based on TOS or IP precedence. You can specify a value from 0 through 63.
- **fragments** – Applies to fragmented packets that contain a non-zero fragment offset.

NOTE
This option is supported only when the <*protocol*> parameter is IPv6. This option is not applicable to filtering based on source or destination ports, TCP flags, and ICMP flags.

- **priority-force** – Forces packet outgoing priority.
- **routing** – Applies only to IPv6 source-routed packets.
- r**outing-header-type** – matches specific routing header.
- **sequence** – Specifies where the conditional statement is to be added in the ACL. You can add a conditional statement at particular place in an ACL by specifying the entry number using the sequence keyword. You can specify a value from 1 through 4294967295, as shown in this example.

```
PowerConnect(config)# ipv6 access-list ipv6-sip-dip-sample1
 deny 183 any 5001::/32
 deny 185 any host 6001::50b9
 permit 187 7017::/32 any copy-sflow
 permit 189 8017:abdc::/64 7001::/32 mirror
 permit tcp host 1616:1000:1000:1000:1000:1000:1000:1011 host
8800:1000:2000:2000:2000:2000:2000:2022 drop-precedence 2
 deny udp host 1717:1000:1000:1000:1000:1000:1000:1011 host
9900:2000:2000:2000:2000:2000:2000:2022 drop-precedence-force 1
 permit ahp host 202::12 host 201::101
 permit esp host 202::12 host 202::102
 permit ipv6 host 202::12 host 203::103 dscp 8
 permit sctp host aaa:1:202::12 host bbb::2
 permit ipv6 host 3003::110 any
 deny ipv6 dd17::/32 any fragments
 permit ipv6 a3b1:7551::/32 any priority-force 4
 permit ipv6 b3b1:7552::/32 any routing
 permit ipv6 any any routing-header-type 51
 deny 53 any 9001:a001::/32 sequence 10000
```

For ICMP

Syntax: [**no**] **ipv6 access-list** <*acl name*>

Syntax: **permit** | **deny icmp**
<*ipv6-source-prefix/prefix-length*> | **any** | **host** <*source-ipv6_address*>
<*ipv6-destination-prefix/prefix-length*> | **any** | **host** <*ipv6-destination-address*>
[**ipv6-operator** [<*value*>]]
[[<*icmp-type*>][<*icmp-code*>]] | [<*icmp-messge*>] | **beyond-scope** | **destination-unreachable** | **echo-reply** | **echo-request** | **header** | **hop-limit** | **mld-query** | **mld-reduction** | **mld-report** | **nd-na** | **nd-ns** | **next-header** | **no-admin** | **no-route** | **packet-too-big** | **parameter-option** | **parameter-problem** | **port-unreachable** | **reassembly-timeout** | **renum-command** | **renum-result** | **renum-seq-number** | **router-advertisement** | **router-renumbering** | **router-solicitation**] | [**copy-sflow**] | | [**drop-precedence** <*dp-value*>] | [**drop-precedence-force** <*dp-value*>] | [**dscp** <*dscp-value*>] | [**mirror**] | [**priority-force** <*number*>] | [**sequence**]

The icmp protocol indicates the you are filtering ICMP packets.

To specify an ICMP type, enter a value from 0 through 255 for the <*icmp-type*> parameter.

To specify an ICMP code, enter a value from 0 through 255 for the <*icmp-code*> parameter.

You can use these ICMP wild cards for IPv6 packet filtering.

- **destination-unreachable** – Matches all unreachable type codes.
- **time-exceeded** – Matches all timeout type codes.
- **router-renumbering** – Matches all router renumbering type codes.

To specify an ICMP message, enter one of the following options:

- beyond-scope
- destination-unreachable
- dscp
- echo-reply
- echo-request
- flow-label
- fragments
- header
- hop-limit
- mld-query
- mld-reduction
- mld-report
- nd-na
- nd-ns
- next-header
- no-admin
- no-route
- packet-too-big
- parameter-option
- parameter-problem
- port-unreachable
- reassembly-timeout
- renum-command
- renum-result
- renum-seq-number
- router-advertisement
- router-renumbering
- router-solicitation
- routing
- sequence
- time-exceeded
- unreachable

The following example shows a configuration to filter ICMP packets.

```
PowerConnect(config)# ipv6 access-list ipv6-icmp-sample2
 permit icmp any any echo-reply
 permit icmp any any echo-request
```

```
deny icmp any any unreachable
deny icmp any any time-exceeded
permit icmp any any 146 0
permit icmp any any 1
```

For TCP

Syntax: [**no**] **ipv6 access-list** <*acl name*>

Syntax: **permit** | **deny tcp**
<*ipv6-source-prefix/prefix-length*> | **any** | **host** <*source-ipv6_address*>
[<*tcp-udp-operator*> [<*source-port-number*>]]
<*ipv6-destination-prefix/prefix-length*> | **any** | **host** <*ipv6-destination-address*>
[<*tcp-udp-operator*> [<*destination-port- number*>]]
[**ipv6-operator** [<*value*>]] [**tcp-operator** [<*value*>]]
[**copy-sflow**] | [**drop-precedence** <*dp-value*>] | [**drop-precedence-force** <*dp-value*>] |
[**dscp** <*dscp-value*>] | [**eq** | **gt** | **lt** | **neq** | **range** <*port-number*>] | [**established**] | [**mirror**]
| [**priority-force** <*number*>] | [**sequence**] | [**syn**]

The tcp protocol indicates the you are filtering the TCP packets.

The <*tcp-udp-operator*> parameter can be one of the following:

- **eq** – Applies to the TCP or UDP port name or number you enter after **eq**.
- **gt** – Applies to TCP or UDP port numbers greater than the port number or the numeric equivalent of the port name you enter after **gt**. Enter "?" to list the port names.
- **lt** – Applies to TCP or UDP port numbers that are less than the port number or the numeric equivalent of the port name you enter after **lt**.
- **neq** – Applies to all TCP or UDP port numbers except the port number or port name you enter after **neq**.
- **range** – Applies to all TCP port numbers between the first and second TCP or UDP port name or number you enter following the **range** parameter. The range includes the port names or numbers you enter. For example, to apply the policy to all ports between and including 23 (Telnet) and 53 (DNS), enter the following: **range 23 53**. The first port number in the range must be lower than the last number in the range.

The <*source-port number*> and <*destination-port-number*> for the tcp-udp-operator are the numbers of the source and destination ports.

The **tcp-operator** [<*value*>] parameter specifies a comparison operator for the TCP port. This parameter applies only when you specify tcp as the protocol. You can enter one of the following operators:

- **established** – Applies only to the TCP packets. If you use this operator, the policy applies to the TCP packets that have the ACK or RST bits set on (set to “1”) in the Control Bits field of the TCP packet header. Applies only to established TCP sessions, not to new sessions.
- **syn** – Applies to the TCP packets with the SYN bits set on (set to “1”) in the Control Bits field of the TCP packet header.

For UDP

Syntax: [**no**] **ipv6 access-list** <*acl name*>

Syntax: **permit** | **deny udp**
<*ipv6-source-prefix/prefix-length*> | **any** | **host** <*source-ipv6_address*> [**tcp-udp-operator**

[<*source port number*>]]
<*ipv6-destination-prefix/prefix-length*> | **any** | **host** <*ipv6-destination-address*>
[**tcp-udp-operator** [<*destination port number*>]]
[**ipv6-operator** [<*value*>]]
[**copy-sflow**] | [**drop-precedence** <*dp-value*>] | [**drop-precedence-force** <*dp-value*>] |
[**dscp** <*dscp-value*>] | [**eq** | **gt** | **lt** | **neq** | **range** <*port-number*>] | [**mirror**] | [**priority-force** <*number*>] | [**sequence**]

The udp protocol indicates the you are filtering the UDP packets.

The <*tcp-udp-operator*> parameter can be one of the following:

- **eq** – Applies to the TCP or UDP port name or number you enter after **eq**.
- **gt** – Applies to TCP or UDP port numbers greater than the port number or the numeric equivalent of the port name you enter after **gt**. Enter "?" to list the port names.
- **lt** – Applies to TCP or UDP port numbers that are less than the port number or the numeric equivalent of the port name you enter after **lt**.
- **neq** – Applies to all TCP or UDP port numbers except the port number or port name you enter after **neq**.
- **range** – Applies to all UDP port numbers that are between the first and second TCP or UDP port name or number you enter following the **range** parameter. The range includes the port names or numbers you enter. For example, to apply the policy to all ports between and including 23 (Telnet) and 53 (DNS), enter the following: **range 23 53**. The first port number in the range must be lower than the last number in the range.

The <*source-port number*> and <*destination-port-number*> are the numbers of the source port and destination port.

The following example is a configuration to filterTCP and UDP packet:

```
PowerConnect(config)# ipv6 access-list ipv6-tcp-udp-sample3
 permit tcp host 3003::11 gt 1023 host 3001::11 range 1024 1026
 deny udp host 3003::12 lt 1025 any neq 1024
 permit tcp 3001::/32 host 3002::11 syn
 permit udp any eq msg-auth 3000::/64
 permit tcp host 3003::11 gt 1023 host 3001::11 range 1024 1026 established
 deny tcp 3003::/64 range 1023 1025 host 3000::11
```

CAM partitioning

The size of the extended ingress IPv6 L4 key is 640 bits. The size of the standard ingress ACL key is 320 bits. In internal TCAM, different sized keys can reside next to each other in the same block. In external TCAM, blocks are allocated for ACLs, and different sized keys cannot reside in the same block. An ingress IPv6 L4 key cannot reside in the same block with other ingress ACLs.

You can configure CAM partition to have an ingress ACL into internal TCAM and an egress ACL into external TCAM. The ingress IPv6 L4 key can reside in the same TCAM with other ingress ACLs, but must reside in a different block in the external TCAM.

You can select one key per interface for the following packet types (port or VLAN).

- IPv6 packets
- IPv4 and ARP packets
- Non-IP packets

The following key types apply to layer 2 ACLs:

- Ingress L2 non-IP Key 0
- Egress L2+IPv4+L4 Key

The following keys apply to ether type IPv4, IPv6, or ARP:

- Ingress L2+IPv4/6 Key 1 -- ether type = IPv4 or IPv6
- Ingress IPv4+L4 Key 2 -- ether type = ARP
- Egress L2+IPv6 Key -- ether type = IPv6
- Egress L2+IPv4+L4 Key - ether type = ARP or IPv4

At ingress, each packet is subjected to two lookups. You can direct the system to use a different key for each lookup. Make sure that the source MAC, destination MAC, VLAN ID and ether type are the same for all layer 2 ACL fields. If layer 2 field locations are not same, you will have to create a separate TCAM entry for each layer 2 IPv6 ACL rule or packet type (IPv4, IPv6, and non-IP) combination, for the layer 2 IPv6 ACL to work on all packet types.

Applying an IPv6 ACL

To apply an IPv6 ACL, (for example “access1”), to an interface, enter commands such as the following.

```
NetIron(config)# interface ethernet 3/1
NetIron(config-if-e100-3/1)# ipv6 traffic-filter access1 in
```

This example applies the IPv6 ACL “access1” to incoming IPv6 packets on Ethernet interface 3/1. As a result, Ethernet interface 3/1 denies all incoming packets from the site-local prefix fec0:0:0:2::/64 and the global prefix 2001:100:1::/48 and permits all other incoming packets.

NOTE
IPv6 ACLs are supported on POS interfaces.

Syntax: [**no**] **ipv6 traffic-filter** <*ipv6-acl-name*> **in** | **out**

For the <*ipv6-acl-name*> parameter, specify the name of an IPv6 ACL created using the **ipv6 access-list** command.

The **in** keyword applies the specified IPv6 ACL to incoming IPv6 packets on the router interface.

The **out** keyword applies the specified IPv6 ACL to outgoing IPv6 packets on the router interface.

Applying an IPv6 ACL to a VRF

A VRF interface can be one physical port, a virtual interface, or a trunk port consisting of multiple physical ports. As with regular IPv6 ports, you can apply an inbound or outbound IPv6 ACL to a VRF interface to filter incoming and outgoing traffic respectively. This type of ACL is called a IPv6 VRF ACL.

Distinction between IPv6 ACLs applied to regular and VRF interfaces

IPv6 ACLs (both inbound and outbound) can only be applied at the IPv6 interface-level, which may be a physical or a virtual interface. If a physical port is a member of one or more virtual interfaces, the IPv6 ACL must be bound at the corresponding ve level (not at the physical port level). You cannot change the VLAN membership of a physical port with an IPv6 ACL.

When an IPv6 VRF is dynamically configured on an interface port, all IPv6 addresses on that interface are deleted. IPv6 ACL binding on the interface is not be cleared because IPv6 ACL programming is independent of the VRF membership of the interface.

To apply an IPv6 ACL, for example “access1”, to a vrf, enter commands such as the following.

```
NetIron(config)# vrf 20
NetIron(config-vif-20)#ipv6 traffic-filter access1 in
```

Syntax: **[no] ipv6 traffic-filter** <*ipv6-acl-name*> **in | out**

For the <*ipv6-acl-name*> parameter, specify the name of an IPv6 ACL created using the **ipv6 access-list** command.

The **in** keyword applies the specified IPv6 ACL to incoming IPv6 packets on the router interface.

The **out** keyword applies the specified IPv6 ACL to outgoing IPv6 packets on the router interface.

Controlling access to a router

You can use an IPv6 ACL to filter control incoming and outgoing connections to and from a router. To do so, you must create an ACL and then specify the sequence in which the ACL is applied to incoming or outgoing connections to the router.

For example, to permit incoming connections from remote hosts (2000:2383:e0bb::2/128 and 2000:2383:e0bb::3/128) to a router (30ff:3782::ff89/128), enter the following commands.

```
NetIron(config)# ipv6 access-list remote-hosts permit 2000:2383:e0bb::2/128
30ff:3782::ff89/128 sequence 10
NetIron(config)# ipv6 access-list remote-hosts permit 2000:2383:e0bb::3/128
30ff:3782::ff89/128 sequence 20
NetIron(config)# ipv6 access-class remote-hosts in
```

Because of the implicit deny command at the end of each IPv6 ACL, the router denies incoming connections from all other IPv6 hosts.

NOTE
The **ipv6 access-class** command is applicable only to traffic coming in or going out the management port.

Syntax: **[no] ipv6 access-list** <*name*> **deny | permit** <*ipv6-source-prefix*>/<*prefix-length*> **| any** <*ipv6-destination-prefix*>/<*prefix-length*> **| any [sequence** <*number*>**]**
